Synthetic dyes such as ruthenium complexes may offer high efficiency in PEC however, due to its expensive cost and rarity as well as toxic materials, substantially lead to the use natural dye as sensitizer [9]. Up till now, various natural dyes pigments from plants and fruits has been utilized such as anthocyanins, betalains, chlorophyll and carotenoids because of their low cost in extraction process while having good light absorption in visible region [10-13]. Among all of the natural dye pigments, betalains is the most suitable candidate as a sensitizer to TiO_2 photoelectrode as its having essential anchoring group that can attached efficiently onto TiO_2 surface which is carboxyl group [14].

Red pitaya fruit is one of the new focuses for dye-sensitizers as it rich in betalains pigment. Betalain can be found in both peel and flesh of the fruit and also can be divided into the red-violet betacyanins and yellow-orange betaxanthins group that promise variants in colour. However, in this study focused more on pitaya peel as it is a leftover product especially in beverage industries. The deep purple colour observed in pitaya peel contributes by at least seven known betalain that have identical maximum light absorption (λ_{max}) namely betanin, isobetanin, betanidin, isobetanidin, phyllocactin, and bougainvilllein-r-I [15]. The advantage of betalains possess over other pigments is its anchor group that adsorb efficiently onto atoms of semiconductor. The study of betalain dye molecules bonding to the TiO_2 subtrate has been reported previously. They suggested that ability of betalain's anchor group, carboxyl is the key factors to an efficient PEC reaction [16].

So far, the literature study work on pitaya peel dye in PEC water splitting is still barely known [17]. Thus, our research particular interest is the uses of natural pitaya peel dye molecules as light harvester sensitizer and also finding the influence of dye molecules added in liquid electrolyte.

Materials and Methods

Dye pigment extraction

Pitaya peel was macerated with double distilled water in a blender until completely homogenized in room temperature. The mixture is filtered by using vacuum filter to extract the dye and stored at 20 ºC prior to analysis. Any contact of the dye extract to the light was inhibited to avoid change in colour.

Fabrication of thin films

Prior to fabrication process, Fluorine-doped Tin Oxide (FTO) glasses were cleaned using ultrasonicator by immersed into three different solvent sequentially; ethanol (Merck), acetone (Merck) and single distilled water for 5 minutes each at 30 ºC. After that, the cleaned FTO glasses were dried at room temperature. In the meantime, TiO_2 paste was prepared using nanoparticles powder of titanium dioxide P25 Degussa (Sigma Aldrich) mixed with double distilled water at ratio 1:3 of mass (g) to volume (ml). Then, the paste was stirred by using spatula to ensure

homogenous mixture. The TiO_2 paste was coated on top of FTO glass by Doctor Blade method and the thickness of thin films were controlled by taping the scotch tape at sides of FTO glass. Later, TiO_2 thin film were calcined and sintered in a furnace at 450 ºC for 2 hours with constant heating of 5 ºC/min. The preparation is carried out in duplicates to prepare TiO_2 with dye sensitizer thin films.

After cooling down, the sintered TiO_2 thin film was soaked into a container filled with pitaya peel dye up to 24 hours in room temperature and dark condition to allow the adsorption of the dye molecules as a sensitizer. Later, the non-adsorbed materials on TiO_2 with dye sensitizer thin film were removed by distilled water. The thin film stored at 0ºC for further analysis and any contact with light is prevented to keep its colour stability.

Characterization and Photoelectrochemical (PEC) test of thin films

All of thin films prepared were characterizes using X-ray diffraction measurement, XRD (Bruker D8 Advance diffractometer) with CuKα radiation in determining its structure and crystallinity. The percentage of the anatase and rutile crystalline phase was determined using following Equation 1 [18]:

$$\text{Anatase (\%)} = \frac{1}{1+1.265\left(\frac{I_{rutile}}{I_{anatse}}\right)} \text{ x } 100\% \quad (1)$$

where $I_{anatase}$ and I_{rutile} are the intensities at highest peak of anatase and rutile phase respectively for TiO_2. Menawhile, the size of crystal can be measured by using Scherrer Equation 2 [19]:

$$D = \frac{K\lambda}{\beta \cos \theta} \quad (2)$$

where K is the crystal shape factor (0.9), λ is the wavelength of x-ray (CuKα1 = 0.15406 nm), β is full width at half the maximum intensity (rad) and θ is diffraction angle.

The morphology, grain sizes, and thickness of the thin films were studied with scanning electron microscope, SEM (Zeiss AM10). Meanwhile, the light absorption of thin films was measured by UV-Vis spectrophotometer (PerkinElmer Lambda 35). Light absorption of thin film can be calculated using following Equation 3:

$$T = e^{-\alpha d} \quad (3)$$

where T is normalised transmittance, α is the absorption coefficient, *d* is the thickness of the film (cm). Besides that, the optical absorption coefficient is corresponding to the energy band gap (E_g) determined by using the Tauc formula (Equation 4):

$$Ah\nu = B(h\nu - E_g)^n \quad (4)$$

where A is a absorption coefficient, B is a constant; E_g is optical band gap energy of the film and n is the exponent. For crystalline semiconductors, n is ½, 3/2, 2, and 3 when the transition is direct allowed, direct forbidden, indirect allowed and indirect forbidden respectively.

For the study of photoelectrochemical (PEC) activity, FTO glass coated with thin films were assembled with copper wire as described by Minggu et al [20] to form photoelectrodes. A PEC cell set-up with optical window was used with three electrodes system which consists of a working electrode (fabricated photoelectrodes), a counter electrode (platinum electrode) and a reference electrode (Saturated Calomel Electrode) whereas double distilled water with dye as electrolyte. Beforehand, the electrolyte was purged with nitrogen gas for 30 minutes. The analysis was carried out under 100mWcm^{-2} Xenon full arc lamp as light source with Ametek Versastat 4. The initial and final potential was set to -0.5V and 1.5V respectively where the scan rate is 0.05V/s.

Results and Discussion

Morphological analysis

The images of surface and cross sectional morphology for bare TiO_2 and TiO_2 with dye sensitizer thin films can be observed using Scanning Electron Microscopy (SEM) as shown in Figure 1. The surface of TiO_2 thin film demonstrates porous with good uniformity which can be benefit to support dye adsorption [21]. The thickness of bare TiO_2 has been measured from cross-sectional image which is approximately 6 µm meanwhile dye-sensitized TiO_2 is approximately 8 µm which is 2 µm thicker than the bare TiO_2. Dye particles were not clearly visible on the surface and cross-sectional of TiO_2 with dye sensitized thin films due to very small size of dye molecule. Besides that, the particles size of TiO_2 is almost in the same size and agglomerated with 40 nm in average.

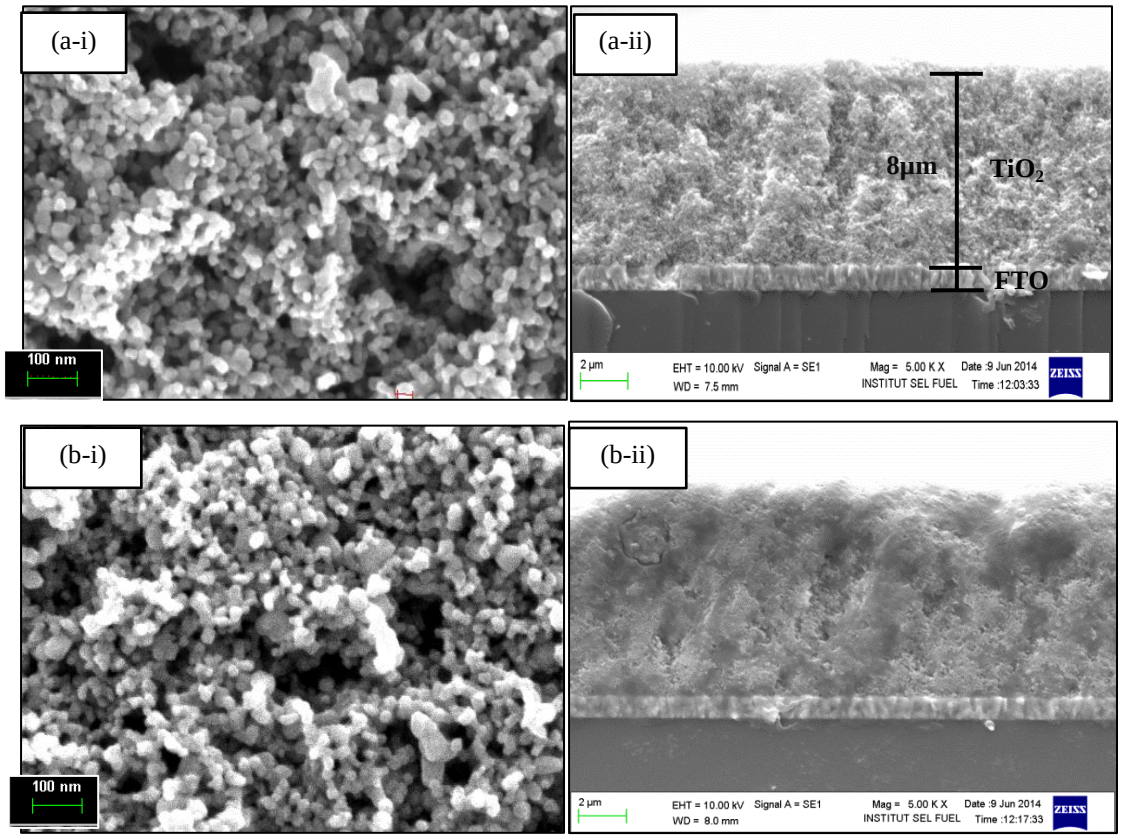

Figure 1. SEM images of (a) bare TiO_2 and (b) dye-sensitized TiO_2 thin films for its (i) surface and (ii) cross sectional respectively

Crystalline structure of thin films

Figure 2 shows the X-Ray Diffraction (XRD) pattern of TiO_2 and dye-sensitized TiO_2 thin films deposited onto FTO surface. The P25 Degussa TiO_2 nanoparticles contain 74 % anatase and 26 % rutile with average crystallite size of 20 nm obtained from Equation (1) and (2), respectively. Anatase peaks were observed at 2θ of 25.43°, 48.15° and 54.70° where correspondingly located at plane (101), (200) and (105) which in agreement with reported by Hamadanian et al. [21]. Meanwhile, the strongest peak of rutile appears at 27.55° at plane (110). In general, anatase phase is phocatalytically more active compared to rutile due to low rate of eletron-hole recombination [22]. Besides, the addition of dye sensitizer on TiO_2 thin films did not change the percentage of the anatase and rutile crystalline phase. However a new diffraction peak was exhibited at 2θ of 26.64° due to the present of mineral salts in dye

which later form crystal phase. In addition, there is increment in intensity of TiO_2 peaks which suggest that the crystallinity of TiO_2 is improved with adsorption of dye particles to TiO_2 crystal lattice.

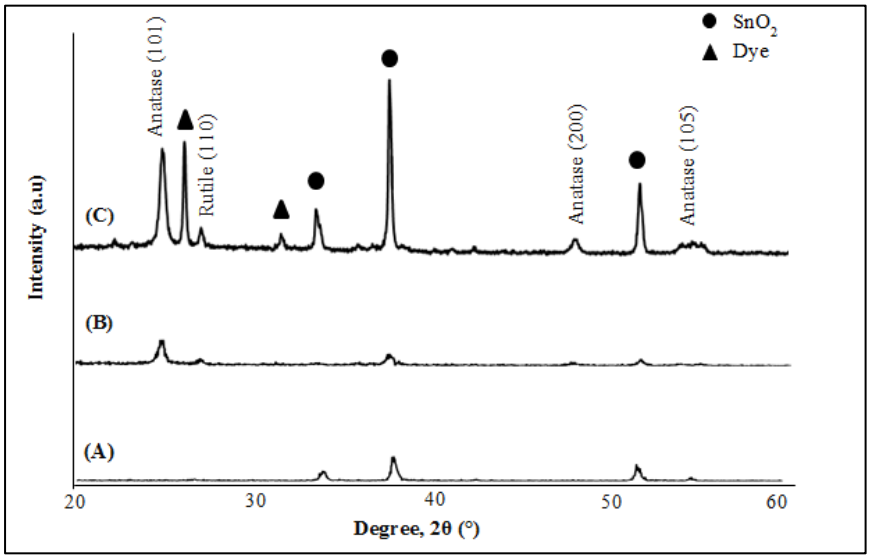

Figure 2. X-Ray Diffraction (XRD) pattern of (A) FTO, (B) TiO_2 and (C) dye-sensitized TiO_2 thin films deposited onto FTO

Optical light absorption and band edge analysis

Measurement of optical light absorption and band edge of pitaya peel dye and thin films has been done using UV-Visible spectrophotometer. The visible light makes majority of solar spectrum at wavelength range between 400 nm and 800 nm. Generally, the natural pitaya peel extracts contains mixture of several group pigments of betalain. In this study, the maximum light absorption (λ_{max}) for betalain pigments at about 546 nm as shown in Figure 3 which almost same as characteristic absorption of betacynanin, one of the red violet betalain group [23]. It shows that they have good light absorption at visible light portion and can utilize more photon energy. From the equation (3) and (4) shown in Section 2.3, the energy band gap, E_g of pitaya peel dye is 2.1 eV which include in the range of ideal band gap for PEC($1.23\ eV < E_g < 3.0\ eV$).

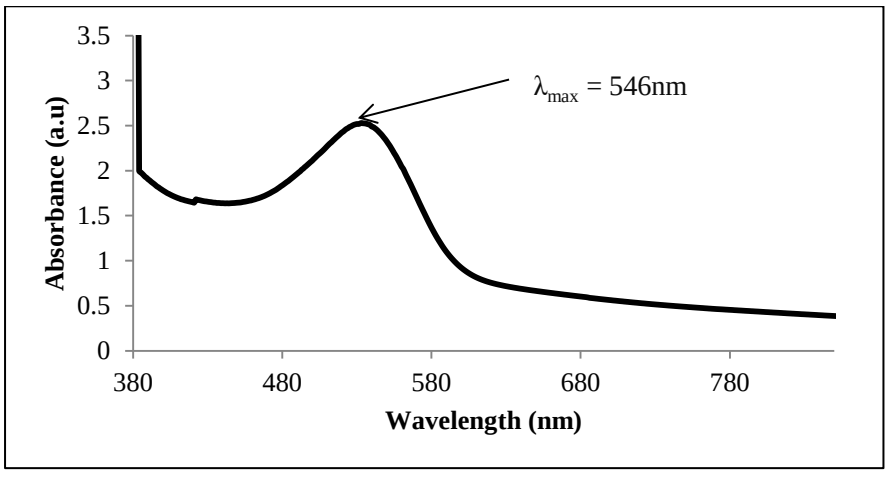

Figure 3. UV-Vis spectrum of pitaya peel dye pigment

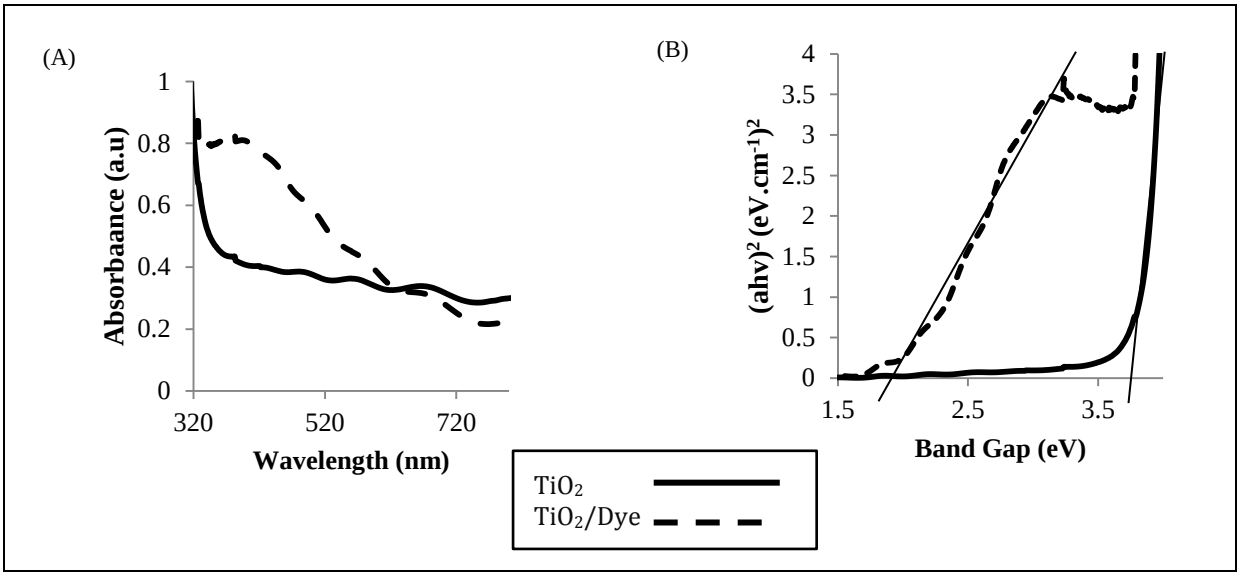

Figure 4. Optical light absorption (A) and direct allowed transition band gap (B) of bare TiO_2 and dye-sensitized TiO_2 thin films respectively

Photoelectrochemical analysis

Figure 5 shows measurement of photocurrent density for bare TiO_2 and dye-sensitized TiO_2 photoelectrodes in different concentration of dye in water electrolyte. The highest photocurrent density achieved by bare TiO_2 are by 6.25% and 12.5% v/v concentration of pitaya peel dye in the electrolyte which is 93 $\mu A/cm^2$ as shown in Figure 5 (A). However, the increased concentration of dye in electrolyte has decreased the photocurrent density with 66 $\mu A/cm^2$ at 100% v/v concentration of dye. In the meantime, the lowest photocurrent for bare TiO_2 is 43 $\mu A/cm^2$ without the addition of dye molecule electrolyte (0% v/v). From the Figure 5(B), dye-sensitized TiO_2 shows the increment in photocurrent density compared to bare TiO_2 where the highest photocurrent gained is 127 $\mu A/cm^2$ in 6.25% v/v concentration of pitaya peel dye in the electrolyte. Meanwhile, zero adding of dye molecule (0% v/v) has produced the lowest photocurrent which is around 52 $\mu A/cm^2$.

From the result, the present of dye-sensitizer layer on top of TiO_2 film has enhanced the production of photocurrent. This is due to the betalain molecules in pitaya peel dye-sensitizer has improved the light absorption of TiO_2 thus reducing the band gap. Besides that, functional group of carboxylic acid in betalains have forms a reversible binding with high equilibrium binding constant between TiO_2 surface and dye molecules in order to establish bonds and attached efficiently [24]. In dye-sensitized TiO_2 photoelectrode, the absorption of photon energy cause the electron transfer from highest occupied molecular orbital (HOMO) to lowest unoccupied molecular orbital (LUMO) following dihydropyridinie which attached on carboxyl group of dye-sensitizer. This caused photoexcitation dye state coupled electronically with an acceptor states in conduction band TiO_2 and lead to fast electron injection and increased photocurrent generation [10, 16, 25].

In the other hand, water is a poor electrolyte [26] and proven in this study as having the lowest photocurrent density for both bare TiO_2 and TiO_2 with dye sensitizer (0% v/v). However, the addition of dye molecules in electrolyte has shown increment in the photocurrent generation for both photoelectrodes. This may due to degradation of dye in electrolyte has made it as an electron donor to fill-up holes leaved by photoexcited electrons. Moreover, for dye-sensitized TiO_2 photoelectrode, dye-added molecules in the electrolyte has reduce driving force of desorption of the dye from TiO_2 surface hence increase its stability in water [27].

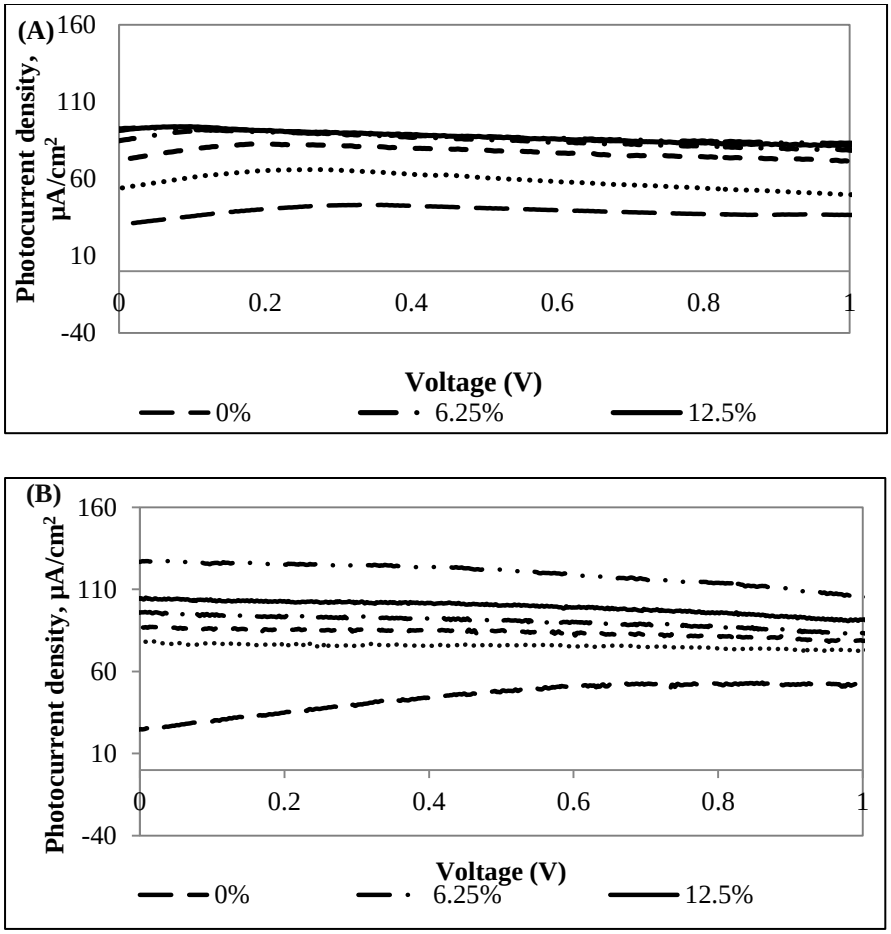

Figure 5. Performance of photocurrent density of (A) bare TiO_2 and (B) TiO_2 with dye sensitizer on different concentrations of pitaya peel dye in electrolyte

Conclusion

In this work, dye-sensitized TiO_2 was successfully fabricated using pitaya peel dye. There is no significant change in morphological studies of dye-sensitized TiO_2 thin film compare to bare TiO_2 due to its very fine of dye particle size. However, the crystallinity of TiO_2 has improved by the present of dye's crystal structure without change its phase. Besides, the light absorption dye-sensitized TiO_2 also has extended into visible light region. By using pitaya peel as dye-sensitizer has shown an increment in photocurrent generation in water splitting reaction. Furthermore, additional of dye molecules also has influenced photocurrent density where dye-sensitized TiO_2 photoelectrodes with 6.25% v/v of dye in electrolyte has the highest photocurrent density with 127µA/cm^2 under the Xenon lamp.

Abstract

Polypyrrole is a conductive polymer that is widely used in electrochemical applications. To identify the effects of different parameters on the synthesis of polypyrrole, an experimental design based on an orthogonal array L_9 (3^4) proposed by Taguchi was applied. The parameters investigated were the oxidant type, molar ratio of oxidant: pyrrole, reaction time and dopant concentration, whereas the response variables observed were the yield, particle size and conductivity. Field Emission Scanning Electron Microscope (FESEM) characterization was used to study the morphology characteristics of the polypyrrole particles. Based on the signal-to-noise (S/N) ratio and the results of analysis of variance (ANOVA), the molar ratio of oxidant: pyrrole and the oxidant type significantly affected the yield and conductivity of the synthesized polypyrrole particles.

Keywords: design of experiment, conductive polymer, yield, particle size, conductivity

Abstrak

Polipirola merupakan polimer konduktif yang digunakan secara meluas dalam aplikasi elektrokimia. Bagi tujuan mengenal pasti kesan-kesan parameter yang berbeza pada sintesis polipirola, reka bentuk eksperimen berdasarkan ortogon L_9 (3^4) yang dicadangkan oleh Taguchi telah digunakan. Parameter yang dikaji ialah jenis oksidan, nisbah molar oksidan: pirola, masa tindak balas dan kepekatan pendopan, manakala pemboleh ubah sambutan yang diperhatikan adalah jumlah hasil, saiz zarah dan kekonduksian. Pencirian FESEM telah digunakan untuk mengkaji morfologi zarah polipirola. Berdasarkan nisbah isyarat-hingar (S/N) dan hasil analisis varians (ANOVA), nisbah molar oksidan: pirola dan jenis oksidan memberi kesan yang ketara kepada hasil dan kekonduksian dari sintesis polipirola.

Kata kunci: reka bentuk eksperimen, polimer konduktif, jumlah hasil, saiz zarah, kekonduksian

Introduction

Conducting polymers, such as polyaniline (PAni), polypyrrole (PPy), and polythiophene (PTh), have found many industrial applications due to their unique characteristics, such as the dual function of ionic and electronic conductivity, large surface area and good mechanical properties [1-4]. Among the conductive polymers, PPy has attracted much attention because of its high conductivity [5], good environmental stability [6], electrocatalytic activity [7] and ease of synthesis [8]. Therefore, it has been widely used in electrochemical applications (e.g., as an

electrode material, in electrochemical energy storage [9], as a catalyst support in fuel cells [10], in supercapacitors [11] and in solar cells [12].

Polypyrrole can be synthesized by an electrochemical method [13], chemical oxidative polymerization [14], the reactive self-degradation template method [15], and micro emulsion polymerization [16]. Among the methods of PPy synthesis, the chemical oxidative polymerization method is extensively used because it is cheap, fast, and easy to scale up [17]. Several parameters have been reported to influence the chemical polymerization of PPy such as temperature, polymerization time [18], oxidant species [19], dopant type and dopant concentration [20]. However, prior studies have only examined the effect of one parameter individually and kept the other parameters constant. The Design of Experiments (DOE) method can be used to simultaneously evaluate the parameters for the synthesis of PPy, and this design also reduces the number of experiments.

An experimental design using the Taguchi approach has been implemented by numerous investigators to study the effect of different parameters on the synthesis of polymer particles. For example, a study by Hajian et al. [12] applied the Taguchi method to investigate several factors in the synthesis of polyvinyl butyral. Another study by Shahbazian et al. [1] reported the influence of five operating variables on the polymerization of vinyl chloride using the Taguchi method. The variables studied were temperature, water to monomer weight ratio, concentration of initiator and emulsifier, and agitation speed. The effect of each factor was comprehensively discussed, and the relative optimum condition was also determined. Ashassi-Sorkhabi and Bagheri [21] applied the Taguchi method to optimize the factors affecting the sonoelectrochemical synthesis of the PPy-SiN nanocomposite. The factors investigated were current density, synthesis time and amount of nanoparticles.

In this study, the Taguchi method was used to investigate the effects of (A) oxidant type, (B) molar ratio of oxidant:pyrrole, (C) time and (D) dopant concentration on the chemical synthesis of PPy. The response variables observed included the yield, particle size and conductivity.

Materials and Methods

The synthesis of PPy was carried out using the chemical oxidative polymerization method [22]. A certain amount of TsOH was added to 100 mL double-distilled water in a 250 mL round-bottom flask and stirred for 15 min. Fresh pyrrole (1.0 mL, 14.4 mmol) was added to the above solution, and the mixture was stirred for 45 min at room temperature to obtain a dark solution. An oxidant was added dropwise to the above mixture. Then, the mixture was stirred for a certain amount of time. The black products were filtered and washed repeatedly with ethanol and distilled water until the filtrate was colourless, and then the products were dried under vacuum at room temperature for 24 h.

The particle size of the samples was obtained using a particle sizer analyzer (Malvern Zeta sizer, model Nano zs/ZEN 3600). The conductivity of the samples was measured using Electrochemical Impedance Spectroscopy (EIS) over a frequency range of 10^2 to 10^4 Hz with 10 mv at room temperature using a two point probe cell. The morphologies and chemical composition of the samples were characterized using Field Emission Scanning Electron Microscopy (FE-SEM) coupled with Energy Dispersive X-Ray Spectroscopy (EDX) (ZEISS, Germany).

In this work, a Taguchi L_9 orthogonal array was used to study the effect of different parameters and determine the optimal conditions. Four factors at three levels were used in this design of experiment, as presented in Table 1 and Table 2, respectively. The response variables observed were yield, particle size and conductivity.

Table 1. Parameters and levels used in this experiment

Parameters		**Levels**		
		1	**2**	**3**
A	Oxidant type	APS	$FeCl_3$	H_2O_2
B	Molar ratio of oxidant: pyrrole	1 : 1	3 : 1	5 : 1
C	Time (h)	1	8	24
D	Dopant concentration (M)	0.01	0.05	0.1

Table 2. Experimental layout using a L_9 orthogonal array

Exp. No.	**A** **Oxidant type**	**B** **Molar ratio**	**C** **Time (h)**	**D** **Dopant concentration (M)**
1	1	1	1	1
2	1	2	2	2
3	1	3	3	3
4	2	1	2	3
5	2	2	3	1
6	2	3	1	2
7	3	1	3	2
8	3	2	1	3
9	3	3	2	1

The S/N (signal-to-noise) is a quality indicator that is used to evaluate the effect of changing particular parameter on the process performance. Generally, there are three categories of performance characteristics in the analysis of the S/N ratio [23-26].

Type S (smaller is better):

$$S/N_S = -10 \log \left[\frac{\sum_{i=1}^{n}(yi^2)}{n}\right] \quad (1)$$

Type B (Bigger is better):

$$S/N_B = -10 \log \left[\frac{\sum_{i=1}^{n}\left(\frac{1}{yi^2}\right)}{n}\right] \quad (2)$$

and Type N (nominal is better):

$$S/N_N = 10 \log \frac{\left(\frac{1}{n}\right)(((\sum_{i=1}^{n} yi)^2/n) - (\sum_{i=1}^{n} yi^2 - ((\sum_{i=1}^{n} yi)^2/n)/n-1))}{(\sum_{i=1}^{n} yi^2 - ((\sum_{i=1}^{n} yi)^2/n)/n-1} \quad (3)$$

where n is the number of replicates and yi is the response variable at ($i = n$).
In this study, the S/N ratio was selected according to the criterion that smaller is better for particle size and bigger is better for both yield and electronic conductivity.

Results and Discussion

Morphology of the polypyrrole particles

The FE-SEM morphology for the PPy particles obtained in this experiment was presented in Figure 1. As shown in Figure 1, all the PPy particles exhibited agglomerates of various sizes depending on the synthesis parameters.

Table 3 shows the chemical composition of the PPy particles as obtained by EDAX. The results confirmed that the presence of sulfur originated from the dopant (TSOH). The presence of chlorine and iron elements from experiments no. 4 to no. 6 may come from $FeCl_3$, which was doped into the PPy/TSOH particles as the oxidant.

Taguchi experimental design analysis

The Taguchi method was used to identify the optimal conditions and to select parameters that have the most influence on the yield, particle size and electronic conductivity of polypyrrole. The results of the measurement and S/N ratio values of the Taguchi method are shown in Table 4. As shown in Table 4, the smallest particle size (0.394 µm) was found in experiment no. 1, whereas the highest yield (0.69 g) and electronic conductivity (0.730 S/cm) were found in experiments no. 3 and no. 6, respectively.

Table 4. Experimental measured value and S/N ratio for yield, particle size and electronic conductivity of polypyrrole particles

No.	Yield		Particle Size		Electronic conductivity	
	Raw data (g)	S/N ratio (dB)	Raw data (µm)	S/N ratio (dB)	Raw data (S/cm)	S/N ratio (dB)
1	0.09	-20.92	0.394	8.09	0.085	-21.41
2	0.34	-9.37	0.481	6.36	0.270	-11.37
3	0.69	-3.22	0.675	3.42	0.043	-27.33
4	0.07	-23.10	1.574	-3.94	0.660	-3.61
5	0.22	-13.15	0.430	7.33	0.230	-12.77
6	0.43	-7.33	0.772	2.25	0.730	-2.73
7	0.01	-40.00	0.965	0.31	0.014	-37.08
8	0.20	-13.98	0.675	3.41	0.029	-30.75
9	0.49	-6.20	1.059	0.50	0.030	-30.46

The mean S/N ratio for each parameter level is summarized in Table 5. As shown in Table 5, the molar ratio of oxidant: pyrrole (76.91 %) has the highest value for yield and the oxidant type (82.62 %) has the highest value for electronic conductivity. Therefore, it can be concluded that the molar ratio of oxidant: pyrrole and oxidant type are the parameters that are significant and affect the yield and electronic conductivity, respectively. In contrast, all the parameters were found almost equally to affect the particle size (Table 5).

Table 5. Mean S/N ratio for yield, particle size, and electronic conductivity

Factor	A	B	C	D
Parameter	Oxidant type	Molar ratio	Time	Dopant concentration
Yield				
Level 1 (dB)	-11.17	-28.00	-14.08	-13.42
Level 2 (dB)	-14.53	-12.17	-12.89	-18.90
Level 3 (dB)	-20.06	-5.58	-18.79	-13.43
ρ (%)	11.67	76.91	5.65	5.78

Figure 2 displays the graphs for (a) yield, (b) particle size and (c) electronic conductivity. As shown in Figure 2 (a), the optimum levels for each of the parameters are A1, B3, C3, and D3. Therefore, based on the graph, the optimum conditions for maximizing the yield are an oxidant type of APS, a molar ratio of oxidant:pyrrole of 5:1, a polymerization time of 24 hours and a dopant concentration of 0.1 M. Figure 2 (b) displays the optimum levels for decreasing particle size, which are as follows: A1, B2, C1, and D1, i.e., an oxidant type of APS, a molar ratio of oxidant: pyrrole of 3:1, a polymerization time of 1 hour and a dopant concentration of 0.01 M. Finally, to maximize the electronic conductivity (Figure 2 (c)), the optimum conditions are at A2, B3, C2, and D2, i.e., an oxidant type of $FeCl_3$, a molar ratio of oxidant: pyrrole of 5:1, a polymerization time of 8 hours and a dopant concentration of 0.05 M.

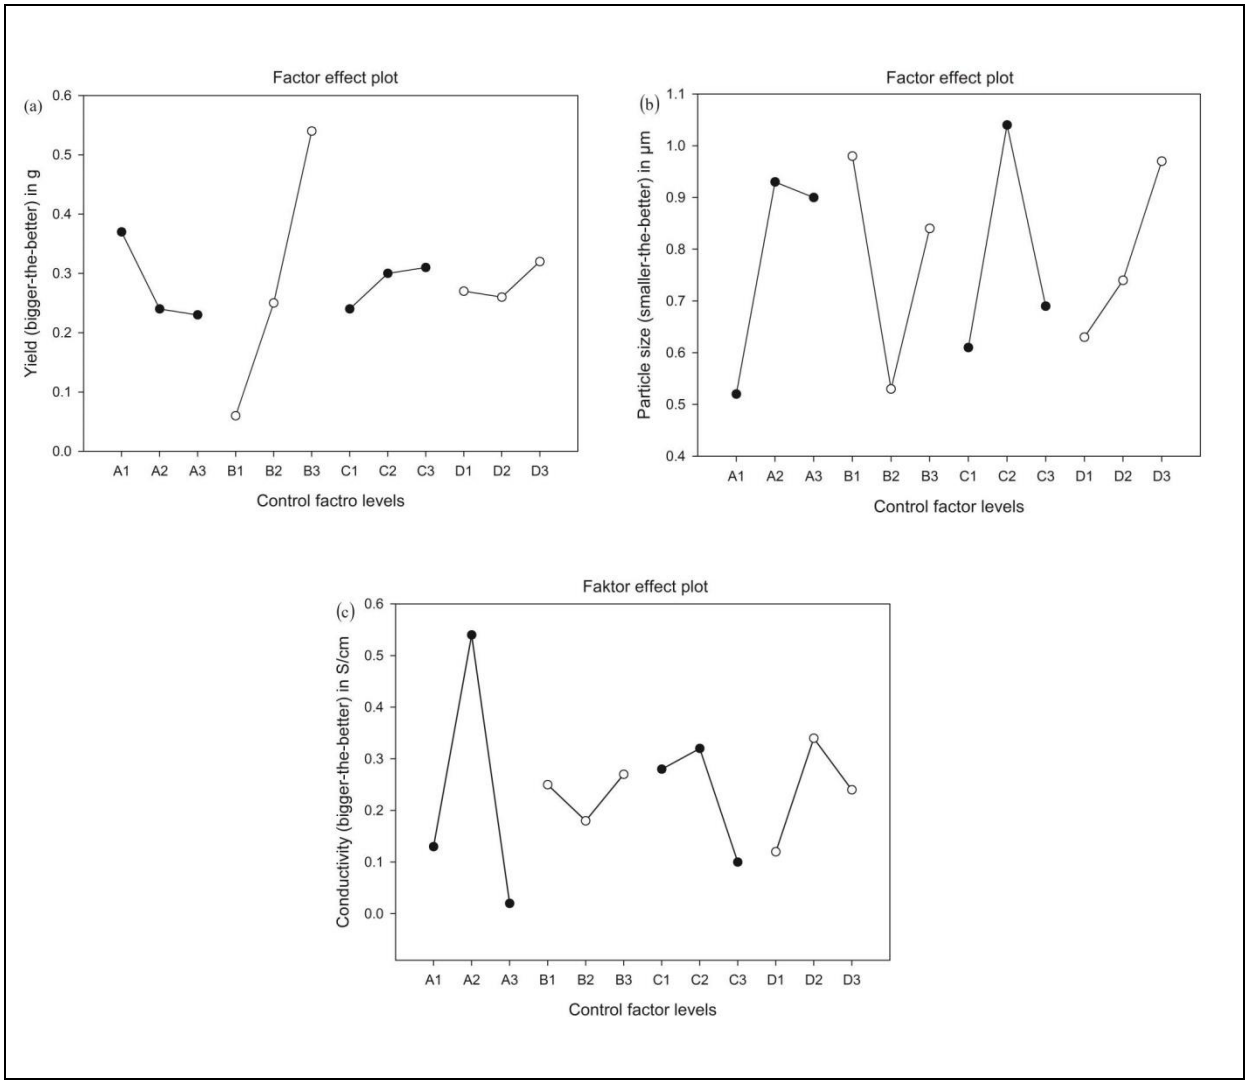

Figure 2. Graph for (a) yield, (b) particle size, and (c) electronic conductivity

In addition to S/N ratio, the variance analysis (ANOVA) was performed to investigate which process parameters significantly affect the response variables. The results of the ANOVA for yield, particle size and electronic

conductivity are presented in Table 6. As shown in Table 6, the order of significance of the factors for yield is as follows: B> A> D> C, whereas for particle size and electronic conductivity the order is: A> B> D> C and A> C> D> B, respectively.

Table 6. The ANOVA table of yield, particle size, and electronic conductivity for selected factorial model

Factor	Yield				Particle size				Electronic conductivity

Total	1036	8			119	8			1265	8		

Additional experiments at level A2, B3, C1, and D2 were conducted to confirm the Taguchi method. The results of the experiments as well as the prediction are shown in Table 7. There are good agreements between the predicted and experimental results for the yield, particle size and electronic conductivity. Thus, the synthesis process for the polypyrrole particles can be improved using the Taguchi method.

Table 7. Results of the confirmation for yield, particle size and electronic conductivity

	Level	Yield		Particle size		Electronic conductivity	
		Yield (g)	S/N ratio (dB)	Particle size (μm)	S/N ratio (dB)	E. Conductivity (S/cm)	S/N ratio (dB)
Prediction	A2B3C1D2	0.43	-7.33	0.771	2.26	0.73	-2.73
Experiment	A2B3C1D2	0.40	-7.96	0.725	2.79	0.77	-2.27

Effects of process parameters on the synthesis of the polypyrrole particles

Three types of oxidants were used to study their effects on pyrrole polymerization. All the solid products observed from the different types of oxidants were dark in colour. From the results of the Taguchi analysis shown in Figure 2, when APS was used, the products obtained the highest yield (0.37 g) and smallest particle size (0.52 μm), whereas when $FeCl_3$ was used, the highest conductivity (0.54 S/cm) was obtained. When H_2O_2 was used as the oxidant, it produced the lowest yield (0.23 g) and conductivity (0.02 S/cm) and the larger particles size (0.90 μm). The PPy synthesized using APS as the oxidant produced a higher yield than $FeCl_3$ and H_2O_2 because APS has more oxidizability towards the pyrrole monomers than the other oxidants [19, 27]. The high conductivity obtained with $FeCl_3$ as the oxidant compared to APS and H_2O_2 is due to the presence of iron ions. This result is in agreement with the previous work by Lascelles et al. [28]. They also found that the synthesis of polypyrrole silica particles using $FeCl_3.6H_2O$ produces a significantly higher conductivity than $(NH_4)_2S_2O_8$ and H_2O_2.

The effects of the molar ratio of oxidant to pyrrole on the yield, particle size and electronic conductivity are shown in Figure 2 (a-c). The product yield increased from 0.06 g to 0.54 g as the molar ratios of oxidant to pyrrole increased from 1:1 to 5:1. The same observation was also found by Li et al. [27] for the polymerization of PPy using APS as the oxidant. They also noted that the amount of oxidant required to produce sufficient PPy particles is at least equal to the monomer (molar ratio of oxidant/monomer higher than 1). From Figure 2 (b), when the molar ratios increased from 1:1 to 5:1, the particle size of PPy decreased first from 0.98 μm to 0.53 μm and then increased

again (0.84 µm). This is consistent with the finding of Li et al. [27]. They emphasized that at a lower concentration of oxidant, less Py radicals are formed, the polymerization process is slow, and thus smaller particles are formed. When the oxidant concentration is too high, more monomers are oxidized into radicals, and the particle size increases. The amount of oxidant also influenced the electronic conductivity of the PPy. Figure 2 shows that as the molar ratio increased from 1:1 to 5:1, the conductivity decreased first from 0.25 S/cm to 0.18 S/cm and then increased with a maximum of 0.27 S/cm at a molar ratio of 5:1.

Figure 2 also shows the influence of polymerization time on the synthesis of the PPy particles. The yield of the PPy particles increased from 0.24 g to 0.31 g when the polymerization time increased from 1 to 24 h. The same trend were also observed by Omastova et al. [29] and Pina et al. [11] for the pyrrole polymerization using silver nitrate and gold as the dopant, respectively. From their studies, the yield increased from 0.394 g to 4.939 g and 1 % to 99 % when the polymerization time increased from 24 to 168 hours and 8 to 72 hours, respectively. Thus, the longer the reaction time, the more PPy particles formed. Figure 2 also shows that as the polymerization time increased from 1 h to 24 hours, the particle size increased first from 0.61 µm to 1.04 µm and then decreased to approximately 0.69 µm, whereas the electronic conductivity increased from 0.28 S/cm to 0.32 S/cm and decreased after a polymerization time of 24 hours (0.10 S/cm).

When TsOH as a dopant into the polymerization was introduced, the yield increased from 0.27 g to 0.32 g as the dopant concentration increased. This is because the TsOH acted as both dopant and template at the higher concentration. Upadhyay and Kumar [15] showed that the yield of the sample increased from 43.12 % to 58.63 % with an increase in CTAB (dopant) concentration from 1 mM to 3 mM. They also observed that the particle size increased from 0.63 µm to 0.97 µm when the concentration of dopant (TsOH) increased. However, the conductivity of the PPy particles was found to increase from 0.12 S/cm to 0.34 S/cm when the dopant concentration was increased from 0.01 M to 0.05 M. Upon further increase in the dopant concentration, the conductivity decreased to 0.24 S/cm. Yang and Liu [30] observed a similar trend for the polymerization of PPy with the addition of PHMPS as the dopant. Their results showed that the conductivity of the samples increased when the feeding ratio of PHMPS was increased from 1 to 10 wt % and subsequently decreased. Several other investigators also reported the same observation [14-15, 22, 31].

Conclusion

In this study, an orthogonal Taguchi L9 array was used to investigate the effects of the synthesis parameters on the polymerization of pyrrole. The parameters studied were oxidant type, molar ratio of oxidant: pyrrole, time and dopant concentration. The results showed that the molar ratio of oxidant: pyrrole and the oxidant type significantly affected the yield and electronic conductivity, respectively. As the molar ratios of oxidant to pyrrole increased from 1:1 to 5:1, the product yield also increased from 0.06 g to 0.54 g. Additionally, when using $FeCl_3$ as the oxidant, the highest conductivity (0.54 S/cm) was obtained compared with APS and H_2O_2.

Abstract

The application of composite membranes for high temperature polymer electrolyte membrane fuel cell has attracted interests. Nafion-metal dioxide composite membranes are considered among the research niche. In this study, Nafion membranes and Nafion-zirconia composite membranes with 1, 3 and 5 wt. % of hydrous zirconia were prepared accordingly. All membranes were characterized by quantitative analysis techniques such as thermogravimetry analyse, diffraction scanning calorimetry and Fourier transform infrared. All composite membranes showed high glass transition temperatures and improved water retention properties, compared to the Nafion membrane. The composite membrane with 3 wt. % of zirconia showed the highest thermal resistance at 90°C.

Keywords: high temperature PEM, glass transition temperature, conductivity, composite membrane, Nafion-zirconia

Abstrak

Penggunaan membran komposit dalam operasi sel bahanapi membran penukar proton pada suhu tinggi semakin mendapat perhatian pengkaji. Membran komposit Nafion-logam dioksida adalah antara bidang kajian dalam kumpulan ini. Bagi kajian ini, membran Nafion dan membran komposit Nafion-zirkonia dengan 1, 3, dan 5 wt. % telah disediakan. Kesemua membran dicirikan menggunakan teknik analisis kuantitatif seperti analisis termogravimetri, kalorimetri imbasan kerbedaan dan Fourier inframerah. Kesemua membran komposit mempunyai suhu peralihan kaca yang tinggi dan keupayaan penahanan air yang lebih baik berbanding membran Nafion. Membran komposit dengan 3 wt. % zirkonia menunjukkan ketahanan suhu tinggi pada suhu operasi 90°C.

Kata kunci: PEM suhu tinggi, suhu peralihan kaca, konduktiviti, membran komposit, Nafion-zirkonia

Introduction

Fuel cells are electrochemical devices which convert the energy from the reaction of fuel and oxygen into electric energy continuously with water and CO_2 as the byproducts [1]. Polymer electrolyte membrane fuel cell (PEMFC) is one of the fuel cell types, for temperature ranging from 60 - 100 °C. Nafion membranes are the most commonly used polymer electrolytes in PEMFC application as it has excellent chemical, mechanical and electrochemical properties as well as high proton conductivity at ambient temperature and high humidity condition. This water-based electrolyte needs to be kept in a hydrated condition for the best performance and a maximum conductivity of 0.083 S/cm at 100% relative humidity (RH) [2].

However, the membrane tends to shrink at low humidity and swells under excess water conditions due to its molecular structure. The ionic groups form clusters of 2 – 4 nm in diameter, which are connected by narrow channels; the size of these clusters is proportional to the water level in the membrane, which can explain the shrink-swell behavior of the polymer [3]. Therefore, developing membranes with good stability for both thermal and mechanical properties is desirable. Many methods have been developed to produce composite membranes, including incorporating hygroscopic metal oxides such as SiO_2 [4], TiO_2 [5] and ZrO_2 [6] into the Nafion polymer structure. Incorporating a hydrophilic, inorganic material into the perfluorinated polymer is an alternative way to increase the binding energy of water [7]. The membrane strength and performance increased, as the organic polymer formed strong interaction with the inorganic component having large specific area [8].

In this study, a series of Nafion-ZrO_2 composite membranes with 1, 3 and 5 wt. % of hydrous zirconia loading were prepared with the purpose of increasing the thermal resistance of membrane, thus increasing the proton conductivity of the membrane. The hygroscopic property of zirconia was expected to improve the thermal strength of the membrane by increasing the glass transition temperature.

Materials and Methods

Materials

The 5 wt. % Nafion solution (EW 1100) and Nafion 115 were purchased from DuPont, USA. Zirconium (IV) oxychloride octahydrate ($ZrOCl_2.8H_2O$), ammonium solution (NH_4OH), dimethylformamide (DMF), sulfuric acid (H_2SO_4, 98 %) and hydrogen peroxide (H_2O_2, 30 %) were all purchased from Aldrich. Deionized water was used as the solvent in all experiments.

Preparation of the Nafion-ZrO_2 composite membrane

Nafion solution was evaporated at room temperature to obtain solid Nafion. The solid Nafion was then dissolved in DMF and stirred for two hours. Meanwhile, the hydrous zirconia was prepared via film casting process according to the method proposed by Chuah et al [9]. $ZrOCl_2.8H_2O$ was dissolved in distilled water. Dilute aqueous ammonia was added drop-wise to the solution with vigorous stirring until the pH of the solution reached 10. The obtained precipitate was washed with distilled water several times to remove the chloride ions before being oven-dried at 100°C for 12 hours. Matrices of 1, 3 and 5 wt% of Nafion-ZrO_2 were mixed in a DMF solution. Subsequently, the mixture was casted onto a container and heated at 80°C for 2 hours, before the temperature was increased to 110°C for six hours to enhance the polymer strength and remove excess solvent. After that, the recast composite membrane was detached from the container and washed with a 3 wt % H_2O_2 and 0.5 M H_2SO_4 solution. These samples were labeled as NZ01, NZ03 and NZ05 according to the loading of 1 wt%, 3 wt% and 5 wt% of hydrous zirconia, respectively. A similar method was used to prepare the recast Nafion.

Characterization of the Nafion-ZrO_2 composite membrane

The infra-red spectra of the composite membranes (NZ01, NZ03 and NZ05) were recorded to detect the functional groups chemical change in the polymer as compared to pure Nafion membrane. A Thermo Fisher Scientific FTIR (Nicolet 6700) spectrophotometer was used in the analyses.

The DSC spectra of the prepared composite membranes were obtained using a DSC 1 Star System (Mettler Toledo). Membrane samples were cut and weighed to 0.25 g in an aluminum crucible. Measurements were performed over the temperature range of 30 – 300 °C with a heating rate of 20 °C /min under nitrogen gas.

The ionic conductivity of the membranes was measured with a potentiostat (Autolab, PGSTAT 128N) in the frequency range between 1 mHz and 100 kHz. The membrane samples were immersed for 30 minutes in de-ionized water at the desired temperature before being placed on electrode cells for measurements. The measurement was carried out at room temperature and at 90 °C in order to study the effect of operating temperature and compositions of the inorganic compound embedded in the polymer matrix towards conductivity at 90 °C. The graph of the negative imaginary impedance versus the real impedance was plotted for each set of data. The bulk impedance R_b of the samples was determined from the curve and thus, the ionic conductivity, σ, was calculated using Equation 1.

$$\sigma = t/(R_b * A) \quad (1)$$

where, *t* is the sample thickness (cm), *A* is the effective contact area of the film and the electrode (cm^2) and R_b is the bulk resistance (Ω).

Results and Discussion

Structure analysis

Figure 1 shows the FTIR spectra of recast Nafion; NZ01, NZ03, NZ05 composite membranes; and hydrous zirconia. The peaks at 3455.03 – 3428 cm^{-1} are assigned to the bending vibrations of water molecules and the OH stretching mode of the adsorbed water [10]. It is observed that the broad peak of the -OH peak increases with the addition of the zirconia composition. The peaks at 1198.28 cm^{-1}, 1198.25 cm^{-1} and 1198.32 cm^{-1} are attributed to the $-CF_2-CF_2-$ vibration, as reported by Zhai et al. [11]. The $–SO_3-$ peaks appear at 1059.26 cm^{-1}, 1058.19 cm^{-1} and 1055.21 cm^{-1}. The IR spectra of NZ01, NZ03 and NZ05 are similar to that of recast Nafion, except for the appearance of a small peak near 1500 cm^{-1}, indicating the existence of hydrous zirconia molecules in the composite membranes. The peak that appears around 1530.49 – 1520.22 cm^{-1} indicates the Zr-OH bending vibrations. Peaks at 514.28 cm^{-1} and 513.72 cm^{-1} show the Zr-O vibrations, which are overlapped by the transmittance peaks of the Nafion [12]. As mentioned by Pan et al., the overlapping peaks suggest that the addition of zirconia does not affect the crystallinity or the molecular structure of the Nafion membrane [6].

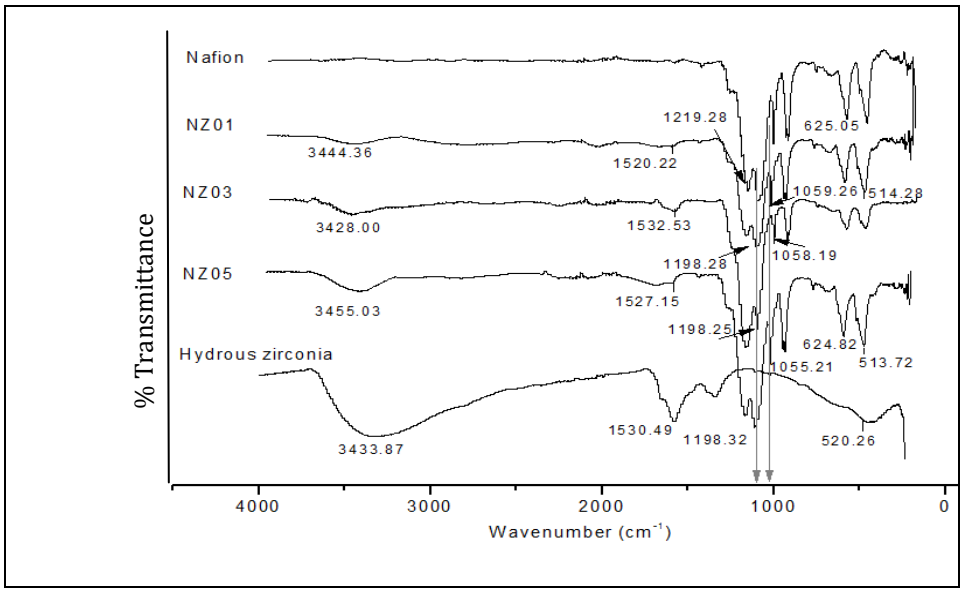

Figure 1. FTIR spectra of Nafion and Nafion-ZrO_2 composite membranes

Thermal properties

The results obtained from thermal gravimetric analysis (TGA) is shown in Figure 2. The TGA curves show a three step degradation, which is the loss of physically and chemically bound water (below 200 °C), the decomposition of sulfonic acid groups or desulfonation (250 – 400 °C) and main chain degradation (400 –800°C) [13]. As expected, recast Nafion degrades faster than the composite membranes in all three degradation steps.

The magnified portion of the graph shows the first part of the degradation. Low of mass loss (<6 %) is shown for the composite membranes at this temperature range. The degradation of the Nafion membrane was caused by the breakage of the perfluorinated backbone and the side-chains in the membrane. The desulfonation of the membrane starts at approximately 280 °C for the recast Nafion membrane, whereas it begins higher for the composite membranes, at the temperatures of 300 °C for NZ01 and NZ03, 280 °C for NZ05, which indicates the breaking of

C-S bonds. NZ05 has the lowest desulfonation temperature among the composite membranes, which is similar to the recast Nafion.

For the third step of the degradation, it is clearly seen that the Nafion decomposes at a lower temperature than the composite membranes. Iwai and Yamanishi [14] have reported that cations with larger ionic radii show higher thermal stability when reacted with Nafion and Zirconia is a metal oxide with large molecular radius. Therefore, the composite membranes have higher thermal retention as a higher temperature is needed to activate the energy barrier and break the bond.

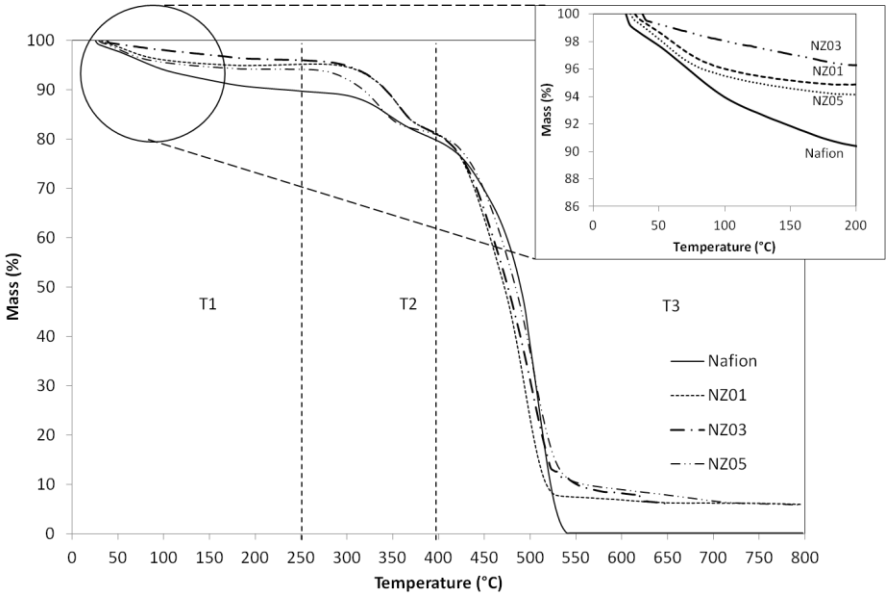

Figure 2. TGA curves for Nafion and composite membranes. T1: Water loss, T2: desulfonation, T3: main chain degradation.

Figure 3 shows that an endothermic peak appears at approximately 70 – 90 °C, which increases up to 3 wt. % of hydrous zirconia content, indicating the enhanced water retention. These broad peaks (ranging from 50 – 140 °C) caused by the structural change in the membrane cluster as shown in the FTIR spectrum. The composite membranes show different behavior than Nafion membrane as temperature increases. This observation is consistent with the report by Sacca et al [2], where zirconia functions well as a hygroscopic compound in improving the water content in the membrane, although the pattern shows a decrease for NZ05. At the desulfonation phase, the recast Nafion degraded slower than the Nafion membrane, as they have amorphous zirconia to resist the degradation. A broad exothermic peak appears at approximately 350 °C for all composite membranes, which is attributed to the dehydroxylation of the hydrous zirconia with increasing temperature. The exothermic event is then followed by another weight loss due to main chain degradation. The exothermic peak with weight change is assigned to the releasing of hydroxyl groups at a high temperature, resulting in the formation and crystallization of the amorphous zirconia [15]. Another two peaks of crystallization appear at approximately 450 °C and 550 °C, indicating another phase change in the hydrous zirconia.

From Figure 3, it is seen that Nafion had loss almost 10 % of mass at 300 °C but the NZ01 and NZ03 composite membranes had retain more than 95 % of their weight while NZ05 had 8 % mass loss at the same temperature. Above 300 °C, all membranes decompose rapidly as the membranes starts losing their sulfonyl chain in the Nafion matrix. However, the temperature shifted for the composite membranes, due to the nature of the hygroscopic inorganic component; increasing water content in the composite membrane [16]. Thermal degradation of Nafion

membrane occurs at 308 °C; whereas the degradation temperature shifted to 333 °C for both NZ01 and NZ03, and at 317 °C for NZ05. Shao has reported that the increment of degradation temperature is due to the addition of metal oxide (such as SiO_2, TiO_2, ZrO_2) into the Nafion matrix as the inorganic compound is temperature tolerant filler [17].

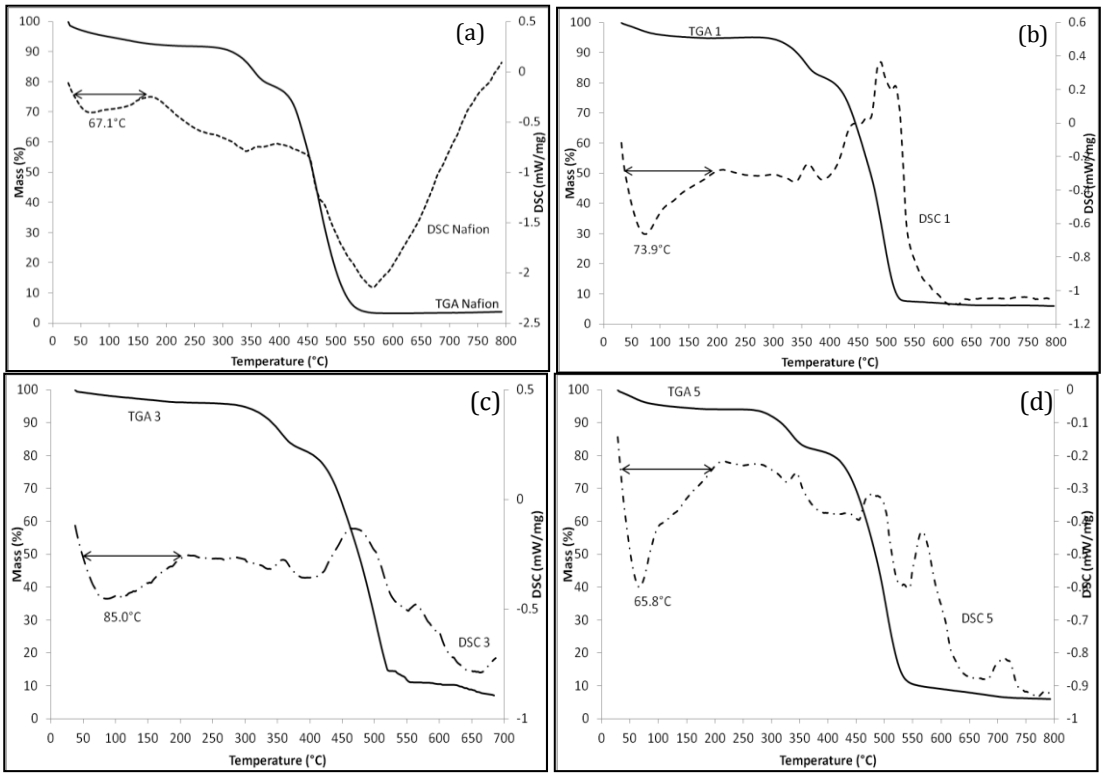

Figure 3. TG and DSC curves of composite membranes, taken at 10°C/min, under N_2, for (a) Nafion, (b) NZ01, (c) NZ03, (d) NZ05.

As for the glass transition temperature (T_g), another test was conducted using differential scanning calorimetry (DSC). The related results are shown in Table 1, increased in the sequence of: Recast Nafion < NZ05 < NZ01 < NZ03. It is seen that the T_g value of Nafion membrane is observed at 117.73 °C, which is lower than the T_g of the composite membranes. Whilst, NZ03 has the highest T_g = 171.50 °C, indicating the strength of the membrane to resist high temperature is improved. Incorporation of the amorphous zirconia particles into Nafion polymer matrix would improve the thermal stability and increase the T_g [18]. The occupied inorganic particles resulting on more energy needed for starting segmental motions, which would increase the T_g value. However, the T_g value decreases for NZ05, despite having the same thickness with NZ03 composite membrane. Probably, the presence of excessive inorganic particles has weakened its structure by forming a brittle membrane [2].

Membrane conductivity

Figure 4 shows the typical impedance curves of four different membranes. Fundamentally, all depicted spectra consist of two arcs, one each for low and high frequency. The basic circuit of a circle is R(RQ), as depicted below the plotted graph. The graph shows the increasing diameter of the arcs within the composition, except for NZ05 which represent increase conductivity.

Table 1. Thermal properties of recast Nafion and composite membranes

Membrane	Thickness (µm)	Residue (%)	Glass transition temperature (Tg)
Nafion	127.00	3.64	117.73
NZ01	107.07	6.01	139.62
NZ03	121.47	6.02	145.28
NZ05	122.97	5.89	141.33

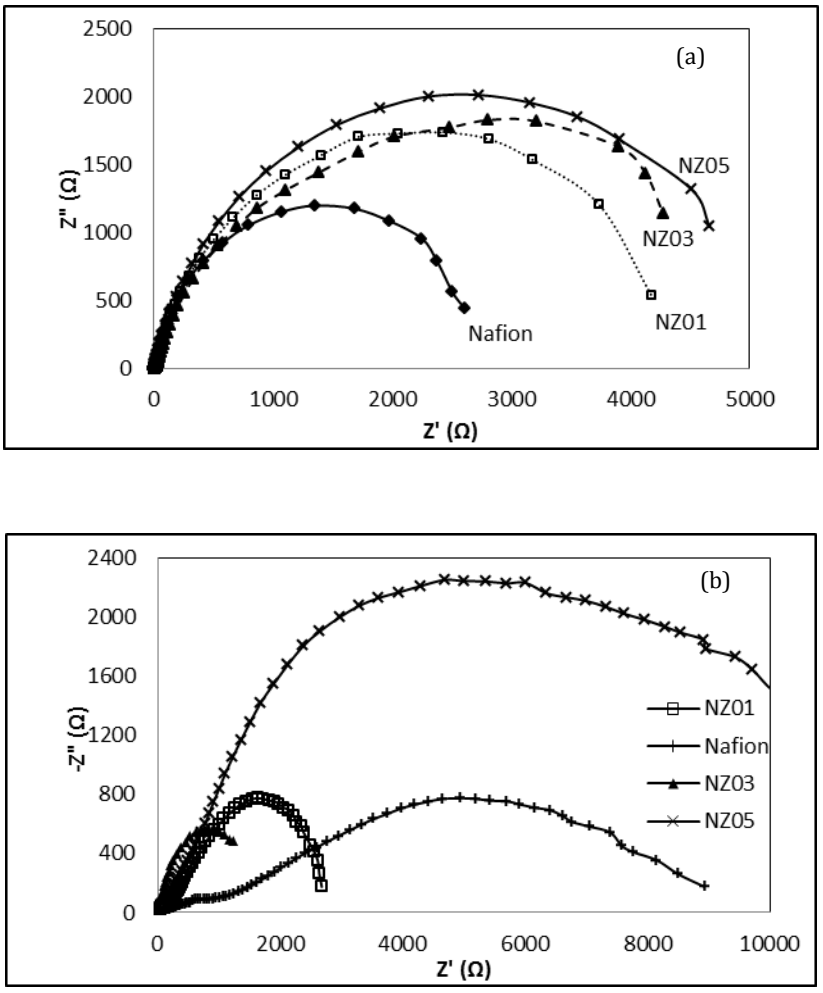

Figure 4. Impedance curves of Nafion and the composite membranes (a) room temperature and (b) at 90°C

The equivalent circuit that is presented in Figure 4 provides a good fitting for these responses. Each circuit consists of two sets of resistor-capacitor pairs. The calculated conductivity of the Nafion membrane at room temperature is 8.32×10^{-3} S/cm. From the obtained data, the ionic conductivity of the composite membranes ranges from 1.41×10^{-2}

S/cm to 1.62 x 10^{-2} S/cm. These values increase proportionally with the zirconia composition, which is consistent to the results reported by Uma [19].

Impedance curves for the Nafion and the composite membranes at 90 °C were shown in Figure 4b. The circle diameters for NZ01 and NZ03 are smaller than the Nafion membrane and the NZ05 composite membrane. A decreased diameter results in higher conductivity. Compared to the value for room temperature measurements, NZ01 and NZ03 at 90°C have circles in smaller diameter, indicating good conduction of the membranes. As the temperature increases, the conductivity is also increases [20]. The calculated conductivity increases from 0.014 to 0.042 S/cm for NZ03 and increased from 0.014 to 0.022 S/cm for NZ01. On the contrary, the conductivity is decreased for the Nafion and the NZ05 composite membrane. For the commercial Nafion, the plotted arcs have the same equivalent circuit (two arcs) as at room temperature but with larger diameter, resulting in a lower conductivity. This effect is caused by the weak thermal resistance of Nafion, as a result of which the membrane starts to shrink at a temperature near 100 °C [21].

Conclusion

In this study, Nafion-ZrO_2 composite membranes were prepared through film casting process and characterized for their structure, morphology, thermal stability and conductivity. The Nafion membrane exhibited lower conductivity than the composite membranes at room temperature under fully hydrated conditions. Despite an increase in temperature, the conductivity of the composite membranes improves. This effect is due to the hygroscopic properties of hydrous zirconia, which has an optimal content of 3 wt. %. Whenever excess hydrous zirconia is used, the conductivity decreases and it affects the *in situ* performance of the membrane in the membrane electrode assembly (MEA) due to the increase in the particle size. Through understanding that the composite membrane has an improved water uptake and conductivity at room temperature and at 90 °C, further investigation will be conducted in the future to explore the effect of hydrous zirconia on the performance at moderate temperature (100 °C).

Abstract

This study is focused on development of membrane electrode assembly (MEA) for direct formic acid fuel cell (DFAFC). The effects of the backing layer, the loading of the gas diffusion layer (GDL), the carbon structures and the electrolyte membrane types, and fuel concentrations on the DFAFC's performance are investigated. Two types of backing layer are used in either a carbon paper (CP) or carbon cloth (CC) form, and three different types of carbon structures, carbon black (CB), carbon nanofiber (CNF) and carbon nanotube (CNT), are studied. A single cell DFAFC is tested to obtain the performance of the MEA, including the open circuit potential (OCP), current density, and power density. From the results, carbon paper indicates a much better performance than carbon cloth and gas diffusion layer (GDL) with 1 mg cm^{-2} loading shows a uniform surface morphology under scanning electron microscopy (SEM) and records a higher power density than 2.5 mg cm^{-2}. Moreover, it is found that the power density increases with increase of the formic acid concentration up to an optimum concentration. However, the optimum fuel concentrations are different for each type of carbon structure. The highest power density is obtained using a combination of CNT and electrolyte membrane of Nafion 117 at 18.36 mW cm^{-2} using 10 M fuel concentration.

Keywords: electrode; performance, microporous, characteristic, direct formic acid fuel cell

Abstrak

Kajian in tertumpu kepada pembangunan himpunan membran elektrod (MEA) untuk asid formik sel bahanapi langsung (DFAFC). Kesan lapisan sokongan, kandungan lapisan resapan gas (GDL), struktur karbon and jenis membran elektrolit, serta kepekatan bahan api terhadap prestasi DFAFC diselidiki. Dua jenis lapisan sokongan sama ada kertas karbon mahupun kain karbon, dan tiga jenis struktur karbon; karbon hitam (CB), nano-serat karbon (CNF) dan nano-tiub karbon (CNT) digunakan dalam kajian ini. Sel tunggal DFAFC diuji untuk memperoleh prestasi MEA termasuk keupayaan litar terbuka (OCP), ketumpatan arus dan ketumpatan kuasa. Berdasarkan hasil kajian, kertas karbon menunjukkan prestasi yang lebih baik berbanding kain karbon. Manakala, GDL dengan kandungan 1 mg cm^{-2} menunjukkan morfologi permukaan yang seragam di bawah mikroskop pengimbas elektron (SEM) dan merekodkan ketumpatan kuasa yang lebih tinggi berbanding 2.5 mg cm^{-2}. Sementara itu, ketumpatan kuasa meningkat dengan peningkatan kepekatan asid formik sehingga kepekatan optimum. Ketumpatan kuasa yang tertinggi diperoleh melalui kombinasi CNT dan membran elektrolit Nafion 117 pada nilai 18.36 mW cm^{-2} menggunakan kepekatan bahan api 10 M.

Kata kunci: elektrod, prestasi, mikroporos, pencirian, asid formik sel bahanapi langsung

Introduction

A fuel cell is a source of renewable energy which excludes the combustion process. Hence it does not release any harmful pollution as a side-product of the reaction. Direct formic acid fuel cell (DFAFC) is one of the fuel cell type which has a higher open circuit potential (OCP), at 1.40 V, than the proton exchange membrane fuel cell (PEMFC) (1.23 V) and direct methanol fuel cell (DMFC) (1.18 V). Therefore, the DFAFC has a high potential to be commercialized as a microfuel cell due to its high output power compared to other liquid fuel cells like DMFC [1] and it is the most suitable technology to replace the battery.

The membrane electrode assembly (MEA) is the heart of a fuel cell, where the main electrochemical reaction takes place and produces electricity. Hence, it is the most crucial part of the fuel cell as well as the direct formic acid fuel cell (DFAFC) [2]. Currently, there are a lot of studies focusing on the optimizing the MEA for the fuel cell [3-5]. However, the conventional characteristics of an anode may not be suitable for the DFAFC due to its formic acid properties. As a result, formic acid fuel presents the difficulty of mass transport constraints through absorption media in the anode, which is usually in a hydrophobic condition [6]. For instance, the Nafion content in the GDL will increase the proton transport moving towards the cathode [7]. The mass transport constraints on the anode depend on the nature of the anode absorption media and formic acid concentrations. This constraint is due to the hygroscopic nature of formic acid in the absorption of hydrophobic media [8]. Therefore, it is necessary to develop a good anode as well as anode absorption media and MEA, including the formulation and the types of materials to overcome the mass transport constraints at the DFAFC's anode.

Based on Sharma and Pollet [9], CB is a conventional catalyst support used for the platinum (Pt) catalyst and Pt alloys in the research and commercialization of fuel cells. However, the use of CB is constrained by problems such as the presence of sulfur impurities and pores that trap microporous nanoparticle catalyst. This means that the active site of reaction cannot be reached by the reactants, resulting in deterioration of the catalytic activity. Zainoodin et al. conducted a study on the effects of the porous layer structure at the anode on the performance of DMFCs. They used three types of carbon powder structures; CB, mixtures of CB and CNF, and CNF. From the results, it was found that the CNF structure recorded a higher performance for methanol concentration in the range of 2 to 5 M [10]. This explains the impact of high electrical conductivity and good use of the catalyst in CNF as the GDL for DMFCs.

Generally, the fuel of formic acid has better compatibility with Nafion membrane [1] than methanol in DMFCs. However, formic acid also has a certain limit of concentration to prevent a high fuel crossover from the anode to the cathode, and this reduces the DFAFC performance. Besides the fuel concentration, Jeong et al. reported that the thickness of the membrane also influences the crossover of formic acid, which affects the performance [11]. On the other hand, Kim et al. found that Nafion 117 was the best electrolyte membrane for 12 M formic acid, with 84 mW cm^{-2} power density generated at 0.43 V [1].

In this study, the MEA is developed for the use of DFAFC. The effects of the backing layer, the loading of GDL, the carbon structures and the electrolyte membrane types, and fuel concentrations on the passive DFAFC's performance are investigated. The characterization of the electrode was analyzed, including the morphology structure, hydrophobicity level and electrical conductivity, and will be discussed on the basis of DFAFC performance.

Materials and Methods

Fabrication of anode's diffusion layer and MEA

Homogeneous carbon ink was prepared by ultrasonication of the carbon with 5 % Nafion solution and isopropyl alcohol. The ink was coated on the backing layer to make the GDL and dried in an oven at 80° C for about an hour. At the anode side, two types of backing layer, i.e. carbon paper (CC) and carbon paper (CP), and three different carbon structures were used (shown in Table 1) and two GDL loadings were investigated at 1.0 mg cm^{-2} and 2.5 mg cm^{-2}. For the cathode, CP with 2.5 mg cm^{-2} CB loading was used throughout the study. Meanwhile, for the catalyst layer, 8 mg cm^{-2} catalyst loading of palladium (Pd) black (Alfa Aesar) was used as catalyst at the anode side, while platinum (Pt) black was used at the cathode side. For the electrolyte membrane, Nafion 117 (DuPont) and NRE 212 (DuPont) were used and the active area for the MEA was 4.84 cm^2. For the MEA preparation, the

anode and cathode were then assembled by the hot-pressed process with the electrolyte membrane at 135 °C and 50 kg cm^{-2} for 3 minutes.

Table 1. Properties of carbon powder

Carbon structure	Specification	Manufacturer
Carbon black (CB)	Purity > 99% Relative density 1.7-1.9 g cm^{-3} at 20^0C	Cabot
Carbon vaporised growth nanofiber (CNF)	Outer diameter 200-600 nm Length 5-50 µm Purity >95.0%	Cheaptubes
Multiwall carbon nanotube (CNT)	Outer diameter 100-150 µm Length 20 µm Purity ≥95	Sigma- Aldrich

Characterization of anode and single cell DFAFC operation

The physicochemical properties and surface morphology of the GDL were observed with a contact angle measurement (KRÜSS Drop Shape Analysis by Fischer) and SEM (ZEISS), respectively. Contact angle measurements were done by using deionized water, methanol fuel (0.5 – 2 M) and formic acid fuel (0.5 – 6 M). SEM images were taken before the catalyst layers were coated onto the GDL. Meanwhile, the electrical conductivity test for the backing layer with different GDL was conducted by using the four point probes technique (Jandel Model RM3) to measure electrical resistivity towards the plane of the GDL. As a result, the through plane electrical conductivity of the GDL can be calculated by applying 5 mA current.

The electrochemical reaction for a half-cell as well as single cell DFAFC was measured and studied based on cyclic voltammetry (CV) and current–voltage (I–V) testing using WonATech potentiostat (WMPG1000). The CV test involved three electrodes, which are Ag/AgCl as reference electrode, and platinum wire as counter electrode, while the working electrode used for the measurement was the anode prepared with different carbon structures with active area of 1 cm^2. For the electrolyte of the half-cell reaction, 0.5 M H_2SO_4 was added to 0.5 M formic acid to maintain a constant pH and stabilize the reference electrode potential. The scan rate for this electrochemical measurement was set at 50 mV s^{-1} in the range of 0.02 to 1.2 V and the electrochemical surface area (ECSA) was determined via CV analysis. For a single cell DFAFC, the cell was operated passively at 25 ºC with ambient pressure by injecting a formic acid solution at 5 ml with a certain concentration from 4 M to 16 M into the reservoir under ambient conditions.

Results and Discussion

Effect of backing layer and GDL loading

The contact angle surfaces for the backing layer for a series of different concentrations of methanol and formic acid are shown in Figure 1. At this measurement, both commercial CC and CP were used without the GDL coated and had the same Teflon loading of 20 wt.%. From the figure, it is clear that different levels of hydrophobicity were obtained at different liquid fuel concentrations. For instance, the contact angle is very similar, at 92°, using 2 M methanol and 6 M formic acid.

In the case of the hydrophobicity profile, the contact angle for carbon cloth and carbon paper with a solution of methanol decreased significantly with the decrease in the methanol concentration gradient from 0.5 M to 2 M. However, for formic acid, the contact angle decreased with increasing formic acid concentration from 0.5 M to 3 M for both backing layers, while there was a significant decrease from 3 M to 6 M especially for carbon paper, as shown in Figure 1. The contact angle between the formic acid and carbon cloth is observed to be higher than with carbon paper. A similar tendency of the contact angle decreasing with the increasing concentration of formic acid was also obtained in previous studies by Uhm et al. [8].

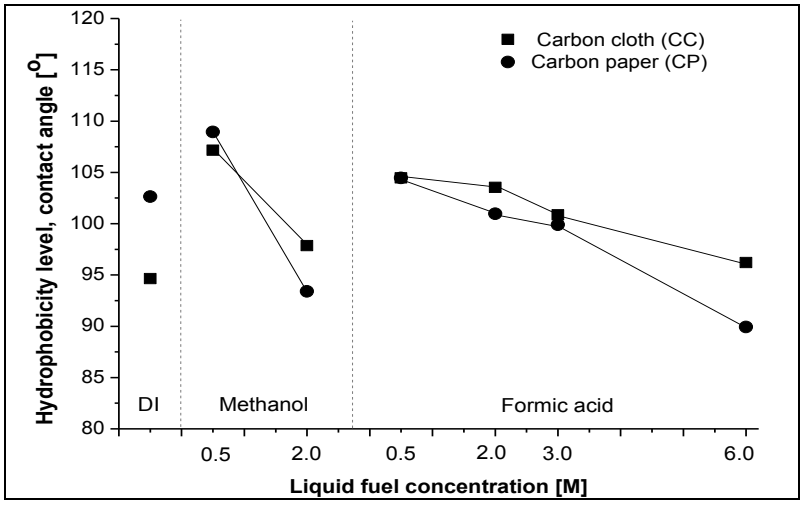

Figure 1. Hydrophobicity level for carbon support without GDL in different fuel concentrations

Nevertheless, the values of the contact angles for all backing layers with liquid fuel concentrations are greater than 90°, which indicates a hydrophobic surface layer of support. Chen et al. reported that a static contact angle between 0° and 90° was hydrophilic while a contact angle greater than 90° was hydrophobic [12]. The wetting of porous solids also involves a contact angle phenomenon but it is complicated by the presence of a porous architecture that can be seen in the next section and shows the surface of the GDL. Konduru stated that a high reading of the contact angle and a rough surface on the carbon support and GDL restrict the accuracy of the contact angles [13]. In the case of formic acid fuel, Uhm et al. reported that the hydrophobicity level in the direct liquid fuel cell (DLFC) could control the liquid fuel transport to a certain extent for the reaction process and hence affected the performance of the cell [6]. Therefore, measuring the hydrophobicity level for different liquid fuel types and concentrations shows that the DMFC and DFAFC should have a different GDL or electrode structure to prevent the mass transport limitation of the fuel. Therefore, it is important to maintain the hydrophobicity level at the optimum condition in the GDL.

The GDL requires good electrical conductivity to support the catalyst and to ensure a good contact between the catalyst and ionomer material, which has an ionic contact with the electrolyte membrane [10]. Figure 2 shows the measurement data of electrical conductivity for different GDL structures, i.e., different backing layers and carbon structures, with 2.5 mg cm^{-2} carbon loading. From the figure, the backing layer without GDL provided a high conductivity. However, it has a drawback in terms of durability and this affects the water management in the electrode in order to prevent the flooding phenomenon. It was found that the GDL structure with CNT has the highest electrical conductivity compared with other microporous layers for both CP and CC at 1.25 S cm^{-1} and 1.46 S cm^{-1}, respectively. However, the electrical conductivity of the CB and CNF is still within the range of appropriate electrical conductivity of GDL, between 0.40 S cm^{-1} and 1.64 S cm^{-1} [14]. CNT has higher conductivity due to its unique structural, mechanical and electrical properties and also has a high aspect ratio to form a network of conductive tubes [15].

Moreover, it was observed that the electrical conductivity of the carbon cloth was higher than that of carbon paper. It was suggested that the carbon cloth with its highly porous structure provided a good support to build a uniform layer of GDL, and hence higher electrical conductivity was obtained. Figure 3 shows the performance of the DFAFC using different types of backing layer and GDL loading at the anode using 4 M formic acid. In general, the power density for carbon cloth is lower than for carbon paper with the same structural carbon. This might be influenced by coarse structure in the carbon cloth's surface. The performance of each carbon support with different carbon structures with 2.5 mg cm^{-2} loading is low.

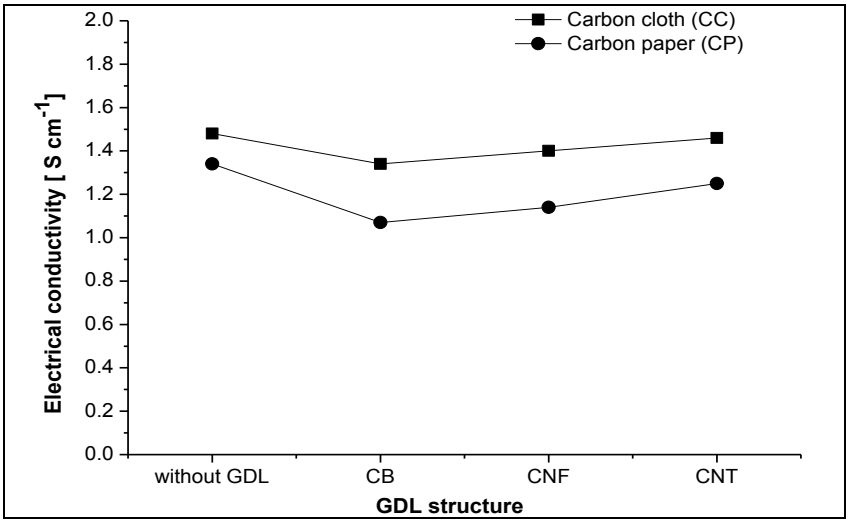

Figure 2. Electrical conductivity for different structures of GDL

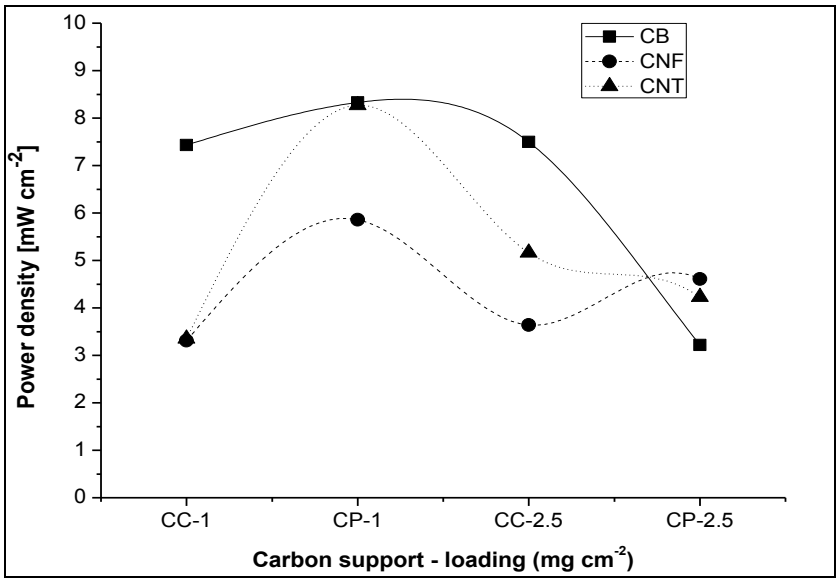

Figure 3. DFAFC performances for different types of carbon and loading at 4 M formic acid

From the observation, the microstructure layer with CP as support with a loading of 1.0 mg cm^{-2} (CP-1) recorded the highest power density. The porous structure of carbon cloth causes all the ink of the carbon to diffuse to the carbon support. This phenomenon prevents the GDL surface giving good support as a catalyst layer. This explains the maximum power density obtained by the carbon loading of 2.5 mg cm^{-2} of carbon black compared to other microstructures (CNF and CNT) with carbon cloth. As the size of the nanostructure particles decreases, they tend to agglomerate during the ultrasonication process, which hinders the absorption of fuel to react with the catalyst. Therefore, it is easier for the CB to achieve the homogeneous level compared to the other carbon powder. Hence, the high loading (2.5 % mg cm^{-2}) of CNF and CNT is not preferable for this application.

However, CNF and CNT with 1.0 mg cm^{-2} loading at the CC diffuse more easily due to the pore size. Hence, using CP that requires a loading of 1.0 mg cm^{-2} is preferable because it offers good diffusion for the catalyst to react with the formic acid as fuel. From the results, carbon powders achieve higher performance for all layers of the microstructure. CP with a loading of 1.0 mg cm^{-2} microstructure for both CB and CNT recorded high performances, at 8.15 mW cm^{-2} and 8.27 mW cm^{-2}, respectively. From the results acquired, carbon paper as the support layer will provide a better performance with a loading of 1.0 mg cm^{-2} than with 2.5 mg cm^{-2}. Therefore, CP with a loading of 1 mg cm^{-2} was used as the backing layer for the following study to fabricate the anode.

Effect of carbon structure, electrolyte membrane and fuel concentrations

Figure 4 shows the image of the anode's GDL morphology structure through SEM using different carbon structures at the carbon paper: a) without GDL; b) CB; c) CNF), and d) CNT. As seen in Fig. 4, different structures can be observed with different carbon structures or without the GDL. By comparing the morphology, it is clear that the CP without a microporous layer of GDL has a surface layer of coarse fibers compared with a GDL.

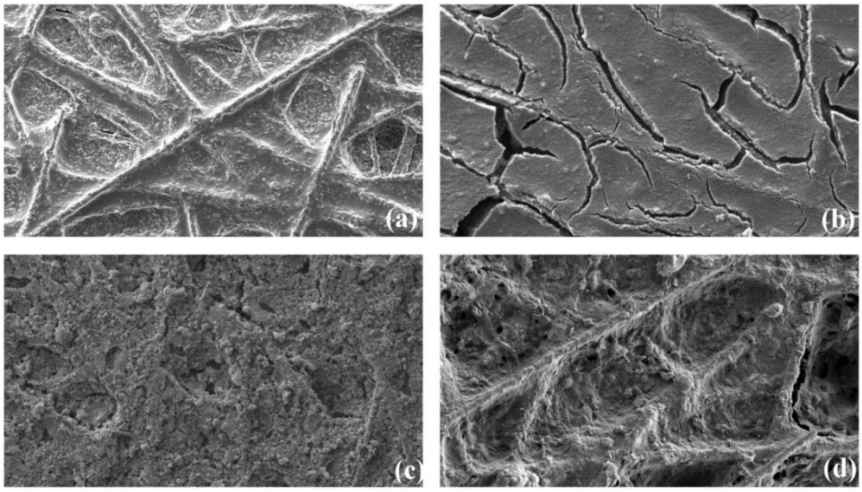

Figure 4. SEM images of CP support with GDL loading 1.0 mg cm^{-2} for (a) without GDL, (b) CB, (c) CNF and (d) CNT at 200 X magnification and a scale of 100 µm

The structure of the GDL with CB gives a smoother surface than without a microporous layer support. However, the GDL with CB (Figure 4 (b)) results in a cracking layer which increases the loss of the catalyst because it may be adsorbed on the cracked microporous layer. Figure 4 (c) and (d) shows that the dispersion of carbon ink CNF and CNT is more even. The CNT structure in Figure 4 (d) presents some of the carbon fiber from the carbon paper due to the smaller size of CNT compared to CNF, as previously mentioned in Table 1. The smooth surface ensures good GDL contact with the catalyst layer, but also nanostructured carbon can be used to improve the electrical properties and structure of the GDL [16] for the DFAFC.

Figure 5 shows the CV test on the anode with different GDL-Pd coatings for carbon paper as a backing layer with 1.0 mg cm^{-2} GDL loading. From Figure 5, the peak of the reaction, recorded at 0.6 – 0.75 V, may be associated with the rate of reaction on the Pd catalyst layers with different adsorption. The electrochemical surface area (ECSA) values for CB-Pd, CNF-Pd and CNT-Pd are 12.81 cm^2 mg^{-1}, 21 cm^2 mg^{-1} and 23.58 cm^2 mg^{-1} respectively. It can be seen that the rate of reaction with a CNT anode as the absorption layer is higher than with the CB and CNF, achieving a current density of 22.3 mA cm^{-2} with the same pattern of curves. Smaller ECSA value for CB indicating lower electrocatalytic activity towards formic acid reaction compared to CNT as catalyst support.

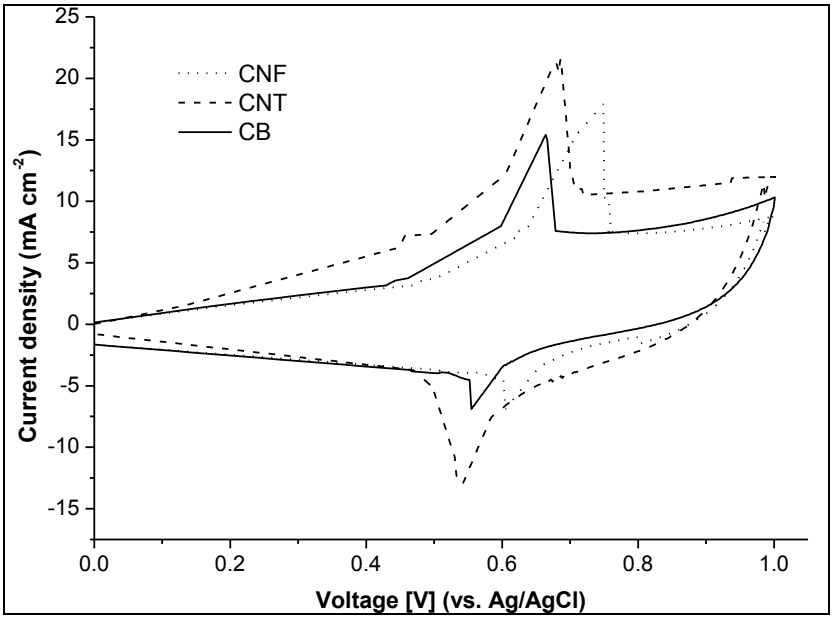

Figure 5. Cyclic voltammetry for anode with different structures of GDL

The CB carbon structure that is commonly used has the problem of elemental sulfur impurities and pores that trap microporous nanoparticles and degrade the catalyst activity. In addition, it is also thermochemically unstable, which inhibits the DFAFC's ability to curb erosion events on the carbon support, which deteriorates when in contact with the catalyst support [9].

Figure 6 shows the maximum power density obtained for different types of membrane and carbon structure. The different in electrode structures (by using different carbon material) would affect the MEA, and hence affect the cell performance. These indicate the different between current and power densities (shown in the Fig. 5 and Fig. 6, respectively) for different carbons used are due to the different in their carbon properties. The CNT showed a highest performance of current and power density compared to that CB and CNF. In general, the polarization curve profile for DFAFCs is similar, where the samples obtained show lower performance, i.e., maximum power density, at low fuel concentrations, and increase with concentration until the optimum concentration. From Fig. 6 it can be seen that the optimum concentration for the DFAFC for every sample is 10 M, whereas only one sample, N117-CP-CNF, achieved the maximum power density on a formic acid concentration of 13 M. The performance drops after the optimum concentration is achieved.

At low concentrations, formic acid cannot accommodate fuel operation at a high current density due to the presence of the mass transport limit [17]. The formic acid concentration of 10 M is the optimum concentration acquired, which matches the results of studies by past researchers [1, 17, 18]. However, when the concentration increases from the optimum concentration and above until 16 M, the DFAFC performance will decrease due to low catalyst activity and the occurrence of fuel flux crossing [1, 18]. The decline in performance at high formic acid concentrations may also be caused by the very nature of formic acid, which is hydrophilic and thus dries the layer near the membrane, which can inhibit proton transfer [19]. Meanwhile, Nafion 117 membrane gives a much higher performance overall, with a range of 10.43 mW cm^{-2} to 18.36 mW cm^{-2} compared to NRE 212 membrane with a range of 6.77 mW cm^{-2} to 8.91 mW cm^{-2}. As the NRE 212 membrane thickness is very similar to Nafion 112 membrane, the finding by Rhee et al. that the rate of crossing for Nafion 112 is higher compared to Nafion 117 indicates the same cause of the decline of performance in this study [19]. For a cell that uses CNF carbon structure as the GDL with NRE 212 membrane, the optimum concentration that is acquired by this cell is different from the use of N117, which is 10 M, like the optimum concentration achieved by other MEAs. The highest maximum power

density that is achieved for MEAs is 7.67 mW cm^{-2} for the 10 M and the lowest is 4.10 mW cm^{-2} for the 4 M of formic acid fuel.

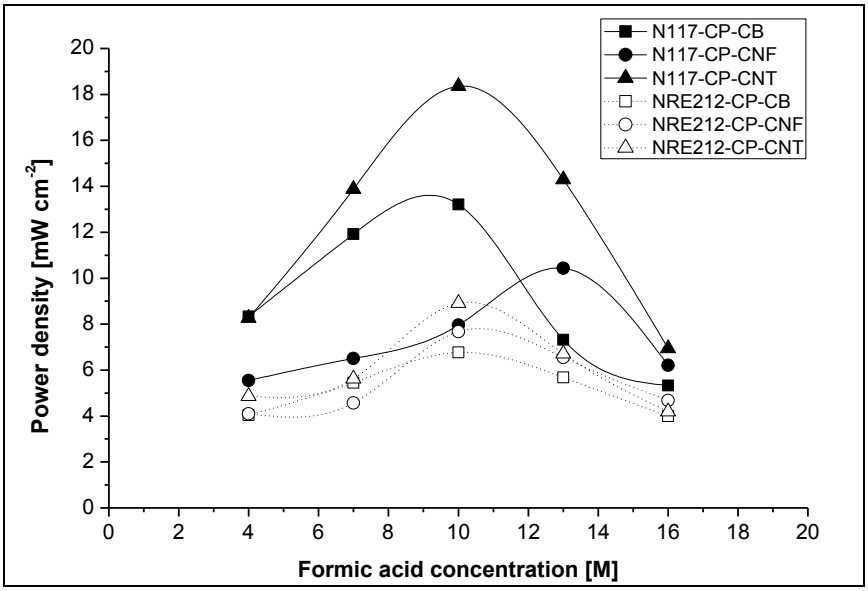

Figure 6. Single cell performance with different MEA combinations for 4–16 M formic acid

Overall, single cell performance using N117 electrolyte membrane gives a higher performance compared to the use of NRE 212 membrane. The decline in performance with the use of NRE 212 membrane is the same as found in research by Tsujiguchi et al., who state that formic acid flux is the highest compared to N115 and N117 membrane [20]. This further reinforces the main reason for the decline in performance that occurs when using NRE 212 membrane. According to Park et al., the diffusion layer can increase the overall performance of the catalyst and fuel cell depending on its structure [21].

Conclusion

The effects of the backing layer, carbon structures, carbon loading and membrane thickness on DFAFC performance were investigated in order to fabricate high performance of MEA. The maximum power density of 18.36 mW cm^{-2} was obtained by using the combination of CP as carbon support with a 1.0 mg cm^{-2} CNT layer and N117 as the electrolyte membrane at 10 M formic acid. High ECSA values for CNT as catalyst support for Pd in CV testing indicate that CNT have high potential to reduce the loading of catalyst usage due to the improve catalyst utilization. Hence, it can give a good support for efficient catalyst utilization as well as reduce the cost. Therefore, a good and thorough understanding of electrode structure and electrochemical properties is needed in order to increase the performance and durability of passive DFAFCs for mobile power sources.

Abstract

Bipolar plate is one of the key parts in the fuel cell technology with the advantages of a higher electrical conductivity and mechanical properties are high. Injection molding is one of the manufacturing method that being used in the manufacture of bipolar plates. The critical powder loading and rheological properties of the feedstock are an important factor in the process of injection molding in the manufacturing process of bipolar plate. The critical powder loading feedstocks with a mixture of polypropylene and graphite have been conducted with the torque method test. The appropriate critical powder loading the using a graphite filler material was produced with the composition of 75 % the weight of an optimum load and 25 % weight of polypropylene. The rheological studies have also been carried out using capillary test for determining critical loading powder by increasing the viscosity of the feedstock. The test results showed that the rheological properties of the feedstock with optimum powder loading to exhibit pseudoplastic properties are suitable for injection molding process with the n less than one.

Keywords: injection molding, polymer composite, bipolar plate, fuel cell

Abstrak

Plat dwikutub adalah salah satu bahagian utama pada teknologi sel bahanapi dengan kelebihan sifat kekonduksian elektrik dan mekanik yang tinggi. Pengacuan suntikan adalah salah satu kaedah pembuatan yang digunakan dalam pembuatan plat dwikutub. Pembebanan serbuk genting dan sifat reologi bahan suapan adalah faktor penting dalam proses pengacuan suntikan semasa proses pembuatan plat dwikutub. Pembebanan serbuk genting bahan suapan dengan campuran polipropilina dan grafit telah pun dijalankan dengan kaedah ujian nilai tork. Pembebanan serbuk genting yang sesuai menggunakan bahan suapan grafit telah dihasilkan dengan komposisi 75 % berat yang merupakan beban optimum dan 25 % berat polipropilena. Kajian reologi juga telah dijalankan menggunakan ujian rerambut bagi menentukan beban serbuk genting dengan peningkatan nilai kelikatan bahan suapan. Keputusan ujian sifat reologi didapati bahawa bahan suapan dengan beban serbuk optimal mempamerkan sifat pseudoplastik yang sesuai bagi proses pengacuanan suntikan dengan nilai *n* kurang daripada 1.

Kata kunci: pengacuan suntikan, komposit polimer, plat dwikutub, sel bahanapi

Introduction

Conductive polymer composite (CPC) materials generally comprise a mixture of polymers and conductive fillers, such as carbon-based and metallic fillers. Conductive materials contribute to the improvement of electrical and mechanical properties (e.g., critical load) of a material, particularly for carbon-based materials, such as graphite (G), carbon black (CB), carbon nanotubes, and carbon fiber (CF) [1 – 3]. One of the applications of CPC is the bipolar plate, which requires high electrical conductivity for electron mobility. The properties of CPC materials favor their application in the manufacture of bipolar plates. Among various carbon-based fillers, graphite is the optimal material type because of its chemical stability [4], corrosion resistance [4], lightness [5 – 8], and high electrical conductivity [9]. Achieving the required properties when such materials are utilized depends on the manufacturing method. Compression and injection molding are two of the most commonly used methods to fabricate bipolar plates. Injection molding has an advantage over compression molding when used for mass production; injection molding has better factor cycle time and compact ability during production than compression molding. Several factors, such as process parameters, contribute to the success of the manufacturing process. However, the most important factors are the characteristics that correspond to the properties of the feedstock. Feedstock injection molding is a balanced blend of filler powder and binder matrix. Three important factors influence powder loading injection molding; these three factors are the rheological properties of a good feedstock for production, mechanical properties of the materials, and tight dimensional control and limited distortion [10].

A number of studies have been conducted to determine the load range of the feed for the powder filler material. Generally, ceramic powder carbon-based filler is the material used; it is injected at a load range of 50 % to 55 % by volume. Previous studies [11 – 13] have indicated that the appropriate critical load could be up to 65 % by volume. Other studies have reported the use of alumina powder as filler at feedstock composition of 80.5 wt.% filler (50 % by volume) [14]. Feedstock with different types of metals as fillers are commonly injected during powder loading at 56 % [15, 16] to 60 % by volume [17, 18]. Injection of fillers such as G, CB, and CF has also been successfully conducted at filler composition of up to 60 % by weight [19]. The load volume of feedstock refers to critical filler loads in the feedstock up to the maximum that can be injected. An increase in the volume load of feedstock affects feedstock viscosity [20]. Relative changes in viscosity influence critical powder loading. Feedstock viscosity is highly dependent on particle size, particle size distribution, solid loading, and specific surface area [21]. A study has demonstrated through modeling that powder load is influenced by particle size distribution [22]. Studying the critical powder loading feedstock of polypropylene (PP)/G is necessary to determine the maximum powder load of G fill in the appropriate feedstock injection molding process. A detailed investigation of the maximum powder loading of this feedstock has never been conducted.

The current study investigates the critical powder load by using mixer torque variations and analyzing the viscosity behavior of G feedstock. Rheological analysis with various G fillers was conducted on the composition of the feedstock to determine the feedstock's pseudo-plastic nature and mold reliability.

Materials and Methods

A matrix polypropylene (PP) (injection molding grade, impact copolymer SM 240) with a melting point of 160 °C to 170 °C, density of 0.9 g cm^{-1}, and MFR of 10 g/10 min was utilized. PP allows for balance between stiffness and impact resistance. PP was purchased from Polypropylene Malaysia Sdn. Bhd. Natural G was obtained from Asbury of 3243 (99 % purity, 44 μm average normal powder size, 3 m^2 gr^{-1} surface area, 27.8 S cm^{-1} electrical conductivity, and 2.31 kg m^{-3} density); the technical aspects of the utilized natural G were provided by the supplier. The morphology of the G powder was observed with a scanning electron microscope (SEM; Zeis EVO MA10). The morphology of graphite filler is important to know the effects that occur during the test (Figure 1).

Figure 1 show that the morphology of natural graphite flakes has different shapes and sizes. Shaped pieces of G particles have better electrical properties than others in the form of a sphere [23, 24]. The process of mixing the powder and testing the critical powder loading (G and binder PP) was performed with an internal mixer (Haake Remix Roller rotor type 600R with Haake Polylab TM programming). The PP melt was mixed in a chamber at a volume of 50 cm^3 and filler composition of 60 wt. % to 80 wt. % of graphite. The mixing parameters were 200 ºC and 50 rpm for 2 hours. The experimental torque values were observed and found to be unstable [24]. Feedstock viscosity was measured with a Shimadzu capillary rheometer (CFT 500D) with a capillary diameter (*D*) of 0.1 cm,

length (*L*) of 1 cm, and *L*/*D* of 10 at 160 ^{o}C. The measurement was done at a temperature of melts viscosity of the feedstock with a given load and power passing through the capillary.

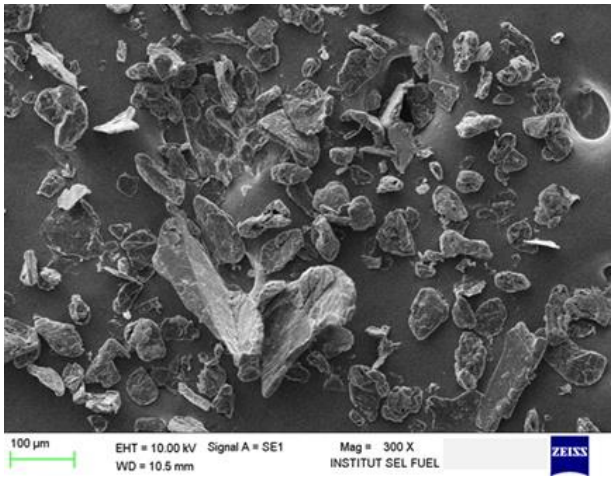

Figure 1. Morphology of graphite powder

Results and Discussion

Critical powder loading was determined by observing the changes in the value of the torque variations (critical solid loadings) of the G feedstock. Generally, with the increase in filler material content during the process, torque slowly increased during mixing until an unstable condition was reached. The results in (Figure 2) show an increase in torque blending at 80 wt. % of the powder filler. The blending process became uncertain after this increase. Torque did not reach a steady state and fluctuated instead. These results indicate that the critical load mix was approximately 75 wt. % of the filler powder. These results are similar to those of ceramic-based materials and metals reported in [13] at 80.5 wt. % of filler. In this study the critical powder loading test has been carried out three times the test at between 139 minutes to 142 minutes. Based on observations of time tests showed phenomenal torque value changes are likely the same, at 80 % by weight graphite. This situation showed that the increase in the torque tends to depend on the content of graphite powder filler. The feedstock includes G filler with different particle sizes. The particle size distribution was shown in (Figure 3), which illustrates the variations in particle size and percentage of different feedstock. The differences in particle size were divided into small-sized [d(0.1): 18.85 µm], mean- or mid-sized [d(0.5): 56.43 µm], and large-sized [d(0.9): 127.08 µm].

Particle sizes have a significant impact on critical powder load, where the amount of large particles that result in high critical loading filler is large [10, 25]. The consolidation of particles with various sizes in the feed material affects density. In particular, the composition of the dominant particle size in the feedstock material has a significant effect on density. Small particles can be added to fill the empty spaces between large particles to increase density [17, 18]. The particle size of the powder filler affects the determination of density and maximum aspect ratio of the feedstock [26]. During the blending process, the powder particles are arranged according to shape and size to achieve a stable level because neither the blending process nor excessive pressure can force particles to enter a dense compound [27, 28]. High packing densities can be achieved if the particle size is not uniform [27, 28]. The gap that forms between coarse particles because of restructuring allows the entry of a large number of fine particles, thereby contributing to the density of the random feedstock. Critical powder loading is also influenced by particle size, and density affects size variation, as shown in the feedstock schematic in (Figure 3). Based on SEM observation on the composition of 75 % by weight graphite was found that the structure of graphite flakes form more compact. This condition is known of the composition of the particles homogeneously mixed to form a bond between the particle size large, medium and small. The other factor is the flakes particles very easily formed a solid

structure as shown in (Figure 4). In a simple illustration of the bond between the graphite particles with different sizes are shown in (Figure 5).

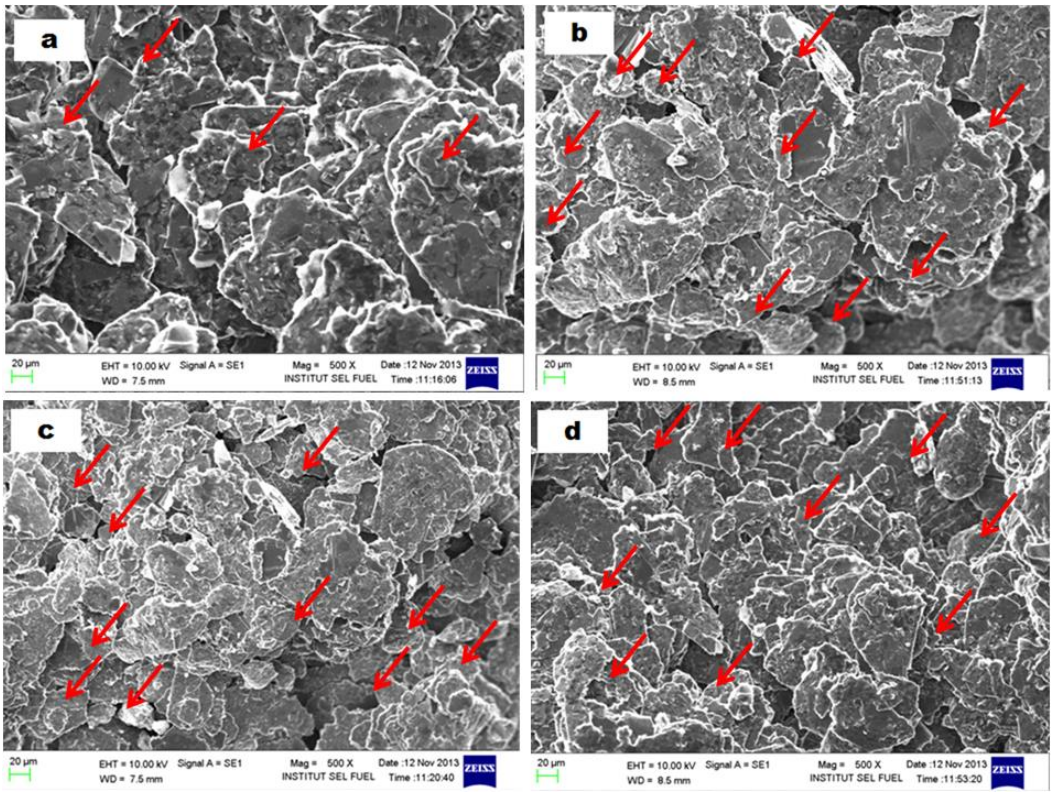

Figure 4. SEM of G feedstock (a) 60 wt.%, (b) 65 wt.%, (c) 70 wt.%, and (d) 75 wt.%

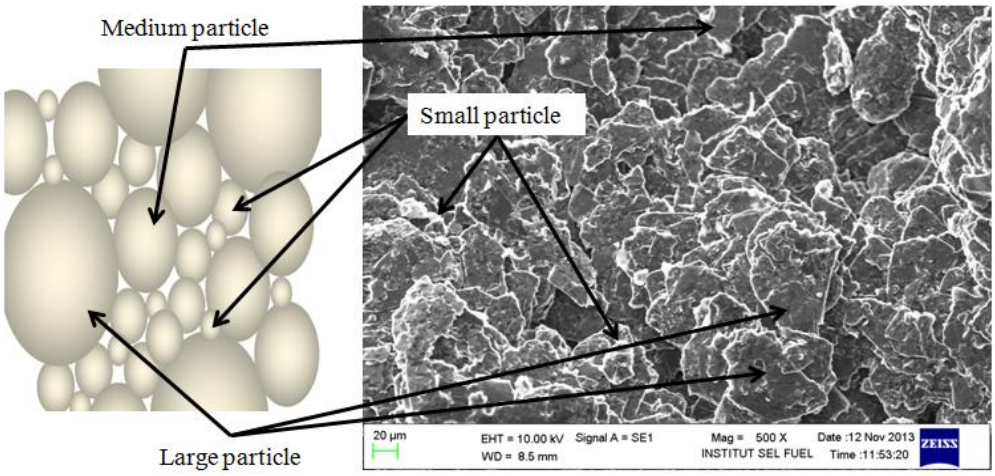

Figure 5. Schematic of different graphite particle sizes

The results of the viscosity test indicated an increase in viscosity versus the shear rate at the maximum filler powder content of 75 wt. % (Figure 6). The increase in viscosity was inversely proportional to the increase in shear rate.

This finding is consistent with that of previous studies [17, 18] and thus reveals that the materials that are pseudo-plastic using the PIM process.

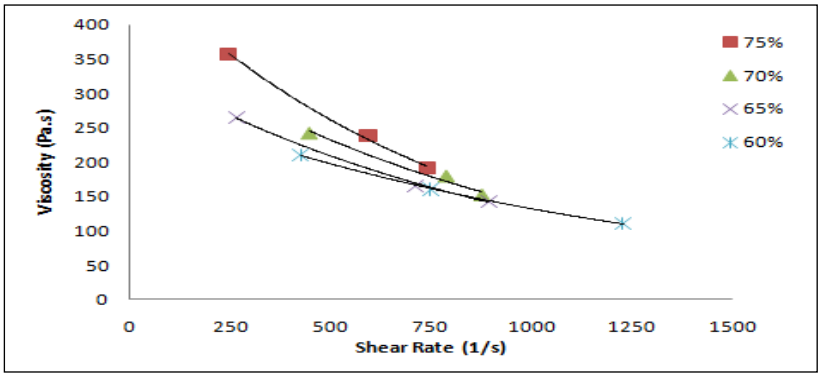

Figure 6. Feedstock viscosity versus shear rate at different powder loadings

The increase in feedstock viscosity was also affected by the increase in surface area, which occurred because of the increase in small particle variations in the filler. The improved composition of small particles simultaneously increased the surface area and caused agglomeration, which increased feedstock viscosity. The agglomeration in the feedstock fine powder formed a bond between the powders. This phenomenon occurs naturally because of the force of attraction between the surfaces of particles with varying strengths. The agglomeration of small particles in the feedstock is difficult to overcome [29]. Previous studies on critical powder loading using G do not exist; nevertheless, this phenomenon shows similarities with the viscosity of ceramic feedstock because the use of solid powder materials and polymers as ceramic composite has the same characteristics as mixed feedstock. Studies that dealt with this phenomenon reported that the increase in surface area in feedstock containing ZrO_2 and polymer ethylene-vinyl acetate copolymer grade at feedstock composition of 20 vol. % to 50 vol.% ceramic powder has an impact on lowering the activation energy flow [29]. High shear rate at low powder load shows more polymer components than filler components. Viscosity and shear rate suitable for injection molding have already been reported in numerous studies. Studies recommend maximum viscosity of 1,000 Pa.s and shear rate in the range of 100 s^{-1} to 100,000 s^{-1} [27, 29]. The results of rheological studies on feedstock PP/G in the present study indicate viscosity at 80 Pa.s. The shear rate is below the level allowed for injection molding processing (1,700 s^{-1}). The test results show that feedstock viscosity and shear rate are generally within the range suitable for injection molding. The variations in viscosity caused by temperature at different powder loadings are shown in (Figure 7). A high load is required when the powder has high viscosity. Viscosity decreased when the feedstock temperature increased. By contrast, an increase in viscosity reduced the shear rate, as shown in (Figure 6). The increase in viscosity is anticipated because of the increase in powder filler content consisting of fine powder agglomeration. Devaluation of viscosity occurs when the percentage content of fine powder is low. Increasing the coarse powder content reduces feedstock agglomeration [30, 31]. Changing on the different powder loading results in a change in feedstock shear rate. Similar conditions were observed during injection molding, wherein shear rate was applied to the material at a given pressure value. The ratio between the filler and matrix polymer powder is significant to the success of the current and subsequent processes.

High powder loading makes it easy to control the dimensions. An extremely high powder loading (very small binder matrix) produces a mixture with remarkably high viscosity, which could complicate the injection molding process [10, 27]. The critical composition of the powder mixture can be achieved by reducing the concentration of the polymer matrix. Reduction of the polymer matrix concentration also sets the highest filler powder loading. When the powder loading exceeds the critical limit, the viscosity of the mixture becomes extremely high [32]. The results of the mean flow index behavior, *n*, for all compositions show that all feed materials exhibit a pseudo-plastic behavior (Table 1.). The value of *n* indicates the uniformity of the flow of a mixture in the capillary during testing

[30, 31]. The decrease in the viscosity of pseudo-plastic materials with the increase in shear rate was noticeable at a low powder load. The n value was less than 1, which indicates that the feed material exhibits shear thinning. A feedstock should have an *n* value of less than 1 during injection molding [29].

	190	78.937	0.285	796.74
	200	78.937	0.444	932.04
75	180	82.146	0.331	352.30
	190	82.146	0.312	660.47
	200	82.146	0.366	837.11

The ability of feedstock containing high G filler to flow during injection molding is indicated by the value of n, which should be small. The effect of increasing load on the feedstock powder through injection can be obtained by developing the relationship between particle and particle bonding in the composite. The value of *n* is obtained with Equation (1) [27, 29] as follows:

$$\tau - \tau_y = k(\gamma)^n \quad (1)$$

The calculation of the n value and moldability α shown in Table 1., where n is the average resulting from the composition of 60 wt. % to 75 wt. % of G filler, shows that n is smaller or less than 1. This situation proves that the feedstock is pseudoplastic and that qualified feedstock can be injected because of flow ability. The determination of moldability index value (α) is an important method to predict the suitability of an material for the injection molding

process as shown in Table 1. The result of the calculation shows that the largest value at 200 °C for each weight percent graphite filler. It means the larger values of moldability, the more easily feedstock was provided by the injection molding process [18, 27]. The activation energy (E) of a feedstock is strongly related to its viscosity [33]. An improvement in viscosity significantly affects the rate of increase of the activation energy value. This relationship occurs because of the different particle sizes arranged in the feedstock. In this study, a parallel increase in viscosity was observed with the addition of the filler material into the feedstock. The difference in the composition of fine- and large-sized particles contributed to the changes in viscosity. Another factor that affected the increase in viscosity was the content and composition of small particles. These results are consistent with the findings on microstructures because viscosity increased in a parallel manner with the increase in G filler content at a composition of 60 wt. % to 75 wt. %.

The composition of in-sized particles also improved when density was increased, resulting in an increase in viscosity. The obtained SEM images show an increase in small-sized particle content in the feedstock. Studies on the effect of size on viscosity have shown that a feedstock mixture with fine-sized particles has a higher melting point than that with large-sized particles. Different particle sizes also influence the temperature of the process; fine-sized particles are more likely to increase the temperature of the process compared with rough-sized particles [30, 31]. The differences in the activation energy values (shown in Table 1) are due to the thermal expansion between the components of the material; this expansion occurred because of differences in particle size and agglomeration in the fine particles. This phenomenon occurred at 60 wt. % and 65 wt. % of graphite. Furthermore, activation energy was affected by the decrease and increase in G content (wt. %). Graphite powder dispersion between small and large particle sizes was evenly distributed. Nevertheless, agglomeration should occur between particle dispersion on small particle sizes to increase the activation energy, as shown at 70 wt. % G and 75 wt. % of graphite. This condition will increase the interaction among various particle sizes so that feedstock viscosity can increase. The viscosity of the obtained feedstock was still acceptable because the injection provided G dispersion in a uniform feedstock, which resulted in an improved particle distribution network and electrical conductivity between the particle surface and various particle sizes. The mechanical properties of the composite materials were increased by the dispersion of particles with different sizes, which filled the gaps, thereby increasing density.

The microstructures of the feedstock are shown in Figure 4. Compaction with particle sizes was parallel to the increase in filler content in the feedstock from 60 wt. % to 75 wt. %. The improvement of G filler composition with different particle sizes indicated the potential for increased density. These results are supported by studies on the microstructures shown in (Figure 4) and indicate an increase in the content of small-sized particles that appeared to be more dispersed in the feedstock. The increase in the amount of small-sized particles significantly affected feedstock viscosity, as shown by the red arrows in (Figure 4(d)). The SEM observation shows the difference of the shape and size of particles in the presence of polypropylene as a binder, a white coat over the form of graphite. The decrease in filler content resulted in a decline in the dispersion of small-sized particles. The decrease in the amount of small-sized particles in the filler content is shown in (Figure 4(a)), which shows the composition of the filler content to be 60 wt. % of graphite. These results are consistent with those obtained by Bobek et al. [34], who found that high packing densities can be achieved when particle size is not uniform. The variations in particle size are also shown in the schematic of particle size in (Figure 5).

The particle dispersion conditions in the blending process provide the opportunity to form porosity. An increase in porosity occurs when the filler content in the feedstock decreases slightly, instead of porosity reduction in feedstock occurring because of filler content increase. The increase in filler content with filler size variation denotes the possibility of small particles filling the gaps in the feedstock and ultimately reducing porosity. Dispersion of particles different sizes also showed homogeneous up to contribute to an increase in viscosity, in which the homogeneous properties is the important properties of the feedstock [35].

Conclusion

This study showed that a suitable feedstock composition determined by fitting should involve balance between the powder filler and binder matrix, particularly during injection molding. Critical solid loading of 75 wt. % was found to be the optimal composition of the powder and binder; it affected the stability of the injection molding process. At the maximum critical load of 75 wt. % of the filler, torque stability remained normal. At 80 wt. % composition,

torque became unstable. This situation suggests that an increase in maximum viscosity and is unsuitable for injection molding. High viscosity was caused by the density of the filler content compared with polymeric materials that serve as a binder in the filler. The differences in the size and composition of the powder particles increased viscosity significantly because solid particles increased the density of the feedstock powder. An improvement in density and viscosity affected the injection molding parameters such as injection pressure and flow of the feedstock.

Abstract

The short term exposure (4 days) was done to *Fungia fungites* using different concentration of Irgarol to establish the health effects of this species by measuring their fatty acid composition. It was done by comparing fatty acid composition of the fresh, control and exposed groups. The results indicated that, fresh and control samples of *F. fungites* were not significant different ($p > 0.05$) and dominated by Saturated Fatty Acids (SAFA) followed by Polyunsaturated Fatty Acids (PUFA) and the Monounsaturated Fatty Acids (MUFA). However, trends of other tested groups (20, 100 and 500 µg/L) were significant different ($p < 0.05$), with species suffered more as the dose of chemicals increased. For example, α-Linolenic acid (C18:3ω3) was not detected in *F. fungites* which exposed in this biocide at 100 and 500 µg/L whereas C20:5ω3 was not detected in all exposed groups. These ecotoxicological data proved that Irgarol may affect the fatty acids composition of coral reef organisms even if exposed at the low levels of this biocide.

Keywords: Irgarol, booster biocides, fatty acids composition, *Fungia fungites*, coral reef organisms

Abstrak

Pendedahan jangka pendek (4 hari) telah dilakukan ke atas *Fungia fungites* menggunakan kepekatan Irgarol yang berbeza untuk membangunkan kesan kesihatan spesies tersebut dengan mengambilkira komposisi asid lemak mereka. Ianya telah dilakukan dengan membandingkan komposisi asid lemak bagi kumpulan segar, kawalan dan yang telah didedahkan. Keputusan menunjukkan bahawa, sampel segar dan kawalan *F. fungites* tidak berbeza secara bererti ($p > 0.05$) dan didominasi olah Asid Lemak Tepu (SAFA) diikuti oleh Asid Lemak Tidak Tepu Poli (PUFA) dan Asid Lemak Tidak Tepu Mono (MUFA). Walaubagaimanapun, corak bagi kumpulan lain yang diuji (20, 100 and 500 µg/L) adalah berbeza secara bererti ($p < 0.05$), dengan spesies mengalami sengsara yang lebih apabila dos bahan kima ditingkatkan. Misalnya asid lemak α-Linolenat (C18:3ω3) tidak dikesan dalam *F. fungites* yang terdedah dengan biosid peransang ini pada 100 and 500 µg/L manakala C20:5ω3 tidak dikesan dalam semua kumpulan yang terdedah. Data ekotoksikologi ini membuktikan bahawa Irgarol berkemungkinan menjejaskan komposisi asid lemak organisma terumbu karang sungguhpun jika terdedah pada tahap yang rendah oleh biosid ini.

Kata kunci: Irgarol, biosid perangsang, komposisi asid lemak, *Fungia fungites*, organisma terumbu karang

Introduction

Irgarol-1051 is one among the commonly used alternative antifouling chemical after the prohibition of tri-butyltin (TBT) by International Maritime Organization (IMO) [1, 2]. It was reported that, Irgarol-1051 is very effective in prevention of attachments of biofoulings in recreational boats and yachts [3, 4]. In addition, the Irgarol is considered as a photosystem II inhibitor, which prevents photosynthesis and block conversion of excitation energy into chemical energy [5]. It has been broadly detected in aquatic ecosystems [6–10]. The significant concentrations of Irgarol have been also reported in coastal sediments [11–13]. Numbers of studies have demonstrated the impacts of Irgarol on marine organisms such as corals. For example, Owen et al. [7] reported that 60 ng/L of Irgarol reduced ^{14}C incorporation in the *Madracis mirabilis*, while 63 ng/L reduced net photosynthesis of intact corals. Moreover, 50 ng/L reduced photosynthetic efficiency (F0/Fm0) of *Seriatopora hystrix* [5]. It is also revealed that 1000 ng/L of Irgarol significantly reduced the photosynthesis rate of *G. fascicularis* and 100 ng/L reduced the settlement of coral larvae [4, 10]. The concerns on toxicity nature of Irgarol-1051 to marine habitats lead some countries such as Denmark, UK and Sweden to restrict the use of Irgarol as an antifouling paint to the boats under 25 m [14]. Studies on detection and distribution have reported the level of Irgarol 1015 in the coastal waters of Asian countries, for example, Singapore [15] and Malaysia [2], however, very little is known about its impact to corals in this region. To our knowledge only the study by Ali et al. [16] has reported the effects of Irgarol to the fatty acid composition of Asian Sea-bass (*Lates calcarifer*) from Malaysia. This study therefore presents the ecotoxicological data on the impact of Irgarol-1051 in the *F. fungites* by measuring fatty acid composition after exposed at different doses for four days in laboratory.

Materials and Methods

Sample collection

Fresh corals (*F. fungites*) were taken from Bidong Island, Terengganu Malaysia. The corals were acclimatized for 2 weeks in well aerated holding polyethylene tanks (500 L), containing natural seawater with a salinity of 30 ppt, under a natural photoperiod 12:12 hours (light: dark) cycle. The water in the tank was passed through a 1-mm filter, treated with UV-sterilized and refilled daily. The coral was not fed at all.

Chemical

A stock solution of 1000 mg/L Irgarol was prepared by using acetone and the working concentrations were made up by spiked the required concentrations to the sea water.

Experimental procedures

F. fungites were acclimatized for two weeks in the laboratory before the acute exposure tests to Irgarol for 96 hours. Water quality characteristics were measured daily: dissolved oxygen (DO) 7.2 ± 0.5 mg/L, and pH 7.69 ± 0.2, but the temperature was automatically controlled to 27 $^{\circ}C$ using cooling chiller throughout the whole experiment duration. After the two weeks acclimatization period, corals were transferred into different experimental tanks containing three litres of water and exposed to test concentrations of 20, 100, and 500 µg/L of Irgarol in three replicates for 96 hours. The control and acetone (check-up tanks) were kept for the sake of comparison. After four days (96 hours), the tissue of the coral were removed by using water pick and taken to the laboratory for fatty acid analysis.

Analytical procedure

Tissues of *F. fungites* coral were taken as samples for fatty acid composition analysis. The one step method [17] was used in this experiment to combine extraction and esterification processes using a single tube. Three replicates of each tissue samples (200 – 300 mg) were mixed with 4 mL of hexane and 1 mL of internal standard solution in a 50 mL centrifuge tube. After adding 2mL of 14% BF_3 in methanol and a magnetic stirring bar, the head space of tube was flushed with nitrogen gas and then closed tightly with a Teflon-lined screw-cap. The capped tube was heated on a hot plate at 100 °C for 120 min under continuous stirring. After cooling to room temperature, 1 mL of hexane was added followed by 2 mL of distilled water. The tube was then shaken vigorously for 1 min and centrifuged for 3 min at 2500 rpm (650 ×g). Of the two phases which formed, the upper phase was hexane layer containing the FAMEs. Finally, approximately 1 – 2 mL of the hexane layer was transferred using a Pasteur pipette into a clean sample vial to be injected into the GC-FID for FAME analysis.

Fatty acid concentrations (C_{FA}, mg/g of dry sample) were calculated by comparing the peak area of fatty acid in the sample with the peak area of internal standard as equation (1) follows:

$$C_{FA} = {}^{A_S}/_{A_{IS}} \times {}^{C_{IS}}/_{W_S} \quad (1)$$

where A_S = peak area of fatty acid in the sample in chromatogram, A_{IS} = peak area of internal standard in chromatogram, C_{IS} = concentration of internal standard (mg) and W_S = weight of sample (g). Qualitatively (as a percentage), composition of individual fatty acids were calculated by comparing the peak area of each fatty acid with the total peak area of all fatty acids in the sample.

Gas chromatography conditions

The FAMEs were separated and quantified using a gas chromatograph (GC 14-B Shimadzu) equipped with flame ionization detector. Separation was performed with an FFAP-polar capillary column (30 m × 0.32 mm internal diameter, 0.25 µm film thickness). Purified hydrogen was used as a carrier gas. After injection at 60 °C, the oven temperature was raised to 150 °C at a rate 40 °C min^{-1}, then to 230 °C at 3 °C min^{-1}, and finally held constant for 30 min. The flame ionization was held at 240 °C. FAME peaks were identified by comparing their retention times with those of authentic standards (Supelco Inc.). Fatty acids were designated as an n:pωx, where n is the number of carbon atoms in the aliphatic chain, p is the number of double bonds and x is the position of the first double bond from the terminal methyl group. The analytical precision for samples was generally < 5 % for total amounts and major components of FAMEs.

Results and Discussion

Fatty acid composition

The fatty acid results were calculated and presented as mean ± standard deviation (Table 1). Significant differences among the mean value of treatments were treated by One-way Analysis of Variance (ANOVA) followed by Least Significant Different (L.S.D). Two-way Analysis of Variance was used to support one way Analysis of Variance to get the F-probability interactions between chemicals, concentrations and / or species. Duncan's multiple range test (p <0.05) were calculated.

Fatty acid composition data for acute exposure of the *F. fungites* in Irgarol are presented in Table 1. The corals were dominated by SAFA 27.4 ± 6.17 (54.3 %), 23.8 ± 5.04 (49 %) and 23.2 ± 6.33 (50.6 %) mg/g dry weight, followed by PUFA 20.5 ± 5.48 (40.6 %), 23.2 ± 6.67 (47.8 %) and 20.9 ± 6.31 (45.8 %) mg/g dry weight and last is MUFA 2.25 ± 1.14 (5.06 %), 1.15 ± 0.69 (3.21 %) and 1.65 ± 0.74 (3.61 %) mg/g dry weight of fresh, control and acetone samples respectively.

In this study, *F. fungites* samples exposed with 20, 100 and 500 µg/L Irgarol have the same trend as fresh, control and acetone samples of SAFA > PUFA > MUFA (Figure 1). It was noted that SAFA, PUFA and MUFA are reduced as the dose of Irgarol increased in tested species. It is also interesting to note that in *F. fungites* (Figure 1), MUFA groups contributed less in the total FA among all exposed groups. The behavior of some groups of corals organisms to show different trends as in fresh and control samples can be justified by the fact that the activities in these groups were affected not only by the chemicals but also the ability of the individual organism to fight the toxic behavior of the used chemical.

Saturated fatty acids (SAFA)

The *F. fungites* are relatively enriched in Saturated Fatty Acids (SAFA) and the total SAFA are not significant different (p > 0.05) between fresh and control groups, however the other groups and individual SAFA were significant difference (p < 0.05) in this species (Table 1). Palmitic acid (C16:0) was found dominant in all SAFAs of the *F. fungites* (Table 1) and showed a significant difference (p < 0.05) between the samples. SAFA is pronounced more in average in *F. Fungites* (Figure 1). It was also reported that palmitic acid was the predominant in SAFA group as found in freshwater channel catfish (*Ictalurus punctatus*) (19.2 %) [18], and in freshwater rainbow trout (*Oncorhynchus mykiss*) (21.3 %) [19]. The fresh water species domination on SAFA fatty acids is also reported in the study conducted by Jabeen and Chaundhry [20].

Table 1. Fatty acid composition (mg/g) dry weight of tissue samples of *Fungia fungites* (mushroom) after 96 hours acute exposure test. Values are means ± standard deviation (SD) for n=3.

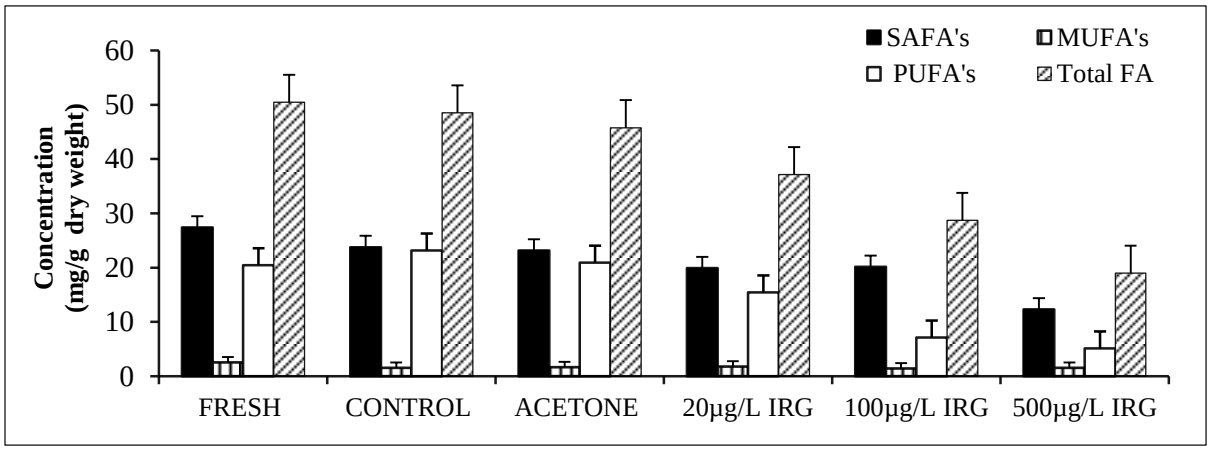

Figure 1. Fatty acid concentration of different classes and total fatty acid (mg/g dry weight) from tissues of Fungia fungites after exposed at different concentrations of Irgarol. Values are mean ± S.D, n = 3.

Mono unsaturated fatty acids (MUFA)

The ΣMUFA for *F. fungites* were significant difference in fresh, control, acetone and other exposed concentrations (Table 1). It is observed that MUFA contribution is less in total fatty acids in *F. fungites* (Table 1). This is due to the fact that, only palmitoleic acid (C16:1) was observed in the GC-FID where the rest of MUFA were below the detectable limit. In fact, Ho and Paul [21] found about 8 % only of oleic acid in total fatty acid in Asian sea bass. However, Steiner-Asiedu et al. [22] found that freshwater tilapia (*Tilapia* sp.) had significantly higher oleic acid levels than flat sardine (*Sardinella*) and sea bream (*Dentex*). The level of oleic acid in American freshwater channel catfish flesh was also reported higher; about 50 % [23] compared to less than 1% in sardine and sea mullet [24].

Polyunsaturated fatty acids (ΣPUFA)

The sum of Polyunsaturated Fatty Acids (ΣPUFA) in *F. fungites* was not significantly different among fresh, control and acetone samples ($p > 0.05$). α-Linolenic acid (C18:3ω3) was dominant PUFA in *F. fungit*es (66.8 % fresh sample) (see Figures 1 & 2). The rest of the PUFA in this species have less contribution. The higher levels of omega 3 and 6 in this species was not surprising because seawater organisms obtain their omega-3 and 6 FA from oceanic plankton [16, 25] or are fed fishmeal containing these FA [26].

Individual fatty acids were not detected in some exposed groups which differed with fresh and control groups (Figure 2). For example, α-Linolenic acid (C18:3ω3) was not detected in *F. fungites* exposed in this biocide at 100 and 500 µg/L whereas C20:5ω3 was not detected in all exposed groups (Figure 2). As expected, individual fatty acids in 500 µg/L exposure groups were much affected than the rest of the groups in *F. fungites* (Figure 2). The results show an inverse relationship between the dose of chemical used and activities of the *F. fungites* in the tanks. It is clear that, as the concentration of the Irgarol increased in different exposed tanks there was a decrease in activities of *F. fungites.*

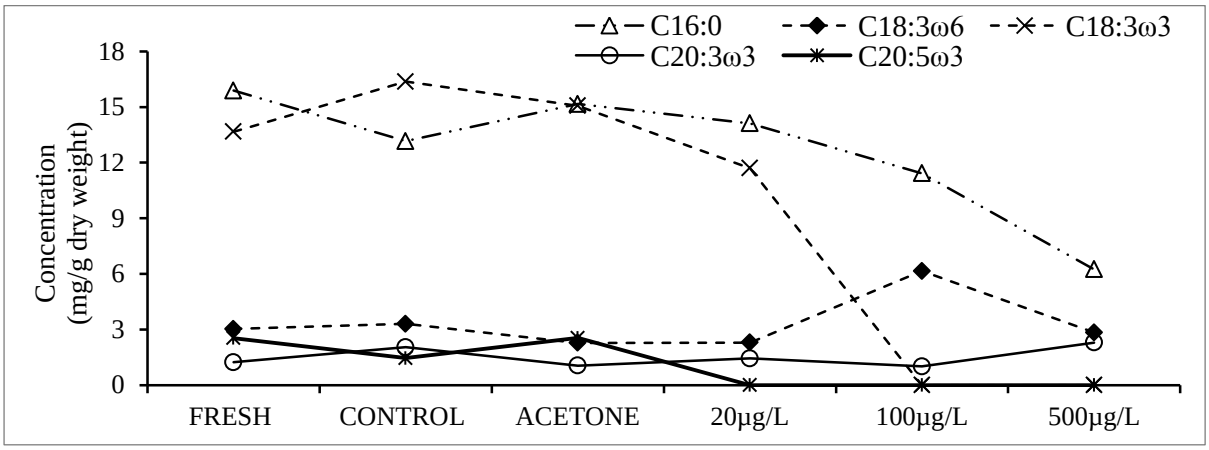

Figure 2. Individual Fatty acid concentrations of *Fungia fungites* exposed at different doses of Irgarol.

Conclusion

This paper explains the toxicological responses of *F. fungites* upon exposure to different concentrations of Irgarol in laboratory experiments. It can be concluded that; acute exposure of *F. fungites* (96 hours) to different concentrations of Irgarol had shown significant impact to the fatty acid composition. Fresh, control and all exposed samples of *F. fungites* were in trend of SAFA > PUFA > MUFA, however the exposed samples suffer more as the dose of Irgarol increased. The results of this study reveal that Irgarol is toxic and reduce the fatty acid composition of the coral even at the low level of exposure (20µg/L) and for a short period of time (96 hours). There is a need of further researches to be conducted in this area of specialization so as to understand more effects of these new antifouling chemicals to marine organisms as well as in coral reef using different species.

Acknowledgement

We sincerely acknowledge the Ministry of Education of Malaysia (MOE) for providing fund to support conducting this study using Fundamental Research Grant Scheme (FRGS/1/2011/STWN/UMT/02/3) and Higher Centre of Excellent (HiCOE) program. We also acknowledge University of Malaysia Terengganu (UMT) special Institute of Oceanography and Environment (INOS), School of Marine and Environmental Sciences, and the State University of Zanzibar (SUZA) for their support in conducting this research.

Abstract

The performance of new phosphate sensor was investigated using fluorescence spectrometer in the form of immobilized Al-morin on poly(glycidyl methacrylate) (pGMA) microspheres. pGMA microspheres that were synthesized by using suspension photopolymerization exhibited spherical-shaped morphology with diameters from 1.5 to 5.3 µm. The studies were carried out at pH 5 and the ratio of aluminium (III) chloride hexahydrate to morin was 3:1 (v/v). At pH 5, $H_2PO_4^-$ was measured at 548 nm emission wavelength. The relative fluorescence intensity was inversely proportional to $H_2PO_4^-$ concentrations. The linear range was observed between 6.6 – 58.8 µmol/L with detection limit (LOD) of 0.7 µmol/L. Ion interference study demonstrated that Al-morin was highly selective towards $H_2PO_4^-$.

Keywords: phosphate sensor, polymer microspheres, aluminium-morin, fluorescence

Abstrak

Prestasi sensor fosfat baru telah dikaji dengan menggunakan spektrometer pendarfluor dalam bentuk Al-morin terpegun pada mikrosfera poli(glisidil metakrilat) (pGMA). Mikrosfera pGMA yang disintesis dengan menggunakan pemfotopolimeran ampaian mempamerkan morfologi berbentuk sfera dengan diameter 1.5 hingga 5.3 µm. Kajian telah dijalankan pada pH 5 dan nisbah aluminium (III) klorida heksahidrat kepada morin adalah 3: 1 (v/v). Pada pH 5, $H_2PO_4^-$ diukur pada gelombang pancaran 548 nm. Keamatan pendarfluor relatif adalah berkadar songsang dengan kepekatan H_2PO_4- Julat linear diperhatikan antara 6.6 – 58.8 µmol/L dengan had pengesanan (LOD) pada 0.7 µmol/L. Kajian gangguan ion menunjukkan Al-morin adalah sangat selektif kepada $H_2PO_4^-$.

Kata kunci: sensor fosfat, polimer mikrosfrera, aluminium-morin, pendafluor

Introduction

Phosphorus can be divided into organic phosphate and inorganic phosphate. Phosphate ions that move freely in water known as orthophosphate (P_i) which is an inorganic phosphate [1]. High phosphate content in water can cause eutrophication. Eutrophication is the excess nutrients in aquatic ecosystems that bring to an excess algae growth and cause water and environmental problem [2]. Thus, monitoring phosphate in drinking water is vital to ensure that water quality follows the standard. The maximum concentration of phosphate recommended by World Health

Organization (WHO) is 1 mgL^{-1}[3]. Besides, the determination of phosphate concentrations in body fluids is necessary to diagnose hyperparathyroidism, hypertension [4], vitamin D deficiency, mineral and bone disorder, kidney failure [5] and Franconia syndrome [6, 7].

Optical sensor is a device that converts light rays into electronic signals [8]. Fluorescence, luminescence, chemiluminescence and UV–visible spectrophotometers are commonly applied instruments in optical sensors [3]. Fluorescence method is widely used because it is highly sensitive, easy to operate, response rapidly and less costly [9]. Phosphate has known to quench aluminium-morin (Al-morin) fluorescence intensity. During 1950's, Al-morin has been used to detect trace amount of fluoride ion and indirectly phosphate was determined to be an interfering ion [10]. Previously, Hong et al. [11] reported that Al-morin immobilized on PVA/PVC plasticized composite membrane based on sandwich configuration has been used in phosphate detection. This technique had improved the indicator leaching problem however produced narrow linear range of phosphate detection (11.0 – 51.4 µmol/L). In order to overcome its limitation, Lin et al. [12] claimed that Al-morin immobilized on pretreated PVC membrane is more sensitive as it produces wider linear range (44.1 – 110.2 µmol/L).

In this work, phosphate sensor was developed by immobilizing Al-morin onto poly(glycidyl methacrylate) (pGMA) microspheres which were synthesized by suspension photopolymerization technique. High surface area of pGMA microspheres is suitable for Al-morin immobilization matrix in order to increase the reaction site for phosphate detection. The microspheres are also a water-insoluble polymer, causing it to be applicable in phosphate sensing. All characterizations of immobilized Al-morin phosphate sensors were analyzed by fluorimetric method.

Materials and Methods

Apparatus and reagent

Chemicals including morin hydrate (98%, MP Biomedicals LLC), aluminium (III) chloride hexahydrate ($AlCl_3.6H_2O$) (99 %, Systerm), glycidyl methacrylate (97 %, Sigma Aldrich), ethylene glycol dimethacrylate (9 8%, Sigma Aldrich), polyvinyl alcohol (98 %, Sigma Aldrich), 2,2-dimethoxy-2-phenylacetophenone (99 %, Sigma Aldrich), potassium dihydrogen phosphate (99 %, Systerm), potassium carbonate (K_2CO_3) (99 %, Sigma Aldrich), potassium acetate (CH_3COOK) (99 %, Sigma Aldrich), potassium chloride (KCl) (99 %, Sigma Aldrich), potassium fluoride (KF) (99 %, Sigma Aldrich), potassium nitrate (KNO_3) (99 %, BDH Chemicals Ltd), potassium sulfate (K_2SO_4) (99 %, Sigma Aldrich) and ethanol (95 %, Sigma Aldrich) were used as received.

The surface of microspheres was observed using Zeiss LEO 1450VP Scanning Electron Microscope (SEM). Infrared spectra of the microspheres were recorded by Fourier Transform Infrared spectrometer (Perkin Elmer) using attenuated total reflection (ATR-FTIR) spectrometry method. Response of Al-morin complex on fluorescence intensity was measured by Perkin Elmer Fluorescence Spectrometer at 548 nm emission wavelength.

Synthesis of Al-morin complex

A concentration of 23.2 µmol/L Morin solution was prepared in ethanol and 16.6 µmol/L aluminium (III) chloride hexahydrate ($AlCl_3.6H_2O$) in deionized water. Al-morin complex was formed by mixing $AlCl_3.6H_2O$ with Morin in 3:1 (v/v). The formation of Al-morin was then confirmed when the fluorescence emission of Al-morin was determined to be at wavelength 510 nm as reported in the literature [12].

Synthesis of poly(glycidyl methacrylate) (pGMA) microspheres

An mount of 1 ml of glycidyl methacrylate (GMA), 1 ml of ethylene glycol dimethacrylate (EGDMA), 5 ml of 1% polyvinyl alcohol (PVA) and 1.6 % (w/w) of 2,2-dimethoxy-2-phenylacetophenone (DMPP) were placed in a vial. The mixture was sonicated within 15 minutes. The suspension was transferred into a petri dish and photocured under continuous nitrogen flow for 10 minutes. The microspheres were collected by centrifugation at 2000 rpm for 10 minutes. They were then left to dry at room temperature. pGMA microspheres were characterized by Scanning Electron Microscope (SEM) and Attenuated Total Reflectance-Fourier-transform Infrared (ATR-FTIR) spectrometer.

Immobilization of Al-morin onto pGMA microspheres

An amount of 20 – 30 % (v/v) of Aluminium-Morin (Al-morin) complex was added into the mixture of GMA monomer, 1 ml ethylene glycol dimethylacrylate (EGDMA), 5 ml of 1% polyvinyl alcohol (PVA) and 1.6% (w/w) of 2,2-dimethoxy-2-phenylacetophenone (DMPP) in a vial. The mixture was sonicated within 15 minutes then it was transferred into a petri dish for photocuring procedure under continuous nitrogen flow for 10 minutes. The microspheres were collected by centrifugation at 2000 rpm for 10 minutes and dried at room temperature. pGMA/Al-morin microspheres were characterized by SEM and ATR-FTIR.

pH analysis

The optimum pH for Al-morin to react with 110.2 µmol/L dihydrogen phosphate ($H_2PO_4^-$) was studied. pGMA/Al-morin microspheres were soaked in pH 1 buffer solution before they were next soaked into phosphate solution prepared at pH 1 for 5 minutes as reported previously [13]. These steps were repeated for analyzing the same concentration of phoshate solution at pHs ranging from 1 to 7. Fluorescence intensity before and after Al-morin reacts with phosphate were recorded by calculating the relative of fluorescence intensity at 548 nm.

Effect of phosphate concentration

pGMA/Al-morin microspheres were soaked in dihydrogen phosphate ($H_2PO_4^-$) solution prepared at pH 5 buffer with concentrations ranging from 0.7 – 124.9 µmol/L for 5 minutes. They were initially soaked at pH 5 buffer to remove the unreacted monomer. The fluorescence intensity of immobilized Al-morin before and after reacting with phosphate for each concentration was measured at 548 nm.

Effect of interference ions

Interference study was carried out by preparing a fixed concentration of $H_2PO_4^-$ (110.2 µmol/L) in the presence of common anions including carbonate (CO_3^{2-}), acetate (CH_3COO^-), chloride (Cl^-), fluoride (F^-), nitrate (NO_3^-) and sulfate (SO_4^{2-}). Each anion at the same concentration as $H_2PO_4^-$ was prepared. Fluorescence intensity of pGMA/Al-morin microspheres soaked in the analyte containing $H_2PO_4^-$ and interference ions were recorded at 548 nm.

Results and Discussion

Characterization of Al-morin immobilized onto pGMA

Morphology of pGMA microspheres

pGMA microspheres were used as a matrix to immobilize Al-morin complex. High surface area of these microspheres makes it possible to act as a matrix with good physical properties and these microspheres are chemically stable. pGMA microspheres were prepared using a rapid synthesis method, which is suspension photopolymerization. The droplets of monomer mixtures form pGMA at room temperature in the presence of DMPP. The polymerization process was terminated by the removal of the ultraviolet (UV) light source. The schematic polymerization of GMA is presented in Figure 1.

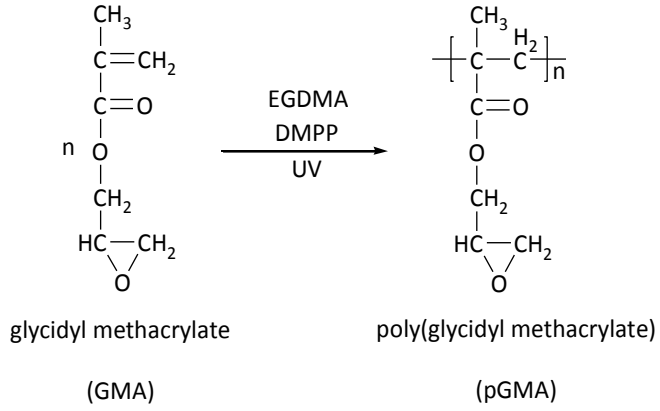

Figure 1. Polymerization of GMA microspheres

The spheres produced by this approach varied in size from 1.5 to 5.3 µm and are polydisperse. The size maintains even after Al-morin was immobilized onto pGMA microspheres. This observation might be due to the entrapment of chemical doping technique used to immobilize Al-morin which did not involve any chemical bonding. The presence of Al-morin causes pGMA/Al-morin microspheres to exhibit rougher surface compared to pGMA. The roughness of the microspheres surface has provides higher surface area [14]. SEM micrographs of pGMA microspheres and pGMA/Al-morin are presented in Figure 2.

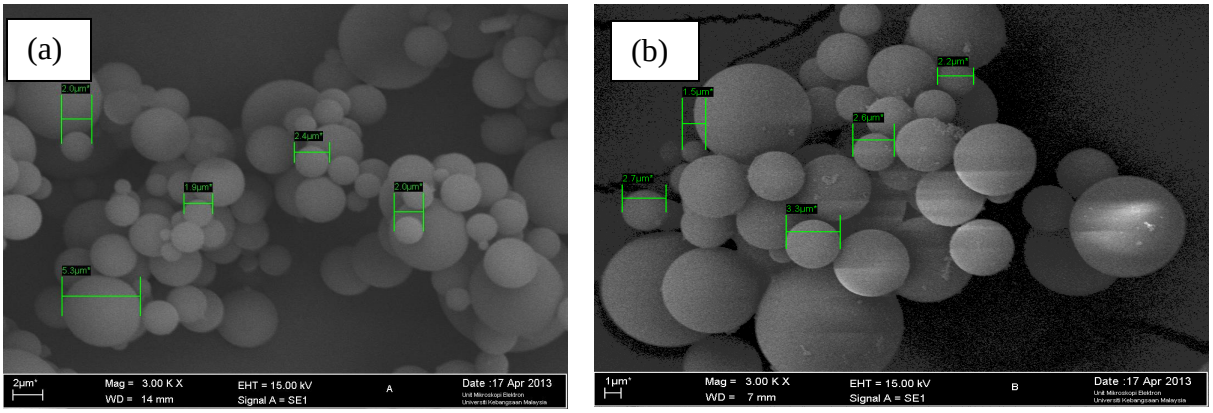

Figure 2. Surface morphology of microspheres (A) pGMA and (B) pGMA with Al-morin

Spherical matrix is capable to maximize the surface area of sensor reagent and reduce the response time by allowing the analyte to penetrate through the matrix [15]. This shows that pGMA provides high surface area for phosphate detection and increases the chemisensor sensitivity. Microspheres optical chemisensor can reduce sample volume, increase sensitivity, shorten response time and reduce detection limit [16].

ATR-FTIR spectra of pGMA/Al-morin

ATR-FTIR spectra of pGMA and pGMA/Al-morin microspheres are shown in Figure 3. Both types of pGMA spectra have recorded a strong band at 1721 cm^{-1} (pGMA) and 1722 cm^{-1} (pGMA/Al-morin) due to C=O vibrations. Furthermore, bands of 843 cm^{-1} and 905 cm^{-1} correspond to the epoxy groups. No additional peak can be seen between pGMA and pGMA/Al-morin bands. This result confirms that the pGMA and Al-morin involved entrapment method which does not involve any chemical bonding between Al-morin complex and the GMA polymer.

Optimization of pGMA/Al-morin

pH analysis

Figures 4 shows graph of fluorescence intensity versus pH that was measured at 548 nm respectively. pH 5 was determined to be the optimum pH for pGMA/Al-morin to react with $H_2PO_4^-$. Mohr and Wolfbeis [17] have reported that $H_2PO_4^-$ is the predominant form of phosphate at pH 5. At pH <5, low fluorescence intensity could be related to the protonation of $H_2PO_4^-$ to form H_3PO_4 resulting in a poor ability of $H_2PO_4^-$ to interact with Al-morin. Furthermore at pH >5, gradual decrease in fluorescence intensity is observed which may be due to hydroxide ions interference and formation of other form of phosphate ions [18].

Effect of phosphate concentrations

Morin (2',3,4',5,7-pentahydroxyflavone) is brown in colour when dissolves in ethanol and turn to light yellow solution as it is diluted. Free morin is weakly fluorescent and it becomes stronger as it forms a complexe with aluminium [19]. However, the fluorescence of Al-morin complex quenches distinctly when phosphate is introduced into the system [12]. The proposed reaction between Al-morin with $H_2PO_4^-$ is shown in Figure 5.

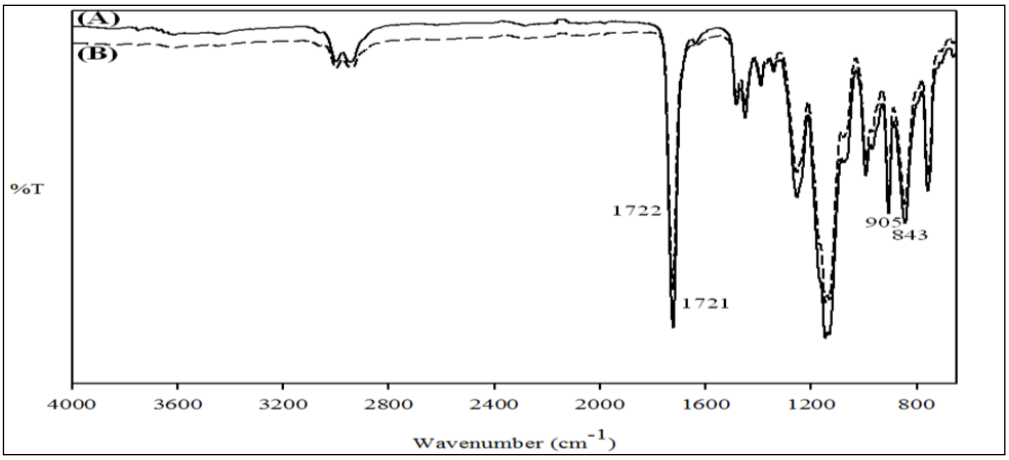

Figure 3. ATR-FTIR spectra of (A) pGMA and (B) pGMA/Al-morin microspheres

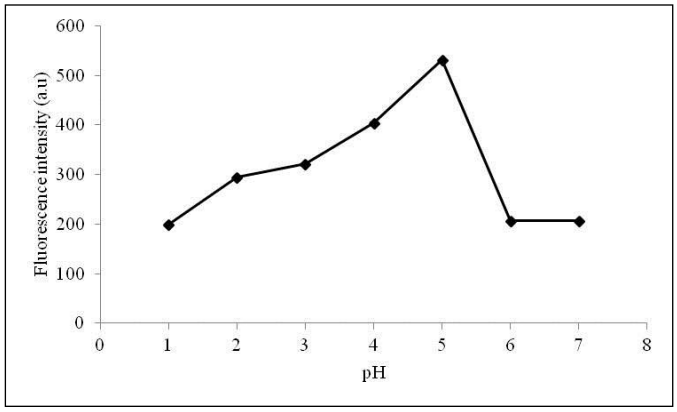

Figure 4. Effect of pH on pGMA/Al-morin with $H_2PO_4^-$

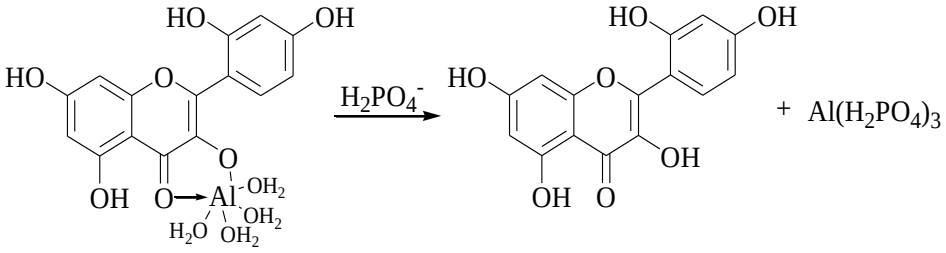

Figure 5. Proposed chemical reaction of Al-morin with phosphate anion.

Study on the effect of phosphate concentration was carried out at pH 5 to investigate the ability of immobilized Al-morin in detecting $H_2PO_4^-$ at various concentrations. The pGMA/Al-morin microspheres was allowed to react with

$H_2PO_4^-$ at a fixed concentration within 5 minutes before analyzing by fluorescence spectrometer. Figure 6 shows the fluorescence intensity of pGMA/Al-morin reached equilibrium at 124.9 µmol/L $H_2PO_4^-$ with the linearity from 6.6 to 58.8 µmol/L (inset) and a detection limit as low as 0.7 µmol/L. This sensor produced higher range of phosphate concentration compared to poly(vinyl chloride) and poly(vinyl alcohol) based membrane may be due to larger surface area provided by pGMA microspheres [11, 12, 20].

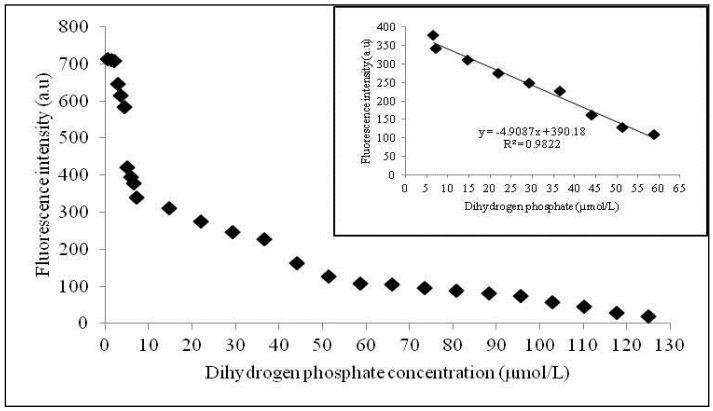

Figure 6. Calibration curve and linear range (inset) of pGMA/Al-morin based sensor towards different phosphate concentrations at pH 5.

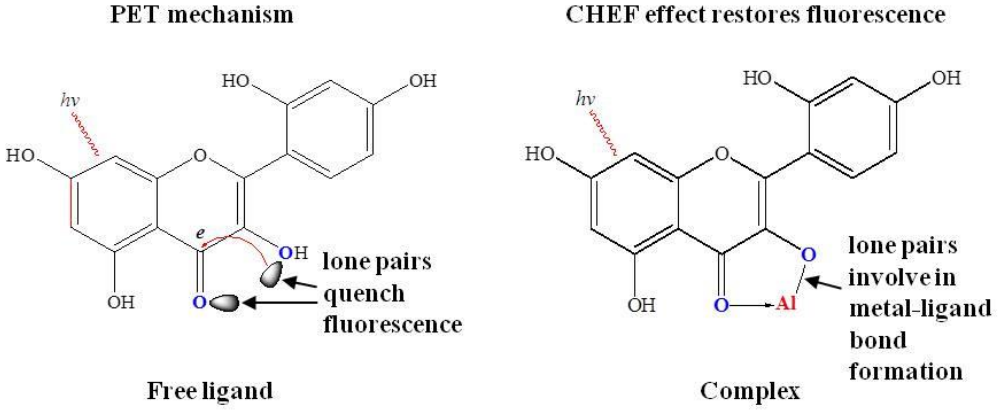

Figure 7. PET and CHEF effects on morin complexation.

The relative fluorescence intensity is inversely proportional to $H_2PO_4^-$ concentrations. The quenching of fluorescence could be further explained in Figure 7 [21]. It is possibly an example of CHEF (Chelation-Enhanced Fluorescence) and PET (Photoinduced Electron Transfer) phenomenons. CHEF effect is related to the photoinduced electron transfer (PET) mechanism. In the PET mechanism, exciting radiation induces electrons in the free ligand to transfer from the lone pairs on donor atoms (O-donors) to the π-system of the fluorophores and resulting in fluorescence quenching. These same lone pairs which involve in bonds formation with metal ions reduce the PET quenching effect. This occurrence leads to the CHEF effect, where metal ions can be detected by the increment of fluorescence intensity [22]. In this case, introducing $H_2PO_4^-$ to the system reduces the fluorescence intensity as aluminium detaches from morin by forming aluminium dihydrogenphosphate, $Al(H_2PO_4)_3$. This is due to poor fluorescence of non-chelating morin. Simultaneously, PET involves explaining about this phenomenon. Lone pairs

on morin O-donor atoms are no longer chelated with metal ion thus leading to increase PET quenching effect and indirectly reduce the fluorescence intensity.

Effect of Ions Interference

According to Table 1, pGMA/Al-morin was highly selective for $H_2PO_4^-$ over other anions which were commonly present in water samples such as CO_3^{2-}, CH_3COO^-, Cl^-, F^-, NO_3^- and SO_4^{2-}. The higher affinity for $H_2PO_4^-$ over other anions may be caused by the presence of appropriately spaced cationic charges, Al^{3+} [23]. All the interfering ions do not affect much on the detection of $H_2PO_4^-$ because the percentage of interference was less than 10% [24 – 26].

Table 1. Percentage of ion interference of immobilized Al-morin at pH 5.

Ion interference	**Percentage of interference (%)**
Carbonate, CO_3^{2-}	1.51
Acetate, CH_3COO^-	0.52
Chloride, Cl^-	5.43
Floride, F^-	0.00
Nitrate, NO_3^-	2.74
Sulfate, SO_4^{2-}	1.58

Performance of pGMA microspheres in the present study and PVC based membranes for immobilizing Al-morin is summarized in Table 2. It is clearly seen that pGMA/Al-morin has improved phosphate sensor performance compared to polyvinyl alcohol/ polyvinyl chloride/ aluminium-morin (PVA/PVC/Al-morin) composite membrane [11] and PVC/Al-morin matrix membrane [12] for $H_2PO_4^-$ detection. pGMA/Al-morin microspheres serves as a useful matrix for rapid phosphate measurement as the response time was recorded within 5 minutes.

Table 2. Summary of Al-morin phosphate sensor performances.

Parameters	**pGMA/Al-morin micropsheres**	**PVA/PVC/Al-morin membrane[a]**	**PVC/Al-morin membrane[b]**
pH	5	4	5
Dynamic range (µmol/L)	0.7 – 124.9	3.7 – 73.5	7.3 – 132.3
Linear range (µmol/L)	6.6 – 58.8	11.0 – 51.4	44.1 – 110.2
Limit of detection (µmol/L)	0.7	0.1	0.1

[a] [11] [b] [12]

Conclusion

A convenient method for preparing pGMA/Al-morin microspheres for the development of optical phosphate sensor has been highlighted. pGMA/Al-morin microspheres have the ability to detect phosphate within a short time, high selectivity and able to measure phosphate concentrations at wider linear range caused by high surface area of the microspheres.

Abstract

A photooxidative system for deep desulfurization of model diesel fuel was explored. Nanoparticles of anatase titania (TiO_2) were synthesized via sol-gel hydrothermal method. The TiO_2 was further modified with bimetallic Cu-Fe using wet-impregnation method followed by calcination process in order to extend the activity region of the photocatalyst to visible-light. A series of bimetallic 2.2 wt% Cu-Fe/TiO_2 photocatalysts with different Cu:Fe mass compositions were characterized for their physical, chemical and optical properties using X-ray diffraction (XRD), field emission scanning electron microscopy (FESEM), high resolution transmission electron microscopy (HRTEM), diffuse reflectance UV-visible spectroscopy (DR-UV-Vis), Fourier Transform Infrared Spectroscopy (FTIR) and Brunauer–Emmett–Teller (BET) surface area analysis. The performance of the photocatalysts was evaluated for photooxidation of dibenzothiophene (DBT) as the sulfur species from model oil in the presence of hydrogen peroxide, H_2O_2 under 500 W visible light illumination. The highest sulfur conversion of 82.36 % was observed for photocatalyst with 10:1 Cu:Fe mass composition.

Abstrak

Sistem fotopengoksidaan untuk proses nyahsulfur daripada model minyak diesel dikaji. Nanopartikel titania (TiO_2) dengan fasa anatas disediakan menggunakan kaedah hidrotermal sol-gel. Pengubahsuaian dengan dwilogam Cu-Fe dilakukan terhadap TiO_2 menggunakan kaedah impregnasi basah diikuti dengan proses pengkalsinan untuk melanjutkan aktiviti fotokatalis ke bahagian cahaya tampak. Siri fotokatalis dwilogam 2.2 wt% Cu-Fe/TiO_2 dengan komposisi jisim Cu:Fe yang berlainan dicirikan untuk menentukan sifat-sifat fizikal, kimia dan optik menggunakan pembelauan sinar-X (XRD), pemancaran medan mikroskopi imbasan elektron (FESEM), mikroskopi transmisi elecktron beresolusi tinggi (HRTEM), spektroskopi pantulan resapan ultraungu-tampak (DR-UV-Vis), spektroskopi transformasi Fourier inframerah (FTIR) dan analisis luas permukaan Brunauer–Emmett–Teller (BET). Kajian terhadap fotopengoksidaan dibenzothiophene (DBT) sebagai spesis sulfur di dalam model minyak menggunakan fotokatalis tersebut dilakukan dalam kehadiran hidrogen peroksida, H_2O_2 di bawah sinaran cahaya tampak 500 W. Prestasi tertinggi penukaran sulfur yang tercapai adalah 82.36 %, daripada fotokatalis yang mempunyai komposisi jisim untuk Cu:Fe sebanyak 10:1.

Introduction

Energy production is one of the most pressing issues of the modern world. The main task of modern refinery is to efficiently produce high yields of valuable products. Gasoline, diesel and non-transportation fuel comprises 75 - 80 % of refinery products. Environmental restrictions regarding the quality of transportation fuels produced and the emissions from the refinery itself are currently the most important issues, as well as the most costly to meet. Sulfur species represent one of the most common impurities in crude oil [1]. The distribution of the sulfur species mainly depend on the origin of the petroleum, type and volume of different stream feeding into the diesel pool. Diesel feeds contain a large number of individual sulfur species, such as dibenzothiophene (DBT) and alkyl derivatives [2].

Sulfur species are undesirable in the refining process as they tend to deactivate some catalysts used in the crude oil processing and cause corrosion problems in pipelines, pumping and refining equipment. Naturally occurring residual sulfur species in fuels will lead to the emission of sulfur oxide gases during combustion. These gases react with water in the atmosphere to form sulfates and acid rain which can damage buildings, destroy automotive paint finishes, acidifies soil and ultimately lead to destruction of forest and various other ecosystems. Sulfur emission also causes respiratory problems, heart diseases, asthma and contributes to the formation of atmospheric particulates. Automobiles are also adversely affected by the presence of sulfur species in the fuels, as the sulfur species have a profound effect on the efficacy of catalytic converters [3].

The current industrial method for removal of sulfur species from fuels is known as hydrodesulfurization (HDS), which operates at high temperature and pressure. This makes HDS a very costly option for deep desulfurization. In addition, HDS is not effective in removing refractory heterocyclic sulfur species such as DBT and its derivatives, especially 4,6-dimethyldibenzothiophene (4,6-DMDBT) [4, 5]. Oxidative desulfurization (ODS) [6, 7], extractive desulfurization (EDS) [8, 9], adsorptive desulfurization [10, 11] and biodesulfurization (BDS) [12, 13] are other desulfurization techniques that have the potential to produce ultra clean fuel. In ODS, the sulfur species are oxidized to sulfone by chemical reaction using oxidants such as hydrogen peroxide (H_2O_2), nitric acid, ozone, air and others.

Recently, research has focused on investigating the desulfurization of sulfur species via photocatalysis [14, 15] utilizing radiation energy. Titanium dioxide (TiO_2) based photocatalysis has been widely employed in environmental purification to decompose organic compounds in air and wastewater since this method can be conducted under mild reaction conditions [16]. Moreover, TiO_2 is inert to chemical corrosion, has a strong oxidizing power (with UV light) and is cost effective [17]. The successful application of photocatalysis in deep desulfurization process has been reported previously to remove thiophenes and derivatives of benzothiophene (BT) and DBT, which are the model sulfur species in gasoline [18, 19], light oil [14, 20] and diesel [21]. The results indicated that photodesulfurization has displayed higher activity compared to the conventional HDS in removing refractory DBT derivatives such as 4-methyldibenzothiophene (4-MDBT) and 4,6-DMDBT [14].

As reported by Matsuzawa et al. [22], DBT and 4,6-DMDBT in acetonitrile are photooxidized to 5-oxide (sulfoxide) and 5,5-dioxide (sulfone) using TiO_2. The application of this photochemical oxidation to desulfurization as been realized in some literatures [22, 23] using oil-water and oil-polar solvent two phase systems. The desulfurization of light oil to a sulfur content of less than 0.05 wt% has been achieved successfully. However, ultraviolet (UV) irradiation was found to be essential to oxidize DBTs and the desulfurization hardly progresses at wavelength, $\lambda > 400$ nm. Therefore, there is a need to develop a photocatalyst system that enables the use of renewable energy resources such as sunlight which provides cleaner and more efficient removal of sulfur species from petroleum fuel oils. Incorporation of transition metal onto TiO_2 structure could produce photocatalyst that displays activity in visible light. Iron (Fe) and copper (Cu) have received much attention as metal dopants as these metals are cheap and abundant in supply. A great deal of research has been conducted using Cu or Fe doped TiO_2, but co-doped Cu and Fe onto TiO_2 is rarely reported. Liu et al. [24] and Zhang [25] degraded organic dye pollutants, Reactive Black 5 (RB 5) and Methyl Orange (MO) in wastewater under UV [24] and visible light [25] radiation, respectively. They showed that co-doped Cu and Fe onto TiO_2 displayed significant enhancement in photodegradation of the organic dye pollutants compared to the un-doped TiO_2.

This paper focused on the synthesis and characterization of Cu-Fe/TiO_2 photocatalysts for the photooxidation of sulfur species in model oil under visible light radiation. Further treatment to the model oil is required in order to

remove the oxidized sulfur species and also the residual sulfur species in order to complete the deep desulfurization process. Example of such treatment is extraction using eutectic ionic liquids which was reported in a separate work [26].

Materials and Methods

Materials and reagents

Titanium tetraisopropoxide, TTIP ($Ti(OC_3H_7)_4$) (Merck, 97 %), *n*-heptane (C_7H_{16}) (Fisher, 99 %), anhydrous iron(III) chloride ($FeCl_3$) (Merck, 98 %), copper(II) chloride dihydrate ($CuCl_2.2H_2O$) (Merck, 99 %), dibenzothiophene, DBT ($C_{12}H_8S$) (Merck, 98 %) and dodecane ($C_{12}H_{26}$) (Merck, 98 %) were used without further purification.

Synthesis of TiO_2

Nanoparticle TiO_2 was synthesized using a method modified from that reported by Khan et al. [27]. An amount 27 mL of titanium tetraisopropoxide (TTIP) was added into 100 mL of *n*-heptane as a solvent. The mixture was stirred at 300 rpm for 2 hours. This was followed by drop wise addition of 7.98 mL distilled water to the mixture, giving a molar ratio of 1:5 for TTIP:H_2O. The mixture was left to age for 72 hours at room temperature. The obtained sol was transferred to a 100 mL teflon-lined autoclave vessel and was heated to 240 ^oC for 12 hours. The resulting precipitate was dried in the oven at 70 ^oC for 12 hours. After drying, the raw TiO_2 was calcined in a furnace at 500 ^oC in ambient air for 1 hour. The calcination process was carried out to remove any residual organic substance and also as an activation process to transform the hydroxides into anatase TiO_2.

Preparation of Cu-Fe/TiO_2

A series of 2.2 wt% Cu-Fe/TiO_2 photocatalysts with different Cu:Fe mass composition (10:1, 9:2 and 8:3) was prepared using wet impregnation method. $CuCl_2.2H_2O$ and $FeCl_3$ were used as metal precursors. Predetermined amounts of $CuCl_2.2H_2O$ and $FeCl_3$ salts were dissolved in distilled water with continuous stirring. The required amount of TiO_2 support was added into the metal salt solution. The suspension was stirred for 1 hour before the solvent was evaporated in a water bath at 80 ^oC and further dried in an oven at 120 ^oC for 18 hours. The raw photocatalysts were ground into fine powder and then calcined at 500 ^oC for 1 hour (10 $^oC \cdot min^{-1}$ ramping). The temperature selected was adopted from previous reported method [26]. The denotation of the photocatalysts was: xCuyFe, where 'x' represents the amount of Cu and 'y' represents the amount of Fe in which 'x' + 'y' = 11. For example, 10Cu1Fe refers 2.2 wt% Cu-Fe/TiO_2 photocatalyst with 10:1 Cu:Fe mass composition. Monometallic Cu/TiO_2 and Fe/TiO_2 photocatalysts with 2.2 wt% metal loading, denoted as Cu and Fe, respectively, were also prepared for comparison purposes.

Characterization of photocatalysts

The X-ray diffraction (XRD) patterns of the calcined TiO_2 and also the prepared Cu-Fe/TiO_2 photocatalysts were recorded using Bruker D8 Advance with CuKα radiation (40 kV, 40 mA) at 2θ angles from 2 to 80° and a scan speed of 4 $^oC \cdot min^{-1}$ to determine the active TiO_2 phase present. Morphology of the photocatalysts were examined using field emission scanning electron microscopy (FESEM, Supra55VP) coupled with energy dispersive X-ray analysis (EDX) and high resolution transmission electron microscopy (HRTEM, Zeiss Libra 200). The light absorption properties of the photocatalysts were recorded using diffuse reflectance UV-visible spectroscopy (DR-UV-Vis) where the Shimadzu Spectrometer 3150 was equipped with an integrated sphere assembly in which $BaSO_4$ was used as the reference material. Tauc Plot, derived from DR-UV-Vis spectrum was employed to determine the band gap energy of the photocatalysts. The BET surface area of the photocatalysts was determined using surface analyzer (Tristar II 3020). Fourier Transform Infrared (FTIR) spectra of the photocatalysts were scanned from 4000 to 450 cm^{-1} at 1.2 cm^{-1} resolution using Perkin Elmer Spectrophotometer. The surface area and pore volume were calculated using the Brunauer-Emmett-Teller (BET) method, and pore size distribution was determined from the desorption branch of the desorption isotherm by the Barrett-Joyner-Halenda (BJH) method.

Photooxidative deep desulfurization process

The photooxidation process involved suspending the photocatalyst in model oil containing 100 ppm dibenzothiophene (DBT) as the model sulfur species in dodecane. Photooxidation was carried out in a glass photoreactor positioned below the light source (500W halogen lamp, λ >400 nm) at a distance 15 cm from the lamp.

The model oil was mixed with 1 $g \cdot L^{-1}$ of photocatalyst. H_2O_2 with a molar ratio of 4:1 (H_2O_2:S) was added and the suspension was stirred in the dark for 30 min to achieve adsorption-desorption equilibrium between DBT in the model oil and the photocatalyst. Subsequently, photooxidation process occurred under visible light illumination. The photooxidation process was monitored by periodic sampling where the photocatalyst was separated from the model oil by filtration prior to analysis using GC-SCD (Agilent 7890A gas chromatograph coupled with Agilent 355 sulfur chemiluminescence detector). The DB-1 J & W 123-1033 (30 m x 320 um x 1 um) column was maintained at 325^oC with helium as carrier gas flowing at 1.1 $mL \cdot min^{-1}$. The auto sampler was in split mode (300 ^oC, 6.16 psi, 50:1 split ratio at 55 $mL \cdot min^{-1}$, split flow 50 $mL \cdot min^{-1}$, septum purge flow 3 $mL \cdot min^{-1}$) and injection volume of 1.0 µL. The detector settings were: burner at 800 ^oC (to ensure complete sulfur combustion), dual plasma controller at 250 – 400 torr, 65 sccm of air flow rate, 40 sccm of H_2 flow rate and 20 – 30 $mL \cdot min^{-1}$ at 3 – 6 psi of ozone flow rate. The efficiency in converting sulfur species to oxidized sulfur species in the model oil was calculated using equation (1):

$$\text{Sulfur conversion (\%)} = \frac{S_i - S_f}{S_i} \times 100\ \% \qquad (1)$$

where, S_i and S_f refer to the initial and final concentrations of sulfur species (DBT) in model oil.

Results and Discussion

X-ray diffraction

The effect of Cu:Fe mass composition on the crystallite phase and crystallinity of the photocatalysts was analyzed. Figure 1 display the XRD patterns of Cu-Fe/TiO_2 with different Cu:Fe mass composition (10:1, 9:2 and 8:3). The photocatalysts were calcined at 500 ^oC for 1 hour prior to analysis. All the samples displayed the typical anatase TiO_2 crystal structure with peaks at 2θ of 25.3°, 38.0°, 48.3°, 54.8°, 55.8° and 62.6° corresponding to (101), (004), (200), (105), (211) and (204) phases, respectively [27, 28]. The preferred orientation corresponding to the phase (101) is observed in all the samples. Both monometallic TiO_2 (Cu and Fe) and bimetallic Cu-Fe/TiO_2 photocatalysts displayed high intensity for the diffraction peak at 2θ = 25.3^o. This indicates larger crystallite size compared to bare TiO_2. There was no indication of the presence of Cu, Fe or Cu-Fe species in all the XRD patterns. This may be due to the presence of highly dispersed Cu and Fe species and also low metal content [29], which are below the detection limit of the equipment [30]. In order for the metal to be detectable by XRD analysis, the concentration of metals should be higher than 5wt% [31]. However, the presence of the incorporated metals can be confirmed from EDX mapping that will be discussed in later section. No peaks attributed to the rutile phase could be detected. This may be due to the calcination temperature, as the transition from anatase to rutile phase normally occurs at temperature above 600 ^oC.

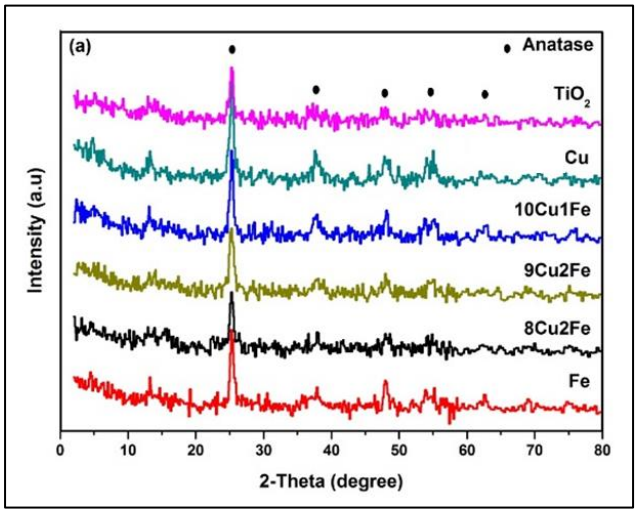

Figure 1. XRD patterns of TiO_2, Cu, 10Cu1Fe, 9Cu2Fe, 8Cu3Fe and Fe

The dominant peak at 25.3° (101) was used to estimate the crystallite size of the photocatalyst using Debye Scherrer's equation [32]. The average crystallite sizes for the photocatalysts are listed in Table 1. The estimated crystallite size for TiO_2 was 11.50 nm. Monometalic Fe showed larger crystallite size compared to monometallic Cu. For the bimetallic photocatalysts, as the composition of Cu decreased, the average crystallite size also showed a decreasing trend. Higher Fe content led to smaller crystallite size in the bimetallic system. Incorporating both Cu and Fe metals decreases the crystallite size compared to single doping. This could be caused by restrained grain growth in the presence of both Cu and Fe, which in turn led to smaller crystallite size at certain mass composition. Similar trend was reported by Kim and Kang [33] where incorporation of both Cu and Ag produced smaller crystallites compared to single doped photocatalyst.

Table 1. Crystallite and particle sizes of photocatalysts from different analysis methods

Sample	Average Crystallite Size (nm)	Particle Size Range (nm)	
	XRD	FESEM	HRTEM
TiO_2	11.50	10.39 – 15.79	10.88 – 16.24
Cu	18.22	17.78 – 19.04	18.03 – 26.11
10Cu1Fe	17.42	17.34 – 17.61	13.51 – 20.67
9Cu2Fe	17.34	17.21 – 17.58	12.92 – 21.01
8Cu3Fe	17.06	16.92 – 17.12	13.04 – 19.17
Fe	19.92	19.84 – 20.11	11.61 – 22.37

Field Emission Scanning Electron Microscopy

FESEM micrographs of photocatalysts at different Cu:Fe mass composition are shown in Figure 2 (a-f). The particles were spherical in shape with slight agglomeration observed for all the photocatalysts. As the Cu:Fe mass composition decreased from 10:1 to 9:2 and 8:3, the average particle size decreased from 17.53, 17.43, and 17.20 nm, respectively. The particles of TiO_2 were small compared to the metal doped photocatalysts with particle size ranging from 10.39 – 15.79 nm (average particle size of 11.39 nm). The average particle size of monometallic Cu and Fe were 18.44 and 20.12 nm, respectively, comparable to the trend observed on the average crystallite sizes from XRD analysis. Detailed particle size distribution as provided in Table 1. No localized metal particles were detected, indicating high metallic dispersion of Cu and Fe on TiO_2. This observation is in agreement with the results obtained from XRD analysis.

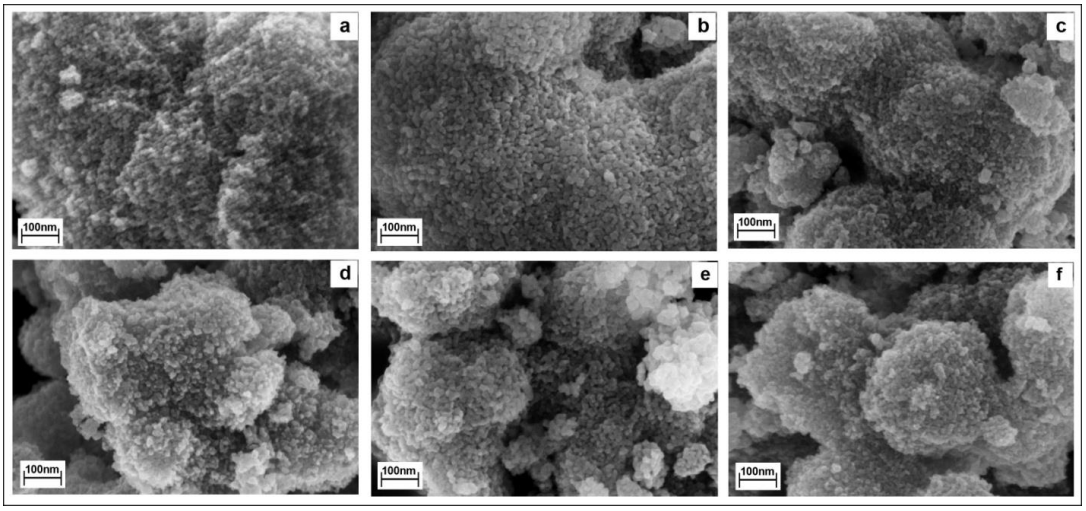

Figure 2. FESEM micrographs of (a) TiO_2, (b) Cu, (c) 10Cu1Fe, (d) 9Cu2Fe, (e) 8Cu3Fe and (f) Fe (100 kX magnification)

Figure 3 shows the EDX mapping of 10Cu1Fe. The elements that were mapped were displayed as colored spots in the images. Cu and Fe metal dopants were uniformly distributed on the TiO_2 surface. As mentioned before, the presence of Cu and Fe metals were not detected from XRD analysis because of the well dispersed small crystallite size of the metal species on TiO_2 [32, 34]. The highly dispersed metal particles on TiO_2 led to better activity thus further enhances the photocatalytic activity [35]. Similar mapping images were obtained for other photocatalysts, showing that the preparation method has successfully incorporated Cu and Fe onto the TiO_2 surface.

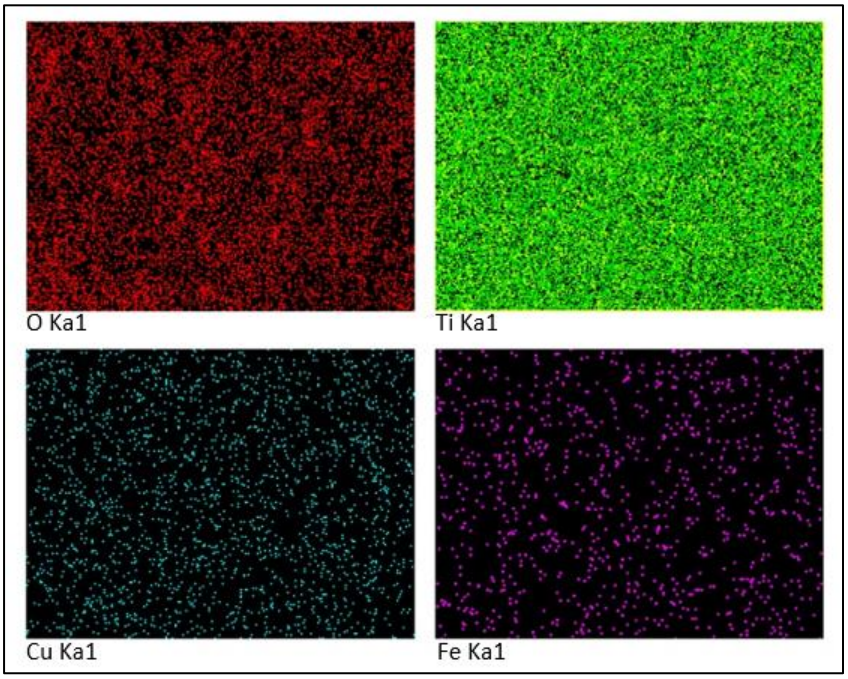

Figure 3. EDX and mapping images of 10Cu1Fe

High Resolution Transmission Electron Microscopy

HRTEM analysis was carried out to determine the detailed morphology of the photocatalyst. Image processing analysis of HRTEM micrographs was used to refine the microstructures for more accurately analyzed single grains and grains boundaries. Figure 4 (a-f) shows the HRTEM micrographs of Cu-Fe/TiO_2 photocatalysts at different Cu:Fe mass compositions. All micrographs showed good crystallite morphology of the particles with mixtures of spherical and polygonal shapes [36]. TiO_2 has the most polygons and as the Fe content increased, the particles became more spherical. The estimated particle sizes of the photocatalysts are tabulated in Table 1. These particle size distribution are in good agreement with the data extracted from FESEM analysis. HRTEM micrographs of the photocatalysts showed agglomeration of particles. This is possible due to high content of surface hydroxyl groups contributing towards the hydrophilic properties [37].

Brunauer-Emmett-Teller

Isotherm plot of 10Cu1Fe is shown in Figure 5. The plot shows Type IV isotherm with hysteresis loop indicating mesoporous structure. The inflection points showed P/Po range of 0.6 – 1.0. The other photocatalysts also displayed similar isotherm. The pore distribution of the photocatalysts was determined by BJH method. Cu-Fe/TiO_2 photocatalysts are mesoporous with an average pore diameter (4V/A) of 13.76, 13.30 and 14.06 nm for 10u1Fe, 9Cu2Fe and 8Cu3Fe, respectively. The BET surface area of the materials for 10u1Fe, 9Cu2Fe and 8Cu3Fe were 49.99, 42.11 and 45.33 m^2/g, respectively, which was comparable.

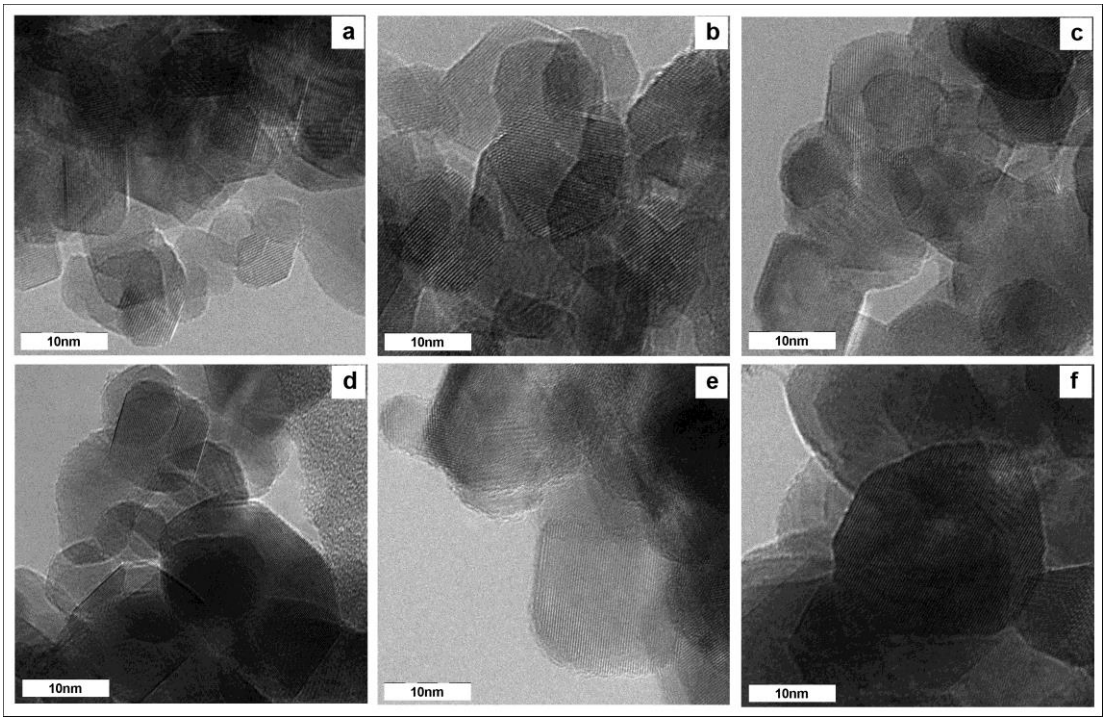

Figure 4. HRTEM micrographs of (a) TiO_2, (b) Cu, (c) 10Cu1Fe, (d) 9Cu2Fe, (e) 8Cu3Fe and (f) Fe

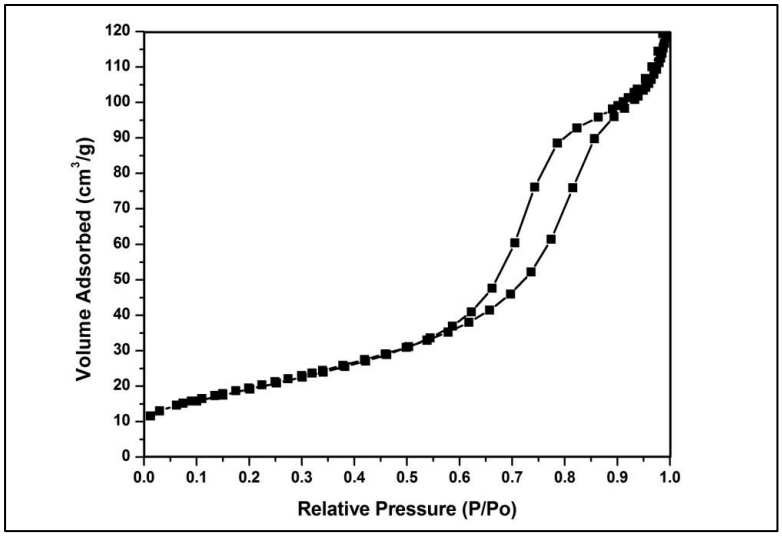

Figure 5. N_2 adsorption-desorption isotherm of 10Cu1Fe

Fourier Transform Infrared Spectroscopy

Figure 6 exhibits the FTIR transmission spectra of Cu-Fe/TiO_2 with different Cu:Fe mass composition with additional 7Cu4Fe. For all the spectra, the broad band around 3400 cm^{-1} was attributed to O-H stretching, and the peak near 1600 cm^{-1} to H-O-H bending [38]. These peaks might be due to the physically adsorbed water. The broad band observed between 400 – 900 cm^{-1} corresponds to the Ti-O stretching vibrations [39]. FTIR is not a suitable

technique to detect the presence of Cu, Fe or Cu-Fe species since the metal–O vibrations are not IR-active. However, these species were detected using EDX.

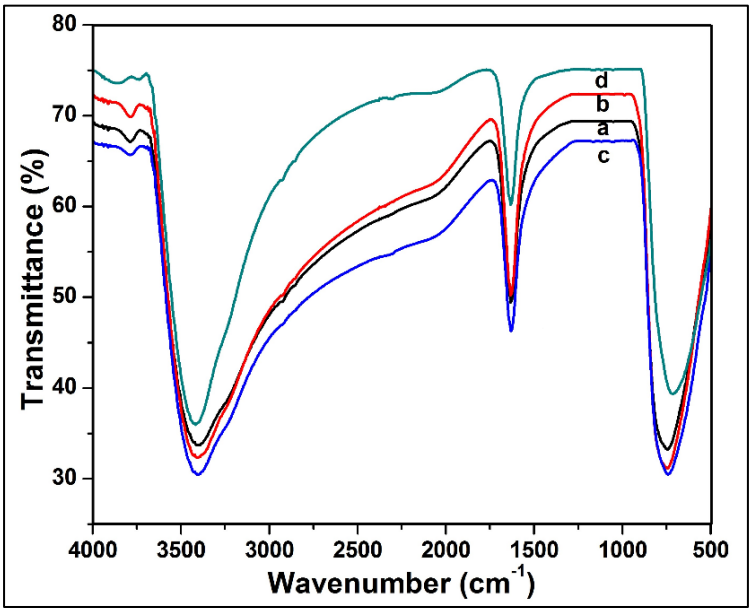

Figure 6. FTIR spectra of (a) 10Cu1Fe, (b) 9Cu2Fe, (c) 8Cu3Fe and (d) 7Cu4Fe

Diffuse Reflectance UV-Visible Spectroscopy

The DR-UV-Vis spectra of the photocatalysts are depicted in Figure 7. The absorption spectrum for TiO_2 shows an absorption edge at 400 nm corresponding to the band gap of 3.09 eV. The absorption band at 323 nm is generally related to the electronic excitation from the valence band O 2p electron to conduction band Ti 3d orbital indicating that Ti is in the form of tetrahedral Ti^{4+} species [40]. All Cu-Fe co-doped photocatalyst shows considerable shift of the absorption edge towards visible region compared to TiO_2. In general, as the Fe content increases, the absorption in the visible region (400 – 780 nm) also increases. It has been generally accepted that the metal dopants introduces a new energy level into the band gap of TiO_2 which is close and above the valence band. Thus, the charge transfer from the valence band to the conduction band from the new energy level requires lower photon energy at lower wavelength [41]. TiO_2 sample doped with Cu-Fe doped TiO_2 sample showed substantial and broader absorption shoulder up to 800 nm. The extended absorption of metal doped TiO_2 samples into the visible region has been explained in terms of excitation of electrons of dopant ion to TiO_2 conduction band. For example, the enhanced absorption observed for the metal doped TiO_2 samples doped with Fe, Cu and Cu-Fe in visible region can be considered to involve excitation of 3d electrons of dopant ion to TiO_2 conduction band according to their respective energy levels [42]. The enhancement of light absorption in the visible region provides a possibility for improving the photocatalytic performance of TiO_2 under visible light irradiation. Doping with Cu-Fe could create sub band states in the band gap of TiO_2 which can then be easily excited to produce more electron-hole pairs under visible light irradiation, hence resulting in higher photocatalytic performance compared to undoped TiO_2. Moreover, a decrease in the band gap energy together with an enhanced absorption intensity of all doped TiO_2 can be seen from the UV-Vis results. This pheonomenon could be due to many factors such as morphology, crystallite size, phase structure and amount of metal loadings [43].

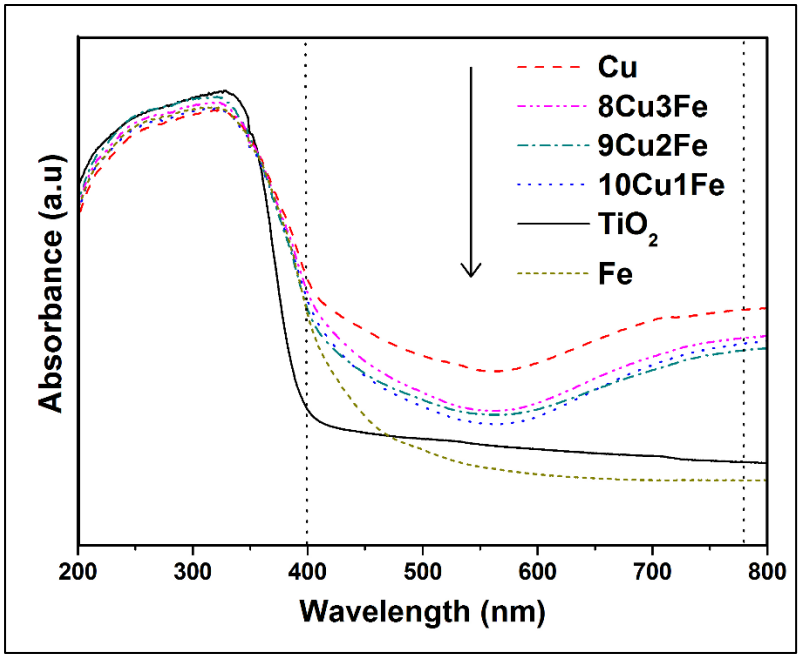

Figure 7. DR-UV-Vis spectra of TiO_2, Cu, 10Cu1Fe, 9Cu2Fe, 8Cu3Fe and Fe

In order to determine the band gap energy of the photocatalyst, reflectance [F(R)] spectra using Kubelka-Munk formalism and Tauc plot was employed for each synthesized photocatalyst [44]. Using the Tauc plot of $[F(R).hv]^n$ vs. hv where hv is the photon energy and n = ½ for direct band gap of the photocatalyst, the linear region of the plot was extrapolated to intersect the photon energy axis to deduce the band gap energy of the respective photocatalyst. The band gap of bare TiO_2 was 3.09 eV and upon incorporation of Cu, Fe or Cu-Fe, the band gap values were reduced. The band gap for Cu was 2.70 eV. The incorporation of Cu and Fe at 10:1 mass composition gave the highest reduction to the band gap (2.69 eV). As the Fe content increases, the band gaps slowly increases from 2.72 to 2.73 eV for 9Cu2Fe and 8Cu3Fe, respectively, indicating some synergistic effect [43]. The band gap for Fe was the highest, 2.82 eV. The blue shift in the absorption of photocatalysts suggested that the dopants successfully generate lower energy level between the valence and conduction bands [45]. The estimated band gap energy of metal doped TiO_2 was lower compared to that of TiO_2 P25 (3.2 eV) [46]. Decreasing band gap energy increases the absorbance in the visible region and indicates that the electron-hole pairs can be generated with metal doping on the TiO_2, which can be attributed to the charge transfer between metal ions and TiO_2 [34].

Photocatalytic performance

The mass composition of metals in the bimetallic photocatalyst plays a significant role in the photocatalytic activity [47]. Figure 8 displays the photooxidative efficiency for DBT conversion of model diesel using the photocatalysts with different Cu:Fe mass composition. The highest DBT conversion was 82.36 % displayed by 10Cu1Fe. It is noteworthy that the monometallic photocatalysts displayed the lowest DBT conversion of 18.95 % for Fe and 54.88 % for Cu compared to the bimetallic photocatalysts. This observation is similar to studies reported by Liu et al. [24] and Zhang [25], where the photocatalytic activity of Cu-Fe co-doped TiO_2 was higher than that of undoped or singly doped photocatalyst.

The formation of electron-hole pairs ($e_{cb}^- - h_{vb}^+$) are important in the photooxidation of DBT. During photooxidation process, the electrons (e_{cb}^-) in the valence band were excited by photons from the light energy. Excited electrons migrate to the conduction band leaving holes in the valence band. Both the electrons (e_{cb}^-) and the holes (h_{vb}^+) can react with entities in the system to produce hydroxyl radicals (•OH) with an oxidation potential of 2.8 V. By incorporating Cu and Fe metals, the recombination rate of $e_{cb}^- - h_{vb}^+$ pairs can be reduced by trapping

these charges. The electrons can be trapped by Cu^{2+} ions to form Cu^{+} or CuO. The potential of Cu^{2+}/Cu^{+} (0.17 V) and Cu^{+}/CuO (0.52 V) are thermodynamically feasible since an electron trapper could provide better separation between the electrons and holes compared to TiO_2 (–0.2 V) alone. Because of this, more holes are available for the photooxidation process. On the other hand, Fe^{3+} can become a trapper for both the electrons and holes simultaneously forming Fe^{2+} and Fe^{4+}, respectively. This is possible due to the energy levels of Fe^{3+}/Fe^{4+} and Fe^{2+}/Fe^{3+} that lie above the valence band and below the conduction band of TiO_2. Theoretically, the stability of Fe^{2+} and Fe^{4+} are lower compared to Fe^{3+} which has a half-filled $3d^5$ orbital configuration. Hence, Fe^{2+} can easily release the trapped electron to be oxidized back to Fe^{3+} which then migrates to the surface to initiate photocatalytic reaction. Fe^{4+} can be reduced to Fe^{3+} by donating the trapped holes to combine with the surface OH groups to give •OH. When the Cu:Fe mass composition were 9:2 and 8:3, the DBT conversion were 74.58 and 75.24 %, respectively.

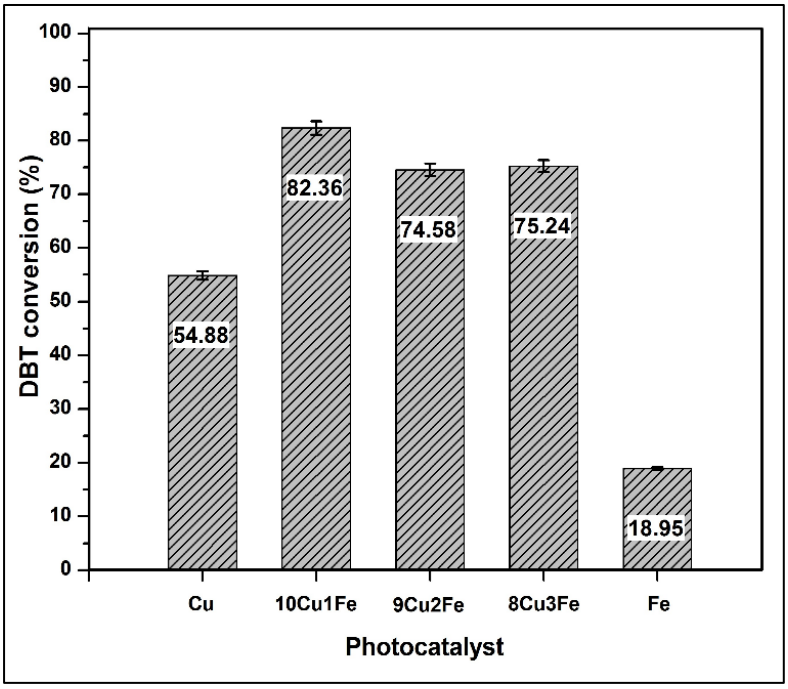

Figure 8. DBT conversion using Cu, 10Cu1Fe, 9Cu2Fe, 8Cu3Fe and Fe

Conclusion

The incorporation of Cu-Fe onto TiO_2 nanoparticles was able to reduce the band gap from 3.09 to as low as 2.69 eV for photocatalyst with Cu:Fe 10:1 mass composition. The lowering of band gap is an indication of shifting of the absorption edge to visible light region, which is important for photocatalysts to harvest energy from the free and abundant sunlight. The presence of bimetallic Cu-Fe co-catalyst was able to enhance the photoactivity of TiO_2 under visible light illumination. Photodegradation of 100 ppm DBT in model diesel using 10Cu1Fe in the presence of H_2O_2 has led to 82.36 % DBT conversion. Although the photocatalyst displayed good DBT degradation, the oxidized sulfur species which are retained in the model oil need to be removed. An integrated photodegradation-extraction system is required to photooxidize the sulfur species followed by removal of the oxidized compounds.

Abstract

Human pharmaceuticals have been shown to occur in considerably high amounts in sewage treatment plant (STP) effluents and surface waters. So far there is no data available on the occurrence of prazosin and simvastatin in leachate sample in Malaysia. Thus, this study is the first report to analysis of prazosin and simvastatin in leachate samples by using solid phase extraction-liquid chromatography-time of flight-mass spectrometry (SPE-LC-TOF-MS). The proposed method included isolation and reconstitute procedure. The linearity range was achieved at 1.5 - 3000 µg/L and 0.8 – 125 µg/L for prazosin and simvstatin, respectively with a determination coefficient (R^2) > 0.99. The limit of quantification (LOQ) for prazosin and simvastatin was calculated at 2.1 and 0.5 ng/L in deionised water (DIW), meanwhile it was recorded at 3.5 and 2.4 ng/L for prazosin and simvastatin in effluent sample, respectively. Two pharmaceutical compounds were detected in the leachate samples: prazosin and simvastatin at concentrations levels of 3850 and 415 ng/L, respectively.

Keywords: prazosin, simvastatin, leachate, solid phase extraction, pharmaceutical pollution

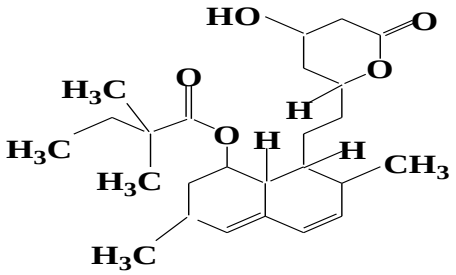
Abstrak

Farmaseutikal manusia telah hadir di dalam effluen loji sisa rawatan dan air permukaan. Sehingga kini, tiada data kajian yang merekodkan kehadiran prazosin dan simvastatin dalam sampel larut lesap di Malaysia. Maka, kajian ini merupakan laporan pertama tentang analisis terhadap prazosin dan simvastatin di dalam sampel larut lesap mengunakan pengekstrakan fasa pepejal-kromatografi cecair-masa penerbangan-spekrometri jisim (SPE-LC-TOF-MS). Kaedah yang dibangun meliputi langkah pemisahan dan nilai isian semula. Julat kelinearan dicapai antara 1.5 – 3000 µg/L dan 0.8 – 125 µg/L masing – masing bagi prazosin dan simvastatin dengan nilai pekali (R^2) > 0.99. Had kuantifikasi (LOQ) bagi prazosin and simvastatin dihitung pada aras 2.1 dan 0.5 ng/L di dalam air ternyahion manakala direkod masing-masing pada aras 3.5 dan 2.4 ng/L di dalam sampel efluen. Dua jenis sebatian farmaseutikal ini dikesan in dalam sampel larut lesap pada aras kepekatan masing-masing adalah 3850 and 415 ng/L.

Kata kunci: prazosin, simvastatin, larut lesap, pengekstrakan fasa pepejal, pencemaran farmaseutikal

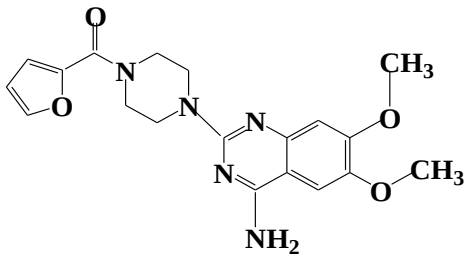
Introduction

The occurrence of pharmaceutical in the aquatic environment has been recognized as one of the emerging issues in environmental chemistry. The widespread presence in the aquatic environment can be explained by their extensive use in medical practice and incomplete removal in wastewater treatment plants (WWTPs) [1]. These compounds present in the environment at trace levels (ng/L - µg/L), hence it is known as micro pollutants. For this reason, in the past century, their detection was infeasible due to lack of sophisticated analytical technique. In recent years, advancements in analytical methods have contributed to the detection of over 100 active agents in pharmaceutical products in different environmental matrices [2, 3]. Scientific research studies conducted in Malaysia and worldwide have reported widespread occurrence of pharmaceuticals in surface water, influent and effluent sewage treatment plants and hospitals [4 – 7]. The reason may related to several ways which are participated to introduce the pharmaceuticals to surface water such as insufficiently treated sewage effluents, production residues, improper disposal of expired medications and unused drugs and accidental spillage during manufacturing and distribution [8].



In leachate samples, the detection of pharmaceuticals has never been studied except few reported papers [9, 10]. Landfills may be sources of a large number of organic compounds known as emerging contaminants (ECs and/or EDCs) such as pharmaceuticals, pesticides, fertilizers and others. Pharmaceutical compounds may occur in concentration of approximately 8.1 mg/kg in typical municipal solid waste. In landfills, these compounds may be degraded/metabolized, adsorbed to solids or dissolved in leachate. Release of these chemicals in the environment may affect public health on humans, animals and ecosystem.

Liquid chromatography - tandem mass spectrometry [LC-MS/MS] is one of the most popular analytical methods used to analyse pharmaceutical residues in water samples due to its versatility, specificity and selectivity. Other different approaches have been tried, including gas chromatography-mass spectrometry (GC-MS), voltammetry, potentiometry and LC-Uv as reviewed in previous studies [11, 12]. In Malaysia, simvastatin has been detected less than limit of detection (LOD) [13] while in Canada; it has been detected in 0.001 µg/L [14]. The differences in concentrations of simvastatin in treated wastewaters between different countries generally reflect different usage patterns, per-capita water consumption, and treatment processes.



The aim of this study is to determine the amount of prazosin and simvastatin in raw leachate, post-biological and post-charcoal adsorption treatment using liquid chromatography-time of flight/mass spectrometry.

Materials and Methods

Prazosin (PRZ) (CAS no.19237-84-4), simvastatin (SMV) (CAS no. 79902-63-9) were obtained from Sigma-Aldrich (USA). Figure 1 shows the chemical structure of these pharmaceuticals with molecular weight. Deionized water (DIW) used was supplied by EASYPure RODI (USA). Acetone, acetonitrile and methanol (HPLC grade) were purchased from Sigma-Aldrich (USA). Formic acid (FA) was supplied by Merck (Germany). Methyl Tertiary Butyl Ether (MTBE) was supplied by J. T. Baker (USA). The cartridges used for solid phase extraction (SPE) were (Oasis HLB 3 cm^3, 60 mg purchased from Waters (USA).

Simvastatin (SMV), 418 g/mol

Prazosin (PRZ), 383 g/mol

Figure 1. Chemical structures of the studied compounds

Site description and sampling activities

The leachate samples namely raw, biological and physico-chemical treated samples used in this study were collected from Jeram sanitary landfill leachate. Jeram sanitary landfill leachate is located in an oil palm plantation near Kuala Selangor Malaysia as shown in Figure 2. It is roughly rectangle in shape and occupied 64.7 hectares. Jeram sanitary landfill has been in operation by Worldwide Holdings since January 2007. This landfill is designed with a capacity to hold 6 million tons of waste. Currently, approximately 2000 tons of solid waste is disposed of at the landfill every day, and to date 4.1 million tons of waste has been added to the landfill [15].

All samples were collected in 1L amber glass bottles with Teflon lined caps to ensure sample integrity using a stain steel bucket previously rinsed with distilled water and methanol. The bottles head spaces were kept to a minimum by filling the bottles to the top. The bottles were rinsed once with sample and filled to the top on the second sampling. Disposable gloves were used to prevent any personal care products from contaminating the sample bottles, then immediately transported to the laboratory. Samples were filtered through a 0.7 µm GF/G filter from Whatman (UK) to remove suspended solids and stored at 4 ^{o}C in order to keep the wastewater characteristics unchanged.

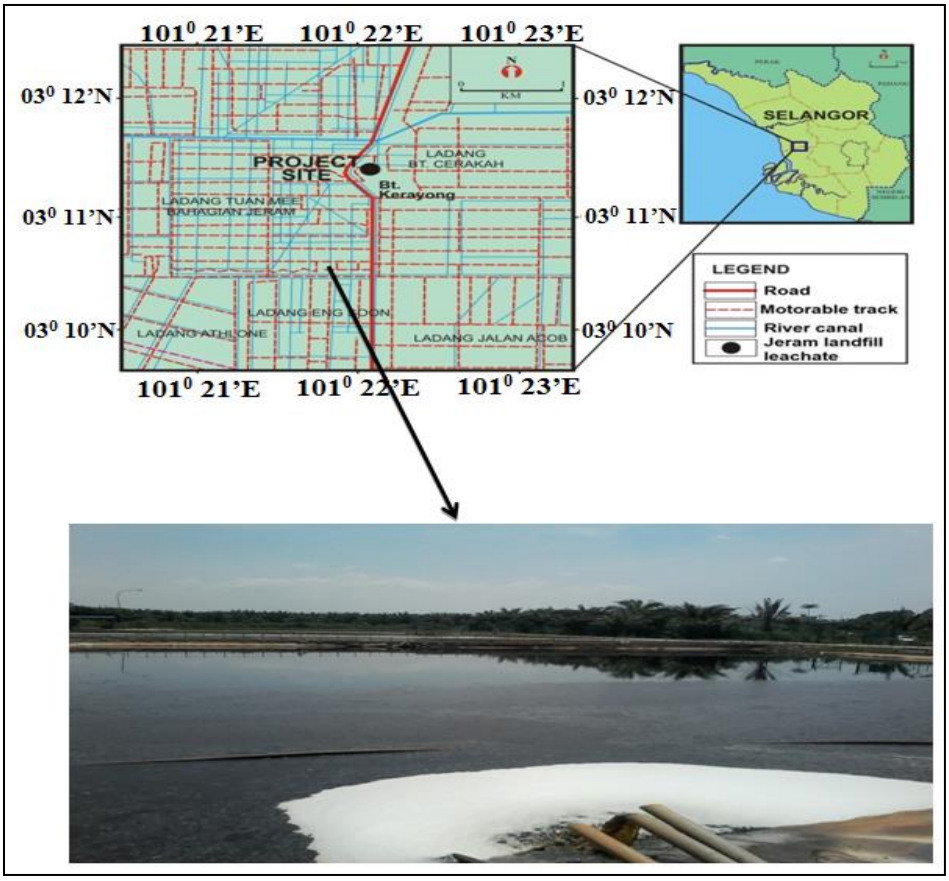


Figure 2. Map to describe location area

Method extraction of Prazosin and Simvastatin

Solid phase extraction procedure used in this study has been described in our previous paper [7]. In summary, the Oasis HLB cartridges (3 cm^3, 60 mg) were preconditioned with 2 mL MTBE, 2 mL of MeOH and 2 mL of deionized water at a flow rate of 1 mL/min. After the conditioning step, an aliquot of 250 mL of sample (after biological and charcoal treatment) were loaded into the cartridge. In case of raw leachate, 10 mL was diluted to 250 mL with deionised water because of its high complexity. Samples were passed through the cartridges at a flow rate of 9.0 mL/min and then, rinsed with 2 mL of deionized water prior to elution. After that, the cartridges were vacuum dried for 25 min to remove excess water. The pharmaceutical compounds were subsequently eluted into 12 mL glass tubes by sequentially passing 5×1 mL MTBE, 2×1 mL acetone–MeOH (21:9, v/v), and 3×1 mL acetone–MeOH (9:21, v/v). The combined eluents were evaporated to dryness under a gentle stream of N_2 gas. Dry extracts were reconstituted with 500 µL MeOH–DIW (10:90, v/v) and then transferred to 250 µL deactivated glass insert with polymer feet inserted in amber glass vials from Agilent Technologies (USA). The extract (30 µL) was automatically injected into LC–ESI–TOF/MS system for analysis.

The LC analysis was performed using a Dionex Ultimate 3000/LC 09115047 (USA) system equipped with a vacuum degasser, a quaternary pump, an auto sampler and a UV-Vis diode array detector. Chromatography was performed on a Thermo Scientific C18 (250 mm × 2.1 mm, i.d.: 5 µm) column. The injection volume was 30 µL. Simvastatin and prazosin were analysed in positive ion (PI) mode and eluted off from the column using mobile phase consisting of (A) 0.1 % FA in DIW and (B) ACN-MeOH (3:1, v/v) at 0.3 mL/min. The elution started at 5 % B and was then linearly increased to 60 % B over 3 min, further increased to 97 % B for 3 min and then kept isocratic for 5 min. Next, the elution was returned to its starting conditions over 11.1 min and allowed to equilibrate for 5 min prior to the next run.

The mass spectrometry was carried out on a TOF instrument (Bruker/Germany) equipped with a Z-spray electrospray interface. The results were obtained with the following settings: MS capillary voltages, 4000/3500 (PI/NI); collision energy for prazosin and simvastatin, 10 eV; drying-gas flow rate, 8.0 L/min; drying gas temperature, 190 °C; set capillary, 4000 V; set end plate offset −500 V; set collision cell RF, 250 Vpp and nebuliser pressure, 4.0 bar. Two adduct ions, namely $[M+H]^+$ for prazosin and $[M+Na]^+$ for simvastatin, were observed using TOF/MS analysis in positive-ion mode. The TOF results were collected between *m/z* 50 – 600. All analytes were acquired using an independent reference spray via the LockSpray interference to ensure accuracy and reproducibility; mixture of sodium hydroxide and formic acid was used as the lock mass *m/z* 90.9766 – 974.8132. The accurate mass was calculated using software Daltonic Analysis incorporated in the instrument.

Quality control

Recoveries of the studied pharmaceuticals were determined by initially spiking the samples with a standard mixture of prazosin and simvastatin (10 µg/L). Six replicates of samples were then enriched using Oasis HLB SPE. Instrumental quantification limits (IQLs) are defined as the lowest concentration with a signal to noise ratio (S/N) of 10. This parameter was estimated by analyzing the standard of decreasing concentration. The LOQ was calculated based on the level of IQLs spiked in each compound using Equation (1), as reported by Vieno et al. [16].

$$LOQ = \frac{IQL \times 100}{Rec\ (\%) \times CF} \quad (1)$$

where IQL is the instrumental quantification limit (ng/L), Recovery (%) is the absolute recovery of the analyte at the IQL spiking level in the corresponding matrix, and *CF* is the concentration factor (1000).

Selectivity of the proposed method was investigated by analyzing the chromatograms obtained from the individual standards, standard mixture, and solvent. Robustness of the method was studied by changing the flow rate of mobile phases (0.29 – 0.31 mL/min), location of instrument (Lab1 and Lab2), and volume of injection (10 – 40 µL).

Results and Discussion

Quality control analysis

Table 1 shows the linearity, limit of quantification (LOQ), instrumental quantification limit and recovery of prazosin and simvastatin obtained using the developed method.

Table 1. Method validation parameters

Compound	Linearity Range (µg/L)	Equation	R^2	IQL (µg/L)	LOQ[a] ng/L	LOQ[b] ng/L	R%[c]
PRZ	1.5 – 3000	Y = 2311.4X – 2485	0.999	1.5	2.1	3.5	66
SMV	0.8 – 125	Y = 14930.1X – 49270	0.997	0.8	0.5	2.4	62

[a] Deionized water, [b] STP effluent, [c] Recovery using STP effluent

It was observed that same retention time was obtained under all the conditions, indicating that the method was robust (Table 2). Thus, it was reliable to perform for analysis of real samples especially high complexity such as leachate samples.

Table 2. Effect of injection volume, lab movement and mobile phase on the robustness of LC method

Figure of Merit	Value	PRZ	SMV
Volume injection (µL)	10 µL	6.95	11.57
	20 µL	6.97	11.58

TOF screening and confirmation

Measuring environmental contaminants in complex matrices is difficult because the analyte signals can be altered by interferences that are present in the real sample together with analytes. To increase the selectivity of TOF measurements, a narrow accurate mass interval was used to reconstruct the chromatographic traces. Extracted ion chromatograms (XICs) were typically extracted using a 20 mDa mass window for prazosin and simvastatin (Figure 3).

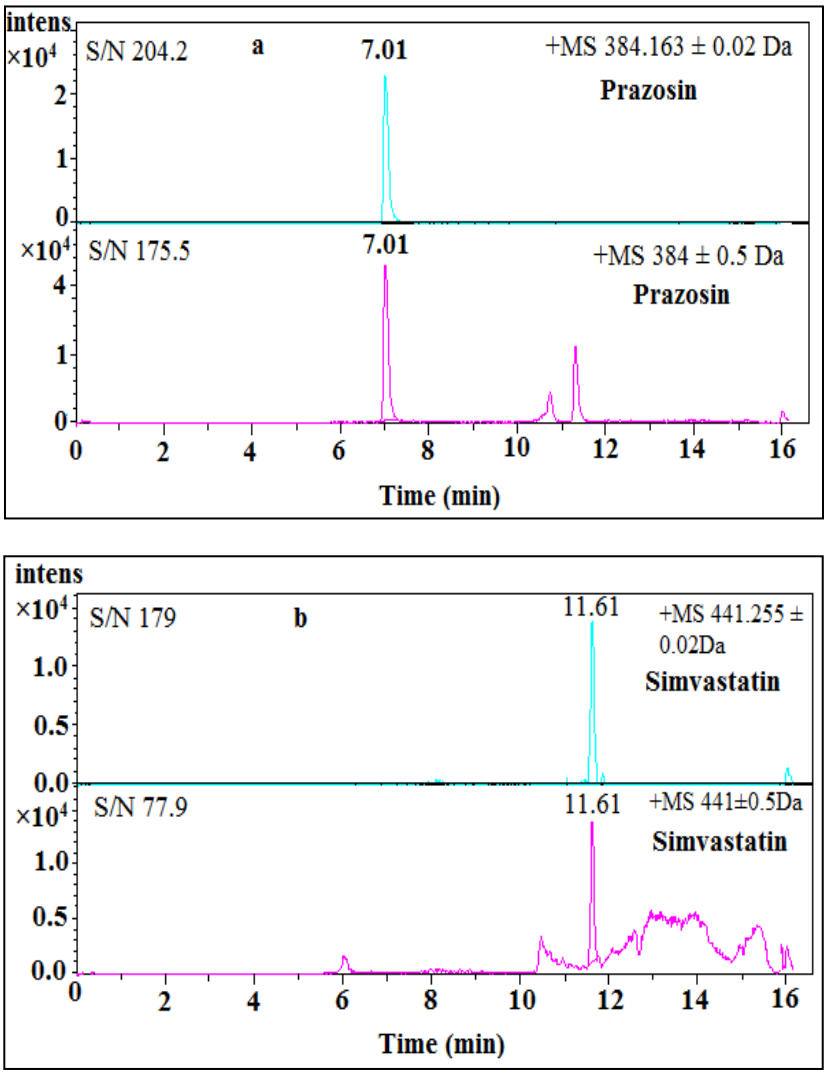

Figure 3. Enhanced selectivity of the LC–TOF/MS analysis corresponding to reconstruct ion chromatogram of (a) prazosin (*m/z* 384) and (b) simvastatin (*m/z* 441) in leachate sample with varying mass windows

Accurate mass data for the molecular ions were processed using Bruker Daltonics Data Analysis software, which provided the elemental formula and mass errors (i.e. differences between the accurate masses and the theoretical values), prazosin was selected as an example (Figure 4). The exact mass measurements and mass errors obtained in the TOF mode for molecular ions are listed in Table 3. The errors obtained were 1.56 and 0.2 ppm for prazosin and simvastatin, respectively.

Analysis of prazosin and simvastatin in real samples

The proposed method was applied to real samples to determine prazosin and simvastatin in raw leachate, post-biological and post-charcoal adsorption treatment leachate. Prazosin and simvastatin were detected and quantified in the raw leachate and treated leachate. Prazosin was commonly used for treatment of hypertension, symptomatic benign prostatic hyperplasia, and severe congestive heart failure [17]. It was detected in surface water and wastewater in the previous study conducted by Al-Qaim et al. [5]. In this study, prazosin was found in raw leachate at relatively high concentration 3850 ng/L while it was detected in leachate samples after biological and charcoal

treatment at concentration 98 and 94 ng/L, respectively which is observed less concentration compared with raw leachate 40 fold-times. It showed that prazosin was persistent as it can be detected after treatment even at low concentration as shown in Figure 5.

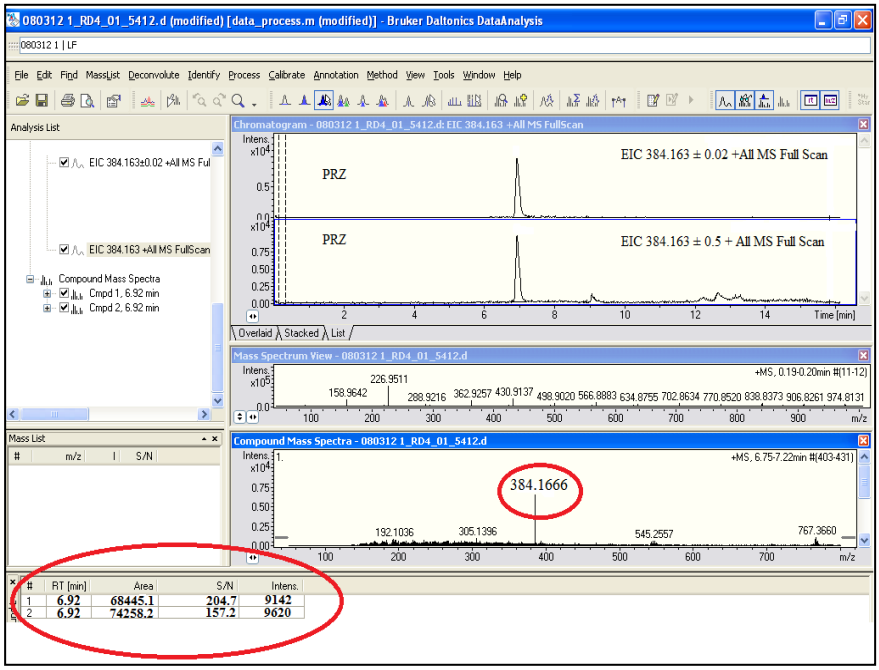

Figure 4. Daltonic data analysis software of prazosin

Table 3. Retention times and accurate mass measurements of molecular ions of target compounds in a standard solution

Peak No.	Compound	Ret. (min)	Elemental Composition	Experimental Mass (*m/z*)	Theoretical Mass (*m/z*)	Error (mDa)	Error (ppm)
1	PRZ	6.95	$[M+H]^+$ $C_{19}H_{22}N_5O_4$	384.1660	384.1666	0.6	1.56
2	SMV	11.59	$[M+Na]^+$ $C_{25}H_{38}NaO_5$	441.2611	441.2612	0.1	0.2

Simvastatin being used in the treatment of primary hypercholesterolemia and it is effective in reducing total and LDL-cholesterol as well as plasma triglycerides and apolipoprotein B [17]. Previously, it was detected in surface water, effluent sewage treatment plants and hospital in Malaysia [7]. Finding study indicates that high concentration of simvastatin (415 ng/L) was detected in raw leachate sample. Other compartment such as biological and physico-chemical (charcoal adsorption) treatments were able to reduce the concentration of samvastatin to 12 and 10.4 ng/L, respectively. However, detection of simvastatin and prazosin in raw leachate may be due to disposal direct of these compounds as a solid form. In the light of these results, the biological and charcoal adsorption treatment processes are insufficient to remove these two compounds as they were detected in treated leachate as well as surface water.

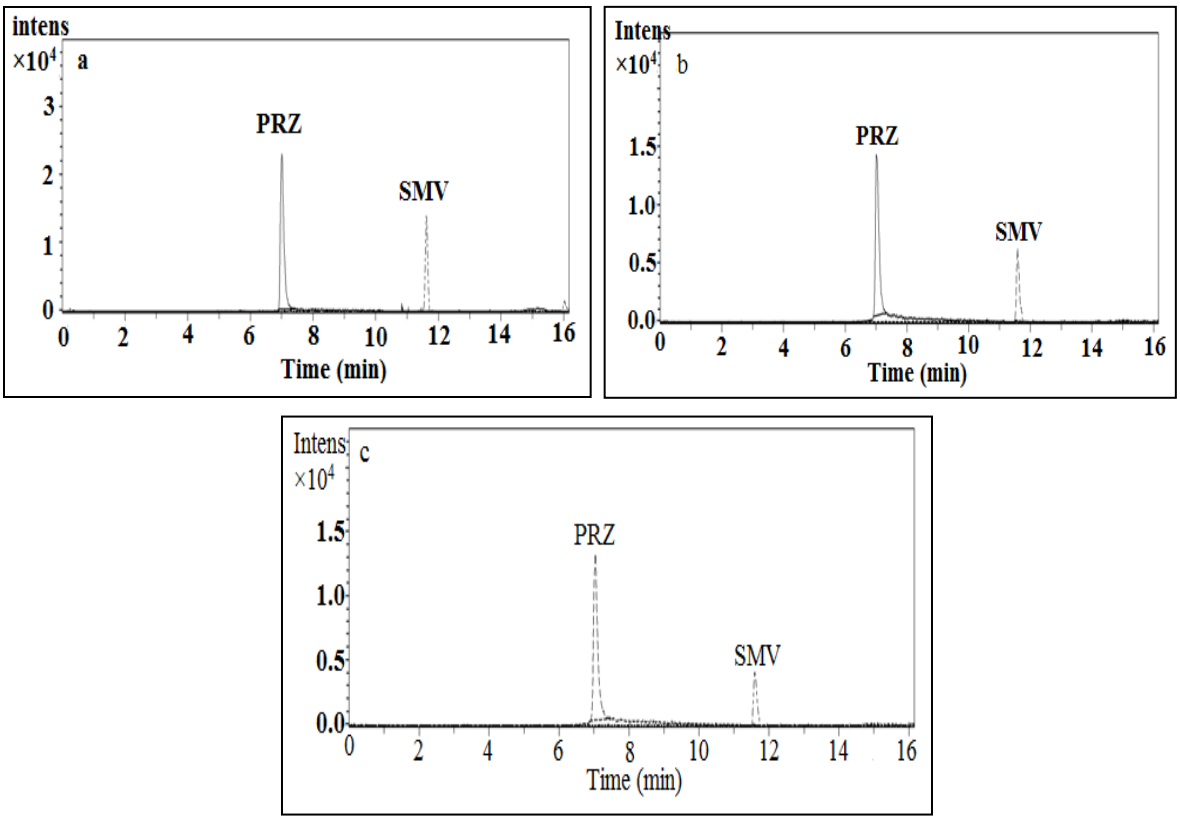

Figure 5. Extracted ionic chromatogram (EIC in PI mode) for prazosin and simvastatin in (a) raw leachate, (b) sample leachate post biological treatment and (c) sample leachate post charcoal adsorption.

Conclusion

The occurrence of prazosin and simvastatin in the leachate after biological and physico-chemical treatments showed that the difficulties are involved in treating this type of samples. Prazosin was persistent compounds as it can be detected after treatment even at low concentration. The detection of trace amounts of prazosin and simvastatin in complex sample indicated that LC-TOF/MS instrument is a powerful technique and very accurate for the analysis pharmaceuticals in water samples.

Abstract

Five different histidine and aspartic acid based tetrapeptides were designed using LOMETS and PyMol. They were chemically synthesized following the solid phase Fmoc-peptide synthesis protocols and were analysed using the reverse-phase High Performance Liquid Chromatography (HPLC) C_{18} analytical column for the purity. The peptides were further analysed by Liquid Chromatography Mass Spectrometry (LCMS) to see if the desired peptides were synthesized systematically. Copper(II) acetate monohydrate was bound to the peptides and the best molar ratio for the binding of these metal salts to peptides was 2:1. These observations were monitored through several spectroscopic techniques. The first physical observations for the successful synthesis of metallopeptides were the colour change, the melting/decomposition points and the solubility of these metallopeptides. Due to the visible colour change of the peptides to metallopeptides, UV-Visible spectroscopy and UV-Fluorescence spectroscopy were used as a qualitative analysis tests and the results were in agreement with other researchers' data from similar researches.

Keywords: copper(II), histidine, aspartic acid, tetrapeptides, spectroscopic

Abstrak

Lima tetrapeptida berbeza yang mempunyai histidine dan asid aspartik direkabentuk oleh LOMETS dan PyMol. Tetrapeptida ini disintesis mengikut skim fasa pepejal peptida dan dianalisis menggunakan fasa sonsang Kromatografi Cecair Berprestasi Tinggi (HPLC) C_{18} turus analisis untuk mengetahui keaslian peptida. Kesemua peptida ini dianalisis mengunakan Kromatografi Cecair-Spektrometer Jisim (LC-MS) untuk mengkaji sintesis peptida secara sistematik. Kuprum(II) asetat monohidrat terikat kepada peptida dan nisbah mol yang terbaik untuk mengikat garam logam ini kepada peptida adalah 2:1. Cerapan ini telah dipantau melalui beberapa teknik spektroskopi. Pemerhatian fizikal pertama untuk logam peptida yang berjaya disintesis ialah perubahan warna, takat lebur/penguraian dan kebolehlarutan peptida logam ini. Oleh kerana perubahan warna yang nyata dalam dari peptida kepada logam peptida, spektroskopi Ultralembayung-tampak (UV-Vis) dan spektroskopi Ultralembayung-Pendafluor (UV-Fluorescence) digunakan sebagai ujian analisis kuantatif dan data yang diperolehi adalah setara dengan perolehan data bagi penyelidikan yang serupa.

Kata kunci: Kuprum(II), histidin, asid aspartik, tetrapeptida, spektroskopi

Introduction

Metallopeptides that are easier and cheaper to synthesise when compared to metalloproteins have caught the attention of many researchers. Metallopeptides, synthesized from metal salt and peptides, are known as *pseudo*-proteins. They imitate the applications of large proteins especially in the industrial field of catalysis as well as in biological applications [1]. Metallopeptides are hybrid structures that combine peptides and metal and in this project, the transition metal copper(II) was used, that has various roles when used as biological probes [2]. The purpose of inserting a metal, particularly a transition metal is to increase the stability of short chain peptides, to provide the active site for various organic catalytic reactions (by behaving like an enzyme), to act as an antimicrobial agent in peptides that have no antimicrobial properties, to improve the anticancer properties of peptides and also to proliferate normal cells, amongst others [3].

The industrial applications of metallopeptides are applicable only when there is an understanding on its synthesis, for instance, the stability of the copper(II)-tetrapeptides will be understood only when data is available on the structure and geometry of copper(II) binding to the peptide. After confirming the stability of the metallocomplex, they can be applied as a catalyst or in biological assays. In this project, copper(II) acetate was bound to tetrapeptides containing metal binding amino acids; histidine and aspartic acid. Sulphur containing amino acids, though they are also metal binding amino acids were not used as they can be hazardous when applied in biological applications. In this research, the confirmation of the binding of metal to side chain of a particular amino acid in the peptides through UV-Visible spectroscopy and UV-Fluorescence is discussed. A brief discussion on how these two spectroscopic techniques can help in predicting the geometry of the copper(II) peptides is outlined, whether they form square planar, tetrahedral or octahedral complexes.

Materials and Methods

Five peptides were designed (P1: (Fmoc)NH-HAAD, P2: (Fmoc)NH-HAFD, P3: (Fmoc)NH-HAVD, P4: NH_2-AGHD, P5: NH_2-PGHD), synthesized and purified. They were characterized by High Performance Liquid Chromatography-Ultraviolet detector (HPLC-UV) for its purity and Liquid Chromatography-Mass Spectroscopy (LC-MS) for confirmation of the formation of peptides by its molecular weight. Copper(II) acetate monohydrate was bound to these five peptides in a 2:1 mole ratio.

Synthesis of metallopeptides

Copper(II) acetate monohydrate ($Cu(CH_3COO)_2.H_2O$ (189mg, 2 mol) was dissolved in deionized water (~10mL until all has dissolved) and heated in a water bath. In a separate test tube, the peptides P1-3 (300 mg) were dissolved in a mixture of deionized water and acetonitrile (20 mL and 10 mL respectively). Except for P4 and P5, these peptides were dissolved in deionized water only (20 mL) as the other three peptides had an FMOC group (hydrophobic group). The metal salt solution (cooled to room temperature) was added dropwise into the peptide solution with constant stirring at 40 – 60 °C. The resultant solution was stirred until the solution changed color and a precipitate was observed. After the precipitate was formed, the stirring was continued for another 1 – 2 hours to ensure that the reaction was completed (No further observation). The precipitate was vacuum-filtered and washed with cold deionized water and dried with acetone [4]. The final product was analyzed and characterized biophysically using UV-Vis and UV-Fluorescence spectroscopy. The product was purified through crystallization.

UV-Visible spectroscopic analysis of Cu(II)-tetrapeptides and its parent peptides

Peptides (10mM) and metallopeptides (5 – 10 mM) were dissolved in 5 mL of water and 10 mL of KH_2PO_4 buffer [11.11 mM] separately and were placed into 1 cm path length rectangular quartz cuvettes. The UV-Vis wavelength range was set from 200 – 1000 nm with fast scanning speed. The average of three scan readings were taken and plotted.

UV-Fluorescence spectroscopic analysis of Cu(II)-tetrapeptides and its parent peptides

Peptides (10mM) and metallopeptides (5-10mM) prepared for UV-Vis were used for UV- fluorescence as well. The samples were placed in a fluorescent cuvette. The scanning wavelength was set from 250 – 650 nm. The excitation wavelength was set to 280 nm. The slit width was 5 nm and the spectrum recorded was an average of three scans at fast speed.

Results and Discussion

Five histidine and aspartic acid based tetrapeptides that were designed computationally had proven random secondary structure and were synthesized and analyzed by HPLC and LC-MS as shown in Table 1. Their physical observations and their % yields are also mentioned.

Table 1. Physical observations, solubility in water and % yields of peptides

No.	Peptides	Morphology of solid	Solubility in water	% yield
P1	(Fmoc)NH-HAAD	White clumps	Hydrophilic	74.0
P2	(Fmoc)NH-HAFD	Whitish-yellow powder	Hydrophobic	74.2
P3	(Fmoc)NH-HAVD	White powder	Hydrophilic	83.1
P4	NH_2-AGHD	White powder	Hydrophilic	69.9
P5	NH_2-PGHD	White powder	Hydrophilic	65.6

Fmoc- Fluorenylmethyloxycarbonyl chloride

The purity of all these peptides was above 80% and they were not purified further. Copper(II) acetate-tetrapeptides (% yields: 50 – 65%) were analyzed by UV-Visible and UV-Fluorescence spectroscopy and the results are discussed in the sections below.

UV-Visible spectral analysis

One of the distinctive features of successful binding is the colour of the metallopeptide (refer to Figure 1). Colour is always associated with d-d transitions, ligand-metal charge transfer (LMCT) and metal-ligand charge transfer (MLCT). This analysis points out where and to what intensity these bands appear and are shown in Table 2.

Figure 1. Copper(II) based tetrapeptides (2, 4, 6, 8 and 10)

The results are in agreement with other reported data that d-d transitions have absorptions at the said wavelength with molar absorptivity in the range of about 2 – 3 $Lcm^{-1}mol^{-1}$ [5] and the charge transfer bands (CT bands) for copper bound peptides normally have similar or lower molar absorptivity than that of d-d transition bands and appear in the range of 400 – 600 nm [6].

No charge transfer bands and only a weak d-d transition band were observed in MP5 probably due to the low concentration of metallopeptide. All the metal salts were expected to bind to the imidazole ring of histidine. This was observed in both the UV-Vis and UV-Fluorescence spectra. According to Boka et al., copper and zinc binds to

the nitrogen (C=N) in the imidazole ring of histidine in the range of 250 – 300 nm giving rise to a strong sharp peak with high absorbance. However, it was also mentioned that copper also binds to the carboxylate side chain of aspartic acid and henceforth, the values are shifted further right (higher wavelength) due to the acidic nature of the metallopeptides [7], as observed in this study.

Table 2. d-d transition, LMCT and MLCT transitions of metallopeptides

Metallopeptides[a]	**Wavelength/nm (log ε/ $Lcm^{-1}mol^{-1}$)**	**Assignment**
MP1 (Cu-P1-Cu)	714 (2.04)	d-d transition
	458 (1.98)	charge transfer
	239 (3.84)	bound to histidine
MP2 (Cu-P2-Cu)	708 (1.60)	d-d transition
	530 (1.72)	charge transfer
	268 (3.74)	bound to histidine
MP3 (Cu-P3-Cu)	737 (2.17)	d-d transition
	648 (2.23)	charge transfer
	270 (3.85)	bound to histidine
MP4 (Cu-P4-Cu)	747 (2.31)	d-d transition
	518 (1.25)	charge transfer
	307 (2.60)	bound to histidine
MP5 (Cu-P5-Cu)	749 (1.16)	d-d transition
	-	no charge transfer
	264 (1.93)	bound to histidine

UV-Fluorescence spectral analysis

UV-Fluorescence measures the intensity of light emitted during the relaxation process when a particular substance absorbs UV radiation. These substances are termed as chromophores. The imidazole ring, -CONH, COOH, and cyclic compounds are important chromophores in peptides. The shift in the wavelength and intensity of fluorescence emitted by these chromophores can be due to the presence of metal and other chromophores that are added into the system [8]. For instance, the presence of copper(II) binding to the nitrogen in the imidazole ring of His or to the COOH of the Asp resulted in quenching due to the formation of new bonds or electrostatic forces of attraction. Similarly, when copper(II) acetate was used to bind to peptides, the presence of acetate, a chromophore, could affect the peptide system. Either, an extra band was observed further down the wavelength or the intensity of the existing band increased [9], as observed in Figure 2.

In most cases, addition of any metal into peptide or protein results in the quenching of its parent peptide as observed in the range of 600 – 650 nm [10]. Just like the UV-vis spectra, a strong signal was observed in the range of 285 – 340 nm (Figure 2). This was due to the presence of the imidazole ring of histidine [7]. In some of the metallopeptides, quenching was observed in this range. For the case of P4 and P5, the absence of Fmoc group at the N-terminal made them unstable and hence such emittance bands were observed. As for the copper(II) complexes of these two peptides (Figure 3), due to the positions of histidine and aspartic acid side by side, and the free N-terminal as a possible candidate for binding of one of the copper(II) ions also led to different results compared to MP1-3.

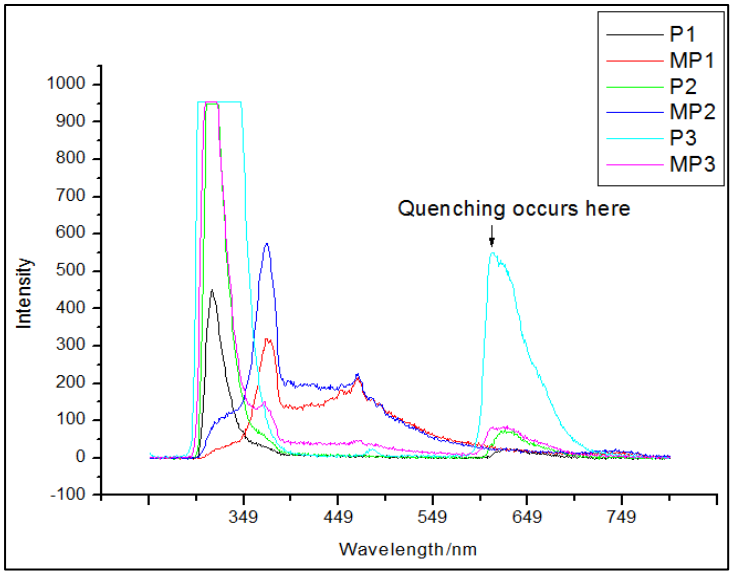

Figure 2. UV-Fluorescence spectra of P1-P3 and its copper(II) complexes

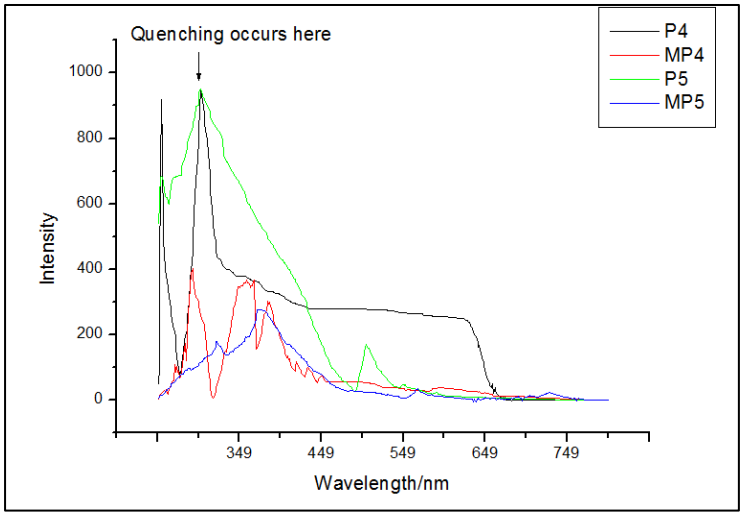

Figure 3. UV-Fluorescence spectra of P4, P5 and its copper(II) complexes

Conclusion

Based on the data reported in this work, it can be concluded that copper(II) acetate bound to the imidazole ring of histidine and at carboxylate of aspartic acid (one copper(II) at each amino acid) for all the peptides. The UV-Fluorescence shows the existence of the acetate (CH_3COO) ion in the complex. From the color of copper-peptides (blue), it was also concluded that water was bound to the complex.. Hence, for each copper(II) complex, the geometry is predicted to be a square planar or tetrahedral. To confirm the structure and the geometry, single crystal X-ray diffraction needs to be carried out but suitable crystals have not yet been obtained.

Abstract

The antimicrobial activities of eleven maleimide derivatives were tested in this study. Out of the eleven samples, *N*-(4-fluorophenyl) maleimide, *N*-(4-chlorophenyl) maleimide and *N*-(4-bromophenyl) maleimide were synthesized by reacting maleic anhydride with 4-fluorophenylaniline, 4-chlorophenylaniline and 4-bromophenylaniline, respectively in the presence of acetic acid, by refluxing overnight. Crystals were successfully obtained after the products were recrystallized with different mixture of solvents. Their chemical structures were confirmed by infrared spectroscopy (IR), ^{1}H and ^{13}C Nuclear Magnetic Resonance (NMR) and melting point determination. Subsequently, all the samples were screened for their biological activity using disc diffusion method. The bacteria chosen for this study were Gram-negative *Escherichia coli*, Gram-positive *Bacillus subtilis* and yeast *Saccharomyces cerevisae*. Positive control for bacteria was streptomycin and nystatin for the yeast. **M1** to **M6** compounds gave remarkable result at low concentrations whereas **M8, M9** and **M11** compounds are mostly inactive up to a high concentration. In contrast, the unsubstituted maleimide, **M7** was highly reactive towards both bacteria and yeast at low and high concentrations.

Keywords: *N*-substituted maleimide, antimicrobial, disc diffusion

Abstrak

Kajian antimikrob terhadap sebelas terbitan *N*-maleimida telah diuji dalam kajian ini. Tiga daripada sebelas sebatian maleimida yang diuji, iaitu *N*-(4-florofenil)maleimida, *N*-(4-klorofenil)maleimida dan *N*-(4-bromofenil)maleimida telah disintesis melalui tindakbalas maleik anhidrida dengan 4-florofenilanilina, 4-klorofenilanilina and 4-bromofenilanilina secara berasingan dalam kehadiran asid asetik, diikuti dengan refluks semalaman. Mendakan tidak berwarna telah diperolehi setelah penghabluran semula dilakukan ke atas hasil sintesis. Pencirian struktur sebatian dilakukan melalui kaedah spektroskopi Infra Merah (IR), ^{1}H dan ^{13}C Resonans Magnet Nukleus (NMR) dan penentuan takat lebur. Seterusnya, kajian antimikrob bagi kesemua sebelas sampel dilakukan melalui kaedah resapan cakera. Bakteria yang digunakan dalam kajian ini ialah *Escherichia coli* dan *Bacillus subtilis* manakala yis yang digunakan ialah *Saccharomyces cerevisae.* Kawalan positif untuk bakteria ialah *streptomisin* dan *nystatin* untuk yis. Sebatian **M1** ke **M6** mencatatkan keaktifan yang baik pada kepekatan rendah. Sebatian **M8**, **M9** dan **M11** kebanyakannya tidak menunjukkan keaktifan walaupun kepekatan dos ditingkatkan. Berbeza pula dengan sebatian **M7**, iaitu maleimida yang tidak mempunyai sebarang kumpulan gantian yang menunjukkan keaktifan yang tinggi terhadap kedua-dua bakteria dan yis pada kepekatan rendah dan tinggi.

Kata kunci: maleimida *N*-gantian, antimikrob, kaedah resapan cakera

Introduction

Microbe resistance has been a challenge for health practitioner and the pharmaceutical industry. The prescription of antibiotics are reported to be related to bacterial resistance. The most commonly found drug-resistant bacteria in hospitals are methicilin-resistant *Staphylococcus aureus* (MRSA) and *Pseudomonas aeruginosa* [1]. The resistance towards various drugs and medicines shown by bacteria and fungi has also become the main reason for failure in chemotherapy of infectious diseases. Therefore, the need for a novel anti microbe agent is highly desirable.

Recently, researchers are focusing on bacterial and fungal enzymes that are responsible for catalysing important biochemical reactions in microbe cells. Biologically active compounds capable of deactivating these enzymes and block the metabolic pathway of these bacteria and fungi selectively in human body are potential novel antimicrobial drugs [2]. Many biologically active compounds including most of the antibiotics are enzyme inhibitors. Compounds that are active towards the thiol group are able to inhibit cysteine protease and other proteins containing important cysteins. Maleimides for instance, portrayed the ability to inhibit cysteine protease and *N*-ethylmaleimide specifically, acts spontaneously and fast with the sulphydryl group.

Cyclic imides such as succinimides, maleimides, phthalimides and their derivatives have an imide ring and the –CO-N(R)-CO- structure that gives them neutrality and hydrophobicity. Previous studies have shown that various kinds of biological activities such as antibacterial, antifungal and antitumor are related to these compounds and their derivatives as shown in Table 1 [3]. Maleimide compounds in specific have shown antifungal and antibacterial properties [4], ability to inhibit Protein Kinase C and antitumor property [5], and analgesic activity [6]. Li research group mentioned about the antifungal activity of simple compounds with dimethylmaleimide structure against *Botrytis cinerea,* which revealed that natural products containing maleimide structure has high biological activity while non-natural products having maleimide structure also shows antifungal activity [7].

Table 1. Antimicrobial activity of *N*-substituted maleimide

Types of Maleimide	**Types of Microbe**		
	E. coli	***B. subtilis***	***S. cerevisiae***
N-(4-chlorophenyl) maleimide	-	-	MIC: 3.90 µg/mL [10]
N-(4-florophenyl) maleimide	-	-	MIC: 3.90 µg/mL [10]
N-(4-bromophenyl) maleimide	MIC: 128 µg/mL [2]	MIC: 64 µg/mL [2]	MIC: 1.0 µg/mL [2]
			MIC: 7.81 µg/mL [10]
N-(2-methylphenyl) maleimide	-	-	MIC: 7.81 µg/mL [10]
N-(4-methylphenyl) maleimide	-	-	MIC: 3.90 µg/mL [10]
N-(*tert*-butyl) maleimide	MIC: 32 µg/mL [2]	MIC: 2.0 µg/mL [2]	MIC: 2.0 µg/mL [2]
N-methylmaleimide	-	-	MIC: 7.81 µg/mL [2]

Studies have also reported that some of the maleimide derivatives that is biologically active is neither haemolytic nor cytotoxic towards the human cancer cell, which indicated the selectivity of action of maleimides towards fungal pathogen [8]. Zentz et al. has reported that *N*-substituted maleimides, *N*-(*tert*-butyl)maleimide in particular shows antibacterial properties towards *Escherichia coli*. [9].

Maleimide compounds are Michael acceptors prone to be attacked at the double bond in the maleimide ring, by nucleophilic species such as the thiol group as shown in Figure 1. The maleimides react specifically on biological molecules containing thiol group and form stable conjugate protein through thioether bond [11]. The thioether bond formed has strong C-S bond which is often irreversible and cannot be reduced by reducing agents. This reaction takes place specifically at pH 6.5 – 7.5. in alkaline condition when pH exceeds 8.5, hydrolysis of maleimide to maleimic acid is prone to take place [12].

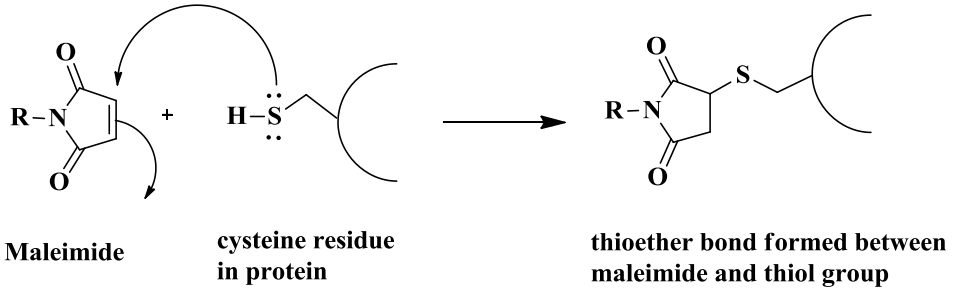

Figure 1. Reaction between maleimide and thiol group

Many types of active protein and enzymes can be found on bacteria cell membrane. When these enzymes react with foreign substances such as drugs, their enzyme activity will change and subsequently inhibit its growth [13].

In this study, we focused on *N*-substituted maleimides, which refer to any maleimide compounds that has substituent groups such as alkyl or halides attached to the nitrogen atom in the maleimide ring. Since biological activitiy of each maleimide derivatives varies from one another, the structure activity relationship display distinct properties that will affect the reactivity of different maleimide compounds. Some of the factors responsible for the different reactivities of maleimide compounds are the presence of aryl group on the nitrogen atom in the maleimide ring [5], the length of alkyl chain on the alkylphenyl group attached to the nitrogen atom in the maleimide ring [7], the lipophilicity and bulkiness of the compound molecule [2] and the presence of any substituents on the maleimide ring [14].

In view of this, 11 samples of *N*-substituted maleimides (**M1** to **M11**) have been tested on three different microbes, namely *Escherichia coli* (Gram negative), *Bacillus subtilis* (Gram positive) and *Saccharomyces cerevisiae* through the disc diffusion method to study the inhibition ability of these samples.

Materials and Methods

Synthesis of *N*-(2-methylphenyl)maleimide (M1)

Maleic anhydride (44.0 mmol) was reacted with *o*-toluidine (42.3 mmol) by dissolving the mixture in THF (50 mL). The reaction mixture was stirred overnight at room temperature (RT) under nitrogen atmosphere. The precipitate formed was filtered and used in next reaction without further purification. The reaction mixture (1.71 mmol) was suspended in dry acetonitrile (40 mL) before the addition of zinc bromide (1.71 mmol) and HMDS (8.55 mmol) and heated at 90 °C for 2 hours before it was allowed to cool to RT and filtered. Subsequently, water (25 mL) was added and acidified with 1M HCl until pH 1. The mixture was washed with ethyl acetate (3 x 50 mL) and the organic layer was dried over anhydrous $MgSO_4$, filtered and concentrated *in vacuo* to obtain black solution. The solution was recrystallized to yield colourless crystalline solid (35%).

Synthesis of N-(3-methylphenyl)maleimide (M2)

Maleic anhydride (44.0 mmol) was reacted with *m*-toluidine (42.3 mmol) by dissolving the mixture in THF (50 mL). The reaction mixture was stirred overnight at RT under nitrogen atmosphere. The precipitate formed was filtered and used in next reaction without further purification. The reaction mixture (1.71 mmol) was suspended in dry acetonitrile (40 mL) before the addition of zinc bromide (1.71 mmol) and HMDS (8.55 mmol) and heated at 90 °C for 2 hours before it was allowed to cool to RT and filtered. Subsequently, water (25 mL) was added and acidified with 1M HCl until pH 1. The mixture was washed with ethyl acetate (3 x 50 mL) and the organic layer was dried over anhydrous $MgSO_4$, filtered and concentrated *in vacuo* to yield yellowish crystalline solid (28%).

Synthesis of *N*-(4-methylphenyl)maleimide (M3)
Maleic anhydride (44.0 mmol) was reacted with *p*-toluidine (42.3 mmol) by dissolving the mixture in THF (50 mL). The reaction mixture was stirred overnight at RT under nitrogen atmosphere. The precipitate formed was filtered and used in next reaction without further purification. The reaction mixture (1.71 mmol) was suspended in dry acetonitrile (40 mL) before the addition of zinc bromide (1.71 mmol) and HMDS (8.55 mmol) and heated at 90 °C for 2 hours before it was allowed to cool to RT and filtered. Subsequently, water (25 mL) was added and acidified with 1M HCl until pH 1. The mixture was washed with ethyl acetate (3 x 50 mL) and the organic layer was dried over anhydrous $MgSO_4$, filtered and concentrated *in vacuo* to obtain yellow powder. The solution was recrystallized to yield yellow needle-like crystalline solid (84%).

Synthesis of *N*-(4-florophenyl)maleimide (M4)
Maleic anhydride (9.0 mmol) was reacted with equimolar of 4-fluoroaniline by dissolving the mixture in 50 mL acetic acid at RT. The reactants are stirred for 6.5 hours. The resulting suspension was refluxed overnight for 17.5 hours at 130 °C and then cooled to room temperature. The resulting solution of maleimide was extracted with ethyl acetate (3 x 50 mL). Extracts were combined and recrystallized (40%).

Synthesis of *N*-(4-chlorophenyl)maleimide (M5)
Maleic anhydride (7.84 mmol) was reacted with equimolar of 4-chloroaniline by dissolving the mixture in 50 mL acetic acid at RT. The reactants are stirred for 5.5 hours at 130 °C and then cooled to room temperature. The resulting solution of maleimide was extracted with ethyl acetate (3 x 50 mL). Extracts were combined and recrystallized (45%).

Synthesis of *N*-(4-bromophenyl)maleimide (M6)
Maleic anhydride (5.81 mmol) was reacted with equimolar of 4-bromoaniline by dissolving the mixture in 50 mL acetic acid at RT.The reactants are stirred for 5.5 hours at 130 °C and then cooled to room temperature. The resulting solution of maleimide was extracted with ethyl acetate (3 x 50 mL). Extracts were combined and recrystallized (51%).

Synthesis of 1-(3,5-bis(trifloromethyl)phenyl)-3-(4-(3-(2,5-dioxo-2H-pirol-1(5H)-yl)phenetyl)phenyl)urea (M8)
4'-ethylene dianiline (1.08 g, 5.1 mmol) in dry CH_2Cl_2 (20 mL) was slowly reacted with 3,5-dimethyl phenylisocyanate (0.5 g, 3.4 mmol) at −5°C and allowed to stir at ambient temperature for 16 hours. The solvent was removed under reduced pressure. The residue was then purified by column chromatography (CH_2Cl_2:EtOAc, 8:1). The product was obtained as yellow solid was dissolved in THF (10 mL) before reacted with maleic anhydride (82 mg, 0.84 mmol). The reaction mixture was stirred at ambient temperature under a Ar atmosphere for 3 hours. The precipitate was filtered and the compound obtained (460 mg, 98%) was carried out to the next step without further purification. The acid derivative (0.20 g, 0.35 mmol) was dissolved in dry CH_3CN (10 mL) and refluxed for 1 hour after the subsequent addition of $ZnBr_2$ (80 mg, 0.35 mmol) and hexamethyldisilazone (0.38 mL, 1.77 mmol). The reaction mixture was filtered and the filtrate was reduced to 10%. The solution was acidified with 0.5M HCI until pH 1 and extracted into CH_2CI_2. The organic layer were combined and dried over $MgSO_4$. The solvent was evaporated *in vacuo* to give the maleimide **M8** as yellow solid (78%).

Synthesis of 1-(4-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenetyl)phenyl)-3-(3,5-dimethylphenyl)urea (M9)
A solution of 3,5-dimethylbenzoic acid (2.0 g, 13.3 mmol) in toluene (50 mL) and thionyl chloride (1.1 mL, 14.6 mmol) was heated to reflux at 80 °C for 16 h. The excess thionyl chloride was distilled off by the azeotropic distillation with toluene under reduced pressure, affording 3,5-dimethylbenzoyl chloride as brownish oil quantitatively. The product was used in the next step without further purification. The acid derivative (2.24 g, 13.3 mmol) in dry CH2Cl2 (20 mL) was added dropwise over 1.5 h to a solution of 4,4'-ethylenedianiline (6.20 g, 29.2 mmol) and Et_3N (3.7 mL, 26.6 mmol) in dry CH_2Cl_2 (50 mL) at ambient temperature under N_2 atmosphere. The reaction mixture was stirred at ambient temperature for 16 hours. The organic phase was washed successively with sat. solution of $NaHCO_3$ and brine, dried over $MgSO_4$ and concentrated by evaporation under reduced pressure. The residue was purified by column chromatography (Hexane:EtOAc, 2:1), affording a yellow solid. The solid (0.5 g, 1.45 mmol) was treated with maleic anhydride (0.14 g, 1.45 mmol) in THF (15 mL) and stirred at ambient

temperature under N_2 atmosphere for 3 hours. The yellow precipitate (66%) was filtered and carried out to the next step without further purification. The acid derivative obtained (0.34 g, 0.78 mmol) was dissolved in dry CH_3CN (20 mL) and refluxed for 2 h after the subsequent addition of $ZnBr_2$ (0.18 g, 10.78 mmol) and hexamethyldisilazone (0.83 mL,3.91 mmol). The reaction mixture was filtered and the filtrate was reduced to 10%. The solution was acidified with 0.5M HCl until pH 1 and extracted into CH_2Cl_2. The organic layers were combined and dried over $MgSO_4$. The solvent was evaporated to give the desired product as yellow crystalline solid (96%).

Synthesis of 2-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyll) acetic acid (M10)
Maleic anhydride (6.05 g, 40 mmol, 1 eq) and 4-aminophenyl acetic acid (3.92 g, 40 mmol, 1 eq) were dissolved in acetic acid (200 mL) and stirred under N_2 at RT for 2 hours before refluxing for 2 hours. The solvent was then evaporated under vacuum and the residue was dissolved in 5% acetic acid in CH_2Cl_2. The solution was passed through a plug of silica eluted with 5% acetic acid in CH_2Cl_2. The fractions containing product as identified by tlc were combined and the solvent removed under vacuum. The residue was then purified by recrystallisation by using chloroform to yield the product as a yellow powder (36%).

Synthesis of 3,5-dimethyl-N-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyl)benzamide (M11)
Cyanuric fluoride (0.85 mL, 10.1 mmol) was added dropwise to a solution of 3,5-dimethylbenzoic acid (1.52 g, 10.1 mmol) and dry pyridine (0.82 mL, 10.1 mmol) in dry CH_2Cl_2 (40 mL) at 0 °C under a N_2 atmosphere. The reaction mixture was stirred at 0 °C for 20 min and then at ambient temperature for a further hour. The reaction mixture was diluted with CH_2Cl_2. The organic layer was washed with saturated NaCl solution, dried ($MgSO_4$) and the solvent was removed by evaporation under reduced pressure to afford a yellow solid (100%). The solid (1.52 g, 10.0 mmol) was then dissolved in dry CH_2Cl_2 (40 mL) was added dropwise (over 4 h) to a solution of 1,4phenylenediamine (3.26 g, 30.1 mmol) in dry CH_2Cl_2 (60 mL), under a N_2 atmosphere. The reaction mixture was stirred at ambient temperature overnight, and then diluted with CH_2Cl_2. The organic layer was washed successively with saturated $NaHCO_3$ solution and saturated NaCl solution, dried ($MgSO_4$) and concentrated by evaporation under reduced pressure. The residue was purified by column chromatography (SiO_2, gradient from 100:0 to 95:5 CH_2Cl_2/MeOH) to give a yellow solid (80%). The solid (0.95g, 3.95 mmol) obtained was dissolved in acetic acid (70 mL) to react with maleic anhydride (388 mg, 3.96 mmol). The reaction mixture was stirred at ambient temperature under a N_2 atmosphere for 6 h, and then heated to reflux for 16 h. The solvent was removed by evaporation under reduced pressure. The residue was purified by column chromatography (SiO2, gradient from 100:0 to 98:2 $CHCl_3$/MeOH) to give a yellow solid (66%).

Antimicrobial screening
All samples were tested using disc diffusion method against *Escherichia coli* (Gram negative), *Bacillus subtilis* (Gram positive) and *Saccharomyces cerevisiae*. The samples were prepared in two concentrations, 1.0 µg/µL (10 µg/disc) and 2.0 µg/µL (20 µg/disc) by dissolving the solid samples in appropriate solvent. The positive control for the bacteria was streptomycin at 10 µg/disc while nystatin at 20 µg/disc was used as positive control for the yeast. Nutrient agar and potato dextrose agar were prepared by dissolving the premixed powder in water following with heating and auto-clave. The dissolved solution was then poured on petri dishes, allowed to dry and ready to be used. The bacteria cultures were then spread on the surface of the Nutrient Agar (NA) and yeast cultures on Potato Dextrose Agar (PDA). Subsequently, the discs were impregnated with (10 µg/disc) and (20 µg/disc) test samples and then placed on the surface of the agar media. Experimental plates of bacteria cultures were incubated at 37 °C for 18 to 21 hours whereas the experimental plates of yeast cultures were incubated for 48 hours at 30 °C. The antimicrobial activity was the determined by measuring the diameter of inhibition zone (IZ) and compared with positive control.

Results and Discussion

Characterization study: N-(2-methylphenyl)maleimide (M1)
M.p. = 150.6-150.8 °C; ^{1}H NMR (400 MHz, $CDCl_3$): $^\delta$H 7.34 (1H, d, *J* = 6.20 Hz, Ar*H*), 7.33 (1H, d, *J* = 6.24 Hz, Ar*H*) , 7.29 (1H, d, *J* = 7.72 Hz, Ar*H*), 7.10 (1H, d, *J* = 7.68 Hz, Ar*H*), 6.85 (2H, s, Ar*H*), 2.15 (3H, s, CH_3); ^{13}C NMR (100 MHz; $CDCl_3$) $^\delta$C 169.7 (*C*=O), 136.6 (*C*=*C*), 134.5 (q, 131.3 (Ar*C*), 130.0 (Ar*C*), 129.5 (Ar*C*), 128.8 (Ar*C*), 126.9 (q, 17.9 (*C*H_3); MS (EI) m/z 187.2 (M^+, 100 %); IR ν_{max} (KBr) cm-1: 2929.45 cm^{-1} (sp^3 CH), 1702.31 cm^{-1} (C=O), 1029.23 cm^{-1} (C-N).

N-(3-methylphenyl)maleimide (M2)
^{1}H NMR (400 MHz, $CDCl_3$): $^{\delta}$H 7.34 (1H, t, *J* = 7.70 Hz, Ar*H*), 7.17 (1H, d, *J* = 7.72 Hz, Ar*H*), 7.11 (1H, d, *J* = 8.44 Hz, Ar*H*), 7.11 (1H, d, *J*= 8.44 Hz, Ar*H*), 6.80 (2H, s, Ar*H*), 2.37 (3H, s, CH_3); ^{13}C NMR (100 MHz; $CDCl_3$) $^{\delta}$C 169.7 (*C*=O), 139.3 (Ar*C*), 134.2 (q, 131.1 (Ar*C*), 129.0 (Ar*C*), 128.9 (Ar*C*), 126.9 (q, 123.4 (Ar*C*), 21.4 (*C*H_3); MS (EI) m/z 187.2 (M^+, 100 %); IR ν_{max} (KBr) cm-1: 2922.57 cm^{-1} (sp^3 CH), 1705.59 cm^{-1} (C=O), 1033.45 cm^{-1} (C-N).

***N*-(4-methylphenyl)maleimide (M3)**
M.p. = 150.5-150.7 °C; ^{1}H NMR (400 MHz, d-Acetone): $^{\delta}$H 7.27 (2H, d, *J* = 8.08 Hz, Ar*H*), 7.22 (2H, d, *J* = 8.44 Hz, Ar*H*), 7.00 (2H, s, Ar*H*), 2.35 (3H, s, CH_3); ^{13}C NMR (100 MHz; d-Acetone) $^{\delta}$C 169.8 (*C*=O), 137.4 (Ar*C*), 134.4 (q, 129.5 (Ar*C*), 129.3 (Ar*C*), 126.5 (q, 20.0 (*C*H_3); MS (EI) m/z 187.1 (M^+, 100 %); IR ν_{max} (KBr) cm-1: 3450.67 cm^{-1} (OH), 2967.11 cm^{-1} (sp^3 CH), 1702.41 cm^{-1} (C=O), 1041.54 cm^{-1} (C-N).

***N*-(4-florophenyl)maleimide (M4)**
M.p. = 151.8 –153.2 °C; ^{1}H NMR (400.1 MHz, d_6-Acetone): $^{\delta}$H 7.45-7.39 (2H, m; 2xAr*H*), 7.28-7.22 (2H, m, 2×Ar*H*), 7.03 (2H, s, Ar*H*); ^{13}C NMR (100.6 MHz, d_6-DMSO): $^{\delta}$C 169.7 (*C*=O), 161.6 (*C*F), 134.5 (Ar*C*H), 128.7 (Ar*C*H), 128.3 (Ar*C*-N), 115.6 (Ar*C*H).

1-(3,5-bis(trifloromethyl)phenyl)-3-(4-(3-(2,5-dioxo-2H-pirol-1(5H)-yl)phenetyl)phenyl)urea (M8)
M.p. = 205.3 – 208.3 °C; ^{1}H NMR (300.1 MHz, d_6-DMSO) : $^{\delta}$H 9.36 (1H, s; N*H*), 8.89 (1H, s, N*H*), 8.13 (2H, s; 2×Ar*H*), 7.61 (1H, s; Ar*H*), 7.39 (2H, d, $^{3}J_{HH}$ 8.4 Hz; 2×Ar*H*), 7.33 (2H, d, $^{3}J_{HH}$ 8.4 Hz; 2×Ar*H*), 7.22 (2H, d, $^{3}J_{HH}$ 8.4 Hz; 2×Ar*H*), 7.18 (2H, d, $^{3}J_{HH}$ 8.4 Hz; 2×Ar*H*), 7.16 (2H, s; 2×C*H*), 2.94 – 2.82 (4H, m; 2×CH_2); ^{13}C NMR (75.5 MHz, d_6-DMSO): $^{\delta}$C 170.0 (*C*=O), 152.4 (*C*=O), 142.0 (Ar*C*), 141.3 (Ar*C*), 136.8 (Ar*C*), 135.5 (Ar*C*), 134.6 (Ar*C*H), 130.7 (q, $^{2}J_{CF}$ 32.7 Hz, Ar*C*), 129.3 (Ar*C*), 128.8 (Ar*C*H), 128.7 (Ar*C*H), 126.6 (*C*H), 123.3 (q, $^{1}J_{CF}$ 272.3 Hz, CF_3), 119.0 (Ar*C*H), 117.8 (m; Ar*C*H), 114.2 (m, Ar*C*H), 36.7 (*C*H_2), 36.3 (*C*H_2) ; ^{19}F NMR (376.5 MHz, d_6-DMSO) : $^{\delta}$F −62.2 (ArC*F*$_3$); MS (ES^-) *m/z* 546 ([M−H]$^-$, 100); HRMS (ES^-) *m/z* calculated for $C_{27}H_{18}N_3O_3F_6$ [M−H]$^-$ 546.1252, found 546.1257.

1-(4-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenetyl)phenyl)-3-(3,5-dimethylphenyl)urea (M9)
M.p. = 229.3 –231.4 °C; ^{1}H NMR (400.1 MHz, $CDCl_3$): $^{\delta}$H 7.81 (1H, s; N*H*), 7.57 – 7.54 (2H, m; 2×Ar*H*), 7.46 (2H, s; 2×Ar*H*), 7.29 – 7.27 (2H, m; 2×Ar*H*), 7.25 – 7.22 (2H, m; 2×Ar*H*), 7.19 – 7.17 (3H, m; 3×Ar*H*), 6.84 (2H, s; 2×C*H*), 2.97 – 2.89 (4H, m; 2×CH_2),2.38 (6H, s; 2×CH_3); ^{13}C NMR (100.6 MHz, $CDCl_3$): $^{\delta}$C 169.8 (*C*=O), 166.1 (*C*=O), 141.8 (Ar*C*), 138.6 (Ar*C*), 137.7 (Ar*C*), 136.2 (Ar*C*), 135.2 (Ar*C*), 134.3 (*C*H), 133.5 (Ar*C*H), 129.4 (Ar*C*H), 129.2 (Ar*C*), 129.1 (Ar*C*H), 126.1 (Ar*C*H), 124.9 (Ar*C*H), 120.4 (Ar*C*H), 37.7 (*C*H_2), 37.3 (*C*H_2), 21.4 (*C*H_3); MS (ES^+) *m/z* 447 ([M+Na]$^+$, 75), 479 (100); HRMS (ES^+) *m/z* calculated for $C_{27}H_{24}N_2O_3Na$ [M+Na]$^+$ 447.1685, found 447.1674.

2-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyll) acetic acid (M10)
M.p. = 160.0 –162.0 °C; ^{1}H NMR (400.1 MHz, d_6-DMSO): $^{\delta}$H 12.07 (1H, s, CO_2*H*), 7.36 (2H, d, $^{3}J_{HH}$ = 8.5 Hz, 2×Ar*H*), 7.26 (2H, d, $^{3}J_{HH}$ = 8.5 Hz 2×Ar*H*), 7.18 (2H, s, 2×C*H*), 3.63 (2H, s, CH_2); ^{13}C NMR (100.6 MHz, d_6-DMSO): $^{\delta}$C 172.5 (CO_2H), 169.3 (*C*=O), 134.7 (Ar*C*-N), 134.6 (*C*H), 130.0 (Ar*C*), 129.9 (Ar*C*H), 126.6 (Ar*C*H),

40.1 (*C*H_2); MS (EI^+) *m/z* 254 ($[M+Na]^+$, 100); HRMS (EI^+) *m/z* calculated for $C_{12}H_9NO_4$ $[M+Na]^+$ 254.0429, found 254.0434.

3,5-dimethyl-N-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyl)benzamide (M11)
^{1}H NMR (300.1 MHz, $CDCl_3$): $^{\delta}$H = 7.86 (1H, s, NH), 7.79–7.74 (2H, m, ArH), 7.47 (2H, s, ArH), 7.37–7.32 (2H, m, ArH), 7.19 (1H, s, ArH), 6.85 (2H, s, ArH), 2.39 (6H, d, J = 0.5 Hz, CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$): $^{\delta}$C = 169.7 (*C*=O), 166.2 (*C*ONH), 138.8 (Ar*C*), 137.9 (Ar*C*), 134.8 (Ar*C*), 134.4 (Ar*C*H), 133.8 (Ar*C*H), 127.2 (Ar*C*), 126.9 (Ar*C*H), 124.9 (Ar*C*H), 120.6 (Ar*C*H), 21.4 (*C*H_3); MS (ES^+): m/z (%) = 321 ($[M+H]^+$, 100), 375 (70); HRMS (ES^+): m/z calc. for $[M+H]^+$ $C_{19}H_{17}N_2O_3$ 321.1239, found 321.1237.

The structure of the 11 maleimide compounds as shown in the following Table 2.

Table 2. Structure of eleven *N*-substituted maleimides

	Name of Compound	Structure	Yield (%)
M1	*N*-(2-methylphenyl)maleimide		35%
M2	*N*-(3- methylphenyl)maleimide		28%
M3	*N*-(4- methylphenyl)maleimide		84%
M4	*N*-(4-florophenyl)maleimide		40%
M5	*N*-(4-chlorophenyl)maleimide		45%
M6	*N*-(4-bromophenyl)maleimide		51%

Table 2 (cont'd). Structure of eleven *N*-substituted maleimides

	Name of Compound	Structure	Yield (%)
M7	Maleimide		*commercial available
M8	1-(3,5-bis(trifloromethyl)phenyl)-3-(4-(3-(2,5-dioxo-2H-pirol-1(5H)-yl)phenetyl)phenyl)urea		78%
M9	1-(4-(4-(2,5-dioxo-2H-pirol-1(5H) yl)phenetyl)phenyl)-3-(3,5-dimethylphenyl)urea		96%
M10	2-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyll) acetic acid		36%
M11	3,5-dimethyl-N-(4-(2,5-dioxo-2H-pirol-1(5H)-yl)phenyl)benzamide		66%

The *N*-substituted maleimides **M1** to **M11** were tested against two bacterial strains and a yeast. The biological screening activity of the studied compounds were determined by disc diffusion method. Data shown in Table 3 indicate that all compounds exhibited notable antibacterial and antifungal activity except **M8**, **M9** and **M11**.

According to Table 3, the reactivity of **M1**, **M2** and **M3** toward all three microbes tested were positive, showing inhibition zone ranging from 9 mm to 21 mm for sample concentration up to 20 µg/disc. Whereas, the inhibition zone for **M4**, **M5** and **M6** were around 10 mm, except for **M5** at 20 µg/disc showed 18 mm inhibition zone on the yeast, *Saccharomyces cerevisiae*. Surprisingly, **M4** which showed inhibition towards *Escherichia coli* at 10 µg/disc, became inactive when the concentration double up to 20 µg/disc. On the other hand, unsubstituted maleimide, **M7** is very reactive towards *Saccharomyces cerevisiae*. **M8** possess a trifluoromethane moiety which is often used to increase the biological stability of a drug. Nonetheless, our finding indicated that samples **M8** to **M11** are generally unreactive, except that **M10** showed a small inhibition zone of 9 mm towards *Saccharomyces cerevisiae*.

Generally, most of the samples were biologically active against the yeast *Saccharomyces cerevisiae* compared to *Escherichia coli* and *Bacillus subtilis*. It is also noted that the biological reactivity of the samples does not directly proportional to the dosage concentration. This might be due to the reason that maleimide compounds only show optimum biological reactivity at optimum dosage. Hence, any concentrations beyond the optimum range would have no effect against the microbes tested. Fascinatingly, maleimides substituted with methyl phenyl group are among the most reactive compounds tested. Their inhibition zone is comparable to that of the positive control.

Table 3. Biological activity of *N*-substituted maleimide towards three microbes

Compound	**Inhibition Zone (mm)**					
	Escherichia coli		***Bacillus subtilis***		***Saccharomyces cerevisiae***	
	10 µg/disc	**20 µg/disc**	**10 µg/disc**	**20 µg/disc**	**10 µg/disc**	**20 µg/disc**
M1	15	15	10	15	21	18
M2	11	13	11	12	15	19
M3	10	11	9	10	12	14
M4	10	-	10	11	10	10
M5	9	12	11	12	15	18
M6	8	10	10	10	12	10
M7	22	25	21	25	30	29
M8	-	-	-	-	-	-
M9	-	-	-	-	-	-
M10	-	-	-	-	-	9
M11	-	-	-	-	-	-
Negative control	-	-	-	-	-	-
Streptomycin 10 µg	16	NA	15	NA	NA	NA
Nystatin 20 µg	NA	NA	NA	NA	NA	-

Note: Experiments are done in triplicate to rule out experimental bias or random error.

In addition, unsubstituted maleimide was more reactive towards the microbes compared to the *N*-substituted maleimide since the maleimide core itself is the main active centre which possess good biological activites [15]. Thus, it is apparent that the introduction of bulky substituents at the *N* position of the maleimide ring had different influence on the biological activities. A possible explanation is that maleimide and derivatives could inactivate some enzymes in the microbes. With change in the polarity and chain length of *N*-phenyl substituents, their capacity to bind to eznyme differs and therefore also had different influence on biological activities.

Conclusion

In conclusion, the present work has demonstrated that unsubstituted maleimide was most reactive while simple *N*-phenyl substituted maleimide exhibit potential activity against the tested microbes. Nevertheless, bulky *N*-phenyl substituted maleimides were biologically inactive with rapid decreasing action towards the microbe when more complex moieties inserted. This might be explained by the nitrogen–carbon distances betweeen the two rings which play an important role in the antimicrobial activities of these compounds. Furthermore, steric hindrance might affect inhibition activity. For further investigation, more sensitive antimicrobe screening method such as dilution method should be used to evaluate the potential of maleimide derivatives against different types of microbes. Structural optimisation of these compounds are underway.

Abstract

Microfungi are a highly diverse group of micro-organisms and important components of the ecosystem with great potential for diverse metabolite production. During a survey of microfungi on leaves in a National Park in Sarawak, an uncommon endophytic microfungus *Aspergillus nomius* was encountered. The metabolite production of this microfungus was investigated by growing it in a liquid basal medium for 2 weeks. Gas Chromatography - Mass Spectrometry (GC-MS) and Fourier Transform Infrared (FTIR) profiling of the secondary metabolites produced by this microfungus in the liquid medium revealed the presence of 46 different secondary metabolites. The metabolites include saturated hydrocarbons, alkyl halides, alcohols and an unsaturated hydrocarbon. Majority of the metabolites produced were saturated hydrocarbons. Tetracosane, Icosane and 10-Methylicosane were the most abundant metabolites identified while heptadecane and 2,4-dimethylundecane were the least abundant respectively. This study is the first GC-MS and FTIR report of secondary metabolites from *A. nomius*. The results from this study confirm the ability of microfungi to produce diverse metabolites, including saturated hydrocarbons.

Keywords: *Aspergillus nomius*, endophytic fungi, gas chromatography, hydrocarbons, secondary metabolites

Abstrak

Kulat mikro adalah kumpulan yang pelbagai daripada organisma kecil dan merupakan komponen penting dalam ekosistem dengan potensi besar dalam penghasilan pelbagai metabolit. Kulat mikro endofitik yang jarang dijumpai, iaitu *Aspergillus nomius* telah ditemui semasa kaji selidik kulat mikro atas daun yang dijalankan di Taman Negara, Sarawak. Penghasilan metabolit oleh kulat mikro ini telah dikaji dengan menumbuhkankannya dalam medium cecair asas selama dua minggu. Penghasilan sebanyak 46 metabolit sekunder oleh kulat mikro ini telah disahkan melalui penggunaan Kromatografi Gas – Spektrometri Jisim (GC-MS) dan profil (FTIR). Metabolit yang terhasil termasuklah hidrokarbon tepu, alkil halida, alkohol dan hidrokarbon tidak tepu. Kebanyakan metabolit yang dihasilkan adalah hidrokarbon tepu. Tetrakosana, Ikosana dan 10 Metilikosana adalah metabolit yang paling banyak dikenal pasti manakala heptadekana dan 2,4-dimetilundekana adalah yang paling sedikit. Kajian ini merupakan kajian pertama penghasilan metabolit sekunder dari *A. nomius* melalui penggunaan GC-MS dan FTIR. Hasil kajian ini mengesahkan kebolehan kulat mikro untuk menghasilkan pelbagai metabolit termasuklah hidrokarbon tepu.

Kata kunci: *Aspergillus nomius*, kulat endofitik , kromatografi gas, hidrokarbon, metabolit sekunder

Introduction

Fungal secondary metabolites are important natural products from fungi. There are many undiscovered volatile organic compounds produced by fungi. The high diversity of fungi with many species yet to be discovered, coupled with the relatively insufficient research on fungal metabolites puts fungi as a promising source of useful compounds for biotechnological, pharmacological, medicinal, agricultural and industrial applications. There are over 5.1 million fungal species in the world as estimated by Blackwell [1] and only few have been studied for their secondary metabolites production [2, 3].

Fungal secondary metabolites are organic compounds that are not involved in the normal growth and development of the fungi [4]. Unlike the primary metabolites, secondary metabolites does not play a key role in the survival of an organism and are frequently produced in high amounts during an organism's transition from active phase of growth to stationary phase [5]. These metabolites are involved in different biological processes in their host such as defence against predators; diseases; parasites; bio-control of pathogens and for communication between micro-organisms and their environment [6, 7]. Fungal metabolites have been useful as anti-cancer drugs, anti-oxidants, anti-viral, immunosuppressive and immunomodulatory compounds [8–11].

Recently, Strobel et al. [12] discovered the production of biodiesel by the microfungus *Gliocladium roseum*. They discovered that *G. roseum* produced an array of chemical compounds which include saturated hydrocarbons such as undecane, alcohols such as 2-Octanol and other compounds classified as esters and acids. In addition, about 270 secondary metabolites were identified from the liquid culture of *Trichoderma harzianum* with some compounds identified for the first time from *T. harzianum* [13]. Considering the high diversity of fungi [1], many species are yet to be studied for their secondary metabolites as compared to the few published reports [3,2].

This study was aimed to identify the volatile secondary metabolites produced in liquid culture of an endophytic microfungus, *Aspergillus nomius* KUB105, isolated during a microfungal survey using Gas Chromatography-Mass Spectrometry (GC-MS) and Fourier Transform Infrared (FTIR).

Materials and Methods

Isolation and identification of the Microfungus

A. nomius KUB105 fungus was isolated during a survey of microfungi on leaves of Belian tree (*Eusideroxylon zwageri*) collected from Kubah National Park, Sarawak, Malaysia. The leaf samples collected were processed for endophytic microfungal isolation [14], plated on 3 % Malt Extract Agar (MEA) and incubated at room temperature. *A. nomius* was then isolated and identified from segments of the leaf samples after seven days. This microfungus was identified based on its microscopic and cultural morphological characteristics in addition to molecular identification to confirm the identity of the microfungus.

Molecular identification of *A. nomius* KUB105: Total genomic DNA extraction

Isolates of *A. nomius* KUB105 was grown on Potato Dextrose Agar (PDA) and incubated at room temperature (27 ± 2 ℃) for three days before harvesting for DNA extraction. Mycelia of the isolates (about 500 – 700 mg) were scraped from the surface of the culture media using sterilized razor blades into a 2 mL eppendorf tube. The total genomic DNA was extracted using the CTAB method [15].

The extracted DNA was verified for successful extraction by gel electrophoresis and if successful, the sample is used immediately for Polymerase Chain Reaction (PCR) or stored at 4 °C for further use. The internal transcribed spacer (ITS) gene regions of the total genomic DNA were amplified by PCR using the primer pairs ITS 5 (5′-GGAAGTAAAAGTCGTAACAAGG-3′) and ITS 4 (5′-TCCTCCGCTTATTGATATGC-3′) [16] in a SensQuest lab cycler. A PCR mixture of 25 µL total volume was used. The master mix contains 5 µL of 5 × Mg free-PCR buffer, 2 µL of $MgCl_2$, 0.5 µL of dNTPs, 1.5 µL of each primers, 0.15 µL of Fementas Taq DNA polymerase and 12.85 µL of double-sterilised distilled water (ddH_2O) and 1.5 µL of DNA template including a tube for control reaction with ddH_2O as template instead of DNA. The PCR programme was set at initial denaturation of 2 min at 94 °C, followed by 35 cycles of 94 °C for 1 min, 55 °C for 1 min, 72 °C for 1 min and final extension of 72 °C for 10 min. The PCR products were gel electrophoresed as described for genomic DNA detection above using 2 µL of

PCR products and 2 µL of DNA marker. Successful PCR products were sent to a private sequencing company (1st-Base, Asia) for both forward and reverse primer sanger sequencing.

The sequences obtained from the sequencing company were confirmed to belong to the proposed microfungi using BLAST-n on the GenBank website [17]. SeqTrace version 0.9.0 software [18] was used to obtain a consensus sequence from the forward and reverse sequences. The sequence obtained was submitted to the GenBank to obtain an accession number. Similar reference sequences were downloaded from GenBank for phylogenetic analysis following a similarity search. Sequences were aligned using T-coffee alignment software [19] and manually adjusted using AliView Version 1.17-beta1 [20] where necessary. Phylogenetic analysis was done using MEGA 5.0 [21].

Cultivation of *A. nomius* KUB 105 for metabolite production

A. nomius KUB105 was initially grown on solidified 3 % MEA at 27 ± 2 °C for 3 days to produce mycelial inoculum for the liquid culture. A liquid basal medium was used for the growth of this microfungus for secondary metabolites extraction using the method proposed by McMullin et al. [22]. The basal medium contained, per litre: 10.00 g glucose, 2.00 g peptone, 0.30 g KH_2PO_4, 0.30 g $MgSO_4$, 0.20 g $CaCl_2$, 0.20 mg $FeSO_4$, 0.10 mg $CuSO_4$, 0.5 mg pyridoxine, 0.5 mg niacin and 0.3 mg $ZnSO_4$. All chemicals were of analytical grade. An amount of 30 mL of the basal medium was poured in 100 mL conical flask and autoclaved for 15 min at 121 °C. After cooling, agar plugs of *A. nomius* were aseptically cut with a 5 mm cork borer into the autoclaved basal medium, sealed with aluminium foil and incubated in a stationary condition for 2 weeks at 27 ± 2 °C with alternating 12 hours darkness and light. Three replicates were prepared.

Extraction and identification of secondary metabolites

After 2 weeks of growth, the liquid culture was filtered using Whatmanns No. 1 filter paper (90 mm diameter) to separate the mycelium from the filtrate. The cell free crude filtrate was then extracted by liquid-liquid extraction method. 30 mL of ethyl acetate was added to the culture filtrate, mixed together and the extraction process was left overnight to ensure maximum extraction. 15 mL of hexane was then added to the ethyl acetate extract. This is to allow the metabolites to be extracted into hexane, since the hexane extract will be injected into the GC-MS. The solvents were then cleaned up using a silica-gel column chromatography. The remaining solvent (hexane) was then carefully evaporated at 40 °C until only 2 mL of the solvent remained. 2 mL of the hexane extract was then used for Gas Chromatography-Mass Spectrometry (GC-MS) analysis. The basal medium hexane extract without the microfungus was also processed to serve as a control.

The secondary metabolites from the hexane extract were identified by a GC-MS (Shimadzu, Japan) equipped with a (QP2010 plus) mass selective detector. The ionization energy used was 70 eV. Preliminary identification was done with a non-polar capillary column (BP5) 30 m × 0.25 mm × 0.25 mm. The oven program had an initial temperature of 50 °C for 5 min, then a 10 °C/min run to 260 °C with a final hold at 260 °C for 10 min. The injector temperature was kept at 280 °C (splitless) and detector temperature was at 280 °C. The carrier gas was purified Helium (99.99 %) at a linear flow rate of 1 mL/min. The MS detector was operated at 280 °C and the scan range was from 40 to 500 m/z.

All detected compounds were putatively identified by mass spectral database search of the National Institute of Standards and Technology (NIST) followed by matching of the mass spectral data. Fourier Transform Infrared Spectroscopy (FTIR) analysis was also done to show the different functional groups present in our sample using a Thermo scientific Nicolet iS50 FTIR machine. Spectral shifts obtained were interpreted with reference to shifts in the peaks of the various functional groups.

Results and Discussion

Identification of the microfungus

The cultural characteristics of the isolates used in this study were similar to those of microfungi in the *Aspergillus flavus* section which includes *A. flavus*, *A. parasiticus* and *A. nomius*. The colony observe colour was green (which indicates the matured spores) with white colour at the margins (the young spores), the reverse side was creamish to light cream-brown (Figure 1). The mycelia reached about 8 cm diameter in seven days and is aerial. The mycelium

is septate with a globus terminal head conidiophore having spores arranged radially in chains and the spore surface is rough. However, in this study, *A. nomius* is different from other members of the *A. flavus* section by having a uniseriate conidial head and a rough conidia (as seen by Scanning electron microscopy, result not shown in this paper) and by its molecular identification (Figure 2) with accession number KR737578.

A. nomius also have an indeterminate sclerotia and a lower optimum temperature for growth as compared to the other species in the *A. flavus* section [23].

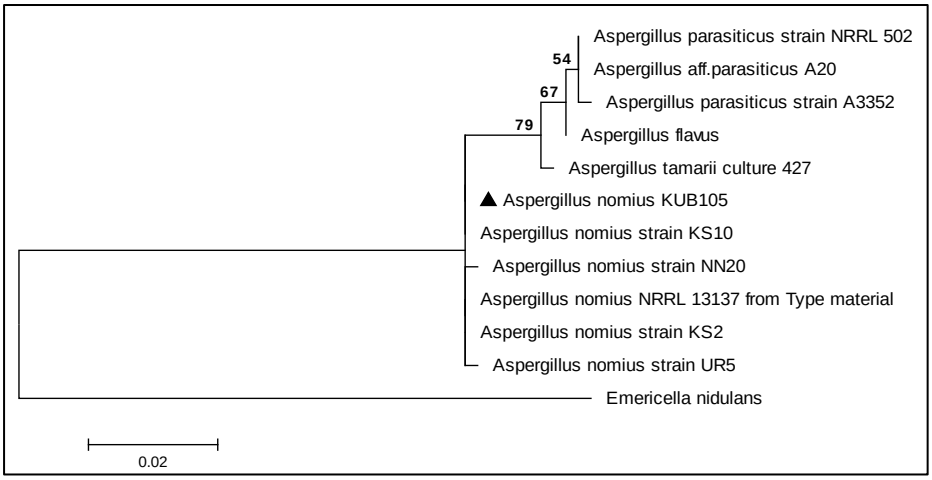

Figure 2. Molecular phylogenetic analysis by Maximum Likelihood method for identification of *A. nomius* KUB105 (KR737578) performed using MEGA5.1

Identification of metabolites from culture filtrate of *A. nomius* KUB105

After subtraction of the compounds in the control, GC-MS chromatograms of hexane extract of *A. nomius* (Figure 3) revealed 46 metabolites identified with reference to NIST mass spectral database which corresponds to each compound's identity. The identified metabolites include 43 saturated hydrocarbons, one alcohol, one ester & one chloro-hydrocarbon (alkyl halide) compounds. Tetracosane was the most abundant compound produced by *A. nomius* KUB105 with the highest peak area, while normal heptadecane and 2,4-Dimethylundecane were the least abundant (Table 1).

Most of these hydrocarbons have also been reported by [24–26], and [27] from culture extracts of *Aspergillus flavus*, *A. niger*; *A. ochraceus*, *A. niger* and *A. carbonarius* respectively. However, these metabolites are reported for the first time from culture extracts of *A. nomius* using GC-MS.

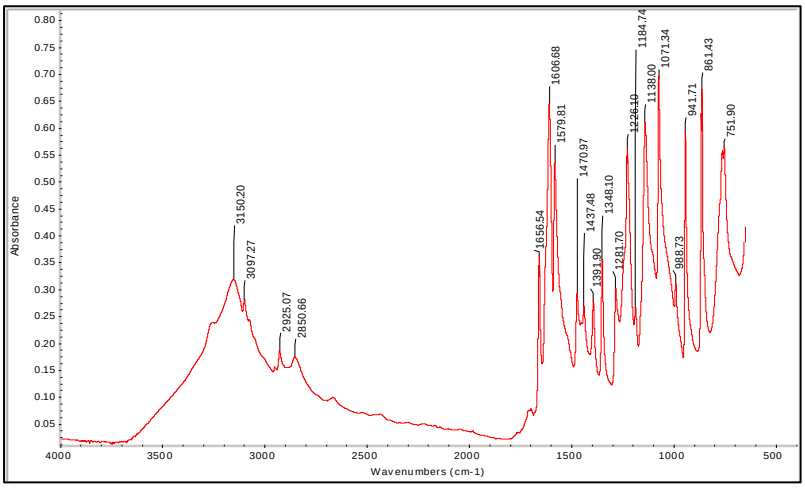

Figure. 4. The FTIR spectrum of the crude extract from liquid culture of *A. nomius* with bands extending from 550 – 4000 cm^{-1}.

The analysis of the FTIR spectrum indicates the presence of hydrocarbons and alcohol in the extract. The peak obtained at 751.90 cm^{-1} (Figure. 4) shows the presence of a C-Cl functional group which can be attributed to 1-Chloroicosane identified by the GC-MS analysis (see Table 1). The numerous peaks obtained between 861.43 to 1656.54 cm^{-1} shows the abundance of C-H functional groups which can be attributed to the saturated hydrocarbon (alkane) compounds [28] produced by the microfungus. Peaks at 2850.66 to 3150.20 cm^{-1} indicates the presence of O-H functional groups matching with 2-Hexyl-1-decanol and n-Heptadecyl acetate identified by the GC-MS. The spectrum from the FTIR further corroborates the spectral identifications obtained by GC-MS analysis.

Saturated hydrocarbons are the main ingredients of diesel fuel [12] and the identification of these compounds from culture filtrate of *A. nomius* and other microfungi indicates a close involvement of microfungi in the formation of these compounds through decomposition of certain organic and inorganic matter. Industrial application of the processes involved in the production of these hydrocarbon secondary metabolites coupled with the high diversity and easy growth potentials of microfungi can be a promising option to finding more sources of renewable energy production.

Conclusion

Our results have shown that saturated hydrocarbons are the major metabolites produced by *A. nomius* KUB105 grown for 2 weeks on a liquid basal medium (as described) at 27 ±2 ^{o}C. The findings in this study further support the claim by other researchers about microfungal hydrocarbon-metabolite production. Also, this study has been able to make the first report of the secondary metabolites produced by *A. nomius* KUB105 identified by GC-MS and FTIR analysis. Further study on the large scale production and purification of these secondary metabolites are necessary to fully utilize these compounds.

Abstract

A novel complex, $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ (dppz = dipyrido-[3,2-a:20,30-c]phenazine, *p*-MOPIP = 2-(4-methoxyphenyl) imidazo[4,5-f][1,10]phenanthroline) has been synthesized and characterized by elemental analysis, ^{1}H Nuclear Magnetic Resonance spectroscopy, mass spectrometry, Fourier Transform Infrared analysis, Ultra Violet visible and fluorescence spectroscopy. Herein, the complex was designed by adding *p*-MOPIP as an intercalating ligand and dppz as the ancillary ligand. The DNA binding properties of the complex with Calf Thymus DNA (CT-DNA) were investigated using spectroscopic methods. The UV-visible absorption band observed at 460 nm corresponded to the metal-to-ligand charge transfer (MLCT) while bands at 358 and 281 nm corresponded to intra-ligand (IL) π-π* transitions of the ligand scaffold in *p*-MOPIP and dppz. The intrinsic binding constant, K_b for this complex was 1.67 x 10^6 M^{-1} and this suggested that this complex, $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ bound to DNA *via* the intercalative mode. Interestingly, the interaction of this complex with CT-DNA also had a 'molecular light switch' effect.

Keywords: ruthenium, DNA binding, molecular light switch

Abstrak

Satu kompleks baru, $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ (dppz = dipyrido-[3,2-a:20,30-c]fenazin, *p*-MOPIP = 2-(4-metoksifenil) imidazo[4,5-f][1,10]fenantrolina) telah dihasilkan dan dianalisis dengan menggunakan analisis elemen, spektroskopi resonans magnet nukleus (^{1}H NMR), spektrometri jisim, analisis inframerah tranformasi Fourier (FTIR), spektroskopi ultra-lembayung dan pendafluor. Penyediaan kompleks telah dilakukan dengan menambah *p*-MOPIP sebagai ligan interkalasi dan dppz sebagai ligan sisi. Ciri-ciri ikatan DNA bagi kompleks ini dengan *Calf Thymus* DNA (CT-DNA) telah dianalisis dengan menggunakan kaedah spektroskopik. Jalur pada 460 nm merujuk kepada caj metal-kepada-ligan (*MLCT*), manakala jalur pada 358 dan 281 nm dikaitkan dengan peralihan π-π* intra-ligan (IL) bagi ligan *p*-MOPIP dan dppz. Nilai pemalar ikatan, K_b ialah 1.67 x 10^6 M^{-1} dan keputusan eksperimen mencadangkan pengikatan berlaku melalui mod interkalasi. Menariknya, kompleks ini juga menunjukkan kesan 'suis cahaya molekul'.

Kata kunci: ruthenium, pengikatan DNA, suis cahaya molekul

Introduction

Ruthenium, as other transition metals, generally have the electronic configuration where the 4d sub-shells are partially filled [1], allowing it to form different sorts of complexes that are suitable for various applications including as anticancer drugs, biosensors, in catalysis and others. Ruthenium complexes have properties that make them active biologically [2]. One of the properties is ligand exchange, where ruthenium(II) and ruthenium(III)

complexes having similar exchange kinetics to those of platinum(II) complexes [3], thus, are able to display similar biological effects as platinum(II) drugs. Additionally, ruthenium has a wide range of accessible oxidation states [4], for instance, ruthenium(II), ruthenium(III) or ruthenium(IV). The reduction and oxidation (redox) potential of metal complexes can be modified and exploited by varying the ligands to improve the effectiveness of ruthenium based drugs in the pharmaceutical industry [5]. Ruthenium(II) complexes with d^6 configuration are predominantly are octahedral and diamagnetic [6]. Recently, researchers have been more focused on the ruthenium(II) polypyridyl complexes due to their photoluminescence which makes them stable and also suitable as DNA probes.

Previously, the development of classical ruthenium drugs was based on the capability of ruthenium to bind with DNA *via* some of the nitrogen atoms of nucleic bases. The interaction between transition metal complexes and nucleic acids were studied extensively in order to develop drugs that could react and bind to nucleic bases. The most important characteristics of ruthenium(II) complexes are that their intercalating ligand must possess extended and planar aromatic structures which is able to stack and insert between the base pairs of the DNA double helix. The intercalating ligand plays an important role in order to make the interaction with DNA happen.

The modification of polypyridyl ligands would allow fine tuning of the configuration and electronic structures of ruthenium(II) polypyridyl complexes therefore, varying the DNA binding properties of these complexes. Nowadays, the researchers are more interested in the complexes that contain one intercalating ligand and two ancillary ligands due to their stability, strong DNA affinity, photochemical properties and various other applications. Ruthenium complexes with stable, inert, coordinatively saturated and water soluble properties are the most ideally suited and extremely valuable as non-covalent probes of both structural and functional aspects of nucleic acid chemistry [7].

Thus, the objective of this study is to synthesis, characterization and evaluate the DNA binding activity of a potential DNA intercalator based on novel complex, $[Ru(dppz)_2(p\text{-}MOPIP)]^{2+}$.

Materials and Methods

Materials

All the chemicals and solvents in this experiment are at least of analytical grade and used as received from the suppliers unless stated otherwise. The reagents used without purification are as follows: ruthenium(III) chloride hydrate, 4-methoxybenzaldehyde, 1,10-phenanthroline, sodium bromide, sodium hydrogen carbonate, magnesium sulfate, ammonium acetate, *o*-phenylene diamine, lithium chloride (LiCl), potassium hexaflorophosphate (KPF_6) and tetra-*N*-butylammoniumchloride. The solvents are listed as follows: nitric acid, sulphuric acid, chloroform, methanol, glacial acetic acid, aqueous ammonia, dimethylformamide, toluene, acetonitrile and ethylene glycol.

Instrumentation

The elemental analysis of the complex was carried out by using Leco CHNS-932 Elemental Analyzer. The nuclear magnetic resonance (NMR) spectra was recorded at room temperature in deuterated acetonitrile (CD_3CN) by using JEOL ECX500 FT NMR 500 MHz spectrometer with tetramethylsilane (TMS) as the internal standard for ^1H. Electrospray Ionization Mass Spectrometry (ESI-MS) of the complex was performed on a triple stage quadrupole Finnigan TSQ7000 mass spectrometer with a diverted inject valve where the spectra recorded were in the scanning range of 50 – 2200 *m/z* ratio. The Infrared absorption spectra were measured by using Perkin Elmer 100 series FT-IR Spectrometer in the range 4000 – 200 cm^{-1}. UV-Visible spectra were recorded over the range of 200 – 600 nm on Shimadzu H.U.V.1650 PC UV-Visible spectrophotometer using quartz cells of 10 mm path length. Emission spectra were recorded over the range 500 – 850 nm using an excitation wavelength of 460 nm on a Shimadzu RF-5301 PC spectrofluorometer at room temperature.

Preparation of the precursor ligand and complex

The precursor ligand, 1,10-phenanthroline-5,6-dione was prepared according to literature [8] and recrystallized in methanol. The precursor ligand was later used to prepare dipyrido[3,2-a:2',3'-c]phenazine (dppz) [9] and 2-(4-methoxylphenyl)imidazo[4,5-f][1,10]phenanthroline (*p*-MOPIP) [10] by following literature methods.

Synthesis of $Ru(dppz)_2Cl_2$

$Ru(dppz)_2Cl_2$ was prepared according to an established method [11]. A mixture of 0.2 g (1.0 mmol) $RuCl_3.3H_2O$, 0.55 g (2.0 mmol) dppz, 0.22 g of LiCl, and 30 mL of DMF was refluxed for 8 hours. The dark solution was stirred in 100 mL of chilled acetone and then kept in the freezer overnight. The crude product was collected by filtration and washed with water. The dried crude product was a fine dark purple powder. Yield: 0.623 g (80.1%), MS, *m/z*: 703 [M^+- 2Cl] ; ^{1}H NMR 500 MHz (CD_3CN, δ ppm): 9.50 (d, 4H), 9.17 (d, 4H), 8.38 (dd, 4H), 8.04 (dd, 4H) and 7.92 (d, 4H) ; IR (ν, cm^{-1}) :3057.49 (sp^2 C-H), 1631.00 (C=N), 1581.31 (C=C), 1073.58 (C-N) and 327.32 (Ru-Cl).

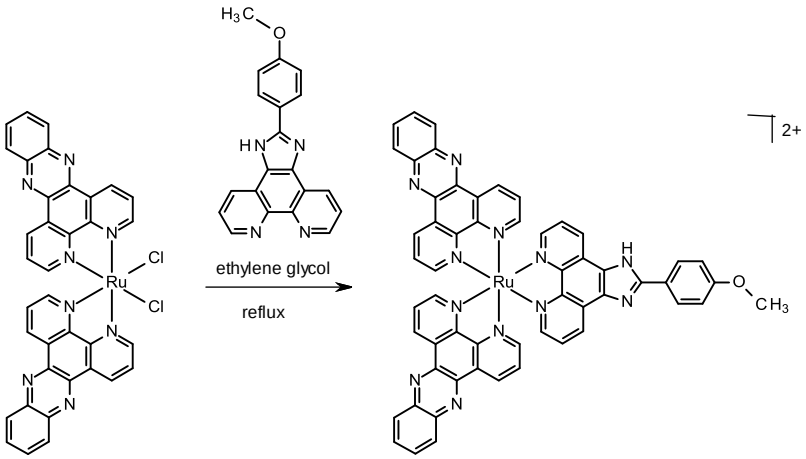
Synthesis of $[Ru(dppz)_2$*p*-MOPIP$_2]^{2+}$

A mixture of 0.034g (0.10 mmol) *p*-MOPIP, 0.08g (0.10 mmol) of $[Ru(dppz)_2Cl_2]^{2+}$ was dissolved in 10 ml of ethylene glycol and refluxed for 4 hours under nitrogen. Upon cooling, concentrated KPF_6 solution was added into the dark solution. Once the precipitation was complete, the solution was filtered by using a grade-4 crucible followed by washing with water. The crude product was purified by column chromatography by using neutral alumina with a 1:1 ratio of acetonitrile and toluene. The orange-red band was collected and analyzed. The final product was a fine dark orange solid. Yield: 0.08g (62.5%); Found: C, 53.2; H, 2.67; N, 13.2 (calculated for $C_{56}F_{12}H_{34}N_{12}OP_2Ru$: C, 52.4; H, 3.0; N, 13.1); MS, *m/z*: 1136.9 [M^+- PF_6^-] and 993.2 [M^+- $2PF_6^-$], ; ^{1}H NMR (CD_3CN, δ ppm): 9.65 (d, 6H, *J*=6.87 Hz), 9.05 (d, 4H, *J*=8.02 Hz), 8.43 (m, 6H), 8.23 (dd, 4H, *J*=3.44 Hz), 8.15 (d, 2H, *J*=9.16 Hz), 7.82 (m, 4H), 7.69 (dd, 2H, *J*=5.73 Hz), 7.20 (d, 2H, *J*=9.16 Hz) and 3.88 (s, 3H) ; IR (*v*, cm^{-1}) :3386.03 (secondary N-H), 2954.87 (sp^3 C-H), 1458.91 (C=C), 1354.91 (C=N), 1022.27 (C-N) and 811.44 (Ar *para*-subs.)

UV-Visible titration

The interaction of ruthenium(II) complex, $[Ru(dppz)_2$(*p*-MOPIP)$]^{2+}$ with CT-DNA was analyzed using UV-Vis spectroscopy. The UV-Vis titration of the complex in a buffer was performed at room temperature using a fixed concentration of the complex with increasing concentration of DNA. The concentration of the $[Ru(dppz)_2$(*p*-MOPIP)$]^{2+}$ solution was 15 μM while the concentration of DNA titrated varied from 0 to 86 μM. The complex-DNA solution was allowed to incubate for10 minutes before the spectra were recorded. The titration processes were repeated several times until no more changes were observed in the spectra which indicated that the binding saturation was achieved. The changes in the concentration of the ruthenium(II) complex due to dilution at the end of each titration were negligible.

Emission titration



The intrinsic fluorescence emission spectra of the complex in Tris-buffer was carried out by using a fixed ruthenium(II) concentration to which increments of the DNA stock solution were added. Ruthenium-DNA solution was allowed to incubate for 5 minutes before the emission spectra were recorded. The excitation wavelength was set at 460 nm.

Viscosity measurements

Viscosity measurements were carried out with an Cannon Flask viscometer, suspended vertically and immersed in a water bath with a constant temperature of 25℃. The flow time was measured with a digital stopwatch and each sample was tested three times to obtain the average flow time. Data were represented as $(\eta/\eta_0)^{1/3}$ *versus* binding ratio, 1/R where η is the viscosity of DNA in the presence of the complex. Specific viscosity values were calculated by the equation $\eta = (t - t_0)/t_0$, where t and t_0 represent flow time of the DNA solution and the blank buffer, respectively.

Results and Discussion

The reaction of $[Ru(dppz)_2Cl_2]$ with *p*-MOPIP in a ratio 1:1 treated with potassium fluorophosphate resulted in formation of $[Ru(dppz)_2$p-MOPIP$]^{2+}$ in PF_6 salt (Scheme 1). The purified complex was obtained as an orange-red fine solid with 62.5% yield. Conversion to chloride salts was done with the treatment of the complex in acetonitrile solution with tetra-*N*-butylammoniumchloride. The complex in PF_6 salt was easily soluble in acetonitrile while as a chloride salt, it was soluble in water.

Scheme 1. Preparation of $[Ru(dppz)_2p\text{-MOPIP}]^{2+}$

Electrospray ionization mass spectrometry (ESI-MS) in acetonitrile showed a peak at *m/z* 1136.9 for $[M^+]$ while the intense peak at *m/z* 496.1 served as the base peak for $[M^{2+}]$. The ^{1}H NMR spectrum of $[Ru(dppz)_2p\text{-MOPIP}]^{2+}$ (Figure 1) in deuterated acetonitrile were properly defined and integrated. There are nine signals which corresponded to the protons of dppz and *p*-MOPIP ligands in the complex. The resonance at 9.65 ppm corresponded to the proton attached to the carbon adjacent to a coordinated nitrogen atom in the aromatic ring while the proton attached to the neighboring oxygen atom was shielded at 7.20 ppm. The proton signal for the methyl group was observed at 3.88 ppm as a singlet peak. Unfortunately, the signal that corresponded to the proton directly attached to nitrogen atom in *p*-MOPIP was not observed in the spectrum, probably due to fast exchange chemistry of the active proton in the imidazole ring or it was obscured by the nitrogen quadrapole broadening property [12]. However, the presence of NH was confirmed by the IR spectrum.

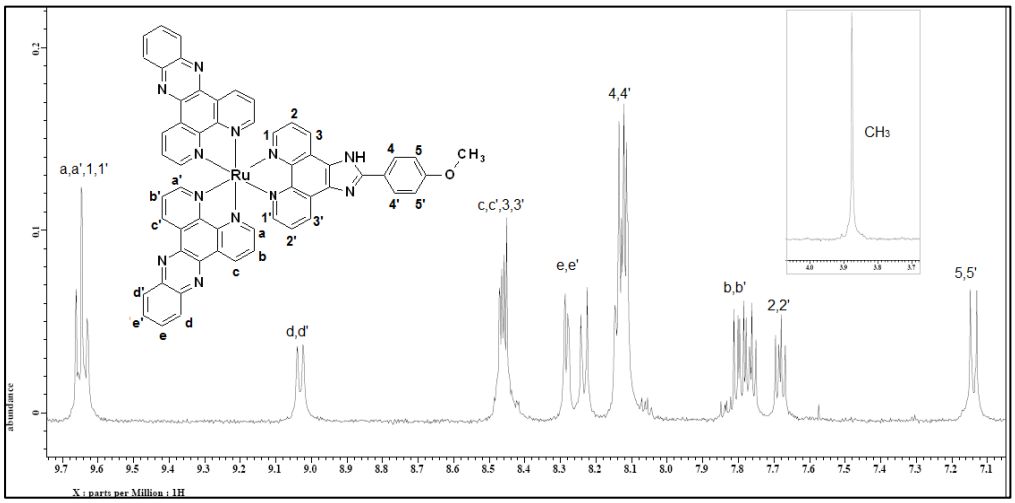


Figure 1. ^{1}H NMR spectrum of $[Ru(dppz)_2p\text{-MOPIP}]^{2+}$

The IR spectrums of the complex were recorded in the region of 4000 – 280 cm^{-1} and the data is summarized in Table 1. A broad and strong peak which gives information on secondary amine group of imidazole *v*(N-H) was

observed at 3386 cm^{-1}. The carbon-nitrogen bonds absorptions *v*(C=N) and *v*(C-N) were at 1638 and 1354 cm^{-1}, respectively. The stretching frequency of *v*(C-O) at 1022 cm^{-1} were indicative of the O-CH_3 group. In addition, a strong out of plane *v*(C-H) bending frequency appeared at 811 cm^{-1} indicating that the substitution in the aromatic phenyl referred to the *para*-position. The accumulated MS, NMR and IR data supported by elemental analysis was consistent with the proposed structure and composition of the complex.

Table 1. IR data of $[Ru(dppz)_2p\text{-}MOPIP]^{2+}$

v	**Wave number (cm^{-1})**	**Intensity**
(N-H)	3386	strong, broad
(sp^3 C-H)	2954	strong, sharp
(C=N)	1638	medium, sharp
(C=C)	1458	strong, sharp
(C-N)	1354	strong, sharp
(C-O)	1022	medium
Para subs ring	811	medium

The UV-Visible absorption spectrum for $[Ru(dppz)_2p\text{-}MOPIP]^{2+}$ was recorded in acetonitrile, with a concentration of 10 µM at room temperature. Through comparison to related molecules [8, 9], the bands centered at around 281 nm (ε = 66600 M^{-1} cm^{-1}) and 358 nm (ε = 17400 M^{-1} cm^{-1}) were assigned to intra-ligand $\pi \rightarrow \pi^*$ transitions in the scaffold. The lowest energy band at 460 nm (ε = 10200 M^{-1} cm^{-1}) was attributed to the metal-to-ligand charge transfer (MLCT) transition of the $Ru(d_\pi) \rightarrow$ ligand. The luminescence spectra of the complex upon MLCT excitation was performed at room temperature and the excitation wavelength was set at 460 nm. Figure 2 displays the emission spectra of complex in acetone (**blue**) and water (**red**) at room temperature to show the effect of the protic solvent on the complex. The complex displayed high luminescence in acetonitrile but almost no emission in water probably due to the presence of the dppz ligands in the complex. In an aqueous environment, the free electron on the nitrogen of the phenazine ring can form hydrogen bonds with water molecules [13,14]. As a result, the excited-state luminescence was quenched [15, 16]. This property is advantageous in DNA-binding studies using an aqueous buffer, where the complex binds to DNA, and the dppz ligands were protected from water, thus intense luminescence could be observed. This phenomenon has been termed as the 'molecular light switch' effect [17].

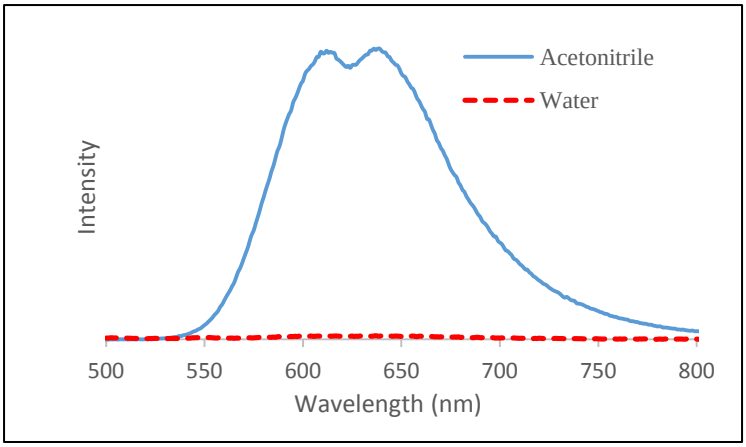

Figure 2. Luminescence spectra of $[Ru(dppz)_2p\text{-}MOPIP]^{2+}$ in acetonitrile and water

DNA-binding studies

The interaction of the ruthenium(II) complex, $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ with CT-DNA was analyzed using UV-Vis spectroscopy. The UV-Vis titration of the complex in a buffer was performed at room temperature using a fixed concentration of the complex with increasing concentration of DNA.

The concentration of the $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ solution was at 15 μM while the concentration of DNA varried from 0 to 86 μM. The complex-DNA solution was allowed to incubate for 10 minutes before the spectra were recorded in order to allow the interaction between DNA and the complex. The titration processes were repeated several times until no more changes were observed in the spectra indicating that the binding saturation was achieved. The changes in the ruthenium(II) complex concentration due to dilution at the end of each titration were too small and thus were negligible [18]. The absorption spectrum of complex with increasing concentration of CT-DNA is shown in Figure 3.

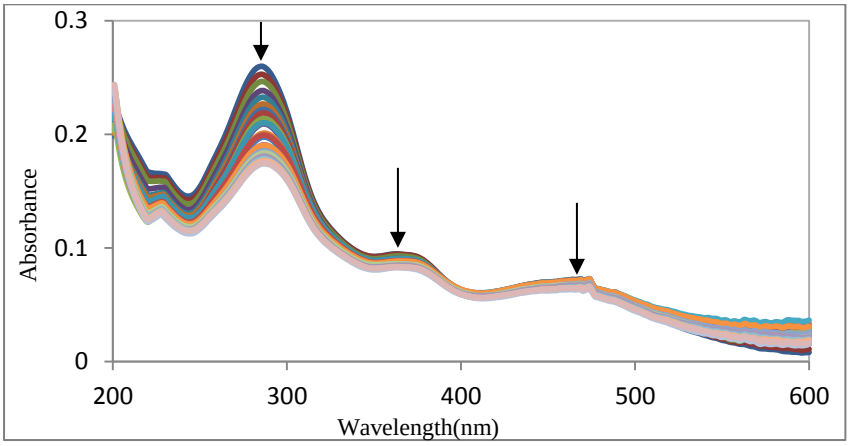

Figure 3. Absorption spectra of ruthenium(II) complex in Tris-HCl buffer upon addition of CT-DNA. [Complex] = 15μM, [DNA]= 0-86 μM

The arrows showed the absorbance changing upon the increase in DNA concentration. Normally, the hypochromic and bathochromic effects are seen during the binding process which is due to the perturbation of the metal centred MLCT band and the ligand centred π-π* band of the complex [19]. For this case, although there was no obvious red shift, hypochromicities was observed. The hypochromicities in the absorption bands for $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ complex by the addition of CT-DNA in aqueous buffer was 29 %. This hypochromism effect has been attributed to the presence of synergic non-covalent interactions: electrostatic, groove or intercalation binding along the outside of DNA helix, and often the extent of hypochromism was parallel to the intercalative binding strength [20].

There were three well resolved bands at 284 nm, 363 nm and 474 nm. The absorption bands decreased with higher concentration of CT-DNA which fit a characteristic feature of CT-DNA binding interaction. The ultraviolet bands at 284 nm and 363 nm correlated to the intra-ligand π-π* transition [19]. The lowest energy bands at 474 nm was assigned to the MLCT transitions pf $Ru(d_\pi) \rightarrow$ ligand according to the other related ruthenium (II) complexes [21].

In order to quantitatively illustrate the DNA binding strength of the complex, the intrinsic binding constant, K_b of complex with CT-DNA was determined by monitoring the changes of absorbance at 284 nm while increasing the concentration of DNA according to the following equation 1 [22]:

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f) \quad (1)$$

where [DNA] is the concentration of CT-DNA in base pairs, the apparent absorption coefficient, ε_a, ε_f and ε_b correspond to $A_{observed}$/[Ru], the extinction coefficient for the free ruthenium complex and the extinction coefficient for the free ruthenium complex in the fully bound form, respectively .

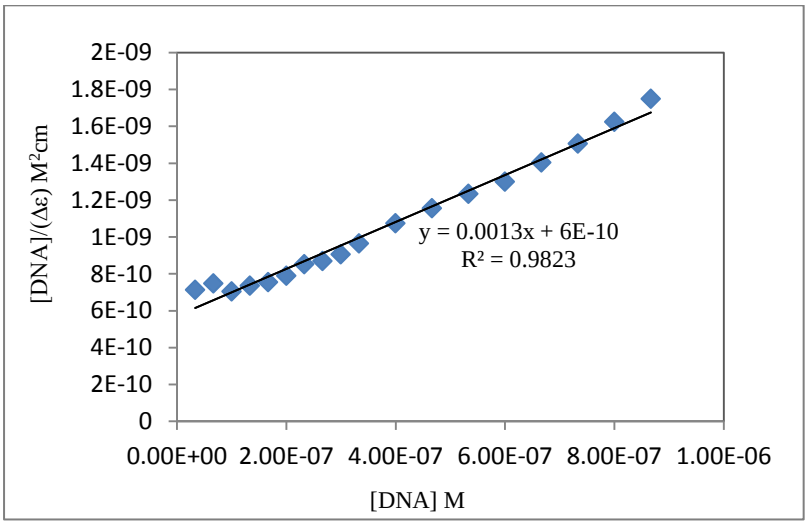

Figure 4. [DNA]/(Δε) vs [DNA] for the titration of DNA with the ruthenium(II)complex

K_b was determined by the ratio of slope to the intercept and the value obtained was 1.67 x 10^6 M^{-1}. By comparing with other similar ruthenium(II) complexes that contained *p*-MOPIP as ligand, this value was greater compared to $[Ru(bpy)_2(p\text{-MOPIP}]^{2+}$ and $[Ru(phen)_2(p\text{-MOPIP})]^{2+}$ where the value of K_b were 5.0 x 10^5 M^{-1} and 0.20 x 10^5 M^{-1} [10, 13], respectively. This signified that $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ bound more tightly to DNA compared to those complexes. In this case, the ancillary ligand dppz might have played an important influence suggesting that the high DNA binding affinity was relative to the dimension of π-conjugated aromatic area of ancillary ligands. This was mainly induced by the extended-aromatic structure of the ancillary ligand which was dppz that increased the action between the complexes and DNA. The dppz itself might also react with DNA consequently giving a higher value of binding constant as mentioned before.

The K_b value was consistent with previous report by Sun et al. [23] on a closely related compound consisting of two dppz ligands in one system, $[Ru(dppz)_2(L^1)]^{2+}$, (L^1=5,5'-di(1-(trimethylammonio)methyl)-2,2'-dipyridyl cation) showed the effect of the intercalating ligand in DNA binding, with K_b values at 0.58 x 10^6 M^{-1}. The distinct structure of *p*-MOPIP which comprised of an extended aromatic area assisted $[Ru(dppz)_2(p\text{-MOPIP})]^2$ to bind strongly to DNA through intercalation compared to $[Ru(dppz)_2(L^1)]^{2+}$ where L^1 contained longer alkyl groups in the ligand. The binding affinity of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ was improved by bis-intercalation due to presence of more than one intercalating ligand in one system, namely *p*-MOPIP and two sites of dppz [8,14].

The intrinsic fluorescence emission spectra of complex in Tris buffer was carried out by using a fixed ruthenium(II) concentration to which increments of the DNA stock solution were added. Ruthenium-DNA solution was allowed to incubate for 10 minutes before the emission spectra were recorded. The excitation wavelength was set at 460 nm.

In the emission spectra (Figure 5), the arrow showed the emission intensity changes upon increasing the DNA concentration. The concentrations of the ruthenium(II) complex and CT-DNA were 30 μM and 0-200 μM, respectively. The interaction of the complex with DNA shows increased emission intensity in buffer solution. However, the emission changes were not so pronounced even after excess addition of DNA because of solvent quenching and enhancement of emission intensity when bound intercalatively to DNA. This implied that the

ruthenium(II) complex could strongly interact with DNA and be protected by DNA efficiently. In other words, the hydrophobic environment inside the DNA helix reduced the accessibility of solvent water molecules to the complex and the complex mobility was restricted at the binding site [24], leading to a decrease of the vibrational modes of relaxation. Increase in emission was an indication of intercalation between CT-DNA and the complex.

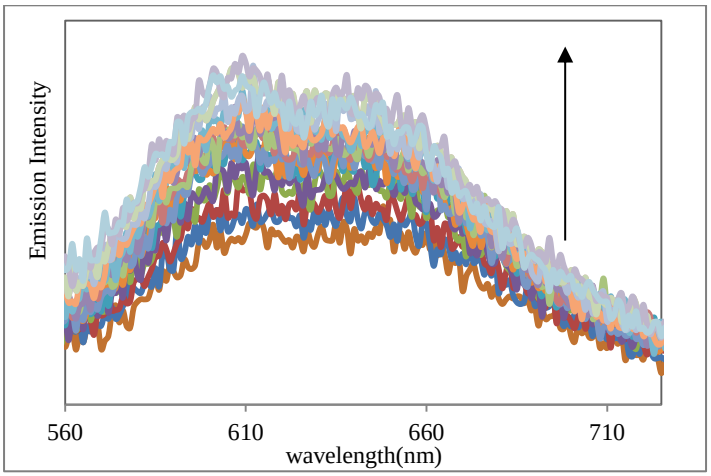

Figure 5. The emission spectra of the ruthenium(II) complex in buffer in the presence of increasing amounts of CT-DNA, [Ru]= 30μM, [DNA] = 0 - 200μM

This result also revealed the selective nature of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ as a molecular switch, responding sensitively to the suitable changes in the structure of the helix, a phenomenon called the 'molecular light switch' effect, due to presence of the dppz ligands.

In order to elucidate the binding mode of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$, viscosity measurements were carried out by keeping a constant concentration of CT-DNA and varying the concentration of the complex. Viscosity measurements provided reliable evidence to study the mode of interaction. Electrostatic or groove binding generally had no significant consequence on the viscosity of DNA, whereas classical intercalation affects the lengthening of DNA helix as base pairs are separated to accommodate foreign molecules, therefore, increasing the viscosity of DNA [25]. As shown in Figure 6, with continuing addition of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ to CT-DNA solution, the viscosity of CT-DNA increased. This result validated the hypothesis that $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ bound to DNA *via* intercalation. This result was in agreement with other previous reports on ruthenium(II) polypyridyl complexes [10, 26].

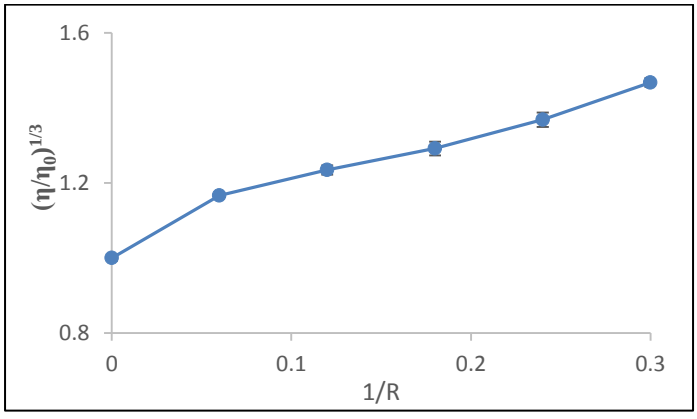

Figure 6. Effect of increasing concentration of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ on the viscosity of CT-DNA

Conclusion

In this study, a novel complex $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ has been synthesized. The structure and composition was supported by analysis *via* ^{1}H-NMR, mass spectrometry, elemental analysis, FT-IR, and UV-Vis spectroscopy. The binding properties of CT-DNA with the complex were studied by UV-Vis titration and viscosity measurements showed that the interaction occurred *via* intercalation mode giving the intrinsic binding constant of $K_b = 1.67 \times 10^6$ M^{-1}. $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ was bound more tightly than similar related complexes. From the comparison, it was clear that the extended aromaticity of the ancillary ligand influenced the binding strength of ruthenium(II) complex to DNA. In the luminescence titration, it was found that the $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ was a highly sensitive spectroscopic reporter of double-helical DNA. Whereas in aqueous solution, the luminescence was detectable only when $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ intercalated in the nucleic acid structure and was perhaps shielded by DNA. Therefore, $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ was concluded that served as a true 'molecular light switch' for the DNA structures. The stark contrast between the 'off' and 'on' states of $[Ru(dppz)_2(p\text{-MOPIP})]^{2+}$ made this complex useful for the quantitative study of DNA and other non-polar microenvironments, a significant outcome for the design of novel intercalator reagents. However, the details of binding of complex with the sequence of DNA is not clear yet and further studies are required.

Abstract

The processing of mineral monazite to produce thorium (Th) and rare earth elements may create a radiological impact if the processing and residue are not properly or safely managed. Malaysian Atomic Energy Licensing Board (AELB) categorized monazite as a radioactive material because the concentration of thorium in the mineral is higher than 1Bq/g. Therefore, the current study aimed to determine the separation percentage of thorium from Malaysian monazite and to assess the radiological impact of thorium during various stages involved in the processing. In this study, monazite was digested by hot sulphuric acid followed by selective precipitation of thorium using ammonia. Neutron Activation Analysis (NAA) and Inductively Coupled Plasma Mass Spectrometry (ICP-MS) techniques were used to determine thorium. The result of the study showed that the average concentration of thorium in Malaysian monazite ore was 17,990.5 ± 1,239.3 ppm. After digestion, 46.56 % of thorium was recovered and about 97.68 % of thorium was separated as thorium hydroxide from the obtained sulphate leach solution. The study also indicated that less than 3% of Thorium entered in the rich rare earth elements filtrate during the separation. The calculated maximum dose that could be received by workers and public from the monazite ore were 61.91 ± 4.27 mSv/y and 54.24 ± 3.73 mSv/y respectively. However, during the processing of 25 g the monazite ore, the worker and public will receive a lower dose in the range of 0.01 – 0.72 and 0.01 – 0.63mSv/y respectively. Based on the results, useful suggestions on how to improve thorium recovery and how to minimize the radiological impact as a whole are provided.

Keywords: thorium, monazite, radiological impact, separation, dose

Abstrak

Pemprosesan mineral monazit untuk menghasilkan torium (Th) dan unsur nadir bumi boleh menyebabkan impak radiologi sekiranya pemprosesan dan residu tidak diuruskan dengan baik. Lembaga Perlesenan Tenaga Atom Malaysia (AELB) telah mengkategorikan monazit sebagai bahan beradioaktif kerana kepekatan torium dalam mineral adalah tinggi iaitu melebihi 1Bq/g. Oleh itu, tujuan utama kajian ini adalah untuk menentukan peratus pengasingan torium daripada bijih monazit dan menilai impak radiologi torium dalam beberapa peringkat yang terlibat dalam pemprosesan. Dalam kajian ini, asid sulfurik telah digunakan untuk menghadam monazit dan diikuti dengan pemendakan terpilih torium menggunakan ammonia. Teknik Analisis Pengaktifan Neutron (NAA) dan Induktif Plasma Pendua – Spektrometri Jisim (ICP-MS) telah digunakan untuk menentukan kandungan torium. Hasil kajian menunjukkan purata kepekatan torium dalam bijih monazit Malaysia adalah 17,990.5 ± 1,239.3 ppm. Selepas penghadaman, peratus mendapatkan torium adalah 46.56 % dan 97.68 % torium telah diasingkan sebagai torium hidroksida daripada larutan larut lesap sulfat. Kajian juga menunjukkan kurang daripada 3 % torium terdapat dalam turasan unsur nadir bumi semasa pengasingan. Dos maksimum yang boleh diterima oleh pekerja dan orang awam daripada bijih monazit telah dikira dan masing – masing adalah 61.91 ± 4.27 mSv/y dan 54.24 ± 3.73 mSv/y. Walau bagaimanapun, semasa pemprosesan bijih monazit, pekerja dan orang awam akan menerima dos yang rendah iaitu masing – masing dalam julat 0.01 –

0.72 dan 0.01 – 0.63mSv/y. Berdasarkan hasil kajian ini, cadangan penambah baikan dalam mendapatkan torium dan bagaimana untuk meminimumkan impak radiologi secara menyeluruh dapat disediakan.

Kata kunci: torium, monazit, impak radiologi, pengasingan, dos

Introduction

Mineral processing industries containing natural radionuclides contribute to radiation exposure to the public and workers with significant doses. The radiation exposure during mineral processing industries can occur on the mining, transportation, or at any stage of mineral processing for generating the products, wastes and by-products [1]. In Malaysia, Naturally Occurring Radioactive Materials (NORM) are mainly found in scales and sludge from the oil and gas industries, iron oxide and red gypsum from the processing of ilmenite and thorium hydroxide in particular from the processing of xenotime and monazite. Other NORM are tin slag produced from the smelting of tin, ilmenite, zircon, and monazite produced from the processing of tin tailing (amang) [2, 3]. These activities are regulated and controlled under the Atomic Energy Licensing Act, 1984 (Act 304).

Malaysia implemented 1 Bq/g for naturally occurring radionuclides from ^{238}U and ^{232}Th decay series in raw material and waste as the control limit of activity concentrations. It stated the annual dose limit for the members of the public and workers from the activity concentration of radionuclides must be below the control limits which are unlikely to exceed 1 mSv/y and 20 mSv/y, respectively [4, 5]. There are two sources of thorium existing in Malaysia namely rare earth minerals and rare earth elements production residue. For instance, Malaysian monazite containing thorium ranged between 6.5 – 7.5 % and the average thorium concentrations in xenotime were 1.5 % [6]. The residue from Asian Rare Earth (ARE) contains 36 % of thorium meanwhile Water Leach Purification (WLP) residue generating from Lynas Advanced Materials Plant (LAMP) containing 0.17 % of thorium with total dose contribution of Th-232, Ra-228, U-238 and Ra-226 for workers and public 3.90 and 0.20 mSv/y, respectively [3, 6, 7]. Practically, the processing of monazite for rare earth production will produce a significant amount of thorium that needs to be managed safely to prevent the public concern and environmental impacts.

Typically, thorium is extracted from its minerals with either hot sulphuric acid or hot strong alkali, converted into thorium nitrate and extracted with tributyl phosphate (TBP) in kerosene for final purification of the thorium [4, 5, 11]. Chemically, monazite is phosphate of thorium and rare earths besides small uranium content. It is particularly rich in the light REEs. Digestion of monazite mineral can be used hot concentrated sulphuric acid or hot alkali. In typical acid process, cracking monazite mineral is performed at >230 ºC as shown in the following equation 1:

$$Th_3 (PO_4)_4 + 6H_2SO_4 \rightarrow 3Th (SO_4)_2 + 4H_3PO_4 \quad (1)$$

In the acid process, thorium and REEs which are water soluble salts in monazite sulphuric solution are filtrated, and thorium is separated from these REEs by reducing the acidity to precipitate thorium as thorium hydroxide usually in the selective precipitation. Moreover, ammonia is used at about pH 1.05. Nitric acid may dissolve thorium hydroxide precipitate. Produced thorium nitrates in acid solutions are widely used to extract thorium into organic solvents. For purification of thorium from impurities, solvent extraction commonly using tributyl phosphate TBP in kerosene is achieved by a multi-stage extracting and stripping process [10 – 14].

In strong alkali digestion, insoluble thorium hydroxide is produced in thorium cake which is easily dissolved in acid as illustrated by the following equation 2:

$$Th_3 (PO_4)_4 + 12NaOH \rightarrow 3Th (OH)_4 + 4Na_3 PO_4 \quad (2)$$

Thorium is purified by solvent extraction in nitric acid media [14 – 16]. Pure thorium nitrate can be converted into thorium peroxide or thorium oxalates which are calcinated at 800 ºC in a furnace to produce high purity thorium oxide [17, 18]. Previous studies separated thorium from the rare earth residue and RE ores in order to minimize the environmental impact of thorium radioactivity and to produce thorium for future nuclear fuel [3, 8, 9].

In the present study, the separation percentage of thorium from Malaysian monazite and the improvement on thorium separation were studied. Radiological impact assessment of thorium was discussed for the whole scenario of Th separation, and it was suggested to minimize the radiological impact as well.

Materials and Methods

Separation of thorium

Malaysian monazite sample was collected from Syarikat Leong Sin Nam, Kempari, Perak and it was grinded to obtain fine powder. In preparing the samples for gamma spectrometry (HPGe), sample together with standard reference material namely (IAEA soil-375) were stored for 4 weeks in sealed plastic containers to re-establish the secular radioactive equilibrium. The specific activities of the natural radionuclides ^{232}Th and ^{238}U were measured for a period of 12 hours by HPGe γ-ray spectrometry. The ^{232}Th specific activity was determined from Ac-228 (911.1 keV) and Tl-208 (583.2 keV) respectively. In addition, the ^{238}U specific activity was assessed using Bi-214 (1764.49 keV).

In preparing the samples for the instrumental neutron activation analysis (INAA), approximate 0.05 g of monazite sample and 0.4 g standard reference material (IAEA 312N) were placed in high-purity polyethylene irradiation vials and sealed by heat sealing process. Triplicates were prepared for each sample. Then, the samples, standard reference materials and standard solution were irradiated for 1 hour in the rotary rack (RR) facility of the TRIGA Mark II reactor at Malaysian Nuclear Agency. The measurements were carried out using a HPGe detector (GC3018) and the analysis of photo peaks were performed using Genie-2000 software (Canberra Inc.).The samples were measured for 1 hour at different cooling times which ranged from 2 days to 4 weeks and measured at 4 cm distances from the detector.

Monazite leach sulphuric acid solution

The digestion of monazite and the selective precipitations of thorium were performed on glass beakers and the measurements of pH were carried out using EUTECH instruments pH700. The thorium concentrations in the aqueous solutions were determined using ICP-MS -ELAN 9000 (PerkinElmer SCIEX).There are two main parts of the process: Digestion of monazite with hot sulphuric acid and dissolving with water to produce monazite leach sulphate solution and separation of thorium from REEs and U by selective precipitation using ammonia and produce thorium precipitate as shown in Figure 1.

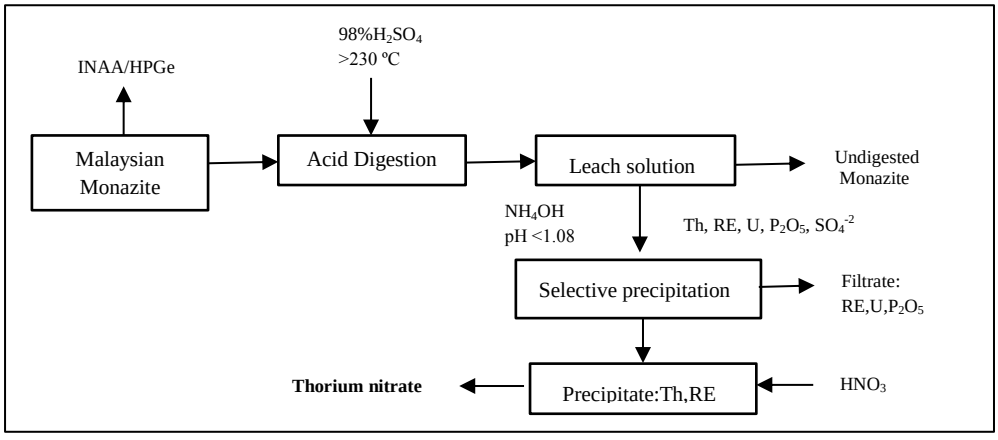

Figure 1. Simplified flowchart for sulphuric acid digestion of Malaysian monazite and recovery of thorium

Digestion of Malaysian monazite

The monazite leach solution used in this study was prepared by digesting approximately 25 g of monazite in 75 ml of 98 % sulphuric acid at 200 °C for 3 hours as digestion time using the glass beakers on the stirring hot plate. Then,

the mixture was cooled to room temperature, adding 200 mL water to dissolve the metal sulphates, and filtering to produce a clear solution.

Selective precipitation of thorium with ammonia

The monazite leach solution contains thorium, rare earths, and uranium with other impurities. Reduction of the acidity of sulphate leach solution at a pH of 1: 05 can precipitate thorium and leave the rare earths and uranium in the solution [10, 14]. In this part, 100 mL of leach solution was used and the selective precipitation for thorium was carried out at pH 1.08 – 1.89 using ammonia. The thorium rich precipitate was filtrated and dissolved in nitric acid to form thorium concentrate solution. ICP-MS used for determination of metal concentrations in the monazite leach solution, thorium concentrate and RE filtrate solutions. Triplicate procedures were performed and separation percentage of thorium from monazite leach solution was calculated.

Radiological impact assessment

Thorium concentrations were determined in Malaysian monazite ore and in each stage of the chemical process to produce the thorium nitrate. Radiological impact was assessed based on the magnitude of radiation hazard and effective dose rates. All the data on the activity concentrations of thorium in each stage of process was obtained from converting the thorium concentration into ppm to Bq/g. The Annual Effective Doses Equivalent for public and workers were estimated using equation (3) as recommended by UNSCEAR 2000 [19].

$$\text{Annual Effective Dose Equivalent (mSv/y)} = \text{Dose rate at 1m (nGy/h)} \times \text{time (h/y)} \times \text{occupancy factor} \times \text{conversion factor (Sv/Gy)} \times 10^{-6} \quad (3)$$

where Dose rate is define as activity of Th (Bq/kg) x conversion factor for Th (0.604 $nGyh^{-1}/Bqkg^{-1}$), Time for public is define as 365 days x 24 hours = 8760 hours and working time for worker is define as 2000 hours. Occupancy factor for outdoor activity is 0.2 and conversion factor is 0.7 Sv/Gy.

Results and Discussion

Thorium and uranium in Malaysian monazite were determined via the NAA and gamma ray spectroscopy. The mean concentrations of thorium and uranium in Malaysian monazite are presented in Table 1. The activity concentrations of thorium and uranium were 15258.14 ± 28.71 ppm (62.41 ± 0.05 Bq/g) and 1445.68 ± 19.38 ppm (17.98 ± 0.24 Bq/g) respectively by gamma spectroscopy. Mean concentrations of thorium and uranium via the NAA were 17,990.52 ± 1,239.3 ppm (73.58 ± 5.07 Bq/g) and 637.29 ± 25.8 (2.61 ± 0.11 Bq/g) ppm, respectively. In addition, the relative error of the INAA for analysis of ^{232}Th and ^{238}U in IAEA 312N was determined and they were calculated as 4.59 % and 9.64 %, respectively. Because the concentration of thorium obtained from NAA was more accurate, it was used for the following calculations of the thorium separation and radiological impact assessment. The study indicated that the different results between these two techniques could be due to radioactive equilibrium, homogeneity problems or gamma rays interferences.

Table 1. Mean concentration of thorium and uranium (ppm) measured in Malaysian Monazite by NAA and Gamma ray spectroscopy

Element	NAA		γ- ray spectroscopy		AELB*
	ppm	Bq/g	ppm	Bq/g	Bq/g
Th-232	17,990.52 ± 1,239.3	73.58 ± 5.07	15258.14 ± 28.71	62.41 ± 0.05	1
U-238	637.29 ± 25.8	2.61 ± 0.11	1445.68 ± 19.38	17.98 ± 0.24	1

*The limit control is imposed by Atomic Energy Licensing Board

As seen from the results presented in Table 1, Malaysian monazite ore was rich with thorium compared to uranium. Moreover, the thorium concentration was much higher than the AELB control limit, and therefore, Malaysian monazite was classified as the radioactive mineral. The low level of uranium in Malaysian monazite does not cause

serious radiological hazard into the environment and public while thorium has a great concern due to its high level concentrations of ore and residue.

Separation of thorium

The study on digestion of Malaysian monazite showed that it could be achieved about 46.56 % of thorium recovery under the previously mentioned parameters and significant amount of thorium was left in the undigested monazite residue. Thorium recovery can be improved if the multi-stage digestion process is required. As a result of this, thorium will decrease in the residue and then reduce the hazard of radioactivity too. At high temperature (< 230 ºC) used in chemical digestion processing, the thorium is converted into refractory and insoluble form (thorium pyrophosphate) and subsequently removed it completely from the residue [8, 20 – 22]. In this study, the temperature was used less than 230 ºC to avoid forming insoluble thorium form. Table 2 shows thorium separation from sulphate leach solution and thorium recovery from Malaysian monazite.

Table 2. Thorium separation from sulphuric leach solution (pH 1.08 – 1.84 by 13.4 M NH_4OH)

Stage of Chemical Extraction Process	**Th Concentration (ppm)**	**Th Recovery* (%)**	**Th Separation (%)**
Monazite ore by NAA	17,990.52 ± 1,239.3		
Sulphuric leach solution	837.61 ± 11.7	46.56	
Selective precipitation			
Sulphuric leach solution in 100 mL	837.61 ± 11.7		
Thorium precipitate	260.10 ± 0.10		
Rich- RE filtrate	7.76 ± 2.93		97.68

*Thorium recovery percentage was calculated using 25 g of Malaysian monazite

The results of this separation showed that most of thorium was separated from the monazite sulphate solution by selective precipitation at pH 1.08 – 1.84 using ammonia. The percentage of the thorium separation obtained in this study was almost 97.68 % and only less than 3% of total thorium was left in the rich rare earth filtrate as shown in Table 2. Furthermore, the different pH and concentration of ammonia as a precipitant were affected the separation percentage results. The obtained thorium precipitate contained only a small amount of rare earth elements which was co-precipitated during the reduction of the acidity. Subsequent purification of thorium precipitated by solvent extraction is required to extract the thorium nitrate from rare-earth elements and other impurities.

Radiological impact assessment

Based on the high concentration of thorium in the Malaysian monazite ore samples (17,990.52 ± 1,239.3 ppm), the risk assessment performed indicates the thorium was responsible for the high risk. The average annual effective doses equivalent received by workers and public from Malaysian monazite were calculated to be 61.91 ± 4.27 mSv/y and 54.24 ± 3.73 mSv/y, respectively. These values are over 3 times for workers and 54 times for public of the annual dose limit.

Table 3 shows the annual effective dose equivalent for public and workers during the processing of 25 g Malaysian monazite. As previously mentioned the radiological risk of Th in each step of the monazite processing depends on distribution of thorium during the processing, whatever the purpose of separation is and whether separating thorium as a product or removing it from the residue in order to produce REEs. From Table 3, it is apparent that the annual effective doses equivalent received by public and worker resulting from 25 g of monazite ore were 1.36 and 1.56 mSv/y, respectively. The dose for public was higher than AELB requirement.

Table 3. Annual Effective Dose Equivalent for public and workers (mSv/y) during the processing of (25 g) Malaysian monazite

Stage of Process	Total content of Th (mg)	Activity of Th (Bq)	Annual Effective Dose Equivalent for public (mSv/y)	Annual Effective Dose Equivalent for worker (mSv/y)
Monazite ore (25 g)	449.76	1839.53	1.36	1.56
Sulphuric leach solution (250 mL)	209.40	856.46	0.63	0.72
Undigested monazite (residue)	240.36	983.07	0.73	0.83
Sulphuric leach solution in 100 mL	83.76	342.58	0.25	0.29
Thorium precipitate	26.01	106.38	0.08	0.09
Rich- RE filtrate	1.94	7.93	0.01	0.01

The results also show that single - stage digestion process decreased the dose to be become the half of the initial raw monazite. Several process stages are required for achieving the minimal thorium in the residue as well as improvement of the experiment parameters.

Undigested monazite residue may cause slightly radiological risk with the annual effective dose equivalent for public 0.73and 0.83m Sv/y for workers, therefore, it is required to manage safely especially whenever using large amount of monazite. However, during the processing of the monazite ore, the worker and public received lower dose in the range 0.72 – 0.01 and 0.63 – 0.01 mSv/y respectively. It may be seen that the radiological risk in the final stages was much less than the recommended value because thorium content was completely separated during the process.

From this scenario, it was indicated that the radiological risk decreases from the initial until the final process if the separation of thorium is well performed and safely managed. Moreover, comparing the radiological impact assessment of our study with LAMP, it can be seen that LAMP reported that maximum dose rates received by workers and pubic resulting from operation of the plant were 5.61 mSv/y and 0.002 mSv/y, respectively. These doses are below AELB requirement and those reported in our study. The present study showed that Malaysian monazite processing caused a significant radiological impact on workers and public.

Conclusion

The results of the current study showed that it was possible to achieve about 46.56 % of thorium recovery by signal stage digesting monazite with hot sulphuric acid and separation percentage of thorium from REEs in monazite leach solution was 97.68 % using selective precipitation by ammonia. The optimum parameters of separation were stated. It can be figured out that most of thorium was separated during ammonia precipitation and co-precipitated few amount of REEs. Improvement of the separation was required for several flows. The calculated maximum doses that could be received by workers are 61.91 ± 4.27 mSv/y and public 54.24 ± 3.73 mSv/y from the Malaysian monazite ore which were high than the control limits. However, the lower dose in the range of 0.01 – 0.72 and 0.01 – 0.63 mSv/y respectively was received by the worker and public during the processing of monazite. The results of the effective dose showed that a regulatory control is required to save the public and workers from these types of activities.

Abstract

The uptake of Acid Blue 29 (AB29), Reactive Orange 16 (RO16) and Reactive Red 120 (RR120) from aqueous solutions by calcined (CLDH) and uncalcined Mg/Al layered double hydroxide (LDH) has been investigated. The adsorption process was conducted in a batch mode at 25 °C. Anionic dye removal was more efficient using the CLDH rather than LDH. The adsorption process by CLDH involved reconstruction and hydration of the calcined LDH and intercalation of AB29, RO16 and RR120. Physical characterization using X-Ray Diffraction (XRD), Scanning Electron Microscopy (SEM) and Fourier Transform Infrared (FTIR) were used to ascertain the 'memory effect' phenomenon that is structural reconstruction to regain its original LDH after rehydration. To gain insight into the mechanism of adsorption by CLDH, the pseudo-first order (PFO) and pseudo-second order (PSO) and intraparticle diffusion (IPD) kinetic models were used to analyse experimental data. Based on the correlation coefficient (R^2), the PSO has better fitting (R^2 = 0.987 – 1.00) compared to PFO (R^2 = 0.867 –0.990). Furthermore the values of maximum adsorption capacity, (q_e) calculated from PSO model are consistent with the experimental q_e indicating that the experimental kinetic data for AB29, RO16 and RR120 adsorption by CLDH are suitable for this model. Recycling of the adsorbent, in cycles of calcination-reconstruction process promised a possibility of regeneration of CLDH.

Keywords: calcined, adsorption capacity, reconstruction, memory effect, regeneration

Abstrak

Penyingkiran pewarna Acid Blue 29 (AB29), Reactive Orange 16 (RO16) dan Reactive Red 120 (RR120) daripada larutan akues menggunakan Mg/Al dwi-hidroksida berlapis berkalsin (CLDH) dan tanpa kalsin (LDH) telah dilakukan menggunakan kaedah berkelompok pada suhu 25 °C. Penjerapan bahan pewarna menggunakan CLDH didapati lebih berkesan berbanding LDH. Penjerapan bahan pewarna oleh CLDH berlaku melibatkan proses penghidratan dan penstrukturan semula CLDH dan juga apitan AB29, RO16 dan RR120. Pencirian fizikal pada bahan penjerap yang diperolehi dengan menggunakan kaedah Pembelauan Sinar-X (XRD), Mikroskopi Imbasan Elektron (SEM) dan Spektroskopi Inframerah Transformasi Fourier (FTIR) telah digunakan untuk mengenalpasti fenomena 'kesan memori', iaitu proses penstrukturan semula kepada LDH selepas berlaku penghidratan. Cerapan lebih lanjut mengenai mekanisme proses penjerapan ini, model-model kinetik pseudo tertib pertama (PFO), pseudo tertib kedua (PSO) dan resapan intrapartikel (IPD) telah digunakan untuk menganalisis data ujian. Berdasarkan nilai pekali korelasi (R^2), model PSO didapati lebih sesuai (R^2 = 0.99 – 1.00) berbanding PFO (R^2 = 0.85 – 0.99). Fakta ini diperkukuhkan lagi dengan nilai kapasiti penjerapan maksimum, (q_e) hasil pengiraan menggunakan PSO yang didapati konsisten dengan q_e ujian ($q_{e,\ expt.}$) untuk AB29, RO16 dan RR120. Kitaran semula bahan penjerap melalui beberapa siri kitaran pengkalsinan-penstrukturan semula juga didapati dapat menjanjikan penjanaan semula CLDH.

Kata kunci: berkalsin, kapasiti penjerap, penstrukturan semula, kesan memori, penjanaan semula

Introduction

Dyehouse effluent usually contain various types of dye classes such as azo, anthraquinone, triphenylmethane,etc. Most of them are synthetic aromatic benzenoid compounds with potential toxic, mutagenic and carcinogenic properties, endangering human health and environment [1]. Generally, they are difficult to treat by conventional water treatment as they are structurally stable to biodegradation [2, 3].The most efficient colour removal from aqueous solution has been attributed to adsorption, which largely employs activated carbon (AC) as adsorbent. Since AC is commercially costly for large scale production and difficult to regenerate, alternative adsorbents are being sought. A positively charged anionic clay known as layered double hydroxide (LDH), with an empirical formula $[M^{II}_{1-x}M^{III}_{x}(OH)_2]^{x+}[A^{n-}_{x/n}\cdot mH_2O]^{x-}$, where M^{II} = Zn, Mg, Co, Ni and M^{III} = Al, Fe, Cr, Ga, etc., A^{n-} = CO_3^{2-}, NO_3^-, Cl^-, SO_4^{2-} [4, 5] is known for its versatile applications as well as excellent adsorbent for anionic species in aqueous solution.

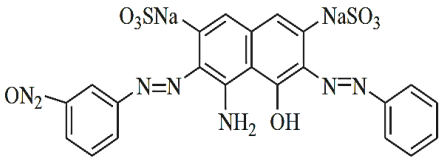
Calcination of LDHs at temperature 400 – 700 °C can decompose LDH containing carbonate or nitrate to release CO_2 or NO_x gas with end products containing a solid mixture of Mg–Al oxide, which can revert to the original structure (reconstruction) of LDH upon rehydration [1, 6]. This phenomenon, well known as 'memory effect' was responsible for enhanced uptake of anionic dye removal by CLDH in comparison to its precursor LDH. The objective of this study is to investigate the kinetic behaviour of AB29, RO16 and RR120 adsorption by CLDH in comparison to its precursor LDH, while at the same time to assess the possibility of regeneration of the adsorbent. Kinetic parameters are important pre-requisites for eventual design of water treatment processes employing the use of adsorbents such as LDH/CLDH. XRD, FTIR and SEM were used to characterize the adsorbents before and after dye adsorption by CLDH. Kinetic models, Lagergren's pseudo-first order [7], Ho's pseudo-second order [8] and intraparticle diffusion [9] were used to gain understanding of the adsorption mechanism of by CLDH.

Therefore, desorption or calcination study was undertaken to evaluate the prospect of regeneration and reuse of the adsorbent.

Materials and Methods

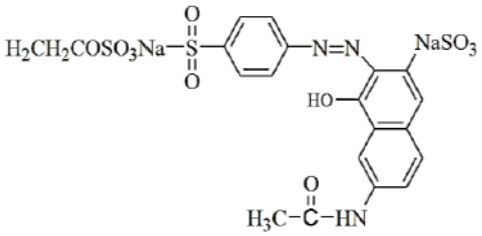
Preparation of adsorbent LDH by co-precipitation method

Synthesis of layered double hydroxide (LDH) of the formula, $[M^{2+}_{1-x}M^{3+}_{x}(OH)_2]A^{n-}_{x/n}.mH_2O$ with M^{2+} = Mg^{2+}, M^{3+}=Al^{3+} and interlayer anion, A^{n-} = NO_3^- was conducted by coprecipitation procedure followed by hydrothermal treatment as outlined by several authors [10 – 12], with slight modification. A solution of $Mg(NO_3)_2.6H_2O$ and $Al(NO_3)_3.9H_2O$ with molar ratio of Mg/Al:4/1 were allowed to mix with 1M NaOH by drop wise addition of NaOH at a rate of 1 mL/min, stirring the mixture all the time using a magnetic stirrer, while keeping N_2 gas bubbling in the solution mixture throughout the coprecipitation process. This was to minimize the inclusion of CO_2 in the solution. The N_2 addition was allowed to continue until the solution's pH reading reached 10.0 ± 0.5 in a 1L beaker. The resulting heavy slurry was poured into stoppered glass bottles, and then aged in a thermostated oil bath shaker operating at 70 °C, 100 rpm for 24 hours duration. Once the resulting white precipitate was cooled, it was washed several times with distilled water until the pH reached 7 – 8, to get rid of excess alkali, after which the solid was separated out by vacuum filtration. The final white solid, named layered double hydroxide (LDH) was dried (80 °C, 24 hours) before being ground and sieved.



Preparation of calcined LDH

Calcination of the synthesized LDH was carried out by heating LDH at a designated temperature (100, 200, 300, 400, 500, 600 and 700 °C) in a furnace (Lenton, UK) for 8 hours. The calcined product (henceforth referred to as CLDH100, CLDH200, etc.) was stored in a desiccator prior to characterization and adsorption studies. The calcined product (CLDHs) were subjected to contact time experiment to study which CLDH (CLDH100, CLDH200, CLDH300, etc.) gave the highest percentage of dye removal and adsorption capacity, and consequently selected for adsorption by CLDH in comparison with its precursor LDH. In carrying out this experiment for a particular dye, the dosage and volume (*W*/*V*) were kept constant.



Preparation of adsorbates

Aqueous stock solutions (1000 mg/L) of RR120, RO16 and AB29 were prepared, from which diluted solutions were obtained for batch adsorption analysis. The chemical structures and physical properties of the three dyes are shown in Figure 1.

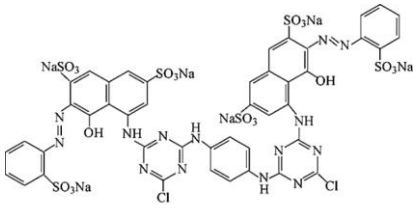

Figure 1. Chemical structures and physical properties of AB29, RO16 and RR120

Adsorption by calcined LDH (CLDH) and uncalcined LDH

The adsorption of AB29, RO16 and RR120 by LDH and CLDH was conducted in a batch mode in duplicates using initial concentration ranging from 50 to 100 mg/L with a constant dose of 0.2 g/L adsorbent at 25 ± 1°C in a thermostated water bath shaker, operating at 100 rpm. Since a previous separate experiment had shown that maximum removal for anionic and acidic dyes occurred at mild acidic pH, the batch adsorption of dyes under study was conducted at the pH of natural solutions without pH adjustment since the dyes are weakly acidic (5.6 – 6.6). This would be cost saving procedure since no extra cost for chemicals would be necessary. At the end of predetermined contact time (0 – 1440 min), the solution was filtered using 0.45 µm cellulose nitrate syringe filter (Whatman) so the remaining dye left in the solution can be measured using UV-Vis spectrophotometer (Secoman UVIKON SL/XS (M8307) at the wavelength of maximum absorption of each dye (Figure 1).

Adsorption data obtained were analysed for amount of dye adsorbed by the LDH and CLDH in terms of adsorption capacity (q_t, mg/g) and percentage dye removal (%) using the Equation (1) and (2), respectively

$$\text{Adsorption capacity, } q_t \text{ (mg/g)} = \frac{(C_0 - C_t)V}{W} \quad (1)$$

$$\text{Dye removal (\%)} = \frac{(C_0 - C_t)}{C_0} \text{ x } 100 \quad (2)$$

where, q_t is adsorption capacity in mg/g, C_o and C_t are initial and final dye concentrations (mg/L) after treatment for certain period of time, t; V is the volume of each dye solution (L) and W is the weight of adsorbent (g). At equilibrium time t_e, q_t=q_e.

Kinetic modeling

The data obtained from these experiments were used to evaluate the kinetic parameters. To gain insight into the mechanism of adsorption by LDH and CLDH, pseudo-first order (PFO) (Equation 3a), pseudo-second order (PSO) (Equation 4a) and intra-particle diffusion models (IPD) (Equation 5) were applied.

Pseudo-first order (PFO) model

The linear expression based on Lagergren's PFO rate equation [7] is represented by Eq. (3a):

$$\log(q_e - q_t) = \log q_e - \frac{k_1 t}{2.303} \quad (3a)$$

The initial rate h_1 (mg/g. min), at t=0 is defined by the following expression:

$$h_1 = k_1 q_e \quad (3b)$$

A linear plot of log(q_e -q_t) versus t enables the determination of k_1 (1/min) and q_e from the gradient and intercept of the plot.

Pseudo-second order (PSO) model

The linear expression for Ho's PSO rate equation [8] is represented by Equation (4a):

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (4a)$$

The initial rate h_2 (mg/g. min), at t=0 is defined by the following equation:

$$h_1 = k_2 q_e^2 \quad (4b)$$

A linear plot of t/q_t versus t enables the determination of k_2 (g/mg.min) and q_e, from the intercept and the slope.

Intraparticle diffusion (IPD) model

The possibility of IPD resistance affecting adsorption was explored by using the Weber-Morris IPD model [9] is represented by Equation (5):

$$q_t = k_p t^{0.5} + C \quad (5)$$

where k_p(g/mg.min) is the intraparticle diffusion rate constant and C. By plotting q_t versus $t^{0.5}$, the values of k_p was calculated from the slope. The value of constant C can be found from the intercept and is a measure of the thickness of boundary layer. Hence, the higher value of C, the greater the effect of boundary layer [13]. Based on IPD theory, the plot is linear if intraparticle diffusion is involved in the adsorption process. Additionally, if these lines pass through the origin then intra particle diffusion is the rate controlling step [14,15].

Desorption and regeneration

The residue after initial adsorption (0 cycle) by CLDH was thermally treated at its calcination temperature and the final product (regenerated CLDH) was again subjected to dye adsorption (1st cycle). This process was repeated until

the 4th cycle when the percentage removal of dye became less than 25 – 30 %. The reusability of regenerated adsorbent was based on percentage dye removal calculated for each cycle using Equation 2.

Characterization

Powder X-Ray Diffraction (PXRD) is a technique used to characterize the crystallite size (grain size), crystallographic structure, and the preferred orientation in polycrystalline or powdered solid samples. The X-ray diffraction (XRD) patterns of LDHs and CLDHs before and after adsorption were recorded using a PanAlytical (Germany) diffractometer under the following conditions: 40 kV, 25 mA, Ni-filtered Cu-Kα radiation (λ = 1.542 Å) and scanning rate of 2θ/min in the range of 10 – 70 °C. The XRD patterns enable the elucidation of basal spacings (d-spacings) of LDHs and CLDHs at pre or post adsorption of dye and give some indications of any change in crystallographic structure. Microstructural examination of LDH and CLDH was carried out using a Carl Zeiss SMT-Supra 40VP (Germany) scanning electron microscope (SEM) to study surface morphologies. The specific surface area of LDH and CLDH was obtained from adsorption/desorption isotherm of liquid N_2 at -196 °C following the standard Brunauer, Emmett and Teller (BET) method using using Micromeritics surface area analyser (USA).

Results and Discussion

Calcination temperature of Mg/Al LDH

Figure 2 shows the results based on a preliminary investigation on percentage of dye removal using LDH calcined at various temperatures (200 – 700 °C). It is obvious that dye removal percentage was highest with LDH calcined at 500 °C (CLDH500). Upon calcination, LDH was transformed to aluminium and magnesium oxides by the loss of interlayer anions, causing the adsorption of dye to increase in the temperature range 200 –500 °C, reaching the highest at 500 °C, corresponding to complete or almost complete decomposition of interlayer nitrate (Equation 6). Until this stage, the process was reversible; it was able to reconstruct its original LDH structure (memory effect) by incorporating anions such as water or anionic dyes or others (Equation 7). Above 500 °C, CLDH was transformed into a spinel which lost the property of reconstruction and reversibility, resulting in the observed decrease in dye adsorption. Other researchers using calcined Mg/Al-LDH to remove pollutants had also used the same temperature (500 °C) to obtain calcined LDH [16 – 18]. Based on this result, subsequent adsorption experiment was conducted using CLDH500.

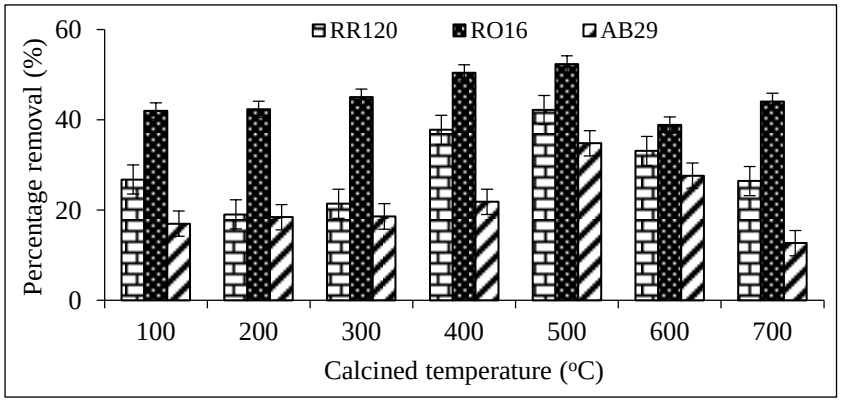

Figure 2. Percentage of dye removal by CLDHs calcined at different temperatures

Decomposition:

$$Mg_{1-x}Al_x(OH)_2(NO_3)_{x/2}.mH_2O \xrightarrow{500\ ^oC} Mg_{1-x}Al_xO_{1+x/2} + (x/2\ NO_2) + (m+1)H_2O \quad (6)$$

Regeneration:

$$Mg_{1-x}Al_xO_{1+x/2} + (x/n)A^{n-} + (m + 1 + (x/2) + y)H_2O \longrightarrow Mg_{1-x}Al_x(OH)_x(A^{n-})_{x/n}.mH_2O + xOH^- \quad (7)$$

Characterization of calcined and uncalcined LDH

X-Ray diffraction

The XRD pattern of precursor LDH in Figure 3(a) consists of three intense lines at low 2θ angle equivalent to diffraction by planes (003), (006) and (009) [7]. These sharp and symmetric peaks indicate the formation of a single well crystallized $MgAlNO_3$. The interlayer distance or (d_{003}) and (d_{006}) of LDHs corresponding to 8.01 Å and 3.99 Å, are due to basal reflections of crystal lattice, indicating successive layer stacking of the brucite-like lamellar sheets of hydrotalcite-like LDHs (ICSD collection code 086655). These values, together with other non- basal spacings at 1.54 Å (d_{110}) and 1.51 Å (d_{113}) are consistent with typical XRD pattern of LDH as reported by several authors [1, 3, 19 – 21]

Calcination up to 500 °C led to the progressive loss of physiosorbed water molecules, then the interlayer water and finally water from dehydroxylation of the brucite layer. The dehydration process was accompanied by the loss of interlayer anion leading to the collapse of the lamellar structure of LDH with the formation of mixed metal oxides $MgO\text{-}AI_2O_3$. As implied in the XRD pattern in Figure 3(b), the layered structure of the original LDHs has been destroyed in CLDH500 (CLDH) as evident from the significant absence of d_{006} and d_{003} peaks. Instead broad diffraction peaks appeared suggesting low structural order with almost total decomposition of the original LDHs with elimination of most interlayer nitrate anions and water. The XRD patterns of CLDH now resemble that of rock salt MgO whose reflection has shifted to higher angle due to the presence of Al^{3+} in in $Mg_{(1-x)}Al_xO_{(1+x/2)}$ [17]. No separated phases for Al^{3+}cations (Al_2O_3) were observed, indicating that these cations were dispersed in the MgO matrix solid solution [19], which is capable of being restored to LDH when rehydrated [5]. These observations were consistent with CLDH patterns cited in the literatures [1, 3, 17]. Figures 3(c – e) also shows that the diffraction patterns of dye- loaded CLDHs displaying peaks corresponding to (d_{003}) and (d_{006}) which are similar to the original LDH's XRD pattern. However the resulting peaks were broadened and with decreased peak intensity. This implies some reduction in crystallinity as a result of calcinations, rehydration and structural reconstruction which have occurred [21]. Due the 'memory effect', the CLDH was able to reconstruct and regain its original LDH when rehydrated [5].

After reconstruction, the basal spacings, notably (d_{003}) were observed to have increased in the dye-loaded CLDH (8.55 Á, 8.47 Á and 8.86 Á), indicating some increase in the interlayer distance. Theoretically, the increase in basal spacing (d_{003}) and (d_{006}) may indicate some dyes were intercalated into the spacing. Being bigger molecule than nitrate, the dye intercalated in the interlayer spacing was expected to result in an increase of the basal spacing or gallery height of the lamellar LDH. However, since the increase was not significantly large, it considered that total intercalation has indeed taken place [5]. The structural reconstruction property, called 'memory effect' forms the basis of regeneration for adsorbent LDH and the main mechanism of dye adsorption by CLDH though surface adsorption is presumed to have taken place as well [19]. This should be possible as surface area of calcined LDH has been reported to increase compared to its precursor LDH. On the basis of larger surface area of CLDH relative to LDH, it is fair to assume that CLDH offers better adsorption efficiency than its precursor.

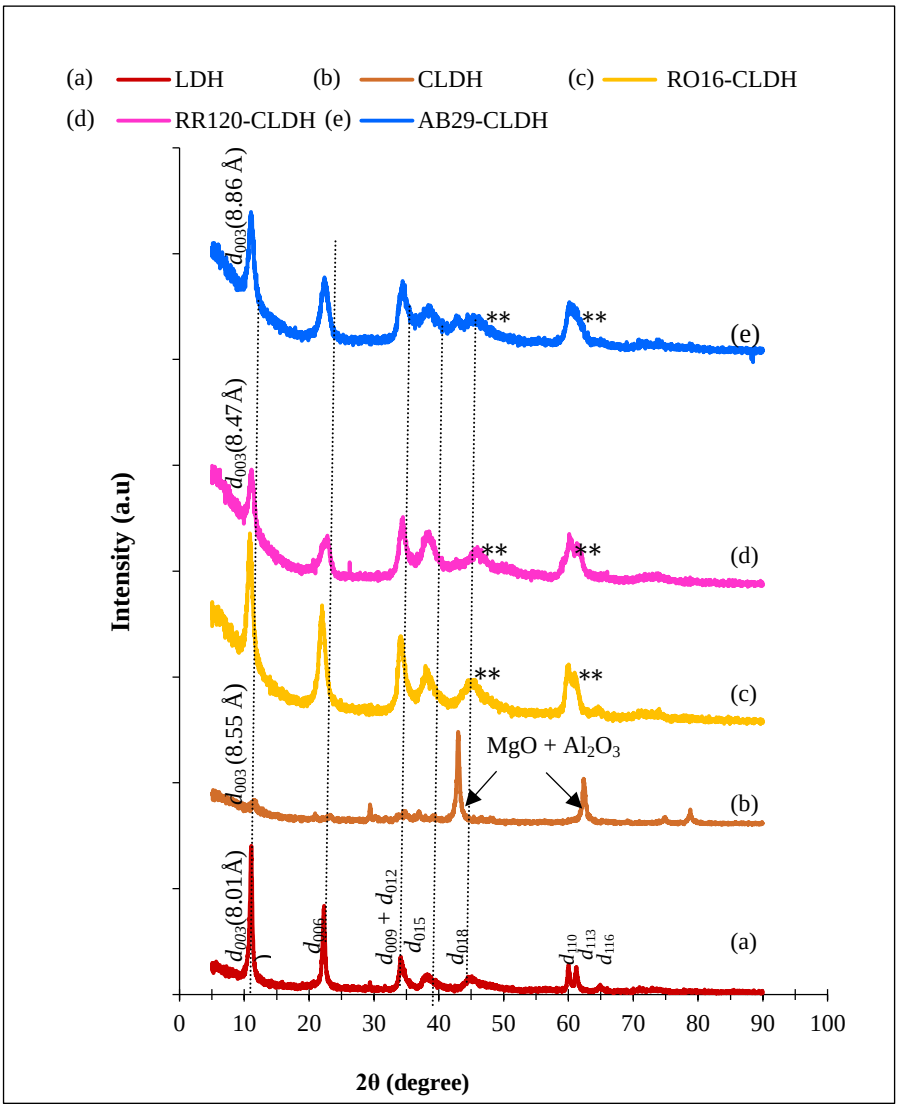

Figure 3. X-Ray Diffraction for LDH, CLDH and Dye loaded CLDH

Scanning electron microscopy

The textural properties of the LDH, CLDH and dye-loaded CLDHs have been investigated by scanning electron microscopy, as shown in Fig. 4 (a – e). It can be seen that the LDH image presents thin irregular aggregates of hexagonal platelets while CLDH resembles bigger platelets with rounded edges, with some still retaining the hexagonal-shaped of precursor LDH materials that were still retained in the CLDH product. This observation was understandable since both LDH and CLDH gave the same N_2 adsorption-desorption analysis results [21]. It has been reported that during thermal decomposition of LDH, the evolution of gas such as CO_2 (from carbonate) or NO/NO_2 (NO_x) from nitrate took place through fine pores at the brucite-like ($Mg(OH)_2$) layers, inducing the creation of channels and chimneys, which account for the increase surface area for calcined LDH. Since adsorption is a surface phenomenon, increase in surface area would enhance adsorption by CLDH. In the current study, the BET surface area for CLDH was found to be 121.58 m^2/g compared to 82.74 m^2/g for uncalcined LDH. Closer examination on SEM images in Fig.4 (a – e) reveals that dye materials have been incorporated onto the CLDH.

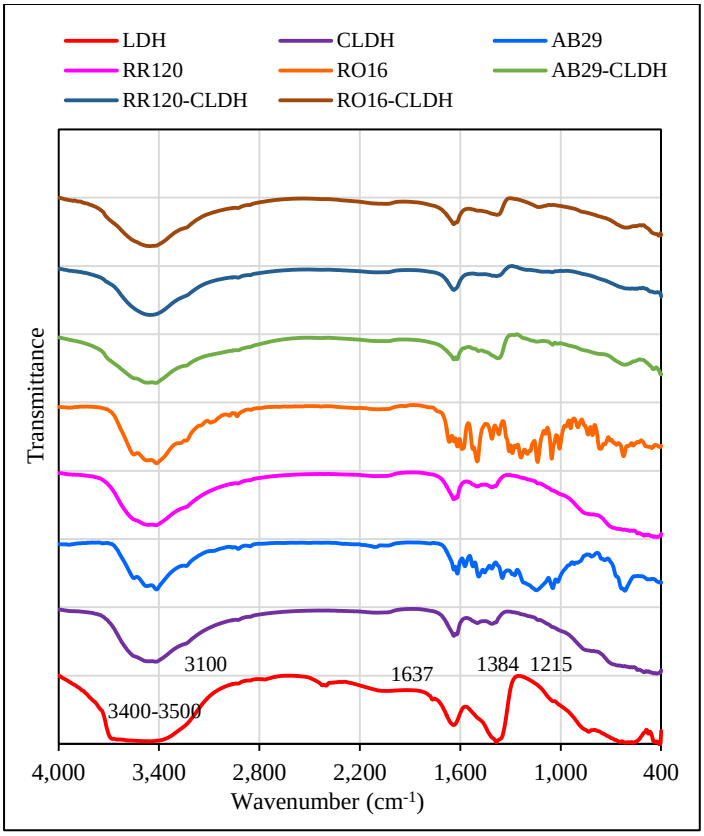
Infrared spectra

The FTIR spectra of LDH, CLDH and dye-loaded CLDHs are presented in Figure 5. The LDH spectrum resembles that of other hydrotalcite-like phases with NO_3^- as the interlayer anions. The broad band at 3455 –3500 cm^{-1}, with a weak shoulder near 3100 cm^{-1} is due to the interlayer water molecules and the H-bonded stretching vibration respectively [7, 22, 23]. The weak peak at 1637 cm^{-1} may be assigned to the H_2O bending vibration of interlayer water, while the strong peak at 1384 cm^{-1} is attributed to the vibration of nitrate species. The bands in the range of 500 – 700 cm^{-1} are indicative of metal–oxygen–metal stretching [23].

Figure 5 shows the absorption bands of dye-loaded CLDH. It may be not plausible to exactly quantify the amount of NO_3^- the LDH or CLDH by FT-IR spectroscopy, but the reduced intensity of the nitrate peaks with reference to the broad band at 3450 cm^{-1} and at 1637 cm^{-1} after dye uptake indicate that anion exchange between NO_3^- ion and dye molecules did take place. The absorption band at around 1421 cm^{-1} in CLDH is indicative of the presence of CO_3^{2-} in the interlayer. The presence of CO_3^{2-} as an impurity may be difficult to avoid under the prevailing experimental conditions with the readiness of CLDH to take up moisture containing CO_2. The expected intercalation of dye in the CLDH interlayer may also be discerned by the presence of absorption band in the region around 1200 cm^{-1} which can be attributed to C-H bending vibration of aromatic dye molecules. The band occurring between 1450 cm^{-1} and 1380 cm^{-1} corresponds to the stretching mode of an azo-compound. The presence of sulfate S=O stretching vibration bands at around 1000 –1250 cm^{-1} and 1065 cm^{-1} due to sulfonic group in the dyes' structures were also observed. The result indicated that the dyes had existed on the surface of the CLDH after adsorption.



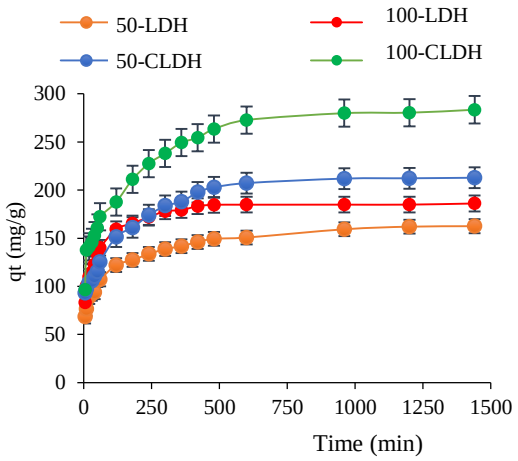


Figure 5. FTIR spectra of LDH, CLDH, dyes and dye-loaded CLDH, respectively

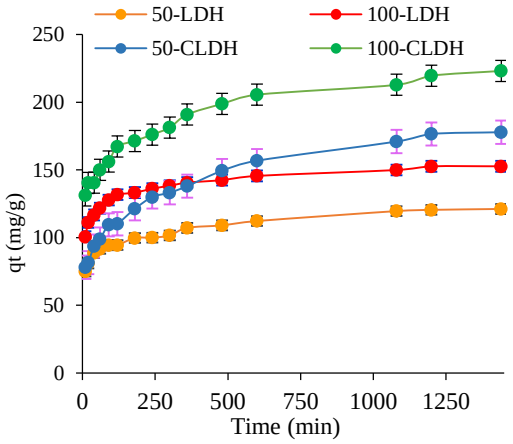
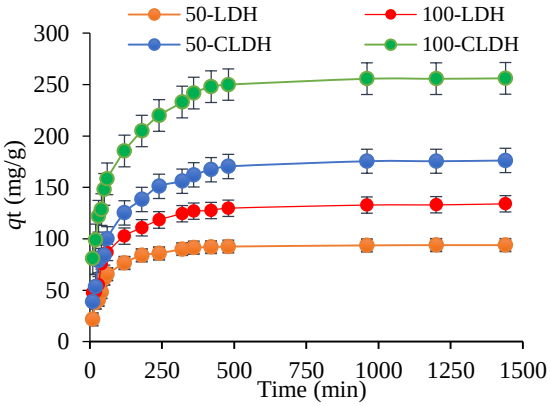
Effect of contact time and initial dye concentrations



The effect of contact time on and initial concentrations on dye removal by CLDH was compared with dye removal by LDH. The results for AB29, RO16 and RR120 are depicted in Figure 6 (a – c) for adsorption capacity, q_t, mg/g. Figure 6 shows that adsorption capacity increased with increased contact time until equilibrium was attained and thereafter remained almost unchanged after contact time of approximately 150 –180 min. For both LDH and CLDH, the adsorption capacity of dye increased rapidly within the first 10 – 20 min, after which the rate of adsorption decreased with time until it gradually approached a plateau due to the continuous decrease in the concentration driving force.

The time curves of dye removal for concentrations 50 – 100 mg/L in Figure 6 (a – c) are smooth and continuous indicating the possibility of a monolayer formation on adsorbent surface [16][23]. As Figure 6 (a – c) depict, the maximum adsorption capacity by CLDH and LDH decreased with increasing initial dye concentration as the number of moles of dye competing for the available surface area of the adsorbent which was fixed for a constant adsorbent dose, increased [16]. The most significant observation in this experiment was the enhanced dye uptake, both in terms of percentage dye removal and adsorption capacity by CLDH over its precursor LDH for any given initial dye concentration. Examples of this elevated dye removal by CLDH over its precursor LDH are highlighted for 50 and 100 mg/L dye concentration for AB29, RO16 and RR120 in Table 1, which shows the values of q_t (mg/g). Calculation for (dye uptake by CLDH/dye uptake by LDH) ratio reveals that the increase was between 150 – 200 %. The increase uptake by CLDH was attributed largely to the 'memory effect' phenomenon which is synonym with structural reconstruction by calcined LDH to its original layered structure when exposed to aqueous solution containing ions such as simple inorganic ions (eg. CO_3^{2-}, SO_4^{2-}, SeO_3^{2-}, CO_3^{2-}, NO_3^-, Cl^-) or polar organic molecules [5]. Among the three dyes, AB29 exhibit the highest dye uptake followed by RO16 and RR120, the same



trend as uptake by pristine LDH. This trend is reflective of binding capacity of these dyes towards the adsorbent LDH and CLDH.

Kinetic of adsorption

The kinetic parameters for PFO, PSO and IPD kinetic models for dye-LDH and dye-CLDH obtained using experimental data for Figure 6 are summarised in Tables 2, 3 and 4, respectively. It is apparent that the values of correlation coefficient (R^2) are mostly quite high (> 0.9) for PFO, PSO and IPD models. Based on the correlation coefficient (R^2), it can be seen that PSO have better fitting (R^2 = 0.99 – 1.00) than PFO (R^2 = 0.85 –0.99). Furthermore the values of q_e calculated ($q_{e,alc}$) from PSO model are more consistent with the experimental q_e ($q_{e,expt.}$), indicating that the experimental kinetic data for AB29, RO16 and RR120 adsorption by LDH and CLDH are suitable for this model. Similar finding was obtained by [17] on Reactive Orange 10 adsorption by CLDH. In addition, the values of ($q_{e,\ calc}$) and q_e ($q_{e,expt.}$) shows that maximum adsorption capacities are higher for CLDH than

those by LDH. The results are consistent with CLDH being a more efficient adsorbent than LDH as dye scavenger from solution. The order of adsorption affinity for adsorbent is reflected from the values of the adsorption capacities. It can be seen that the order of affinity of adsorbent for dyes under study is AB29 >RO16 > RR120. This trend was obeyed by systems, dye-LDH and dye-CLDH.

Table 1. Comparison between dye uptake by LDH and CLDH in terms of adsorption capacity, ($q_{t,expt}$) at t=24 h, T=25 ^{o}C, W/V=0.2g/L for AB29, RO16 and RR120, respectively

Dye	**Adsorbent**	**Concentration**	
		50 mg/L	**100 mg/L**
		qt (mg/g)	**qt (mg/g)**
AB29	LDH	162.501	186.100
	CLDH	212.830	283.506
RO16	LDH	121.160	152.655
	CLDH	177.858	268.140
RR120	LDH	96.338	133.979
	CLDH	176.155	256.074

To understand this trend, factors that influence dye binding capacity to adsorbent have to be considered. These factors include the characteristics and chemistry of the dye such as molecule structure, molecular weight, spatial and steric effect, all of which exert influence on the adsorption onto adsorbent either singly or in concert with other factors present in the aqueous environment. In this case AB9 and RO16, having smaller size than RR120 would be more unhindered during adsorption compared to the bulkier RR120 in terms of spatial and steric effect, even though RR120 has six sulfonic groups (SO_3^-) compared to two in AB29 and RO16. As a result RR120 would have less mobility in attaching itself to adsorbent, even though the sulfonic groups render negative charge to the RR120, thus enhancing the dye ability to attach itself onto positively-charged adsorbent. In terms of negative charges, AB29 would be expected to have similar binding capacity. The fact that acid dye AB29 displayed better binding capacity than vinylsulphone reactive dye RO16 is probably due to a side reaction of RO16 in water. The vinylsulphone group ($-CH_2CH_2SO_2$ -) in RO16 is electron attracting group which induces electron deficiency on the terminal carbon atom, initiating a nucleophilic (addition reaction) attack by electron rich hydroxyl ion, OH^- from water. This hydrolysis can be represented by the reaction:

$$\text{Dye-}SO_2CH = CH_2 + \text{H-OH} \longrightarrow \text{Dye-}SO_2\text{-}CH_2\text{-CH2-OH} \quad (8)$$

As a result of this hydrolysis, RO16 is less available for binding sites on LDH/CLDH with an overall reduction in binding capacity of RO16.

The resulting IPD linear plots of q_t versus $t^{0.5}$ (not shown) show the existence of two or three-staged linear curves, none of which pass through the origin. This is an indication that IPD was not the sole rate limiting step. Moreover, the existence a two or three-linear phases for each concentration implies that most likely the adsorption process involved more than one rate equation.

The calculated values of IPD rate constant, k_p, C and the R^2 values summarized in Table 4 were obtained through fitting the experimenal data at second linear portion of Equation (3)[24]. The correlation coefficients for IPD diffusion model obtained are between 0.746 and 0.979. The R^2-values are quite high and some are close to unity

indicating the validity of application of this model. The values of IPD rate constant, k_p decreased with decreasing initial dye concentration which provided the driving force in overcoming the resistance due to mass transfer [24] and was found to be correlated with the initial dye concentration. The values of *C* give an idea about the thickness of the boundary layer, i.e. the larger the intercept the greater is the boundary layer effect (mass resistance), and the greater is the contribution of the surface adsorption in the rate limiting step[25]. In conclusion the adsorption mechanism of dye uptake by LDH is quite a complex process and cannot be explained by a single kinetic model alone, but could have involved more than single type of kinetic mechanism, all of which may be operating simultaneously [26][27].

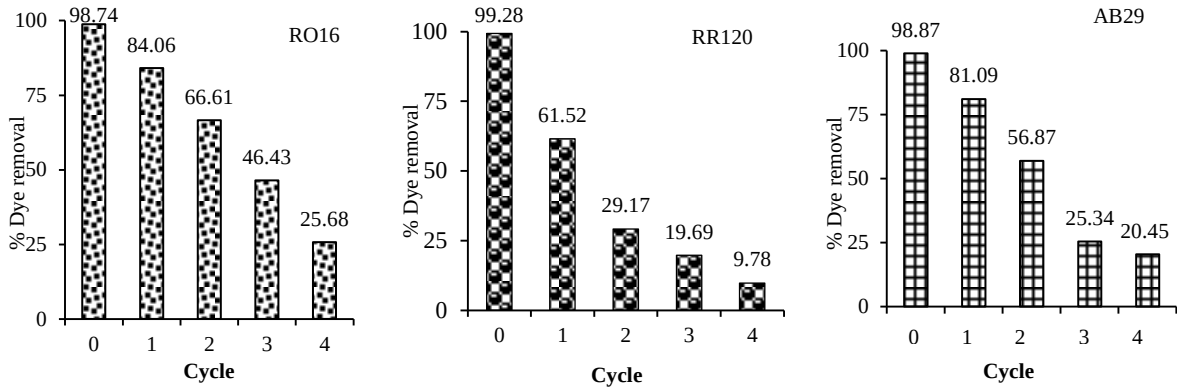
Mechanisms of adsorption by CLDH

Results on dye removal had shown that CLDH exhibited better efficiency than its precursor LDH in removing anionic dyes from solution. The resulting calcined LDH (CLDH) has higher specific surface areas compared to its precursor LDH. Since adsorption is a surface phenomenon, this could be a major factor accounting for the significant increase in the anionic dye affinity for CLDH. During calcination process, fine pores and channels were generated as H_2O vapor and NO_2/NO gas were evolved, resulting in the creation of chimneys and channels in the particles, which ultimately resulted in the increase in specific surface area and smaller pores in the mesoporous CLDH particles.



The diffactograms of calcined materials shown in Figure 3 show that the CLDH displayed its 'memory effect' by reconstructing to its former LDH structure as evident through the re-emergence of (003) and (006) reflections. This is further supported by the observed of somewhat broadened, less symmetrical peaks with reduced intensity in comparison to the original LDH, indicating less ordered platelet–like structure and crystallinity [5], typical of post adsorption products following rehydration and reconstruction. It has been postulated that intercalation via reconstruction had played a role in this process of adsorption by CLDH according to Eq. (8), given the relatively slow increase in dye adsorption as dye concentration was increased (Figure 6). This 'memory effect' may be construed as a reconstruction reaction expressed as expressed by the preceding Equation (8) [21].

It may be concluded that under prevailing conditions, external surface adsorption appeared to be the main mechanism in the adsorption. Furthermore, the peaks corresponding to MgO in CLDH still remained in all CLDH products, indicating that reconstruction was not complete.

Regeneration and recyclability

Regeneration of adsorbent for possible reuse gives an advantage commercially and economically to an adsorbent. The results from four cycles of regeneration were obtained from calcination-hydration process whereby the adsorbed dyes was combusted during calcination, followed by rehydration of the regenerated adsorbent LDH in the

dye solution. As shown in Figure 7, the thermally treated LDHs, exhibited progressive loss in percentage dye removal after each cycle. This percentage loss varied for each dye. After four cycles the efficiency has been reduced to almost 10 – 25 %, and may be regarded as uneconomical for further regeneration. A possible reason for the reduced efficiency is the reduced crystallinity of adsorbent, after undergoing repeated calcination-hydration process [28].

Co= 50 mg/L; *W*/*V*= 0.1 g/50 mL, 25 ^{o}C

Figure 7. Regeneration of CLDH after adsorption by RO16, RR120 and AB29

Conclusion

The adsorption of AB29, RO16 and RR120 was much more efficient by CLDHs than LDHs. Similarly, the adsorption capacities of CLDHs were much higher than that of its precursor LDHs. The affinity towards dye removal follows the order: AB29 > RO16 > RR120. Therefore CLDHs may be recommended for use in sequestering higher concentration of anionic dyes, while LDHs may be more appropriately used for low concentrations. The kinetics of adsorption of anionic dyes was well described by PSO reaction while PFO reaction and IPD kinetics may have contributed to the overall mechanism of dye uptake. Reconstruction of LDH via rehydration and intercalation was evident from X-ray diffraction and FTIR spectroscopy analysis. Recycling and reuse of LDH/CLDH was possible, until the fourth cycle when this is no longer economical. For better performance, only the second and third cycle may be considered when the percentage dye removal could still be maintained at 50 – 66 % for these dyes.

Abstract

This study was carried out to evaluate the chemical changes in short-bodied mackerel during chilled (4 °C) and frozen (-18 °C) storage for 18 days. The chemical changes were monitored at three days interval using Peroxide Value (PV), Thiobarbituric Acid (TBA), Total Volatile Base Nitrogen (TVBN) and Trimethylamine (TMA) tests. The PV of both chilled and frozen mackerel significantly increased ($p < 0.05$) with storage time and the rate was significantly higher in chilled than frozen mackerel. Based on the results, the chilled and frozen mackerel started to become rancid at day 15 and day 18, respectively. Similar trend was observed for TBA value, where the malonaldehyde content significantly increased ($p < 0.05$) for both chilled and frozen mackerel with storage time, and the rate of increase was higher in chilled than frozen mackerel. The TVBN and TMA of chilled mackerel increased significantly during storage time, but the values declined in frozen mackerel which might be due to inhibitory effects of freezing on the bacterial activities and hence avoid accumulation of TMA. Based on the chemical analyses, chilled mackerel spoiled rapidly compared to frozen mackerel.

Keywords: short-bodied mackerel, thiobarbituric acid, peroxide value, total volatile base nitrogen, trimethylamine

Abstrak

Kajian ini telah dijalankan untuk menilai perubahan kimia dalam tisu otot ikan kembung bertubuh pendek semasa penyimpanan pada suhu dingin (4 °C) dan suhu sejuk beku (-18 °C) selama 18 hari. Perubahan kimia telah dipantau selang tiga hari menggunakan ujian Nilai Peroksida (PV), Asid Tiobarbiturik (TBA), Jumlah Bes Nitrogen Meruap (TVBN) dan Trimetilamina (TMA). Nilai Peroksida ikan kembung pada kedua-dua suhu dingin dan sejuk beku meningkat dengan ketara ($p < 0.05$) semasa penyimpanan dan kadar peningkatan PV lebih ketara bagi ikan kembung yang disimpan pada suhu dingin berbanding suhu sejuk beku. Berdasarkan keputusan yang diperolehi, ikan kembung pada suhu dingin dan sejuk beku masing – masing menjadi tengik pada hari ke 15 dan ke 18 penyimpanan. Pola yang sama diperolehi bagi nilai TBA, di mana kandungan malonaldehid meningkat dengan ketara ($p < 0.05$) bagi kedua-dua ikan kembung pada suhu dingin dan suhu sejuk beku semasa penyimpanan, dan kadar kenaikan malonaldehid adalah lebih tinggi terhadap ikan kembung pada suhu dingin. Nilai TVBN dan TMA ikan kembung pada suhu dingin meningkat dengan ketara semasa penyimpanan. Walau bagaimanapun kedua-dua nilai ini menurun bagi ikan kembung sejuk beku disebabkan kesan perencatan sejuk beku terhadap aktiviti bakteria dan seterusnya mengelakkan pengumpulan TMA. Berdasarkan analisis kimia ini, ikan kembung dingin rosak lebih cepat berbanding dengan ikan kembung sejuk beku.

Kata kunci: Ikan kembung bertubuh pendek, asid tiobarbiturik, nilai peroksida, jumlah bes nitrogen meruap, trimetilamina

Introduction

Fish is one of the most highly perishable food products [1] due to high concentrations of free amino acids and volatile bases [2]. In addition, fish is highly susceptible to oxidative rancidity due to large amount of phospholipids containing polyunsaturated fatty acids. Sallam [3] reported that there is a complex process of deterioration occurs in fish which are physical, chemical and microbiological reactions degrading the quality of fish thereby may cause approval or rejection after prolonged storage.

Oxidative rancidity is an autoxidation or hydrolysis process of fats into short-chain aldehydes and ketones and is responsible for rancid flavor and odour. When this process occurs in food, it may result in food rejection even though the food had been held under chilled or frozen storage. Nowadays, Total Volatile Base Nitrogen (TVBN) and Trimethylamine (TMA) are widely used to determine the quality of fish and are very good indicators to measure the trimethylamine, dimethylamine, ammonia and other basic nitrogenous compounds which were produced by spoilage bacteria, autolytic enzyme at frozen temperature, deamination of amino-acids and nucleotide catabolites that are associated with fish spoilage.

Monitoring fish quality is important in many food industries to produce high quality product when fish was used as one of the ingredients. Hence, the objective of this study was to evaluate the chemical changes in muscle tissue of short-bodied mackerel based on PV, TBA, TVBN and TMA tests during 18 days of storage at chilled (4 °C) and frozen (-18 °C) temperature.

Materials and Methods

Sample preparation

Short-bodied mackerel (*Rastrelliger brachysoma*) with average size of 15 to 20 cm and weight of 50 to 100 g were bought fresh from wet market, Kuala Pilah, Negeri Sembilan, Malaysia. The fish were placed in boxes with ice and immediately delivered to the laboratory. Short-bodied mackerel were eviscerated and cleaned before packed in the plastic containers. Then, samples were stored at chilled (4 °C) and frozen (-18 °C) temperature for 18 days and were analysed for PV, TBA, TVBN and TMA every 3 days.

Chemical analyses

All the chemicals used were of analytical grade and were obtained from CHEMOLAB Supplies, Seri Kembangan, Selangor, Malaysia.

Peroxide value (PV) test

Peroxide value of short-bodied mackerel was determined according to method described by AOAC [4] and oil was extracted based on method proposed by Razak et al [5]. The results were determined in terms of miliequivalent of peroxides per kg of fish.

Thiobarbituric acid (TBA) test

The TBA was measured according to the method of Tokur et al [6]. Ten gram of fish was mixed with 100 mL of 0.2 M hydrochloric acid and homogenised prior to distillation (Behr Labor-Technik GmbH, Germany). Approximately within 5 minutes, 50 mL of distillate was collected. An amount 5 mL of distillate was pipetted into test tube and 5 mL of TBA reagent was added. The sample was heated for 30 minutes and was allowed to cool immediately under running tap water. Blank was prepared using distilled water. A pink colour solution was produced and the colour absorbance was measured using a single beam spectrophotometer (Genesys 20 Thermo Scientific, USA) at 538 nm. The spectrophotometric results were multiplied by a constant value of 7.8 and the TBA values were expressed as mg malonaldehyde per kg fish.

Total Volatile Base Nitrogen (TVBN) and Trimethylamine (TMA) test

The TVBN and TMA were measured by distillation method according to method reported by Orak and Kayisoglu [7]. The fish extract was prepared by homogenising 100 g of sample with 200 mL of 7.5 % (v/v) aqueous trichloroacetic acid solution, after which the solution was filtered through Whatman No.1 filter paper. An amount 25 mL of filtrate was poured into a distillation tube followed by 5 mL of 10 % (w/v) aqueous sodium hydroxide solution and distilled for 3 minutes. Distillate was collected in 15 mL of 4 % (v/v) boric acid that contained 0.04

mL indicator (methyl red and bromocresol green) until final volume was up to 50 mL and then titrated with 0.05 M sulfuric acid. For TMA measurement, the same experimental procedure was carried out as in TVBN and the only difference was the addition of 20 mL of 35 % (v/v) formaldehyde to the distillation tube. The amount of TVBN and TMA were calculated from the volume of 0.05 M sulfuric acid used for titration and the results were expressed in mg N/100g of fish. The following formula equation 1 was used [8]:

$$\text{TVBN or TMA (mg N per 100 g)} = \frac{14(\text{g/mol}) \times a \times b \times 300}{\text{Volume of filtrate}} \quad (1)$$

where, a is defined as volume (mL) of sulfuric acid, b is defined as molarity of sulfuric acid

Statistical analysis

All analyses were carried out in triplicate. Statistical analysis of data was carried out using analysis of variance (ANOVA) and the analytical procedure of Scientific Package of Social Science (SPSS) 15.0. Duncan's multiple-range test was used to determine the differences among mean values between storage conditions and storage time at $p < 0.05$.

Results and Discussion

Figure 1 indicated the PV of both chilled and frozen mackerel significantly increased ($p < 0.05$) with storage time and generally the rate was significantly higher in chilled than frozen mackerel. The chilled and frozen mackerel started to become rancid as the PV were beyond the acceptable limit at day 15 (2.10 mEq/kg) and day 18 (2.28 mEq/kg), respectively. According to Orak and Kayisoglu [7], the acceptable limit for peroxide value was 2.0 mEq/kg. Fish oil is one of the highly unsaturated oils where peroxides initially formed are unstable and can react quickly to form secondary oxidation products [9]. Therefore, PV measurement alone is not a parameter reliable in measuring the oxidation of fish oil and for this reason the PV should be used in conjunction with other methods such as TBA test.

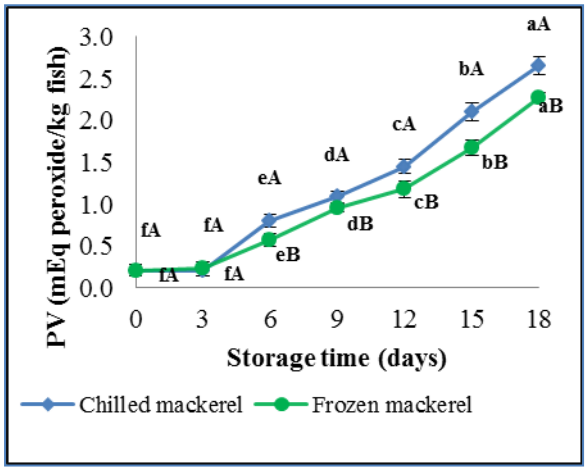

Figure 1. Changes in Peroxide Value of short-bodied mackerel in chilled and frozen storage for 18 days. Values are expressed as mean (A, B) and (a, b, c) marked with different letters were significantly different at $p < 0.05$. Lower case letters indicate the effect of storage time on short bodied-mackerel while upper case letters indicate the effect of storage conditions.

The TBA value is widely used as an indicator for the degree of lipid oxidation according to Tokur et al. [6]. The TBA number is a measurement of malonaldehyde (MDA), which is a by-product of lipid oxidation. The MDA

content was significantly increased ($p < 0.05$) with storage time for both chilled and frozen mackerel, and the rate of increase was higher in chilled than frozen mackerel (Figure 2). Similar phenomenon was reported by Boran et al. [2] where the PV and TBA in fish oils extracted from horse mackerel, shad, garfish and golden mullet were increased with increasing storage time for both storage temperatures. The increasing of the TBA values during frozen storage also has been demonstrated by Rosari et al. [10] where with longer storage days, the TBA values were increased slowly but still not reaching the rejection limit at day 18 for milkfish.

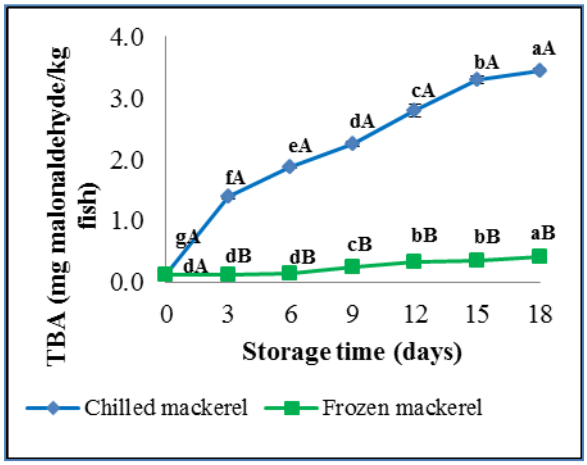

Figure 2. Changes in Thiobarbituric acid (TBA) of short-bodied mackerel in chilled and frozen storage for 18 days. Values are expressed as mean (A, B) and (a, b, c) marked with different letters were significantly different at $p < 0.05$. Lower case letters indicate the effect of storage time on short bodied-mackerel while upper case letters indicate the effect of storage conditions.

The TVBN is a term that includes measurement of trimethylamine, dimethylamine, ammonia and other volatile compound associated with fish spoilage, which increases as spoilage progresses. Figure 3 showed the TVBN of chilled mackerel increased significantly ($p < 0.05$) during storage time, but the values for frozen mackerel declined slowly. A similar pattern of increasing in TVBN values for the control has been reported by Sallam [3] during shelf life evaluation of sliced salmon at chilled condition. According to Raouf et al. [11], this trend was due to the denaturation of muscle protein by surviving microorganisms. On the other hand, the decrement of TVBN values in frozen mackerel may due to the fact that low temperature caused the bacteria become inactive and hence slower the rate of deterioration. The acceptable limit for TVBN that had been stipulated by literatures [7, 12] was 35 mgN/100g sample. Hence, in this study the chilled mackerel had reached the maximum limit at day 9 with TBVN value of 69.91 mgN/100g.

Changes in TMA levels were shown in Figure 4 where similar pattern had been demonstrated in TVBN results for both chilled and frozen mackerel. Trimethylamine (TMA) is usually used to determine the quality of fish because it is rapidly accumulated in the fish muscle under chilled condition. The TMA is always related to the pungent odour occurred in fish muscle and in this study, only chilled mackerel gave pungent odour while frozen mackerel still maintain the fishy odour until the day 18. For chilled mackerel, the TMA values were significantly increased ($p < 0.05$) during storage period while for frozen mackerel the values decreased slowly. The acceptable limit for TMA was 8 mgN/100g as indicated by Orak and Kayisoglu [7], and remarkably in this study, the chilled mackerel reached maximum acceptable limit at day 6 (8.31 mgN/100g). For frozen short-bodied mackerel, similar trend was reported by Orak and Kayisoglu [7] for filleted gray mullet where the TMA values were not significantly affected by storage time. This trend could be due to inhibitory effects of freezing on the bacterial activities and hence avoid accumulation of TMA in the muscle.

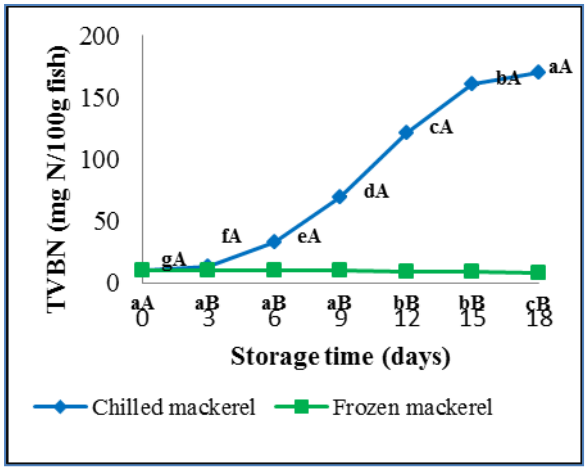

Figure 3. Changes in Total Volatile Base Nitrogen (TVBN) of short-bodied mackerel in chilled and frozen storage for 18 days. Values are expressed as mean (A, B) and (a, b, c) marked with different letters were significantly different at $p < 0.05$. Lower case letters indicate the effect of storage time on short bodied-mackerel while upper case letters indicate the effect of storage conditions.

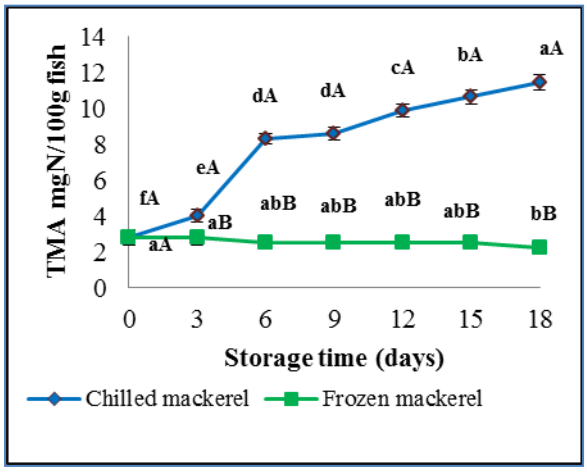

Figure 4. Changes in Trimethylamine (TMA) of short-bodied mackerel in chilled and frozen storage for 18 days. Values are expressed as mean (A, B) and (a, b, c) marked with different letters were significantly different at $p < 0.05$. Lower case letters indicate the effect of storage time on short bodied-mackerel while upper case letters indicate the effect of storage conditions.

Conclusion

There were significant differences in the rate of chemical changes for both chilled and frozen mackerel during 18 days of storage. Frozen mackerel had a slower rate of deterioration than chilled mackerel in terms of oxidative rancidity and microbial activity. Therefore, frozen temperature (-18 °C) can be used in food industry to prolong the shelf life of fish and hence could produce high quality finished products.

Abstract

The low content of lysozyme in albumin makes its purification process becomes complicated and challenge either in lab or industrial scale system. This study aimed to investigate the parameters influencing the purification performance lysozyme from chicken egg white (CEW) namely initial concentration of albumin, pH and ionic strength of buffer solution. Immobilized metal affinity chromatography (IMAC) beads were prepared using chitosan-coated silica beads which then crosslinked with glutaraldehyde (GTA) and reacted with metal ion copper (Cu) for metal ion immobilization to be used as purification tools. The prepared beads were characterized in term of morphology and structure using scanning electron microscope (SEM). Column chromatographic has been utilized for evaluation performance of IMAC for lysozyme separation. Optimum recovery obtained using 20 mg/ml CEW concentration at pH 7, with 0.05 M ionic strength. The finding of this study exhibited a good pathway to design an affinity system for lysozyme purification either from chicken egg white or other sources in the future.

Keywords: lysozyme, chicken egg white, purification, pH, ionic strength, affinity chromatography

Abstrak

Kandungan lisozim yang rendah di dalam albumin membuatkan proses penulenan menjadi semakin rumit dan mencabar sama ada sistem di makmal atau industri. Kajian ini bertujuan untuk mengoptimumkan parameter yang mempengaruhi prestasi penulenan lisozim dari albumin iaitu kepekatan awal albumin, pH dan kekuatan ionik larutan penimbal. Kromatografi affiniti logam pegun telah disediakan dengan menggunakan silika yang bersalut kitosan yang kemudiannya diaktifkan menggunakan glutaraldehid (GTA) serta bertindak balas dengan ion logam kuprum bagi pemegunan ion logam (kuprum) untuk digunakan sebagai alat penulenan. Pencirian silika telah dilakukan dari segi morfologi dan struktur dengan menggunakan mikroskop elektron pengimbas (SEM). Kolum kromatografi digunakan untuk menilai prestasi IMAC bagi pemisahan lisozim. Penghasilan yang optimum diperolehi dengan menggunakan 20 mg/ml kepekatan putih telur pada pH 7 dengan kekuatan ionik sebanyak 0.05 M. Hasil kajian ini menunjukkan cara yang baik untuk mereka bentuk sistem affiniti untuk penulenan lisozim sama ada daripada sumber putih telur atau sumber lain pada masa akan datang.

Kata kunci: lisozim, albumin, penulenan, pH, kekuatan ionik, kromatografi affiniti

Introduction

For many decades, chicken egg white (albumin, abbreviation as CEW) have been used as the subject of study for chemical, biochemical and food technological research because of the importance in human for food supply and also the potential use in biotechnology processes. Chicken egg white is the cheapest source for production of enzyme such as lysozyme using protein fractionation. Industrial application often restricted by the difficulty of recovery and reuse of the enzyme as well the lack of long-term operational stability. In order to overcome the problems, techniques that been applied in the laboratories for the separation of lysozyme from chicken egg white protein which are centrifugation, electrophoresis and chromatography [1]. Moreover, the isolation and purification process of the lysozyme becomes complicated and challenges due to the low content of the lysozyme in the chicken egg white. It is required to apply the effective and large scale protein purification process for lysozyme purification [2]. For the reason, a large quantity of the raw materials from chicken egg white needed in order to get the rational amount of pure lysozyme.

Protein separation and purification using immobilized metal affinity chromatography (IMAC) silica beads has become a powerful technique due to the inexpensive cost, ease of preparation as well high adsorption capacity [3]. The optimize purification conditions are needed to achieve both high yield and purity of the enzyme [4]. Thus, the important parameters of the physico-chemical environment of the feed solution that affect the separation process of lysozyme from chicken egg white such as pH of buffer solution, ionic strength and initial chicken egg white concentration that have been studied using affinity column chromatography as an alternative separation technique which is can be fine tuned to achieve high productivity in protein separation process. However, for the enzyme activity of the lysozyme, it was indicated using *Micrococcus lysodeikticus* as the substrate. The addition of *M. lysodeikticus* to the lysozyme solution in order to detect the enzyme activity that causes the decrease in the optical density. One lysozyme unit was defined as the amount of enzyme causing a decrease of 0.001 per minute in the absorbance at 450 nm where the suspension of 1 mg/ml *M. Lysodeikticus* as the substrate in 1 ml reaction mixture.

Thus, the aim of this research is to provide a new efficient and low cost technique for industrial manufacturing of purified lysozyme from raw chicken egg white using IMAC bead.

Materials and Methods

Chemicals and Materials

All materials used during the conduct of research are of analytical grades. Lysozyme and chicken egg white are purchased from Sigma Chemical Company. All other chemicals were guaranteed or analytical grade reagents commercially available and used without further purification.

Immobilized metal affinity chromatography beads preparation

In this study, chitosan-coated silica beads which then crosslinked with glutaraldehyde (GTA) and reacted with metal ion copper (Cu) for metal ion immobilization been used as IMAC support. Preparation of chitosan-coated silica beads was according to Shi et al. [5] with some modification. Silica gel were washed with 20 % hydrochloric acid solution for 8 hours and been dried at 40 °C before immersed into distilled water to wet the pore surface. Then, the silica gel was immersed into chitosan solution (0.1 wt. % in acetic acid pH 5) for 72 hours for surface coating. The chitosan-coated silica gel then added to NaOH solution for 2 hours and being washed with distilled water before crosslinking the beads with glutaraldehyde (GTA) for 16 hours in incubator shaker. The activated chitosan-silica beads were reacted with metal ion ($CuSO_4$) for 24 hours and kept in the distilled water for storage and been called immobilized metal affinity chromatography (IMAC) beads. Then, the IMAC beads were characterized using scanning electron microscope (SEM) for the morphology and structure study. The IMAC samples were coated with gold before transferred under microscope.

Lysozyme purification from chicken egg white and activity measurements

Chromatographic studied were carried out on IMAC beads using affinity column chromatography according to Ai et al. [6] with some modification. Thus, for the study of the feed solution, there were three factors being identified for the purification process of the lysozyme such as pH of buffer solution, ionic strength and initial CEW concentration. The optimize purification conditions are needed to achieve both high yield and purity of the enzyme as well. The column was equilibrated with 50 mL of phosphate buffer solution. Chicken egg white solution prepared with the

same buffer solution was bumped into the column at a constant volume velocity of 1.0 mL/min for five hours. When the adsorption of the CEW was saturated, the column been washed with 50 mL of same buffer solution to eliminate unbound proteins. The lysozyme adsorbed on the column was eluted by using a mixture solution of 0.3 M imidazole and 0.25 M NaCl in 0.01 M phosphate buffer (pH 6.0). The final lysozyme concentration in elution medium was determined spectrophotometrically using Bradford method [7].

Determination of total protein

The detection and quantitation of the total protein has been detected using Bradford assay method [7] while bovine serum albumin (BSA) has been used as the standard. Different dilutions of BSA standard solutions were prepared by mixing BSA stock solution (1 mg/mL) and phosphate buffer. The absorbance and concentration were analyzed using UV –Vis spectrophotometer at 595 nm by dissolving every 100 µL sample with 3mL Bradford reagent. The absorbance against protein concentration was plotted to obtain a standard calibration curve. The analysis was repeated using the lysozyme obtained from CEW as the sample.

Lysozyme activity measurement

Lysozyme activity was determined by its lytic action on *Micrococcus lysodeikticus* cell suspended in the phosphate buffer. One lysozyme unit was defined as the amount of enzyme causing a decrease of 0.001 per minute at 25 °C and pH 7.0 in the absorbance at 450 nm where the suspension of 2.9 mL of *M. Lysodeikticus* as the substrate mixed with 0.1 mL of diluted lysozyme.

Results and Discussion

IMAC characterization

IMAC beads have been used as one of the successful processes for isolation and purification of the proteins as well enzymes. It was immobilized with 0.1M concentration of metal ions and high amount of enzyme loading can be applied to obtain high yield of lysozyme recovery. Thus, the process also allow for the easy product elution and metal ions regeneration [3].

Figure 1 shows the surface morphology of (a) silica gel and (b) IMAC adsorbent using scanning electron microscope (SEM) with 5000x enlargement. The silica have uneven surface that made it easier to bind with chitosan, glutaraldehyde activator and metal ion copper (Cu^{2+}) as the IMAC adsorbent. The silica that being crosslinked using glutaraldehyde to stabilize the surface of silica for metal ion immobilization [8]. It also provided the best surface area for the enzyme binding and eluted during affinity chromatography of the lysozyme from CEW.

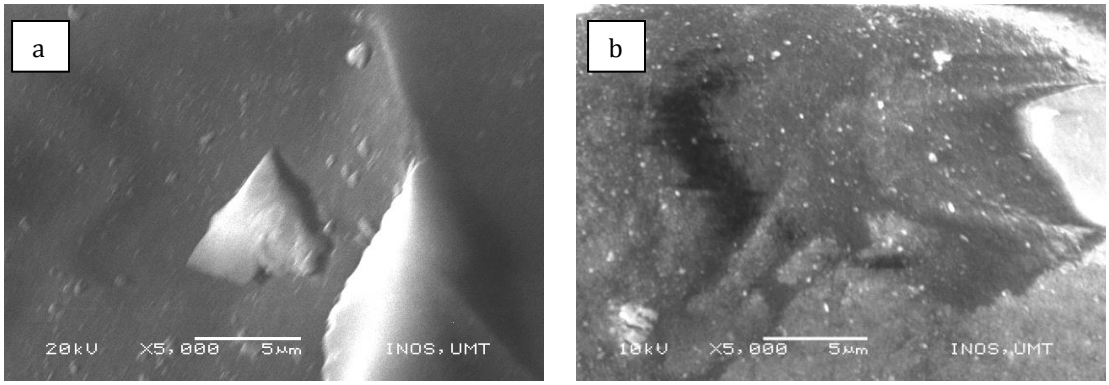

Figure 1. Surface morphology of (a) Silica gel and (b) IMAC adsorbent

Effect of CEW solution concentration, pH and ionic strength of buffer solution

The content of the lysozyme in chicken egg white was about 3.4 % [9] making its purification process becomes complicated. There are some factors that influenced the performance of the lysozyme from CEW which were concentration of the CEW solution, pH and ionic strength of buffer solution. The effects of CEW concentration on

lysozyme separation and purification from IMAC beads was studied using CEW concentration ranged from 5mg/mL to 25 mg/mL of CEW in buffer solution. The results obtained displays in Figure 2 (a) and (b) and there was a remarkable change in the purity of lysozyme even there were only slight difference in the yield obtained.

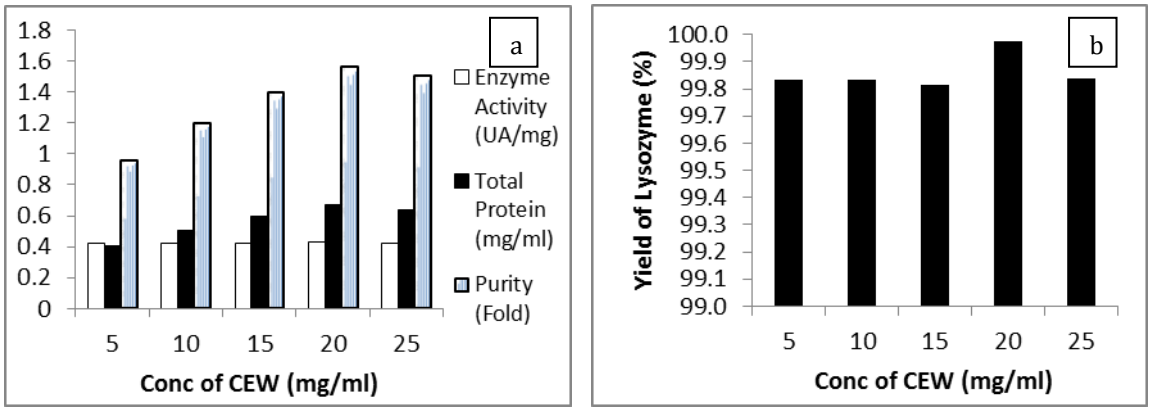

Figure 2. Affinity column chromatography with different concentration of CEW solution (a) enzyme activity, total protein, purity of lysozyme and (b) yield of lysozyme

The highest lysozyme recovery (99.97 %) obtained using 20 mg/mL initial concentration of CEW where the specific activity of lysozyme and total protein concentration in the feed solution were assayed at 0.42 UA/mg and 0.67 mg/ml as well with 1.56 of purification fold. This promising result was due to the equilibrium phase of the CEW concentration at 20 mg/mL and the further increase of initial concentration (25 mg/mL) did not improve the separation performance since all the active site of IMAC beads had been bound with lysozyme.

The increasing of the CEW concentration from 5mg/mL to 20 mg/mL had been promoting the adsorption of enzyme from the surface of IMAC beads and gave higher recovery (yield) of lysozyme. While the concentration of CEW was about 5 mg/mL, the specific activity of lysozyme was also 0.42 UA/mg but the recovery of lysozyme was about 99.81 %. Overall, the initial concentration used in this study promoted very outstanding result when more that 99 % lysozyme can be recovered. This finding can be explained due to the cooperative effect of different interaction mechanisms such as hydrogen bonding, electrostatics and hydrophobic cause by the buffer in the CEW and IMAC beads as well [10].

Figure 3 shows the effects of pH of the buffer solution on the adsorption capacity of lysozyme onto IMAC beads, whereas the best recovery occurred at pH 7 when the specific activity of lysozyme and total protein concentration in the feed solution were about 0.41 UA/mg and 0.33 mg/ml with 0.81 purification fold. At this rate, pH 7 had promoted very high yield recovery of lysozyme which about 99.85 %. The pH of buffer solution provide great effect for the recovery of the lysozyme from CEW since the changes of the solution pH can be altered the electrical charge on the lysozyme as well. The isoelectric point (IEP) of lysozyme was around 11 and at pH value below the IEP, the lysozyme adsorbed was clearly higher than at pH values above the IEP. At pH 7, lysozyme would be cationic since this pH was below than its isoelectric point. This pH 7 was served as a good environment for the lysozyme with the help of electrostatic interaction that has been predominant for recovery of the enzyme from CEW.

At pH 5, the purification capacity of lysozyme was the lowest which about 0.38 UA/mg of lysozyme specific activity with its yield were 95.23 %. This result indicated that the capability of lysozyme coordination with the IMAC beads was not necessarily suitable in acidic condition. This occurrence might result from the protonation of electron donor group in lysozyme molecule, leading to decreasing coordination ability with metal ions [11]. Furthermore, lower performance at the pH approaches IEP of lysozyme at pH 9 was due to the instability

occurrence. This result can be explained as the percentage of HPO_4^{2-} and PO_4^{3-} in buffer solution which acquired a relative higher metal coordinating ability compared to HPO_4^-. This condition would compete with lysozyme for metal binding and increased in alkali condition [12]. Due to lysozyme isoelectric point which at pH 11, lysozyme specific activity just about 0.43 UA/mg and its yield that has been recovered from IMAC beads was about 99.01%. This result might be explained due to the protein aggregation [13] since the lysozyme surface net charge was zero, thus there were no electrostatic repulsive force being effective between the lysozyme molecules at this pH.

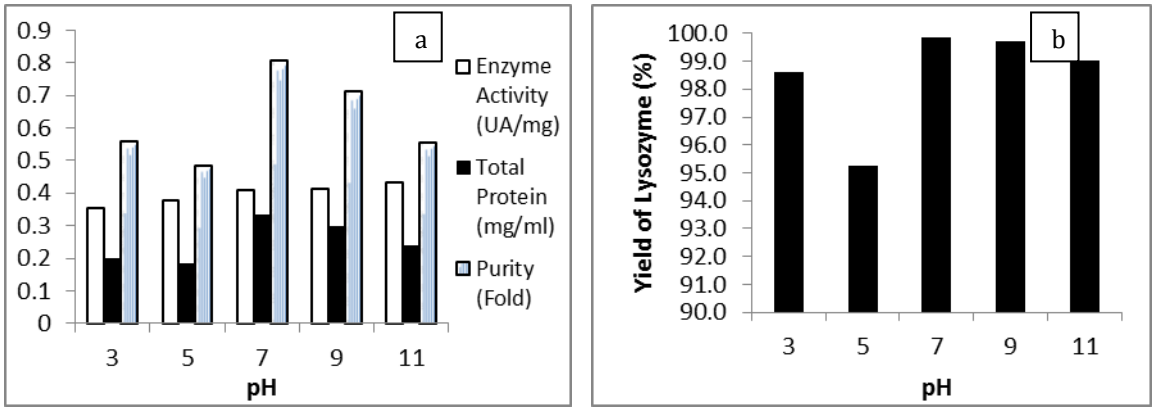

Figure 3. Affinity column chromatography with different pH of buffer solution (a) enzyme activity, total protein, purity of lysozyme and (b) yield of lysozyme

The effect of ionic strength was studied using the CEW solution with a fixed pH 7 since the previous observation determined that pH 7 successfully promoted the best recovery of lysozyme. Since the IMAC beads were highly charged with electrolyte, the effects of ionic strength on lysozyme separation and purification from CEW was studied using addition of NaCl from 0.01M to 0.09M. The results obtained were displayed in Figure 4 (a) and (b) where there was a significant change in the lysozyme recovery through the change in ionic strength of the buffer solution. For the effects of ionic strength, the results that been achieved the best when NaCl was 0.05 M with the 0.33 UA/mg lysozyme specific activity and 0.29 mg/ml of total protein concentration in the feed solution. While the yield of the lysozyme was about 99.24 % with 0.89 purification fold. It was due to the high lysozyme being eluted from CEW.

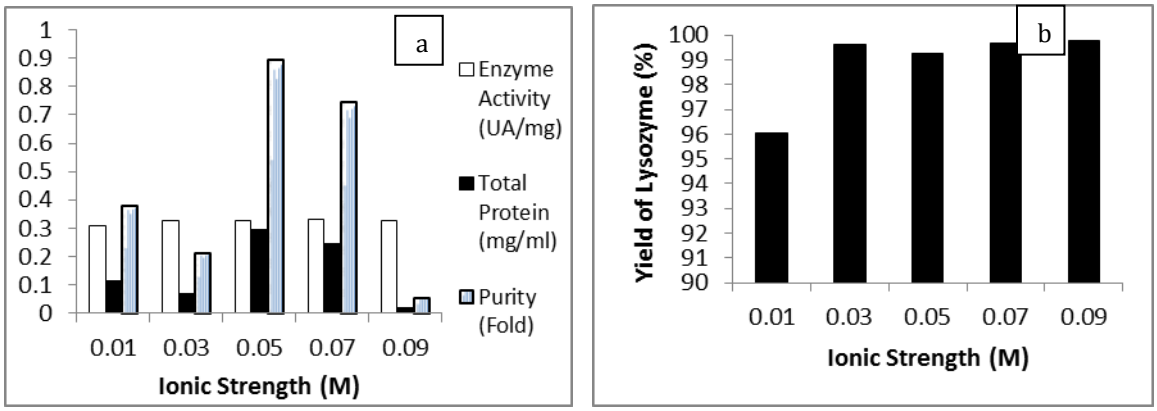

Figure 4. Affinity column chromatography with different ionic strength of buffer solution (a) enzyme activity, total protein, purity of lysozyme and (b) yield of lysozyme

Otherwise, when the NaCl was at 0.03 M, the specific activity of lysozyme was about 0.32 UA/mg and 0.06 mg/ml of total protein concentration in the feed solution. Meanwhile the yield of the lysozyme was obtained at 99.6 %. Although the yield of lysozyme when the NaCl concentration about 0.03 M higher than the concentration at 0.05 M, but the purification fold was just 0.21. It shows that the concentration of 0.05 M NaCl have the highest purity rather than concentration of 0.03 M. The increasing of the NaCl concentration from 0.01M to 0.05M had been encouraged the recovery of the enzyme from the surface of IMAC beads. Then, the hydrophobic interactions among them become strong. Furthermore, the addition of NaCl more than 0.05M caused the recovery capacity to reduce since the ionic strength had affects the chelating bonding of lysozyme on both metal affinity carriers [14]. Besides, in high ionic strength buffer, protein solubility usually reduces which were salt-out effect due to the decreasing activity of water and the neutralization of surface charge. These conditions also assist the formation of protein aggregates, leading to the decrease in lysozyme adsorption onto IMAC beads and reduce the purification of the lysozyme itself.

Conclusion

The process developed using IMAC beads allows the recovery and purification of the lysozyme from chicken egg white (CEW) with high recovery capacity of matrix at low cost and high efficiency. This study proved that concentration of CEW, pH and ionic strength of buffer solution significantly influenced the purification process of the lysozyme from CEW. The most optimum lysozyme recovery was at 20 mg/mL of CEW concentration in buffer solution at pH 7 and ionic strength of 0.05M. Affinity chromatography using IMAC beads was a potential alternative for industrial purposes.

Abstract

Starch from sago (*Metroxylon sagu*) was esterified with octenyl succinic anhydride (OSA) in order to regulate its shortcoming by adding amphiphilic properties. The objective of this work is to determine the physicochemical properties of native sago and OSA sago starches. The OSA sago starch was produced according to the optimum condition generated via response surface methodology (RSM) with 5.00 % OSA at pH 7.20 and a reaction time of 9.65 hours. The esterified sago starch gives a degree of substitution (DS) value of 0.012. The physicochemical properties of OSA sago starch was determined by measuring the amylose content, laser diffraction particle size analyzer, scanning electron microscopy (SEM) and Fourier transform infrared (FT-IR). The amylose content for OSA sago starch was found to be reduced after esterification reaction. The particle size of OSA sago starch was found to increase significantly ($p < 0.05$) compared to their native starches. Scanning electron microscopy (SEM) revealed that OSA starch developed slightly rough surface and their edges lost some definition. FT-IR spectroscopy shows that there was appearance of new absorption correspond to ester carbonyl group (1717 cm^{-1}) and carboxylate RCOO- (1569 cm^{-1}). This study showed that the physicochemical properties of modified starches were influenced not only by DS but also on the botanical origin of the starches.

Keywords: physicochemical properties, sago starch, octenyl succinic anhydride, esterification

Abstrak

Kanji daripada sagu (*Metroxylon sagu*) telah diesterifikasi dengan oktenil suksinat anhidrat (OSA) sebagai usaha untuk mengawal kelemahan dengan menambah sifat amfifilik. Objektif kajian ini adalah untuk menentukan sifat – sifat fizikokimia kanji sagu asli dan OSA kanji sagu. OSA kanji sagu disediakan mengikut keadaan optima berdasarkan kaedah gerak balas permukaan (RSM) dengan 5.00 % OSA pada pH 7.20 dan masa tindak balas selama 9.65 jam. Esterifikasi kanji sagu memberikan nilai darjah pengantian (DS) sebanyak 0.012. Ciri – ciri fizikokimia OSA kanji sagu ditentukan dengan mengira kandungan amilosa, saiz partikel laser pembelauan analisis, mikroskop imbasan elektron (SEM) dan Fourier transformasi inframerah (FT-IR). Kandungan amilosa untuk OSA kanji sagu didapati berkurangan selepas tindak balas esterifikasi. Saiz partikel OSA kanji sagu didapati meningkat dengan ketara ($p < 0.05$) berbanding saiz kanji sagu asli. Mikroskop imbasan elektron (SEM) menunjukkan bahawa OSA kanji sagu menghasilkan permukaan sedikit kasar dan kehilangan beberapa sisi definisi. FT-IR spektroskopi menunjukkan bahawa terdapat kemunculan penyerapan baru yang bersesuaian dengan kumpulan ester karbonil (1717 cm^{-1}) dan RCOO- karboksilik (1569 cm^{-1}). Kajian ini menunjukkan bahawa ciri – ciri fizikokimia kanji diubahsuai bukan hanya dipengaruhi oleh DS tetapi juga berdasarkan pada asal usul botanikal kanji tersebut.

Kata kunci: sifat-sifat fizikokimia, kanji sagu, oktenil suksinat anhidrat, esterifikasi

Introduction

Starch is a carbohydrate polymer which comprised of amylose and amylopectin chains and has been widely used as a functional ingredient in food and non-food application [1]. In order to meet specific requirements, the native starches were chemically modified to improve its properties which require disruption of hydrogen bonding [2]. Chemical modification can be achieved by different types such as esterification, etherification, cross-linking and grafting of starch. Sago starch, like other starch, exhibit hydrophilic nature which is the main constraint that limit the usability of starch. Esterification of starch with octenyl succinic anhydride (OSA) impart an amphiphilic nature by the addition of hydrophobic chain into the starch backbone and broaden their potential uses in the food industry [3]. The succinylated starch tends to swell in cold water, having more stable pasting and gelatinisation properties also giving the derivative surface activity and colloid protector properties [4].

There are a number of methods that can be used to characterize starch, which could be used to identify the unique properties of modified starch. Scanning electron microscopy (SEM) has been used to study the morphology of the starch granules by giving a clear visual variation in size and shape of starch granule [5]. Laser diffraction particle size analyzer has been used to study the particle size by characterize the granule diameter, as the size of starch can influence the rate and efficiency of the chemical modification [6]. The presence of carbonyl group in the starch backbone can be confirmed by FT-IR spectroscopy. The introduction of this group indicate that the succinylation have been successfully made into the starch [7]. The amylose content of starch before and after modification can be as one of the sign to recognize the extent of modification by determining the degree of substitution. Amylose content also has been found to have a significant correlation with the size and shape of the starch granules [8].

Thus, the objective of the present study was to characterize the physicochemical properties of both native and OSA sago starch using different type of instruments.

Materials and Methods

Chemicals and raw materials

Food grade sago starch was purchased from Nee See Ngeng & Sons Sago Industries Sdn. Bhd (Sarawak, Malaysia). The starch was used without any further treatment. Octenyl succinic anhydride (OSA) (Lot# J1097009-A) was donated by Dixie Chemical Company, Pasadena, Texas, USA. Other chemicals used in this study were of analytical grade.

Preparation of OSA starches

OSA sago starch was prepared according to the optimum condition generated by response surface methodology (RSM). The starch was treated according to condition at 5.00 % OSA concentration, pH 7.20 and reaction time of 9.65 hours as reported in our earlier work [9]. The preparation step and calculation of degree of substitution (DS) of OSA sago starch was determined using the method from [10] by using the formula equation 1 and 2 below:

$$\text{OSA substitution (\%)} = \frac{(V_{\text{blank}} - V_{\text{sample}}) \text{ x } 0.1 \text{ x } N \text{ x } 100}{W} \quad (1)$$

where V_{blank} is defined as the volume of HCl required for blank titration, V_{sample} is defined as volume of HCl required to titrate the sample, W is defined as the weight (g) of sample and N is the normality of the HCl solution.

$$\text{DS} = \frac{162 \text{ x OSA substitution (\%)}}{21\,000 - [209 \text{ x OSA substitution (\%)}]} \quad (2)$$

where 162 is defined as molecular weight of the glucose unit, 21 000 is defined as 100 x molecular weight of octenyl succinyl group and 209 is molecular weight of octenyl succinyl group minus the molecular weight of hydrogen atom.

Characterization of OSA starches: ***Amylose content***

The amylose content of starches was estimated following the modification by Ratnayake et al. [11] from the method of McGrance et al. [12]. Starch (20 mg, dry basis) was dissolved in 8 mL of 90 % DMSO. The slurry was vigorously mixed for 20 min and volume to 25 mL in a volumetric flask. The diluted solution (1 mL) was taken out and mixed with deionized water then placed in water bath at 85 °C for 15 min. The vials were left to cool at ambient temperature before make up the volume to 25 mL in a volumetric flask. The diluted solution (1 mL) was taken out and mixed with deionized water (40 mL) and iodine solution (5 mL). The volume of the mixture was adjusted to a final value of 50 mL. Then, the solution was allowed to stand for at least 15 min and the absorbance was read at 600 nm by using UV-VIS spectrophotometer. A standard curve of amylose was plotted in order to determine the amylose content of native and OSA starches.

Particle size of starch

Particles size of OSA sago starch was measured by static multi-angle light scattering method using Mastersizer Hydro 2000 (Malvern Instrument, Malvern, UK) equipped with Scirocco Dry Powder Feeder. An amount 2 g of native and OSA starches were added into the feeder and the OSA sago starch was measured three times. An average droplet sizes were characterized in terms of Sauter mean diameter d_{32}.

Scanning electron microscopy

The microstructure of starch granule and their surfaces after modification with OSA was examined with scanning electron microscopy (SEM). The air-dried starch powders were stuck on double-sided adhesive tape on a specimen holder and then coated with gold in vacuum evaporator. The samples were analyzed using scanning electron microscope (Leo Supra 50VP Field Emission SEM, Carl Zeiss SMT, Germany). The samples were measured at a magnification of 2000x.

Fourier transfer infrared (FT-IR) spectroscopy

FT-IR spectra of native and OSA starches were performed using Perkin Elmer Spectrum One FT-IR spectrophotometer (Massachusetts, USA). The starch samples were dried at 105 °C for 12 hours to remove any moisture. The dried sample was finely grind with KBr in a ratio of 1: 70 (w/w) and scanned over a wavenumber range from 400 to 4000 cm^{-1} with a resolution of 4 $cm^{-1.}$

Statistical analysis

All tests were performed in triplicate. Analysis of variance (ANOVA) was performed using the Duncan multiple range tests to compare treatments means. Significance was defined at $p < 0.05$.

Results and Discussion

Amylose content for native and OSA starches

Table 1 shows the amylose content for native and modified starches after being esterified with OSA. Normally, botanical origin will influence the amount of amylose in the starch where waxy starches contain less than 15 % amylose, regular starch 20 – 35 % amylose and high amylose starch have more than 40 % amylose [13]. The amylose content of native sago starch and OSA sago starch were 30.18 % and 25.27 %, respectively. This result was supported by Ahmad et al. [14] which reported that the amylose content of native sago starch was in the range of 24 – 30 %. According to the amylose content, sago starch can be categorized as a regular starch.

From the result, there was a significant ($p < 0.05$) decrease in amylose content in treated starch. Amylose is located at the amorphous region while amylopectin is in crystalline lamellae. The amorphous region is more accessible than crystalline domains which explain that substitution occur preferentially at amylose chains [15]. As amorphous region is easily accessible, OS group might distribute and disrupt at this region more than in crystalline domains, which explain the reduction of amylose content in esterified starches [16].

Particle size distribution and morphology of starches

The results for particle size analysis are shown in Table 1. The particle size of native sago starch was 29.05 µm. This agreed with the result from [17] which state that the particle size of native sago granules was between 5 to 65 µm and the average was 30 – 31 µm. The particle size of esterified starch shows a significant increased ($p < 0.05$)

when compared to their native state. Structural disorder happens as OS groups incorporate with native starch, making the granule to swell to a greater extent and increase the particle size [18].

Table 1. Effect of octenyl succinylation on DS, amylose content and particle size of starches

Sample	Degree of substitution (DS)	Amylose content (%)	Particle size (µm)
Native sago starch	-	30.18 ± 0.71^{a}	29.05 ± 0.09^{b}
OSA sago starch	0.012 ± 0.00	25.27 ± 0.36^{b}	29.89 ± 0.23^{a}

Values are mean ± standard deviation. Mean within each column with different superscripts letter are significantly different at $p < 0.05$.

Figure 1 shows the SEM image of native and OSA sago starch. Scanning electron microscopy revealed sago starch consists of oval granules with smooth surfaces and non-visible pores [14, 19]. There is an only slight difference in shape of OSA sago starch from their original shape. However, the surface of OSA starch was observed to be rough and their edges lose some definition. The addition of NaOH to maintain the alkaline condition during esterification process might result in surface gelatinization, thus contribute to rough appearance on the surface of OSA starch granules [6]. This observation also could be associated with granule swelling and distruption of starch particles during reaction [20].

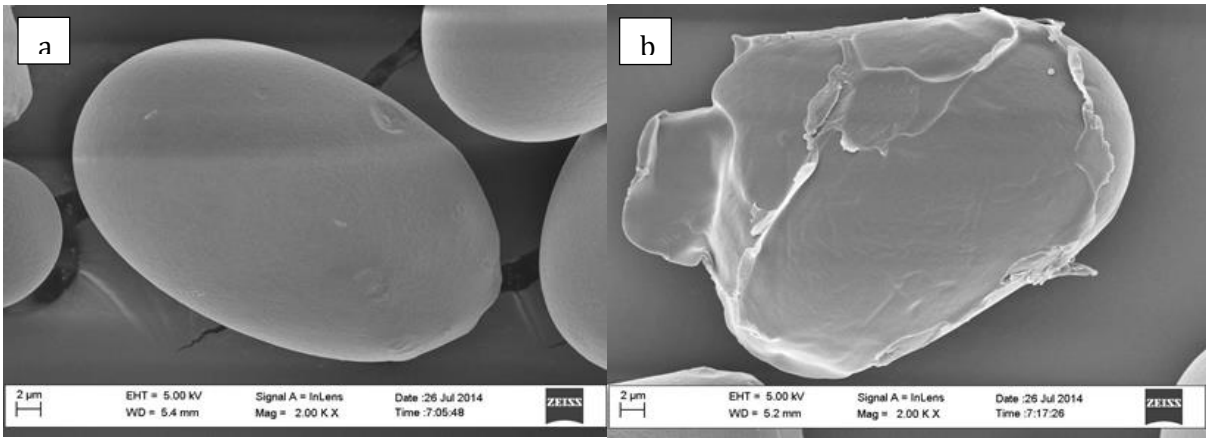

Figure 1. Scanning electron micrographs of a) native sago starch and b) OSA sago starch at 2000x magnification

Fourier transfer infrared (FT-IR) spectroscopy

Fourier transform infrared spectroscopy (FT-IR) was used to detect the presence of OSA groups after esterification. The FT-IR spectra of native and OSA starches are shown in Figure 2. The extremely broad band at 3400 cm^{-1} is resulting from vibration of hydroxyl group (O-H) whereas the band at 2924 cm^{-1} is characteristics of C-H stretching vibration of glucose unit. Compared with native starch, two absorption bands were observed at 1569 cm^{-1} and 1717 cm^{-1} which correspond to assymetric stretch of vibration of a carboxyl group and C=O stretching vibration of an ester group, respectively [21]. The peak at 1647 cm^{-1} was due to tightly bound water present in the starch [22]. The intensity of absorption bands at 1569 cm^{-1} and 1717 cm^{-1} was reported to increase with increasing DS [23].

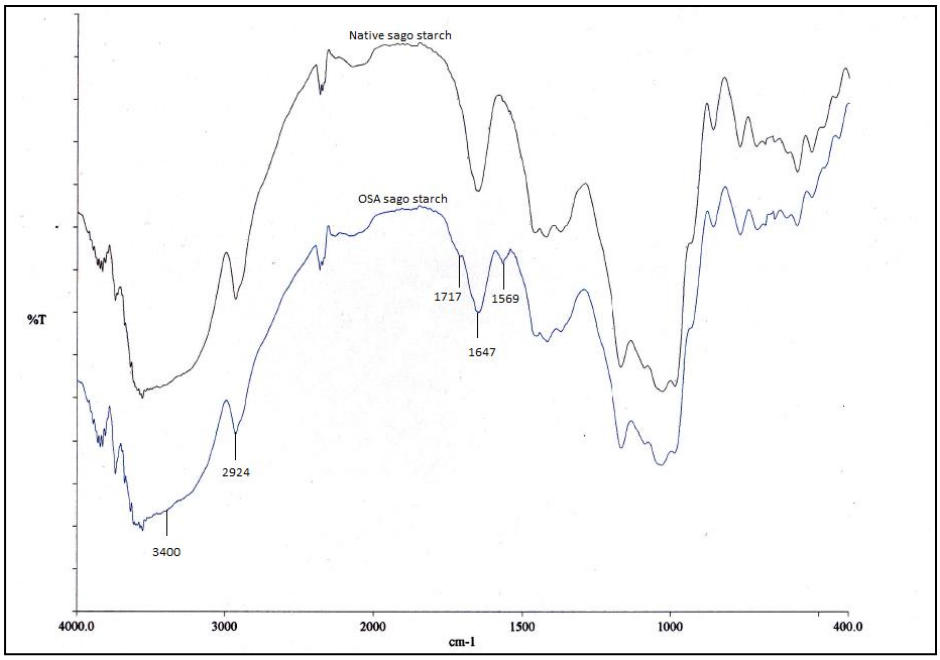

Figure 2. FT-IR spectra for native and OSA sago starches

Conclusion

Our results have shown that the physicochemical properties of native sago starch have been altered after being esterified with OSA. SEM image illustrated that there is only a slight change in the surface of the esterified starch, but does not bring any visible pores or crack on the starch surfaces. Particle size of starch granules was found to increase significantly ($p < 0.05$), which correspond to swelling activity. The amylose content of starch decreased after esterification, indicating that the modification occurred primarily in the amorphous regions and disrupt the linearity of amylose chains. FT-IR spectroscopy confirmed the existence of carbonyl group through absorption bands at 1569 cm^{-1} and 1717 cm^{-1}. The esterification of sago starch with OSA will add the hydrophobic chain to the originally hydrophilic starch molecule hence the modified starch obtains surface active properties which will be useful in stabilizing emulsion. The stabilizing and emulsifying properties of OSA sago starch need further study.

Abstract

Mud clam (*Polymesoda erosa*) was hydrolysed using two different microbial enzymes; alcalase and flavourzyme. The volatile compounds, amino acids and molecular weight associated with umami and bitter taste in mud clam hydrolysate were determined by head space solid phase micro-extraction gas chromatography (HS-SPME-GCMS), High performance liquid chromatography (HPLC) and sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE). The characteristics of hydrolysates produced using alcalase and flavourzyme were compared. In total, eighteen, seven and six volatile compounds were identified in the flesh, alcalase hydrolysate and flavourzyme hydrolysate, respectively. 2-piperidinone volatile compound content which is associated with bitterness was 6.79 % in alcalase hydrolysate and 3.78 % in flavourzyme hydrolysate. SDS-PAGE results showed that alcalase hydrolysate contains smaller peptide (<52 kDa) compared to flavourzyme hydrolysate (<126 kDa). In addition, sensory analysis using quantitative descriptive analysis (QDA) showed that flavourzyme hydroysate was the least bitter but elicited more umami taste compared to alcalase hydrolysate. Further treatments are still needed to enhance umami taste and to remove bitter taste in mud clam hydrolysate.

Keywords: mud clam hydrolysate, volatile compounds, amino acids, molecular weight, sensory

Abstrak

Lokan (*Polymesoda erosa)* telah dihidrolisiskan menggunakan dua microbial enzim yang berbeza; alcalase dan flavourzyme. Sebatian meruap, asid amino dan berat molekul yang dikaitkan dengan umami dan rasa pahit di dalam hidrolisat lokan ditentukan oleh ruang kepala pepejal mikro fasa kromatografi gas (HS-SPME-GCMS), cecair kromatografi berprestasi tinggi (HPLC) dan elektroforesis gel sodium dodekil sulfat poliakrimida (SDS-PAGE). Ciri – ciri hidrolisat dihasilkan menggunakan alcalase dan flavourzyme dibandingkan. Secara keseluruhan, lapan belas, tujuh dan enam sebatian meruap telah dikenal pasti dalam masing – masing pada isi lokan, hidrolisat alcalase dan hidrolisat flavourzyme. Kandungan sebatian meruap; 2-piperidinone yang dikaitkan dengan kepahitan adalah 6.79 % pada hidrolisat alcalase dan 3.78 % pada hidrolisat flavourzyme. Keputusan SDS-PAGE menunjukkan hidrolisat alcalase mengandungi peptida yang lebih kecil (<52 kDa) berbanding hidrolisat flavourzyme (<126 kDa). Di samping itu, analisis deria menggunakan kuantitatif deskriptif analisis (QDA) menunjukkan bahawa hidrolisat flavourzyme adalah yang paling kurang pahit dan memberi rasa umami yang lebih berbanding hidrolisat alcalase. Penambahbaikan lanjut masih diperlukan untuk meningkatkan rasa umami dan untuk menghilangkan rasa pahit dalam hidrolisat lokan.

Introduction

Mud clam (*Polymesoda erosa)* is one of the edible bivalve species. Recently, the utilization of bivalve species becomes famous due to its high protein content and delicacy in coastal areas. Hydrolysate can be useful in food applications especially for flavour enhancer [1, 2]. Hydrolysate refers to proteins that are broken down into peptide of various sizes [3]. Flavour is defined as sensations arising from the integration of signal produced as consequence of smell and taste [4]. According to Su et al. [1], the hydrolysate produced from hydrolytic enzymes can enhance the flavour of the protein hydrolysate because it increases the amount of amino acids and low molecular weight peptides that possess unique taste properties including sweet, sour and bitter tastes. The types of protease and protein substrate affect the functional and flavour profile of the protein hydrolysate [5]. Volatile compounds in protein hydrolysate of various species have been identified by several researchers using different techniques of sample preparation and methods of analysis [6]. In this study, volatile compound was extracted by using headspace solid phase micro-extraction (HS-SPME). This method was claimed to have no solvent interference and consumed less time for sample preparation. Amino acids have the most variation in taste and the effect of amino acids and peptides on food taste has been researched extensively [1, 7].The amino acid compositions is important in protein hydrolysate because it contributes to the nutritional value besides influencing the functional properties and flavour of the hydrolysate [7, 8].There were several studies conducted on protein hydrolysate [9]. However, information on volatile compounds, amino acids, molecular weight and sensory related to the flavour of mud clam protein hydrolysate were limited.

Therefore, the aim of this study is to identify the volatile compounds, amino acid, molecular weight that contribute to the flavour of mud clam hydrolysate by using head space solid phase micro-extraction gas chromatography-mass spectrometry (HS-SPME-GC-MS), High performance liquid chromatography (HPLC) and sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE). The sensory analysis using quantitative descriptive analysis (QDA) was conducted. The bitter and umami flavour of the hydrolysates produced by alcalase or flavourzyme were compared.

Materials and Methods

Raw materials

Mud clam (*Poymesoda erosa*) was bought from a supplier in Kuala Selangor and immediately placed in ice and transported to the laboratory. Upon arrival, the flesh was separated manually and then washed.

Enzymes

Alcalase is a bacterial endopeptidase produced by *Bacillus licheniformis*. Alcalase 2.4 L has a declared activity of 2.4 Anson Units (AU) g−1. Flavourzyme 500 L with declared activity of 500 Leucine Amino Peptidase Units per gram (LAPU/g) is a fungal protease/peptidase complex produced by submerged fermentation of a selected strain of *Aspergillus oryzae*. These two enzymes were obtained from Novozyme (Bagsvaerd, Denmark).

Preparation of mud clam (*Polymesoda erosa*) hydrolysate

Protein hydrolysate was prepared according to the method by Normah et al. [10]. An amount of 453 g flesh and 619 g distilled water was mixed and homogenized in a blender. The mixture was incubated in a circulated water bath. The pH of the mixture was adjusted to pH 8.5 and maintained constant during hydrolysis using 4.0 N of NaOH. Once the pH and temperature (60 °C) has stabilized, alcalase at enzyme-substrate ratio of 3 % was added and the hydrolysis continued for 2 hours. The mixture was continuously stirred using a stirring propeller throughout the hydrolysis period. At the end of hydrolysis, the enzymatic reaction was terminated by placing the samples in a water bath at 90 °C for 15 min. This was followed by centrifugation at 10 000 rpm, 4 °C for 20 min. Supernatant obtained was freeze-dried using the SANYO-Biomedical freeze dryer (ALPHA 1-4 (MARTIN CHRIST)). This procedure was repeated using Flavourzyme 500 L with condition at 55 °C and pH 7. The powdered hydrolysate was stored in -20 °C for further analysis.

Headspace solid-phase micro-extraction (HS-SPME)

One gram of hydrolysate sample was placed into a 15 mL headspace vial and pre-equilibrated for 15 min at 50 °C in thermostatic water bath with vial capped using a silicon septum. Afterward, stainless steel needle, PolydimethylSiloxane (PDMS) fibre was pushed through the vial septum. The fibre was pushed out of the housing

and exposed to the headspace at 55 °C for 30 min extraction time. After extraction, the fibre was pulled into the housing and the SPME device was removed from the vial and inserted into the injection port of GC for thermal desorption of the analysis.

Gas chromatography- mass spectrometry (GC-MS)
GC-MS analysis was performed using Agilent GC-MS (Santa Clara, CA, USA). The sample was desorbed in the injection port at 250 °C for 2 minutes in splitless mode. HP-5MS analytical capillary column (29 m x 250 µm x 0.25 µm, Agilent) and helium gas at a constant flow rate of 0.8 mL/min was used. The oven temperature was programmed at an initial temperature of 40 °C for 2 min followed by an increase of 5 °C/min to 150 °C (held for 5 min) and finally at 10 °C/min to 220 °C (held for 10 min). MS operating conditions (electron impact ionization mode) were an ion source temperature of 200 °C, ionization voltage of 70 eV and mass scan range of m/z 33 – 450 at 2.76 scans/s.

Volatile compound identification
The chromatography peak identification was carried out by comparing their mass spectra with those of the bibliographic data of known compounds from the Wiley 6 library (Hewlett-Packed Co., Palo Alto, CA) and NIST 98 library (Hewlett-Packed Co., Palo Alto, CA) mass spectral database on the basis of the criterion similarity (SI)>800 (the highest value is 1,000). Results are presented as the percent area (%).

Amino acid analysis
An amount of 0.1 grams mud clam hydrolysate or flesh was hydrolysed using 6 N HCl at 110 °C for 24 hours and derivatised using phenyl isothiocyanate prior to AccQ Tag HPLC analysis. The total amino acid was analysed by the AccQTag method using an AccQ Tag column (3.9 x 150 mm) at a flow rate of 1 mL/min equipped with fluorescence detector. The mobile phase used was AccQTaq Eluent A consists of 100 mL Eluent A and 1000 mL deionized water while AccQ Tag Eluent B consists of 60 % acetonitrile and 40 % deionized water. The total running time per injection was 50 minutes.

Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)
SDS PAGE was used to determine the molecular weight of the mud clam flesh and mud clam hydrolysate. An amount of 0.1 g of powdered sample was dissolved in 10 mL deionized water and then filtered using membrane filter with pore sizes 0.45 µm. Filtered solution at 6.5µL was mixed with 2.5 µL NuPAGE®LDS sample Buffer (4X) and 1µL NuPAGE® Reducing Agent (10X). The mixture was heated at 70 °C for 10 minutes in water bath. Ten µL sample was loaded into each well of the SDS-PAGE system comprising of 12 % resolving gel and 5 % stacking gel. Benchmark™ protein ladder is used as a standard marker at the range of 175 to 9 kDa.

Electrophoresis was performed using the XCellSurelock electrophoresis cell (Bio-Rad laboratories, Hercules, CA, USA). Electrophoresis was run for 50 minutes at 100 – 125 mA/gel. After the running process, the gels were washed with 100 mL of ultrapure water. Then, the gel was stained using staining solution containing Coomassie Brilliant Blue dye and heated in a microwave oven at 180 °C for one minute. The gel was shaken again in the orbital shaker for about 2 minutes. The process was repeated twice. The gel were destained using Ultrapure water and shaken with orbital shaker for another 30 minutes.

Identification of bitter and umami taste
Sensory evaluation for bitterness and umami taste of mud clam hydrolysate was conducted using qualitative descriptive analysis (QDA). Ten panellists were trained for three weeks by using caffeine and monosodium glutamate (MSG) solution to represent the bitter and umami taste. Different concentrations of caffeine solutions (0.05 – 2.00 %) and MSG solutions (1 to 200 mM) were prepared and presented to the panellists. The lowest concentration that the panellist could perceive was identified and this concentration was used as the reference to evaluate the degree of bitterness and umaminess of mud clam hydrolysates. A 15 cm scale anchored from ‘none to strong bitterness’ was used for the evaluation. Mud clam hydrolysate (2.5 % (w/v)) were prepared and presented to the panellists.

Statistical analysis

The data obtained was analysed using the Analysis of Variance (ANOVA) to determine significance at 5 % level. Duncan Multiple Range Test (DMRT) was used to identify differences between means. Two sample t-tests were used to compare the mean values. Values were expressed as means ± standard deviations. The significant difference between two means was obtained when t value < p value 0.05.The statistical program used was SPSS software (Version 16.0) for Windows (SPSS Inc. Chicago, IL).

Results and Discussion

Volatile compound analysis

Savoury taste in seafood product is important to give a higher degree of acceptability among customer. This taste is dependent on the composition of volatile compounds. The number of compounds detected and identified were eighteen, seven and six for mud clam flesh, alcalase hydrolysate and flavourzyme hydrolysate, respectively (Table 1). Two different types of volatile alcohol (2-furanmethanol and benzyl alcohol) were only detected in the flesh and flavourzyme hydrolysate. According to Jin et al. [11], alcohols do not affect the flavour of food unless they are present in large amount because of their high threshold values. Mud clam flesh contains higher percent of hydrocarbon compound compared to the hydrolysate. Nor Qhairul Izzreen and Vijaya Ratnam [12] stated that high percentage of hydrocarbon in seafood is very common. Esters are produced by esterification with alcohols and carboxylic acid. According to Jin et al. [11], the content of esters increased slightly in fish processed products. Esters of low molecular weight greatly affect the sweet, fruity and candy-like flavour of salted and fermented anchovies [13]. Nitrogen- containing compound such as pyrazines were reported to have nutty, roasted or toasted aroma in most foods [8, 14]. 2,5 dimethylpyrazine compound was higher (4.09 %) in flavourzyme hydrolysate compared to those in alcalase hydrolysate (1.01 %). These compounds were the predominant aroma active compound in cooked shrimp, crab and seaweed [6, 15, 2]. Fatty acid are considered important compound in seafood flavour [2]. Fatty acid such as 2-propenoic acid, tetradecanoic acid and hexadecanoic acid was only identified in mud clam flesh as shown in Table 1.

Table 1. Major volatile compounds in mud clam flesh, alcalase hydrolysate and flavourzyme hydrolysate

Volatile compounds	Percent area (%)		
	Mud clam flesh	Alcalase hydrolysate	Flavourzyme hydrolysate
2-Furanmethanol	1.84	n.d.	n.d.

Cyclopentadecane	1.57	n.d.	n.d.

n.d. = not detectable

Table 1 (cont'd). Major volatile compounds in mud clam flesh, alcalase hydrolysate and flavourzyme hydrolysate

Volatile compounds	Percent area (%)		
	Mud clam flesh	Alcalase hydrolysate	Flavourzyme hydrolysate
Nonadecane	2.18	n.d.	n.d.
Eicosane	2.63	n.d.	n.d.
Docasane	2.51	n.d.	n.d.
Heneicosane	3.73	n.d.	n.d.
Cholesta-3,5-diene	4.33	n.d.	n.d.
Tetracosane	2.87	n.d.	n.d.
Hexacosane	2.15	n.d.	n.d.
2,5 dimethylpyrazine	n.d.	1.01	4.09
2-Piperidinone	n.d.	6.79	3.78

n.d. = not detectable

According to Natta et al. [2], fatty acids were not found due to thermal degradation of lipids. 2-piperidinone is from amide group which caused bitter flavour was presence in both hydrolysates. The flavourzyme hydrolysate gave significantly lower content of 2-piperidinone (3.78 %) compared to alcalase hydrolysate (6.79 %). This finding was in agreement with amino acid and sensory analysis which indicated that alcalase hydrolysate has significantly higher degree of bitterness compared to flavourzyme hydrolysate. These compounds were also found in fermented castor oil bean [16].

Amino acids content

The amino acids content in mud clam flesh and hydrolysates is shown in Table 2. The total amino acids were 75.23 %, 62.37 % and 47.66 % for alcalase hydrolysate, flavourzyme hydrolysate and mud clam flesh, respectively. The amino acids grouping based on their taste characteristic as described by Tseng et al. [17] are shown in Table 2. The bitter amino acid was predominant taste in those three samples. Alcalase hydrolysate contains highest amount of bitter like amino acids (46.76 %) followed by flavourzyme hydrolysate (37.79 %) and mud clam flesh (30.4 %). The MSG-like amino acids (aspartic acid and glutamic acid) were 5.06 % in alcalase hydrolysate followed by mud clam flesh with 3.45 % and flavourzyme hydrolysate which is 3.28 %. This result was in agreement with sensory data in which alcalase hydrolysate gave higher bitter taste compared to flavourzyme hydrolysate. According to Zhang and Tao [7] who studied on the final taste characteristic of five different types of soy sauce revealed that the balance and interaction between different taste components in amino acid gave different taste to every sauce.

Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)

The molecular weight distributions of mud clam flesh and mud clam hydrolysates are shown in Figure 1. More intense bands with wide molecular weight range were observed in mud clam flesh compared to both hydrolysates. This showed that both enzymes are capable of breaking the protein into the smaller peptides. Mud clam hydrolysate produced from alcalase has lower molecular weight (<52 kDa) compared to flavourzyme hydrolysate (<126 kDa). Therefore, alcalase hydrolysate was bitterer than flavourzyme hydrolysate which is in line with sensory analysis.

Table 2. Total amino acids content ($g100g^{-1}$) in mud clam flesh, alcalase and flavourzyme hydrolysate based on their taste characteristic

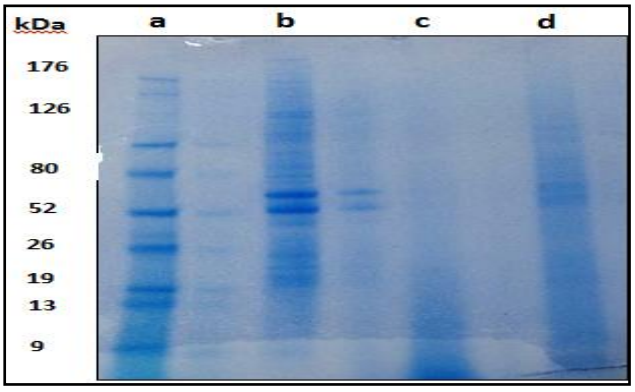

Figure 1. Molecular weight distributions of (a) protein marker, (b) mud clam flesh, (c) alcalase hydrolysate and (d) flavourzyme hydrolysate.

Identification of degree of bitterness and umami taste

The bitterness and umami taste of mud clam hydrolysate were evaluated using caffeine and monosodium glutamate (MSG) solutions. The score for bitterness using 15-cm line scale with anchor from 'none' to 'very strong' for alcalase hydrolysate was 6.60, 3.56 for flavourzyme hydrolysate and 9.66 for caffeine solution.

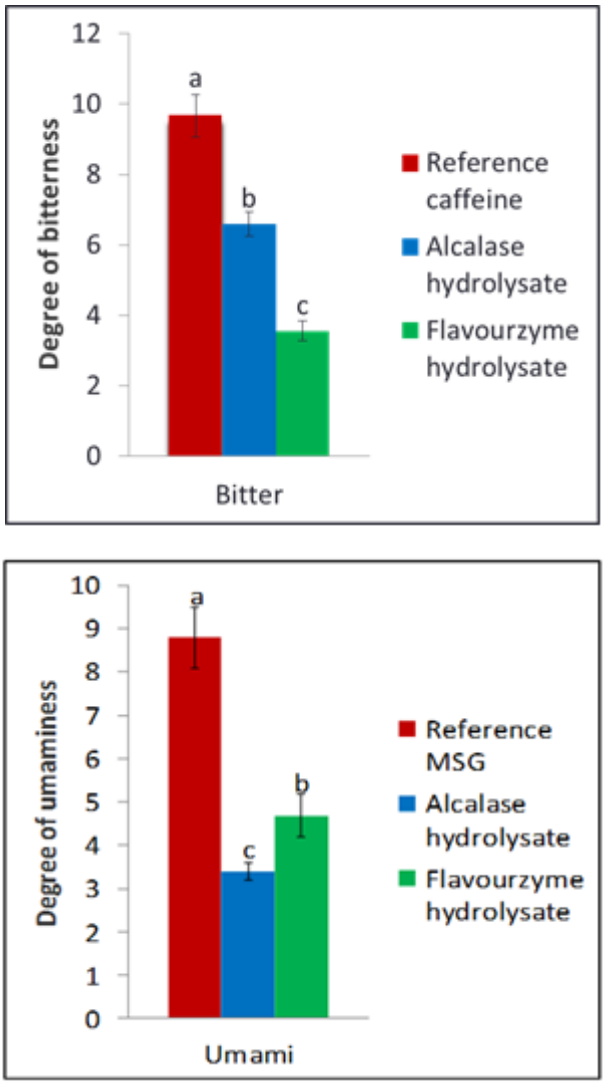

Figure 2. Degree of bitterness and umaminess of mud clam hydrolysates. Values are expressed as means ± standard deviation. Different letters indicate significant different at $p < 0.05$

This result revealed that the bitterness of the hydrolysates and caffeine solution were in the following order: flavourzyme hydrolysate <alcalase hydrolysate < caffeine reference solution. This result was in agreement with total amino acids content in which alcalase hydroysate had higher amount of bitter taste amino acids compared to flavourzyme hydrolysate. For umami taste, the reference monosodium glutamate (MSG) degree of umaminess was significantly higher ($p < 0.05$) compared to alcalase and flavourzyme hydrolysate (Figure 2). Flavourzyme

hydrolysate was perceived to be slightly more umami than alcalase hydrolysate by the panellists which could be associated with higher content of the sweet amino acids.

Conclusion

Volatile compound (2-piperidinone) that contributes to bitter taste was identified in hydrolysate. Alcalase hydrolysate has higher bitter like amino acid content compared to those of flavourzyme. The sensory analysis also suggested that flavourzyme hydrolysate was less bitter than alcalase hydrolysate. Both hydrolysates showed lower umami value than the reference umami solution. Further treatment of mud clam protein hydrolysate is needed to reduce the bitter taste and to enhance the umami taste in order to give more acceptable product.

Abstract

Dietary cholesterol should be limited to less than 200 mg/day. A single large egg yolk contains approximately 275 mg of cholesterol. Thus, consumption of a single egg yolk exceeds the recommended daily intake of cholesterol. This study was focused on determination of the effect of addition of increasing amount of β-cyclodextrin (β-CD) to encapsulate cholesterol in egg yolk. The quality of cholesterol-reduced egg yolk powder was evaluated by determining its nutritional composition and colour analysis. Increasing amount of β-CD (0 – 15 mM) was added in liquid egg yolk and the encapsulated cholesterol in the form of precipitate was removed. The supernatant was dried and the end product; cholesterol-reduced egg yolk powder (CREYP) was analyzed for moisture content, total lipid, fatty acids content, protein and colour. There were no significant difference ($p > 0.05$) in term of total solid content. However, protein content of CREYP was significantly ($p < 0.05$) reduced up to 7 mM β-CD and no further significant reduction was noticed with further addition of β-cyclodextrin. The appearance of the powder became lighter in colour as validated using chromameter; L*, a*, b*, C* and h^o values. The results obtained from this study indicate that cholesterol can be successfully removed from egg yolk. However, slight reduction in protein content was observed. Nutritional composition of CREYP was minimally affected with the removal of encapsulated cholesterol. Therefore, cholesterol-reduced egg yolk powder can be utilized as an essential ingredient in any egg yolk based products.

Keywords: cholesterol, β-cyclodextrin, egg yolk, nutritional composition

Abstrak

Pengambilan kolesterol dalam diet seharusnya tidak melebihi 200 mg/sehari. Sebiji kuning telur mengandungi hampir 275 mg kolesterol. Maka, pengambilan sebiji kuning telur telah melebihi kadar cadangan diet seharian kolesterol. Kajian ini memfokuskan kepada kesan penambahan kuantiti β-siklodekstrin (β-CD) untuk pengkapsulan kolesterol dalam kuning telur. Kualiti serbuk kuning telur kurang-kolesterol di analisis dengan menentukan komposisi nutrien dan analisis warna. Peningkatan kuantiti β-siklodekstrin (β-CD) (0 – 15 mM) ditambahkan ke dalam kuning telur dan pengkapsulan kolesterol di dalam bentuk mendakan dibuang. Supernatan dikeringkan dan hasil produk (serbuk kuning telur kurang-kolesterol) yang terhasil dianalisa untuk jumlah kandungan kelembapan, jumlah lipid, asid lemak, protein dan warna. Tiada perbezaan yang signifikan ($p > 0.05$) dalam jumlah kandungan pepejal. Walaubagaimanapun, kandungan protein kuning telur kurang-kolesterol berkurang secara signifikan ($p < 0.05$) bagi penambahan 7 mM β-CD dan tiada pengurangan yang signifikan dengan peningkatan penambahan β-CD. Serbuk kuning telur menunjukkan pengurangan warna seperti dibuktikan menggunakan kromameter; bacaan L*, a*, b*, C* dan h^o. Keputusan menunjukkan bahawa kolesterol telah berjaya dibuang daripada kuning telur. Walaubagaimanapun, pengurangan sedikit kandungan protein diperhatikan. Kesan pengurangan pengkapsulan kolesterol ke atas komposisi nutrisi serbuk kuning telur kurang-kolesterol adalah sedikit. Maka, serbuk kuning telur kurang-kolesterol dapat digunakan sebagai bahan ramuan penting di dalam mana – mana produk berasaskan kuning telur.

Kata kunci: kolesterol, β-siklodekstrin, kuning telur, komposisi nutrisi

Introduction

Egg yolk contains approximately 50 % of solids. The major constituents of the solid matter in egg yolk are lipids (65 – 70 % on dry basis) and proteins (30 % on dry basis), consisting of proteins in solution referred to as livetin, lipoprotein particles including high-density lipoproteins (HDLs), low-density lipoproteins (LDLs), and phosvitin [1]. Each constituent of yolk possesses special physical and chemical characteristics responsible for its own functional properties. Thus, yolk represents a major source of active principles usable in medical, pharmaceutical, cosmetic and biotechnological industries [2].

Nowadays foods not only intended to provide necessary nutrients, but also to prevent nutrition-related diseases and improve physical and mental well-being of the consumers [3]. It can be assumed that cholesterol-lowering and cholesterol-free products or those containing phystosterol esters, which are considered to lower the cholesterols level, will gain increasing relevance in the coming years [3]. Food companies have developed many methods to reduce cholesterol in food, such as short-path and vacuum molecular distillation, blending in vegetable oils, extraction by organic solvents, cholesterol degradation by cholesterol oxidases, and removal by supercritical carbon dioxide extractions. However, the cost of these are non-selective methods is high, and when cholesterol removed, flavor and nutritional components are removed as well [3, 4, 5]. This was agreed by Heshmati and Khodadadi, [6] where these methods are not applicable to all edible products. For example, *cis* fatty acid isomers are converted to atherogenic trans isomers during vacuum steam distillation method, aromatic and carcinogenic solvents may remain in the food after utilization, and a substantial capital investment and operating costs are required for carbon dioxide extraction procedure [7]. Moreover, the usage of solvents may present health risk or are so harsh that the restoration of the egg texture is impossible [8]. Vegetable oil extraction processes able to achieve substantial removal of cholesterol however, the amount of fresh oil needed for cholesterol extraction, usually 4 – 25 (wt/wt) times more than the egg yolk makes such processes impractical and uneconomical because after extraction such oil must be discarded [8]. Even though there is an improvement in the recyclability of the oil used, still the amount of oil used is in huge amount.

Encapsulation using cyclodextrins (CDs) is a method that has been used during the last few years in the cosmetics, drug and food industries for many purposes. Their molecular structure and shape made CDs to have the ability to act as molecular containers by entrapping guest molecules in their internal cavity [3]. Cyclodextrin can bind to various kinds of low molecule compounds into its cave structure, thereby stabilising the low molecule organic compounds by the inclusion effect [9]. The hydrophobic cavity forms inclusion complexes with a wide range of guest molecules. Non-covalent bonds are formed or broken during the complex formation and in aqueous solution, the complexes readily dissociate remaining the released molecules in equilibrium with the molecules bound within CD cavity [3]. The internal cavity which is hydrophobic allows the cyclodextrins to complex molecules such as aromatic alcohols, fatty acids and their esters and cholesterol.

Fresh eggs in liquid form are also difficult to transport because of their bulkiness, fragility, and highly perishable nature [10]. Therefore egg in powder form, able to overcome this problem. This study is therefore aimed at determining the effects of addition of β-cyclodextrin on the nutritional composition of cholesterol-reduced egg yolk powder dried using oven drying.

Materials and Methods

Materials

Fresh eggs were purchased from local market in Shah Alam, Malaysia. β-CD (purity 99.5%) was purchased from the Sigma Chemical Company (St. Louis, MO, USA). Chloroform-absolute alcohol, hexane (Ph. Eur., GC grade, Merck, Germany) and ethanol (Ph. Eur., Merck, Germany) were used in this study. Purified water (Milli QUV plus water system, Millipore, Molsheim, France) was also been used.

Preparation of cholesterol-reduced egg yolk: *Formation of inclusion complex*

Cholesterol was removed from egg yolk by formation of egg yolk cholesterol:β-cyclodextrin inclusion complex (EYCβIC) following the method used by Awad et al. [11] with some modifications. The egg yolk pH and ^{o}Brix were adjusted to 10.5 and 2.9, respectively with continuous stirring using homogenizer (IKA Ultra Turrax T25 Homogenizer, UK) at 210 ± 10 rpm. The egg yolk was placed in a laboratory shaking water bath (100 rpm, 1 hour, 50 ^{o}C). Diluted egg yolk (5 g) was mixed with increasing amounts of β-CD (0 – 15 mM) with continuous mixing using a vortex mixer (Laboratory equipment, VELP, Italy) at 1600 rpm for 10 minutes. The treated egg yolk was placed in a shaking water bath (100 rpm, 20 min, 50 ^{o}C) and cooled to 8 – 10 ^{o}C for 1 hour and centrifuged at 5000 rpm at 5 ^{o}C for 15 min (Hettich Universal 320, Benchtop centrifuge, Germany). Insoluble β-CD-cholesterol inclusion complex in the form of sediment was separated from the supernatant. The pH of the supernatant was adjusted back to pH 6.0. The supernatant were oven dried (44 ^{o}C, 4 hours) for production of cholesterol-reduced egg yolk powder.

Compositional analysis

Moisture content

The moisture content of the samples were determined in triplicate by drying under vacuum oven at 98 – 100 °C according to the method as described by AOAC, 1975 [12].

Total lipid

Lipids were extracted from the egg yolks using the standard method [13]. According to this method, approximately 4 g well mixed egg yolk was weighed into a 100 mL volumetric flask and 25 mL chloroform-absolute alcohol were added (1:1) the solvent was mixed very slowly from pipette. It was shaken constantly until proteins were coagulated. An additional 60 – 65 mL mixed solvent was added and let stand for 1 hour, shaken every 5 min. At the end of the time it was diluted to volume with mixed solvent and the mixture was let stand until clear. The mixture was then filtered very slowly (filtrate should be clear), solvent was evaporated and egg yolk lipid was obtained. The total lipid content of the samples was evaluated in triplicate.

Cholesterol determination

The supernatant (1 mL) were placed in screw-capped glass tubes (15 x 180 mm). The samples were saponified [14]. The extracts were redissolved in 1 mL of hexane and stored at -20 °C until analysis. The total cholesterol was determined using gas chromatography [15]. The percentage of cholesterol reduction was calculated using the equation given below:

$$\text{Cholesterol reduction (\%) at 15 mM} = \frac{(\text{amount of cholesterol at 0 mM} - \text{amount of cholesterol at 15 mM}) \times 100}{\text{amount of cholesterol at 0 mM}} \quad (1)$$

Fatty acids determination

FAMEs were prepared according to the method as described by Zara et al. [16] with some modifications. FAME analysed were performed on gas chromatograph (Perkin Elmer). Fatty acid methyl esters were separated on a capillary column (HP-5 MS; Agilent 0.25 mm x 30 m 0.25 µm) equipped with an auto-sampler. The initial temperature of 50 °C was held for 3 min, increased to 180 °C at 10 °C min, increased to 220 °C at 5 °C /min and held for 10 min. The column temperature was elevated to 230 °C at 5 °C/min and held at the final temperature for 3 min. Helium was used as the carrier gas at a flow rate of 3.0 mL/min. The detector was set at 240 °C. Fatty acid methyl esters were identified by comparison with retention times of standard mixture. The fatty acid content of egg yolk was calculated using the following formula equation 2 [17, 18]:

$$\text{Concentration (mg/g)} = \frac{\text{Peak area of a given fatty acid} \times \text{concentration of IS (mg/mL) peak area of IS}}{\text{Weight of sample (g)}} \quad (2)$$

IS is defined as internal standard.

Protein determination

The Kjeldahl method of nitrogen analysis was conducted to calculate the protein content [13]. The protein content of liquid egg yolk treated from 0 – 15 mM addition of β-CD was determined in triplicate.

Colour determination

Colour values (L*, a*, b*, C*, h^o) of EY powder treated from treatment of liquid egg yolk with 0 – 15 mM addition of β-CD were measured in triplicate using Chromameter CR-400.

Statistical analysis

Mean values from the three separate experiments or replicate analysis were reported. The statistical significance of observed differences among three treatment means evaluated by analysis of variance (ANOVA) and the comparison of means were carried out by Duncan's multiple range test ($p < 0.05$) by using SPSS 10 for Windows.

Results and Discussion

Moisture content

Moisture content is important in food quality and preservation. Moisture content is expressed as dry basis. Dry basis of moisture content is defined as the ratio of water weight to the dried weight of sample [19]. The moisture content of the egg yolk powder with the addition of increasing amount of β-cyclodextrin was shown in Table 1. Moisture content of the dried egg yolk powder obtained in this study was in the range of 2.4 – 2.7 %. Previous researcher suggested the optimum moisture content for egg yolk powder should be within the range of 2 – 4 %, low enough to extend the shelf life in an environment of low humidity [10].

Table 1. Moisture content of cholesterol-reduced egg yolk powder

Concentration of β-cyclodexrin (mM)	**0**	**1**	**3**	**5**	**7**	**11**	**13**	**15**
Moisture content (g/100 g egg yolk powder)	2.5 ± 0.66[a]	2.4 ± 0.35[a]	2.6 ± 0.48[a]	2.4 ± 0.35[a]	2.6± 0.11[a]	2.5 ± 0.09[a]	2.7 ± 0.11[a]	2.7 ± 0.10[a]

Means within the same row with different letters differ significantly ($p < 0.05$).

Total lipid

The lipid content in egg yolk are principally triglycerides (65 %, w/w), phospholipids (28 %, w/w), cholesterol (5 %, w/w) [20] and were exclusively associated with lipoproteins assemblies [21]. The concentration of lipid in the dried cholesterol-reduced egg yolk powder showed in Figure 1. The reduction of total lipid was from 55 to 48 g/100gm egg yolk powder. Our previous work has shown and proven that certain fraction of cholesterol molecules was included into β-CD cavity which confirmed the formation of inclusion complex and finally in accomplishment of the reduction of cholesterol in egg yolk [22]. Since cholesterol molecules are part of egg yolk lipids, the total lipid contents of egg yolk powder were expected to be slightly reduced. There were no significant differences ($p > 0.05$) in total lipid content as increased in the addition of β-CD concentration.

The reduction of total lipids should be due to removal cholesterol through encapsulation. Egg yolk consists mainly of 68 % low-density lipoproteins (LDL), 16 % high-density lipoproteins (HDL), 10 % livetins and 4 % phosvitins [23]. Cholesterols which were situated in the large spherical of LDL particles, probably the reason why total lipids were reduced along with cholesterol extraction.

The cholesterol removal process such as stirring, separation and centrifugation during separation of cholesterol: β-CD inclusion complexes may affect the decreasing of total lipid content of egg yolk. These results correlated with the study by Kim et al. [24]. Furthermore, Ha et al. [25] suggested that the free fatty acids in food may be reduced because they are trapped in β-CD cavities molecule.

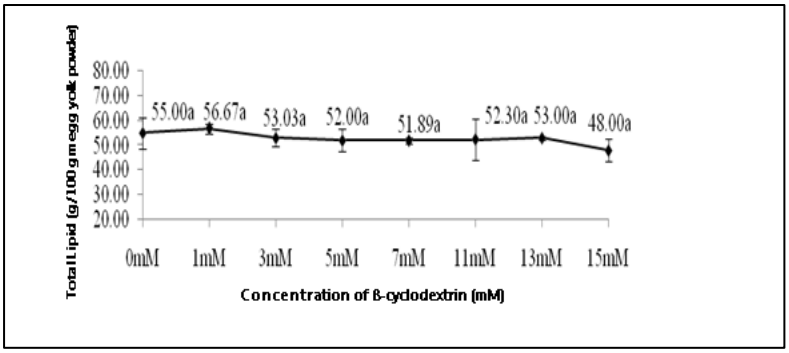

Figure 1. Total lipid content of cholesterol-reduced egg yolk powder

Cholesterol reduction

Increasing amounts of β-cyclodextrin (β-CD) were added to optimize the weight ratio for maximal cholesterol removal from the egg yolk. The concentrations of cholesterol remaining in the supernatant after removal of the pellet inclusion complexes were shown in Figure 2. The curve shows a gradual decrease in the concentration of cholesterol in the egg yolk as the concentration of added β-CD (mM) increased, which is in agreement with the findings of the previous study [26]. At 0 mM β-CD, cholesterol content was 12.51 mg/gm, whereas as 1 mM, 3 mM, 5 mM, 7 mM, 11 mM and 13 mM β-CD were recorded at 10.72, 6.14, 4.36, 3.87, 2.02 and 1.14 mg/gm cholesterol content respectively. Cholesterol-reduced egg yolk powder at 15 mM β-CD was lower than at 0 mM β-CD ($p < 0.05$). At 15 mM β-CD with 0.24 mg/gm cholesterol content left resulted in 98 % cholesterol was extracted from the 5 gm supernatant.

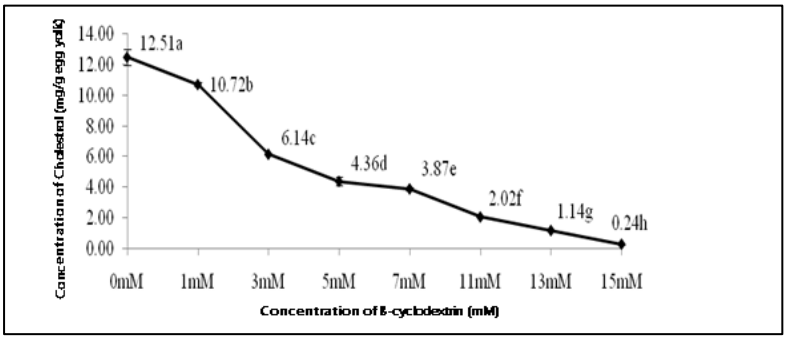

Figure 2. Cholesterol contents of cholesterol-reduced egg yolk powder. Data are expressed as means ± SD. Value with different letters indicates significant difference at $p < 0.05$.

Fatty acids determination

Fatty acids were prepared from different concentration of increasing β-CD concentrations according to the method as described by Zara et al. [16]. Among the different fatty acids tested (Table 2), there were no difference ($p > 0.05$) was observed as increasing β-CD concentrations for linolenic acid (C18:3) with 0.86 ± 0.13^a, 0.56 ± 0.34^a , 0.56 ± 0.46^a , 0.30 ± 0.10^a and 0.48 ± 0.04^a (mg/g fatty acids) for 0 mM (control), 3 mM, 7 mM, 11 mM and 15 mM β-CD concentrations respectively (Table 2). Arachidonic acid (C20:4 (n-6)) showed significant different with the highest β-CD concentrations (15 mM), with fatty acids content of 5.51 ± 0.03^a, 5.39 ± 0.07^a, 5.69 ± 0.09^a, 5.42 ± 0.14^a and 1.67 ± 0.33^b for 0 mM (control), 3 mM, 7 mM, 11 mM and 15 mM β-CD concentrations respectively.

Table 2. Fatty acids content of cholesterol-reduced egg yolk powder

Fatty acids	Concentration β-CD (mM)				
	0	3	7	11	15
Myristic acid C14:0	2.02 ± 0.14^{a}	1.90 ± 0.01^{ab}	1.81 ± 0.08^{bc}	1.69 ± 0.03^{c}	1.45 ± 0.03^{d}
Palmitoleic acid C16:1	22.42 ± 2.87^{a}	24.81 ± 0.51^{a}	16.56 ± 1.89^{b}	22.45 ± 0.93^{a}	20.12 ± 1.57^{b}
Palmitic acid C16:0	118.92 ± 8.40^{b}	133.16 ± 0.72^{a}	118.68 ± 2.04^{b}	105.27 ± 4.35^{c}	48.09 ± 0.62^{d}
Linolenic acid (C18:3)	0.86 ± 0.13^{a}	0.56 ± 0.34^{a}	0.56 ± 0.46^{a}	0.30 ± 0.10^{a}	0.48 ± 0.04^{a}
Oleic acid C18:1 (n-9)	217.8 ± 3.89^{a}	220.62 ± 1.88^{a}	222 ± 1.41^{a}	186.11 ± 5.81^{b}	69.97 ± 1.03^{c}
Linoleic acid C18:2 (n-6)	20.1 ± 0.04^{ab}	18.77 ± 0.40^{b}	24.31 ± 1.71^{a}	18.2 ± 3.59^{b}	18.38 ± 0.20^{b}
Stearic acid C18:0	33.84 ± 2.17^{a}	33.79 ± 0.63^{a}	35.16 ± 0.69^{a}	35.02 ± 0.67^{a}	12.08 ± 0.04^{b}
Arachidonic acid C20:4 (n-6)	5.51 ± 0.03^{a}	5.39 ± 0.07^{a}	5.69 ± 0.09^{a}	5.42 ± 0.14^{a}	1.67 ± 0.33^{b}
EPA C20:5 (n-3)	1.07 ± 0.04^{b}	1.21 ± 0.04^{a}	1.14 ± 0.04^{ab}	0.45 ± 0.05^{c}	0 ± 0.00^{d}
DHA C22:6 (n-3)	1.48 ± 0.16^{ab}	1.71 ± 0.03^{a}	1.30 ± 0.02^{ab}	0.68 ± 0.68^{bc}	0.21 ± 0.10^{c}

Means within the same row with different letters differ significantly ($p < 0.05$).

Whereas for 15 mM β-CD concentration, there was totally lost in EPA as 0 mM (control) having lower EPA content. However, other fatty acids; myristic acid (C14:0), palmitoleic acid (C16:1), palmitic acid (C16:0), oleic acid (C18:1 (n-9)), linoleic acid (C18:2 (n-6)), EPA (C20:5 (n-3)), and DHA (C22:6 (n-3)) resulted in difference in decreasing of fatty acids content ($p < 0.05$) as increasing β-CD concentrations. These results were same as reported by Awad et al. [27]. The changes in concentration of C18:1 (n-9), C18:2 (n-6) and C16:0 might be due to changes in the relatively concentrations of triglycerides and phospholipids, which are composed of different fatty acids [27]. The major fatty acids of triglycerides are oleic acids and palmitic acid. Therefore as the β-CD concentrations were increased, all the fatty acids of the egg yolk powder being tested were decreased.

Protein quantification

The egg yolk protein content was significantly decreased ($p < 0.05$) as cholesterol being reduced with increasing β-CD concentrations from 0 to 15 mM (Figure 3). Protein content in the egg yolk was significantly reduced as β-CD concentration increased up to 7 mM. There was no significant difference with further addition of β-CD. Smith et al. [28] reported that protein reduction of 9.2 % with 89.2 % cholesterol reduction in liquid egg yolk using β-CD which proven better reduction of cholesterol with 98% reduction of cholesterol with almost less than 9 % protein reduction in this study.

Cyclodextrins molecular structure is unique with hydrophilic exterior properties and hydrophobic in central of its cavities. These properties allow them to form non-covalent inclusion complexes by encapsulating of variety of 'guest' molecules into the 'host' which refer to their central cavities through associate and dissociating process. Kim et al. [24] and Kwak et al. [30] reported the protein reduction in milk after removal of cholesterol. It was confirmed that the protein content of cream was reduced during reduction of cholesterol by 4 –10 % β-CD due to entrapment of amino acids in β-CD cavities [29].

Maskooki et al. [31] reported that, the outer surface of β-CD macromolecules has affinity to absorb the negative charges that cover the protein surfaces. Subsequently, parts of protein together with β-CD:cholesterol inclusion complexes leave during centrifugation and separation process. Thus, cholesterol reduction processing such as mixing, separation, and centrifugation may affect decrease of total protein content of egg yolk.

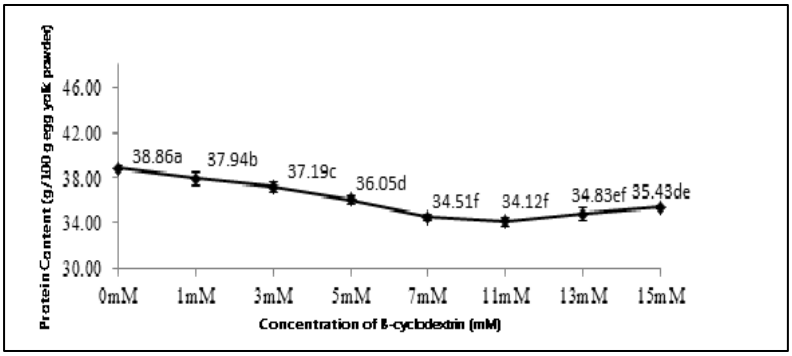

Figure 3. Protein contents of cholesterol-reduced egg yolk powder

Colour determination

The colour analysis of the egg yolk powder produced from the reduction of cholesterol by β-CD: cholesterol inclusion complexes was confirmed by the data obtained (Table 3) from the instrumental analysis using Minolta Chroma Meter CR-300 (Japan) to detect the lightness (L*), redness (a*) and yellowness (b*), saturation, (C*) and hue angle (h^o) values of egg yolk powder. L* value represents lightness (negative towards black, positive towards white), a* value is the red-greenness colour scale (negative towards green, positive towards red) whereas b* value represents blue-yellow colour scale (negative towards blue, positive towards yellow).

The lightness (L*), redness (a*) and yellowness (b*), Chroma (C*) and hue angle (h^o) of egg yolk powder were significantly different with direct correlation with increasing addition amount of β-CD concentrations as cholesterol being reduced.

Table 3. Colour values of cholesterol-reduced egg yolk powder

Egg yolk powder	*L	a*	b*	C*	h^o
0 mM	72.55 ± 0.03^{h}	1.83 ± 0.09^{a}	39.40 ± 0.07^{a}	39.42 ± 0.07^{a}	87.57 ± 0.18^{f}
1 mM	73.06 ± 0.06^{g}	1.48 ± 0.13^{a}	38.49 ± 0.04^{b}	38.50 ± 0.03^{b}	87.88 ± 0.04^{e}
3 mM	73.70 ± 0.15^{f}	1.29 ± 0.07^{c}	36.57 ± 0.04^{c}	36.25 ± 0.22^{c}	88.09 ± 0.11^{de}
5 mM	74.34 ± 0.29^{e}	1.08 ± 0.03^{de}	34.62 ± 0.06^{d}	34.57 ± 0.20^{d}	88.24 ± 0.14^{d}
7 mM	79.53 ± 0.10^{d}	1.13 ± 0.16^{cd}	33.37 ± 0.15^{e}	33.41 ± 0.19^{e}	89.74 ± 0.02^{c}
11 mM	80.68 ± 0.19^{c}	0.95 ± 0.14^{ef}	32.69 ± 0.21^{f}	31.57 ± 0.14^{f}	89.80 ± 0.14^{c}
13 mM	82.47 ± 0.15^{b}	0.86 ± 0.08^{f}	31.70 ± 0.07^{g}	30.71 ± 0.15^{g}	90.03 ± 0.03^{b}
15 mM	83.74 ± 0.12^{a}	0.43 ± 0.41^{g}	28.42 ± 0.07^{h}	28.11 ± 0.03^{h}	92.03 ± 0.19^{a}

Means within a column with different letters differ significantly ($p < 0.05$).

Increasing amount of β-CD concentrations resulted in production of egg yolk powder with reduced in yellow colour. This was proven as the L-values of egg yolk powder was increased showing that the egg yolk powder turn to much lighter colour. Decreasing of redness (a*) and yellowness (b*) intensity colour of egg yolk powder correlate with reduction of yellowness of yolk and finally makes the egg yolk powder became greener and bluer as increased in the addition of β-CD. The colour of egg yolk is attributed to fat-soluble carotenoids (xanthophylls; including lutein, zeaxanthin, β-cryptoxanthin and minor amounts β-carotene) [32]. It appeared that the lightness (L*), redness (a*) and yellowness (b*), were influenced by β-CD concentrations additions with the reduction of cholesterol. Lipid-soluble pigments of egg yolk probably were being trapped by β-CD cavities during the cholesterol removal process.

Chroma (C*) is a measure of intensity or saturation and calculated as $[(a^*)^2 + (b^*)^2]^{1/2}$ and represents saturation whereas h° represents hue angle which is derived from the two coordinates a* and b* and determined as $\tan^{-1} b^*/a^*$ [33]. Hue angle (h°) is expressed on a 360° grid where 0° = bluish-red, 90° = yellow, 180° = green and 270° = blue [34]. Egg yolk powder with yellow coloured sample going from thick yellow to light yellow (towards green) when h^o values was increased as βCD addition also was increased. Whereas C* values of egg yolk powder showed that as egg yolk pigment concentrations reduced, the C* values lessened.

The yellow-orange colour of yolk is due to carotenoid pigments, primarily xanthophylls with minor amount of carotene [31]. Awad et al. [27] reported that β-carotene concentrations of egg yolk powder treatment with β-CD were lower than those of untreated egg yolk powder. Except for problems with colour, these results suggest that CD can be used to produce a low cholesterol egg product with functional properties similar to those of the original liquid egg yolk.

Conclusion

Cholesterol has been successfully reduced from egg yolk using β-CD with minimal depletion of nutritional composition of egg yolk powder. Utilization of cholesterol-reduced egg yolk powder in food can be beneficial to food industry in production of healthy and nutritious products even minimizing the cost of loss in industry due to spoilage and improper handling of native egg yolk.

DETERMINATION OF OPTIMUM CONDITION OF LEUCINE CONTENT IN BEEF PROTEIN HYDROLYSATE USING RESPONSE SURFACE METHODOLOGY

(Penentuan Keadaan Optimum bagi Kandungan Leusina di dalam Protein Hidrolisat Daging Menggunakan Kaedah Gerak Balas Permukaan)

Abstract

The aim of this study is to determine the optimum condition of leucine content in beef hydrolysate. Beef hydrolysate was prepared by enzymatic hydrolysis using bromelain enzyme produced from pineapple peel. Parameter conditions such as concentration of bromelain, hydrolysis temperature and hydrolysis time were assessed to obtain the optimum leucine content of beef hydrolysate according to experimental design which was recommended by response surface methodology (RSM). Leucine content in beef hydrolysate was determined using AccQ.Tag amino acid analysis method using high performance liquid chromatography (HPLC). The condition of optimum leucine content was at bromelain concentration of 1.38 %, hydrolysis temperature of 42.5 °C and hydrolysis time of 31.59 hours with the predicted leucine content of 26.57 %. The optimum condition was verified with the leucine value obtained was 26.25 %. Since there was no significant difference ($p > 0.05$) between the predicted and verified leucine values, thus it indicates that the predicted optimum condition by RSM can be accepted to predict the optimum leucine content in beef hydrolysate.

Keywords: leucine, enzymatic hydrolysis, bromelain, response surface methodology

Abstrak

Matlamat kajian ini adalah untuk menentukan keadaan optimum kandungan leusina di dalam hidrolisat daging lembu. Hidrolisat daging lembu telah disediakan secara hidrolisis enzim menggunakan enzim bromelin yang dihasilkan daripada kulit nanas. Keadaan parameter seperti kepekatan bromelin, suhu hidrolisis dan masa hidrolisis telah dinilai untuk mendapatkan kandungan leusina yang optimum dari hidrolisat daging lembu mengikut reka bentuk eksperimen yang disyorkan oleh kaedah gerak balas permukaan (RSM). Kandungan leusina di dalam hidrolisat daging lembu telah ditentukan dengan menggunakan kaedah analisis AccQ.Tag asid amino menggunakan kromatografi cecair prestasi tinggi (HPLC). Keadaan optimum kandungan leusina didapati pada kepekatan bromelin 1.38 %, suhu hidrolisis 42.50 ºC dan masa hidrolisis 31.59 jam dengan kandungan leusina yang diramalkan adalah 26.57 %. Keadaan optimum telah disahkan di mana nilai leusina diperolehi adalah 26.25 %. Oleh kerana tiada perbezaan yang signifikan ($p > 0.05$) antara nilai leusina yang diramalkan dan disahkan, maka ia menunjukkan bahawa keadaan optimum yang diramalkan oleh RSM boleh diterima dan digunakan untuk meramalkan kandungan leusina yang optimum dalam hidrolisat daging lembu.

Kata kunci: leusina, hydrolisis enzim, bromelin, kaedah gerak balas permukaan

Introduction

Beef consumption has decreased in the last decades due to negative health images [1]. Many studies deal with the opportunities of enhancing the beneficial fatty acids such as increasing the *n*-3 polyunsaturated fatty acids and conjugated linoleic acids (CLA) and reducing saturated fatty acids (SFA) in beef. In addition, limited knowledge is known about the alteration of other nutritional ingredients such as amino acid composition in beef [2, 3]. Meat and meat products are good sources of protein for human consumption. These proteins are well balanced in amino acid and contain all essential amino acids that human cannot synthesize. However, certain people are advised not to consume beef due to health problems. According to Bjoern et al. [4] several essential amino acids such as leucine and phenylalanine or non-essential amino acids such as arginine and glutamine, have shown to directly stimulate insulin secretion from pancreatic beta-cells, resulting in beneficial therapeutic effects in patients with type 2 diabetes.

One of the methods for protein recovery from this meat protein is production of protein hydrolysate through enzymatic hydrolysis. It is widely employed to improve nutritional and functional properties of meat protein. In the effort of attempting to hydrolyse beef protein by using controlled enzymatic hydrolysis process, many factors have to be considered. One of the important factors is the choice of enzymes since different enzymes have different specific activities and optimal working parameters. There were many commercial proteases have been reported to be used for the hydrolysis of beef protein such as alcalase, flavorzyme, bromelain and papain [5 – 7]. However, bromelain is the most preferred to be used in enzymatic hydrolysis as it is proven to give the highest total yield of α-amino groups compared to other proteases such as papain and alcalase [6].

Bromelain enzyme is endopeptidase enzyme. It is related to the family of cysteine protease C1 and has a single chain, glycosylated amino acid cysteine with seven bridges and probably three disulfides [8]. The mechanism of action of cysteine protease to cleave peptide bonds through a double-displacement pathway involving general acid-base formation and hydrolysis of an acyl-thiol intermediate. The initial step in catalytic process involves noncovalent binding of the free enzyme and the substrate to form the complex. This is followed by the acylation of the enzyme with the formation and release of the first product, the amine R`-NH2. In the next deacylation step, the acyl-enzyme reacts with a water molecule to release the second product, with the regeneration of free enzyme [8].

Under standard condition, proteases hydrolysed peptide bond. Bromelain cleave glycol, anayl and leucyl bonds [9]. At pH6, bromelain hydrolysed ethyl ester of L-leuicne, L-arginine, L-glycine, L-phenylalanine, L-tyrosine, L-lysine and L-glycine [10]. In the process of enzymatic hydrolysis, factors such as pH, time, enzyme to substrate level and temperature will influence enzymatic activity. In this context, the main goal of enzymatic hydrolysis of beef was to obtain the maximum leucine content in flank cut of beef. Studying the effect of these hydrolysis parameters on leucine content contribute to the understanding of the protein hydrolysate released. Optimization is one of the methods to find a best alternative from a specified set of alternatives. It is the modern statistically derived experimental designs that are viewed as a way to achieve this purpose.

Response surface methodology (RSM) has been effective in the optimization and monitoring of food processes [11]. Response surface methodology is an empirical modeling technique and was used to estimate the relationship between a set of controllable experimental factors and observed results [12]. A multiple regressions analysis technique that is included in the RSM was performed to determine all the coefficients of linear (X_1, X_2, X_3), quadratic (X_1 X_1, X_2 X_2, X_3 X_3) and interaction (X_1X_2, X_1X_3, X_2X_3) terms to fit a full response surface model for the responses. The goodness of fit of the regression model was defined by determining the coefficient R^2 and adjusted R^2 (multiple correlation coefficient, R), which provides a measure of how much variability in the observed response values can be explained by the experimental factors and their interaction [13]. The lack-of-fit test measures the variation of data with regards to the fitted model and is one of the important aspects of a reduced model. If the model does not fit the data well, the lack-of-fit test will be significant. A model should be rejected if the results showed any significance in the lack-of-fit test [14] Patel et al. [15] testified that an insignificant lack-of-fit indicates a good model. The F value for the lack-of-fit can be obtained by dividing the lack-of-fit mean square by its pure error mean square.

The objective of this study was to determine optimal enzymatic hydrolysis parameter (bromelain concentration, hydrolysis temperature and hydrolysis time) of flank cut of beef to obtain the optimum leucine content by using RSM. Additionally, the degree of hydrolysis and amino acid composition of the optimum beef protein hydrolysate prepared using the optimized hydrolysis conditions were determined.

Materials and Methods

Chemicals and raw materials

All chemicals used were purchased from Sigma Chemical Co. (St Louis, Missouri). Peel of pineapple index 2, variety N36 were obtained from Peninsula Plantation Sdn Bhd, Simpang Renggam, Johor, Malaysia and flank cut of beef were obtained from a slaughter house in MZR Livestock (M) Sdn. Bhd, Rantau Panjang, Klang, Selangor, Malaysia.

Optimisation of enzymatic hydrolysis condition

The optimum enzymatic hydrolysis conditions of flank cut of beef was determined by response surface methodology (MINITAB Software Version 15). The three test variables chosen were bromelain concentration, hydrolysis temperature and hydrolysis time as shown in Table 1. The experiment was optimized by using three-factors, five levels central composite design (CCD). The central composite design composed of 20 treatments including 2^3 factorial points, six axial points (α ±1.68) and six replicates of the central point. The design of experiments and dependent variable values was presented in Table 2.

Table 1. Coded and uncoded variables used in optimisation experiment

Parameter	Code	-1.68	-1	0	1	1.68
Bromelain concentration (% w/w)	X_1	0.5	1.0	1.5	2.0	2.5
Hydrolysis temperature (°C)	X_2	40	42.5	45	47.5	50
Hydrolysis time (hours)	X_3	24	30	36	42	48

Enzymatic hydrolysis of beef

The protein hydrolysate of the beef was produced through enzymatic hydrolysis using bromelain from pineapple peel extract. Clarified pineapple peel extract were purified using cation exchange chromatography to produce purified bromelain. Then the purified bromelain undergo the desalting process whereby this process was carried out by using the diafiltration process. Desalted bromelain was dried using vacuum freeze dryer to produce powdered bromelain. This bromelain powder was used for enzymatic hydrolysis of beef. The enzymatic hydrolysis process was carried out based on Haslaniza et al. [6] method. Two gram (2g) flank cut of beef was placed in 100 mL conical flask. Then, 50 mL of distilled water was added. The mixture was then hydrolysed in the oven (95 °C) for 20 minutes followed by cooling to room temperature condition. The pH of the mixture was adjusted to pH 6 using 4N NaOH. Then, enzyme bromelain at different concentrations (0.5, 1.5 and 2.5% (w/w)) were added followed by the addition of 2 mL of 0.1M L-Cysteine as a catalyst. The mixture was incubated at 200 rpm in an incubator shaker with temperature (40 – 50 °C) and time (24 – 48 hours) according to the experimental design as shown in Table 2. After that, the samples were heated at 95 °C for 15 min to deactivate the enzyme. The protein hydrolysate sample was centrifuged at 7800 x g for 15 min in order to separate any impurities from hydrolysate. The clear supernatants were frozen at -20 °C before the freeze drying process.

Determination of amino acid

The beef protein hydrolysate was hydrolysed using 5 mL 6N HCl at 110 °C for 24 hours. The amino acid content was analysed according to AccQ.Tag Amino acid analysis method [7] using HPLC equipped with a Waters 410 Scanning Flourescence and AccQ Tag column (3.9 x 150 mm). AccQ Tag Eluent A (19 % sodium acetate) and AccQ Tag Eluent B (60 % acetonitrile acid) was used as the mobile phase (flow rate = 1 mL/min). The column temperature was set at 36 ºC. The HPLC system was run by concentration gradient in the process of analysing amino acid.

Table 2. Experimental design by MINITAB Software

R^2 = 99.94%, Adjusted R^2 = 99.89%					

Determination of degree hydrolysis and nitrogen content

The degree of hydrolysis was calculated according to the percentage of trichloroacetic acid (TCA) ratio method as described by Haslaniza et al. [6]. After enzymatic hydrolysis, 20 mL of beef protein hydrolysate was added into 20 mL of 20 % (w/v) TCA to produce 10 % TCA soluble material. The mixture was left to stand for 30 minutes to allow precipitation, and then followed by centrifugation at 7800 x g for 15 minutes. The degree of hydrolysis (DH) was calculated using the following formula equation 1:

$$\% \text{ DH} = \frac{\text{Soluble N in TCA 10\% (w/v)}}{\text{Total N in beef}} \times 100 \quad (1)$$

where DH is defined as degree hydrolysis and TCA is defined as trichloroacetic acid.

The nitrogen content in supernatant, powdered beef hydrolysate and flank cut of beef was determined using CHNS elemental analyser. Before the analysis, all the samples were dried for 1 hour in oven at 110 ^{o}C.

Statistical analysis

The results from CCD was assessed using multi linear regression [16] using an equation 2 below:

$$Y = b_0 + b_1A + b_2B + b_3C + b_4A^2 + b_5B^2 + b_6C^2 + b_7AB + b_8AC + b_9BC \quad (2)$$

where Y represents the predicted response, b_0 is the value for the fixed response at the central point of the experiment, b_1, b_2 and b_3 are linear coefficients, b_4, b_5 and b_6 are quadratic coefficients, and b_7, b_8, and b_9 are cross-product or interaction coefficients.

The R^2 value and the lack of fit value were determined. After the multifactor analysis of variance and the second-order model prediction determinations, the optimal enzymatic hydrolysis conditions were obtained by the desirability function approach. The response surface plots were developed to represent a function of two test variables while keeping the other test variable at the optimal value.

For the verification value, the experimental value of response (leucine) was compared to the predicted value of response (leucine). Data were analysed using t-test method using SPSS 20. A significant difference was considered at the level of $p < 0.05$.

Results and Discussion

Optimization of enzymatic hydrolysis of beef

A central composite design was performed to study the combined effect of three factors (bromelain concentration, hydrolysis temperature and hydrolysis time) on the response, leucine content (%). The predicted and experimental results of the 3-factors, 5-levels central composite design was presented in Table 2. The determination of coefficient (R^2) was 99.94%, which suggested that this quadratic model was appropriately to represent the real relationships among the chosen hydrolysis parameters. The closer the R^2 value to one, the better the fitting of the empirical model with the actual data and the better the correlation between experimental and predicted values [16].

The adjusted R^2 was a corrected value for R^2 after the elimination of unnecessary model terms. If there are many non-significant terms included in the model, the adjusted R^2 would be smaller than R^2. In this present study, it is found that the adjusted R^2 is high and very close to the R^2. Respective values for adjusted R^2 and R^2 were 99.89 % and 99.94 %. The high values of adjusted R^2 and R^2 indicate a high dependence and correlation between the observed values and the predicted values of response.

The effect of experimental variables on the linear, quadratic and interaction terms were tested for adequacy and fitness by analysis of variance (ANOVA). The summary of the results obtained are shown in Table 3. By using lack-of-fit and correlation coefficient determination (R^2), the adequacy of the model can be revealed. The significance of the equation parameter for test variables was assessed by F ratio at a probability (p) of 0.05. The F value predicts the quality of the entire model while considering all design factors all at once.

Table 3. ANOVA test for optimisation of leucine content in protein hydrolysate treated with bromelain

Source	DF	Seq SS	Adj SS	Adj MS	F	P	Status

DF = degree of freedom, Seq SS = sequential sum of square, Adj SS = adjusted sum of square, Adj MS = adjusted mean square, F = fischer, P = probability

The p value is the probability of the factors having very little or insignificant effect on the response. A larger F value signifies a better fit of the RSM model to the experimental data [17]. Datta et al. [18] reported that an F value with a low p value indicates the high significance of the regression model. However, the p value should be lower than 0.05 for the model to be statistically significant [15]. Based on reports by literatures [17, 18, 15] the regression model found in this study was highly significant as denoted by the large F and low p value of 1921.79 and 0.000, respectively. From Table 3, it was observed that the quadratic (square) and interaction factors were highly significant compared to linear factors as indicated by the large F values of 2280.58 and 1988.03 with a low p value of 0.000, each. In this study, the lack of fit model showed a non-significant result ($p > 0.05$) with a p value of 0.456. Thus, the insignificant p value indicates that the model is good and fits well with the experimental data.

Overall, the analysis of variance suggested that the predicted quadratic model for enzymatic hydrolysis conditions of flank beef cut was statistically valid. The second-order polynomial model equation for the optimisation of leucine in beef hydrolysate treated with bromelain is illustrated as follows:

$$Y = 204.095 + 12.988X_1 - 5.103X_2 - 3.124X_3 - 5.271X_1^2 - 0.053X_2^2 - 0.131X_3^2 - 0.315X_1X^2 + 0.601\ X_1X^3 + 0.260X_2X^3$$

where X_1= concentration of bromelain, X_2 = hydrolysis temperature, X_3= hydrolysis time.

Based on Table 4, it was found that the optimum conditions for the target goal with a bromelain concentration of 1.38 % (% w/w), hydrolysis temperature of 42.5 °C and hydrolysis time of 31.59 hours as well as for the minimum goal with a bromelain concentration of 1 % (% w/w), hydrolysis temperature of 47.5 °C and hydrolysis time of 30 hours were feasible to be carried out. Meanwhile, the optimum condition for the maximum goal with a bromelain concentration of 1.93 % (% w/w), hydrolysis temperature of 42.5 °C and hydrolysis time of 38.48 hours was not feasible to be carried out. This is in accordance with the optimum conditions for the target and minimum goals being located in the white area or in the feasible region based on the overlaid contour plots obtained. Meanwhile, the optimum condition for the maximum goal is located in the grey area or non-feasible region. However, the optimum condition for the target goal was chosen because the response value was higher compared to the optimum condition for the minimum goal.

Condition for optimum response

The optimum conditions of enzymatic hydrolysis of flank cut of beef were 1.38% (% w/w) for bromelain concentration, 42.5°C for hydrolysis temperature and 31.59 hours for hydrolysis time.

The Dimension (2D) contour and (3D) surface plots for leucine content in protein hydrolysate treated with bromelain at a feasible optimum condition are shown in Figures 1 and 2, respectively. The shape of the contour plot (circular or elliptical) indicates whether the mutual interaction between test variables is significant or not. A circular contour plot indicates that the interaction between related test variables is negligible. In contrast, an elliptical contour plot indicates that the interaction between related test variables is significant [19]. In this study, results revealed that the contour plot was elliptical, indicating that there is a significant interaction effect between bromelain concentration, hydrolysis temperature and hydrolysis time on the leucine content in protein hydrolysate.

Validation for the optimum condition of leucine content in protein hydrolysate treated with bromelain was performed and the results are 26.25 % and 26.57 % for validation and predicted response, respectively. The suitability of the model equation for predicting the optimum response value was evaluated for the optimum condition of leucine content under conditions where the bromelain concentration is 1.38 %, hydrolysis temperature is 42.5 °C and hydrolysis time is 31.59 hours. Optimisation using actual experimental values was tested using the t-test (SPSS). There was no significant difference ($p > 0.05$) between predicted and verified values. Thus, indicating that the model was significant and can be used to predict the optimisation of leucine content in protein hydrolysate.

Table 4. Comparison values of target and predicted responses for different optimum conditions and experiment feasibilities

Goal		Lower	Target	Upper	Optimum condition			Predicted Response (FITS)	F/NF
					X_1	X_2	X_3		
Target	Leucine (%)	11.751	26.569	26.570	1.38	42.5	31.59	26.5699	F
	FITS 1	11.753	26.661	26.662					
Maximum	Leucine (%)	11.751	26.570	26.570	1.93	42.5	38.48	28.3081	NF
	FITS 1	11.753	26.662	26.662					
Minimum	Leucine (%)	11.751	11.751	26.570	1.00	47.5	30.00	11.7528	F
	FITS 1	11.753	11.753	26.662					

X_1= bromelain concentration (% w/w), X_2= hydrolysis temperature (ºC), X_3= hydrolysis time (hours), FITS= predicted response (%), F= feasible, NF= not feasible

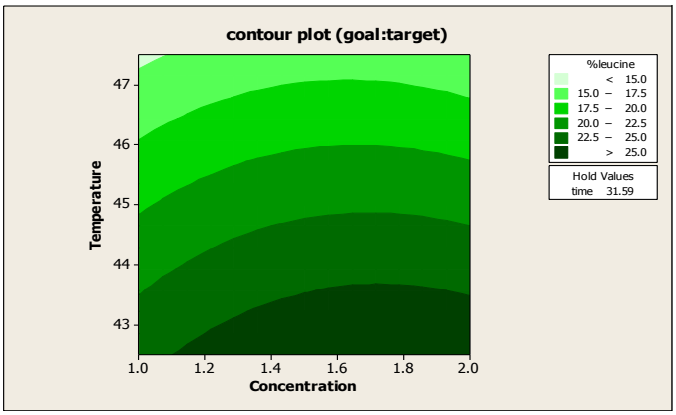

Figure 1. Contour plot of leucine in protein hydrolysate treated with bromelain at a feasible optimum condition, with a bromelain concentration of 1.38 %, hydrolysis temperature of 42.5 °C and hydrolysis time of 31.59 hours (holding value: hydrolysis time at 31.59 hours)

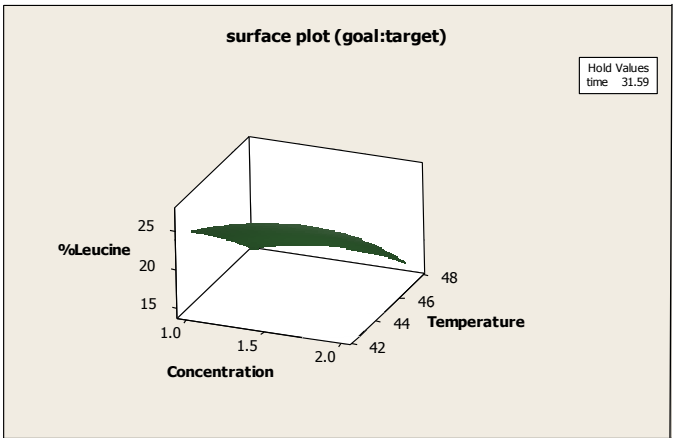

Figure 2. Surface plot of leucine in protein hydrolysate treated with bromelain at a feasible optimum condition with a bromelain concentration of 1.38%, hydrolysis temperature of 42.5°C and hydrolysis time of 31.59 hours (holding value: hydrolysis time at 31.59 hours)

Leucine content, nitrogen content and degree hydrolysis

It was found that leucine content was significantly high in the treated beef compared to untreated flank beef cut. The difference is due to the characteristics of bromelain which contains protease and is able to release more amino acid in treated beef than in untreated beef [20]. Stein et al. [21] carried out an enzymatic hydrolysis of Atlantic cod viscera using different types of enzymes (actinidin, alcalase, bromelain, neutrase, papain and protamex). They found that bromelain gave the highest total yield of the alpha amino group, signifying that the highest amount of peptide bonds could be broken in the reaction.

Table 5. Degree of hydrolysis, comparison of leucine and nitrogen content in flank cuts and beef hydrolysate before and after treatment

Analysis	Flank cut of beef	Flank cut of beef hydrolysate
Leucine	2.277 ± 0.003^{b}	5.453 ± 0.003^{a}
Nitrogen	$13.22\ \%^{b}$	$15.16\ \%^{a}$
Degree of hydrolysis	-	61.73 %

Means within each row was significantly different at $p < 0.05$.

It was found that the nitrogen content in the flank cuts and beef hydrolysate were 13.22 % and 15.16 %, respectively (Table 5). These results corresponds to previous findings by Haslaniza et al. [6] who discovered that cockle meat that went through an enzymatic hydrolysis using a bromelain concentration of 1.5 % had a higher nitrogen content compared to raw cockle meat. The degree of hydrolysis (DH) was determined for the optimum condition of protein hydrolysate. DH refers to the percentage of enzymatically hydrolysed peptide bonds compared to the original peptide bonds in raw materials, representing a number of peptide bonds being degraded during the reaction. DH can be simplified as the percentage of cleaved peptide bonds. In this present study, DH was calculated according to the percentage of trichloroacetic acid ratio. High DH indicates a high level of protein hydrolysed into smaller peptides and free amino acids [7]. Based on this study, it was found that the percentage of the degree of hydrolysis (DH) was 61.73 %, indicating a high DH of beef protein hydrolysis using the bromelain enzyme.

Conclusion

The leucine content of protein hydrolysate from flank cut of beef was significantly affected by the hydrolysis conditions including enzyme concentration, temperature and time. According to the model, the optimum hydrolysis parameters were 1.38 % (w/w) of bromelain concentration, hydrolysis temperature of 42.5 °C and hydrolysis time of 31.59 hours. Based on the optimum hydrolysis condition, the protein hydrolysate was obtained at higher amount of leucine and degree of hydrolysis.

Abstract

Catfish is a cheap source of essential omega-3 fatty acids especially eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Catfish oil was extracted and clean-up using pressurised liquid extraction (PLE) from the viscera of catfish (*Clarias batrachus*). However, the characteristics of catfish oils are sticky, strong fishy odour and can easily be oxidised with short shelf-life. In this study, catfish oil was converted into powder by formation of inclusion complex with β–cyclodextrin. Inclusion complex was prepared by using co-precipitation and kneading methods and compared with physical mixture. The inclusion complex formed were characterised by using field emission scanning electron microscopy (FESEM), differential scanning calorimeter (DSC) and fourier transform infrared spectroscopy (FTIR). FESEM images revealed that inclusion complex using co-precipitation and kneading methods has smaller in crystal sizes and appeared as different morphology compared to physical mixture. DSC proved that co-precipitation method was able to form new solid phase due to shifting of melting point to-higher temperature (145.22 °C). FTIR supported the result by proving strengthening of carbonyl group (C=O). Therefore, co-precipitation method was able to successfully produce inclusion complex of catfish oil, β-cyclodextrin.

Keywords: catfish oil, β-cyclodextrin, co-precipitation, kneading, physical mixture

Abstrak

Ikan keli merupakan sumber murah yang mengandungi asid lemak omega-3 terutama asid eikosapentaenoik **(**EPA) dan a**sid** dokosaheksaenoik (DHA). Minyak ikan keli telah diekstrak dan disulingkan dengan menggunakan pengekstrakan cecair tekanan tinggi (PLE) daripada visera ikan keli (*Clarias batrachus*). Walau bagaimanapun, ciri – ciri minyak ikan keli adalah melekit, bau hanyir yang kuat, mudah teroksida dengan mempunyai jangka hayat yang terhad. Dalam kajian ini, minyak ikan keli telah ditukarkan menjadi serbuk melalui pembentukan kompleks rangkuman dengan β-siklodekstrin (BCD). Kompleks rangkuman telah dihasilkan dengan menggunakan teknik ko-pemendakan dan penggulian serta dibandingkan dengan campuran fizikal. Kompleks rangkuman telah dicirikan dengan menggunakan mikroskop elektron imbasan medan (FESEM), kalorimeter imbasan kebezaan (DSC) dan spektrofotometer infra merah transformasi fourier (FTIR). Hasil kajian daripada imej FESEM menunjukkan bahawa pembentukan kompleks rangkuman menggunakan teknik ko-pemendakan dan penggulian mempunyai saiz kristal yang kecil dan muncul sebagai morfologi yang berbeza dibandingkan dengan campuran fizikal. DSC membuktikan ko-pemendakan mampu menghasilkan fasa baru kerana takat pencairan berubah dari yang asal ke suhu yang lebih tinggi (145.22 ºC). FTIR mendokong keputusan melalui bukti penegangan kumpulan karbonil dan C=O telah digunakan untuk rangkuman. Oleh itu, kaedah ko-pemendakan membuktikan kaedah yang paling sesuai untuk merangkum minyak ikan keli menggunakan β-siklodekstrin.

Kata kunci: minyak ikan keli, β-siklodekstrin, ko-pemendakan, penggulian, campuran fizikal

Introduction

The walking catfish, *Clarias batrachus* represents a cheap priced food fish and a great deal of attention is now being paid for popularization of its mass culture [1, 2]. Recently, catfish have high demand in marketplace since catfish contribute a lot of nutritional value to human and other industry. Every year a considerable amount of total catch is discarded as processing leftovers and that include trimmings, fins, frames, head, skin and viscera. Some of the by-products are utilized, but the main bulk is dumped into waste, creating both disposal and pollution problems. Annual discard is estimated to be about 25 % of the total production of capture [3]. Most of the oil in catfish is found in the viscera, which contain approximately 33 % fats or other lipids which could be converted into edible oil [4]. The oil extracted from fish is rich in polyunsaturated fatty acids (PUFAs) especially those of the omega-3 family, mainly eicosapentaenoic acid (EPA; C20:5n-3) and docosahexaenoic acid (DHA; C22:6n-3). The importance of PUFAs in human health and nutrition is well recognized in preventing cardiovascular diseases, Alzheimer's disease and psoriasis [4, 5].

One of the major drawbacks of oils containing a high amount of omega-3 PUFA such as fish oils is their susceptibility to oxidation which involves the formation of toxic products such as peroxides or volatile compounds which contribute to undesirable off flavours [5]. Encapsulation is a technology of packing solid, liquid or gaseous materials in miniature sealed capsules for release at controlled rates using desired released triggers [6]. Some researchers have reported that the encapsulation of fish oil significantly retards lipid oxidation. It can also mask the objectionable odours caused by volatile oxidation products and enhance the odor of fish oil enriched products [5]. Cyclodextrin has been extensively used in areas such as pharmaceutical, cosmetic and food industries because it is inexpensive and non-toxic. Using the molecular inclusion method, cyclodextrin can solubilise and stabilise active compounds on the molecular scale. Cyclodextrin can form solid phases by self-assembly. This process depends on the solubility, temperature, pH, molecular weight and chemical nature of guest materials [6].

In this study, microencapsulation of catfish oil with β-cyclodextrin (BCD) will be used to overcome this problem. Two methods can be used to produce inclusion complex namely co-precipitation, and kneading [7]. Physical mixture product will usually act as a control [8]. Characterisation of the encapsulated products was performed to confirm formation of inclusion complex. The inclusion complex formed were characterised using Fourier Transform Infrared Spectroscopy (FTIR), Field Emission Scanning Electron Microscopy (FESEM) and Differential Scanning Calorimeter (DSC). The resultant water soluble fish oil in powdered form has many applications such as food, pharmaceutical and medical fields. In addition, results from this study will be useful for future research that involves other fish oils that contain high PUFAs especially DHA and EPA.

Materials and Methods

Materials

The β-cyclodextrin (BCD) (purity: 99.5 %) was purchased from the Sigma Chemical Company (St. Louis, MO, USA). All solvents were of analytical grade. Ethanol (ACS Reagent, Ph Eur Merck, Germany) were of pharmaceutical grade and the water was deionised using a Milli-QUV device (Millipore, Molsheim, France).

Sample preparation

Fresh catfish viscera were obtained from local supplier in Kajang, Selangor. The samples were kept in plastics bags and transported in an insulated container to the laboratory. Upon arrival at the laboratory, the sample was washed under running tap water. The samples were ground with a commercial blender for 10 minutes and kept at -20 °C in the freezer until further use. Prior to PLE extraction method; samples were dried using freeze dryer at -50 °C for 5 days. The dried samples were freezed at -20 °C until needed for extraction.

Pressurised liquid extraction

Extractions were done using ASE 200 accelerated solvent extractor (Dionex Ltd. Camberley, Surrey, UK). Catfish oil was extracted using n-hexane with predetermined optimised conditions (Design Expert 6.0.4, Stat Ease Software): temperature of 96 °C, pressure of 15,140 kPa and static time of 17 min. The extract was evaporated to dryness using a rotary evaporator.

Inclusion complex
The inclusion complex of catfish oil: BCD (1:8) was prepared using the kneading and co-precipitation methods. The kneading method and physical mixture as control were as reported by Zhang et al. [7]. The method for co-precipitation was referring to method by Waleczek et al. [8].

Characterisation of the inclusion complex: ***Differential scanning calorimetry (DSC)***
DSC analyses were carried out using Perkin Elmer DSC1 STAR System. An amount 5 mg sample was placed in aluminium pans and heated at 10°C/min in the temperature range of 0 °C to 300 °C. The measurements were carried out under dry nitrogen at a flow rate of 50 mL/min [8].

Fourier transform infrared spectroscopy (FTIR)
The FTIR spectra of catfish oil, BCD, their physical mixture and the inclusion complex were measured between 4000 and 400 cm^{-1} using a Perkin Elmer Model GX FTIR spectrophotometer (Waltham, MA, USA), with 16 scans at a resolution of 1 cm^{-1}. The KBr disk method was used for the solid samples [8].

Field emission scanning electron microscopy (FESEM)
The surface morphology of the dried samples was examined using a scanning electron microscope, Model Supra 40VP (GEMINI). Prior to analysis, the samples were attached to SEM aluminium stubs via 2-sided adhesive tape. The attached powder was then sputter coated for 50 s at a beam current of 0 mA to obtain a 15 nm layer of gold-palladium alloy and was then examined using a scanning electron microscope operating at 5 Kv [8].

Statistical analysis
A one-way analysis of variance (ANOVA) and Duncan's Multiple Range test ($p < 0.05$) were used to establish the significance of differences in analysis data. The analyses were performed using SPSS 16.0 for Windows software.

Results and Discussion

Differential scanning calorimetry (DSC)
The thermal behaviour of catfish oil with β-cyclodextrin (BCD) inclusion complex was studied using Differential Scanning Calorimetry (DSC). The thermograms of pure BCD and catfish oil-BCD physical mixture, kneading, co-precipitation and pure catfish oil, were represented in Figure 1.

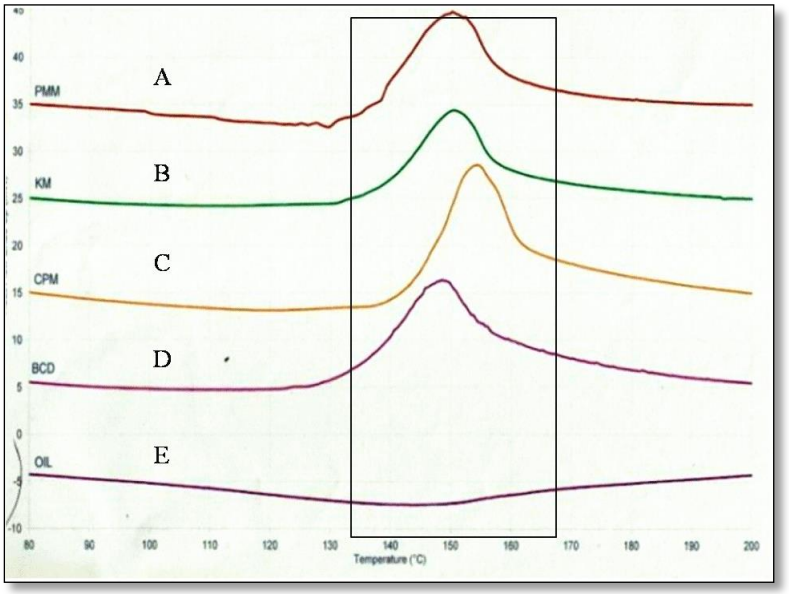

Figure 1. DSC thermograms of physical mixture (PMM) (A), kneading (KM) (B), co-precipitation (CPM) (C), β-cyclodextrin (BCD) (D) and catfish oil (Oil) (E)

Table 1. Data obtained from DSC thermograms.

	T_{Onset} (°C)	T_{Peak} (°C)	T_{Endset} (°C)
Catfish oil (Oil)	92.31 ± 0.05	143.60 ± 0.12	175.39 ± 0.05
β-cyclodextrin (BCD)	139.10 ± 0.11	148.47 ± 0.05	158.50 ± 0.03
Co-precipitation method (CM)	145.22 ± 0.08	154.18 ± 0.05	163.81 ± 0.15
Kneading method (KM)	139.07 ± 0.05	150.31 ± 0.01	159.15 ± 0.02
Physical mixture method (PMM)	138.01 ± 0.04	149.99 ± 0.07	159.36 ± 0.01

Fourier transform infrared spectroscopy (FTIR)

The complexation between catfish oil and BCD was further investigated by using FTIR and the spectra obtained were shown in Figure 2. FTIR is a useful technique used to confirm the formation of an inclusion complex [10].

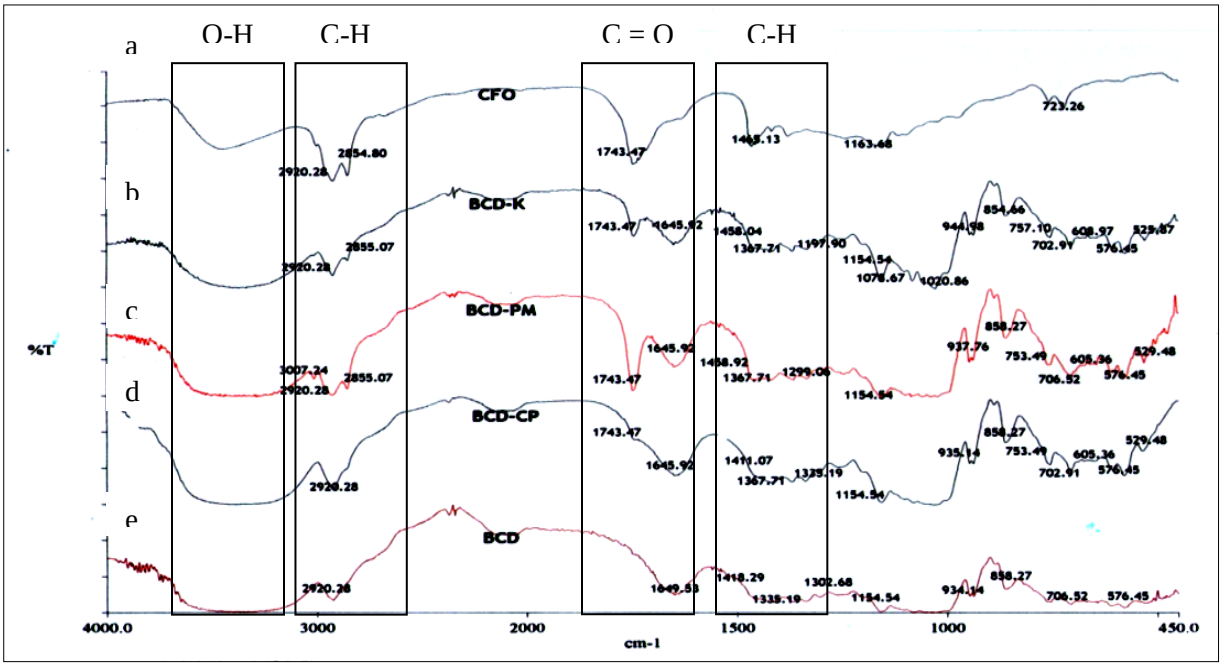

Figure 2. FTIR spectrum of catfish oil (CFO) (a), kneading (BCD-K) (b), physical mixture (BCD-PM) (c), β- co-precipitation (BCD-CP) (d), and β-cyclodextrin (BCD) (e)

Overall, catfish oil bands were masked from cyclodextrin as the main component of complexes formation. Generally, the stretching region of hydroxyl group, -OH was shown at the band range of 3600 – 3200 cm^{-1}. The band at 3400 cm^{-1} indicates the presence of hydroxyl group in the catfish oil. The presence of water in BCD resulted in the presence of broad peak of O-H which masks the presence of –OH in catfish oil.

A few bands of alkanes (C-H) are shown at 2930 – 2800 cm^{-1}. The C-H peak appeared at 2920 cm^{-1} and 2855 cm^{-1} can be observed in the catfish oil and 2920 cm^{-1} for BCD. Inclusion complex band formed by co-precipitation method were shifted to higher wavenumber indicate that the conjugation in catfish oil was reduced in the presence of BCD. This result indicates C-H been used for inclusion complex. The band for carbonyl group

(C=O) peaks appeared at the band range of 1650 – 1620 cm^{-1}. The FTIR studies indicated that a cyclodextrin complex was formed with guest molecules possessing carbonyl group [12].

The intensity of this band appeared reduced for co-precipitation, kneading and physical mixture methods. This indicated that carbonyl group been used for complexation. A few bands of alkanes (C-H) were shown at 1300 – 1512 cm^{-1}. The wavenumber for catfish oil was noticed at 1465 cm^{-1} and 1418 cm^{-1} for BCD. The intensity of this band appeared reduced for co-precipitation and kneading. This indicated that C-H group also been used for complexation. A stronger interaction of inclusion complex might be seen in co-precipitation process due to almost similar peak to the pure BCD compared to kneading and physical mixture.

Field emission scanning electron microscopy (FESEM)
FESEM provides qualitative information on study of pure substance and complexes formation by different methods of preparation. In recent study, FESEM observation was done in collaboration with DSC and FTIR to verify the occurrence of BCD-catfish oil complexes formation. This helps to assess existence of any products during the process [8]. The FESEM images of pure BCD, catfish oil; co-precipitation, kneading and physical mixture products at 2500 times magnification are shown in Figure 3.

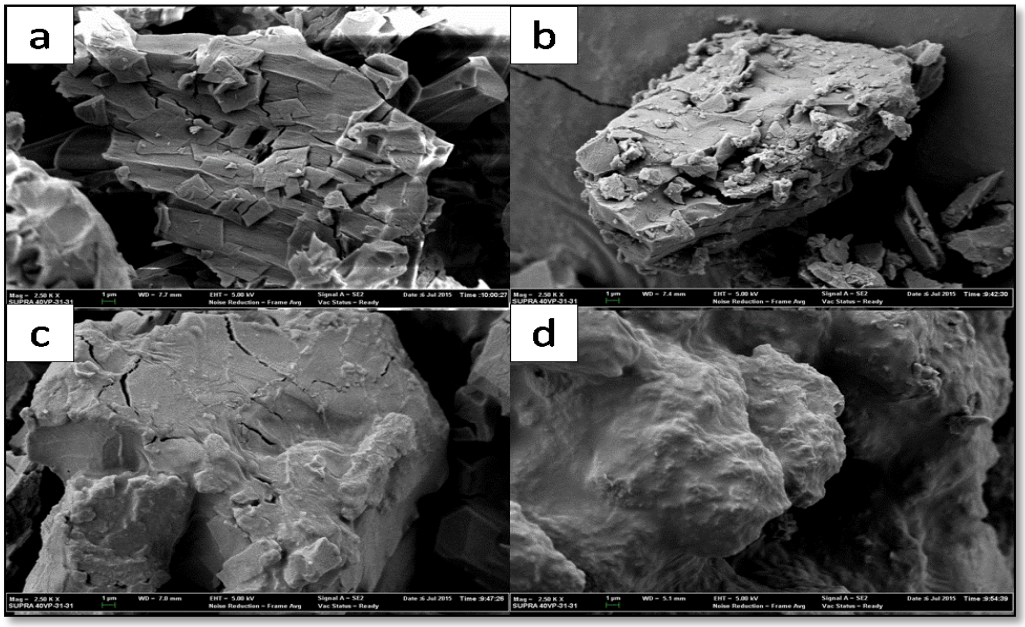

Figure 3. FESEM illustration of (a) β-cyclodextrin (BCD), (b) co-precipitation, (c) kneading and (d) physical mixture at magnification x 2500

Particle size for BCD as shown in Figure 3 (a) was appeared bigger than other samples. It due to the commercial pure BCD was well structured, plated and parallelogram shape. The shape of kneaded complexes as shown in Figure 3 (c) appear quite different from the co-precipitation complexes (Figure 3 (b)). The products appears as irregular and clumping to each other. The drastic change of the particles shape and aspects in the co-precipitation sample were indicative of the presence of a new solid phase, leading us to suggest the existence of a single phase. Previous study by Reddy et al. [11] reported similar findings for a cyclodextrin: celecoxib system. Physical mixture of BCD with catfish oil (Figure 3 (d)) forms sticky and clumps to each other. This appearance as big oily agglomerates was clearly seen under SEM observation. Furthermore, the oiliness of structure can be seen on the surface of the complexes. Thus, an inclusion complex may not formed for BCD using this physical mixture method. This finding supported by Zaibunissa et al. [12] which stated that the new solid phase of oleoresin and cyclodextrins

formed using the co-precipitation method appeared as a crystal structure which was completely different from the original morphology of its pure compounds.

Conclusion

The interaction between C-H and BCD resulted in the formation of an inclusion complex. The formation of the inclusion complex was investigated and confirmed using DSC, FTIR and FESEM analysis. The results obtained from this study will be very useful for producing odourless catfish oil powder from cheap source. Kneading and physical mixture were able to form loose interaction inclusion complex. However, co-precipitation was the chosen method for the potential of future study.

Abstract

Continuing our interest in the genus, a phytochemical investigation on *Uncaria cordata* var. *ferruginea* collected from Hutan Pasir Raja, Malaysia has been carried out. Two flavonols known as quercetin and kaempferol were isolated from the methanolic stem extract of this plant along with other phenolic compounds and terpenes. The two flavonols are reported for the first time from this species. The structure of the compounds were elucidated on the basis of spectroscopic data, mostly 1D-NMR, 2D-NMR as well as comparison with literature.

Keywords: flavonoid, flavonol, kaempferol, quercetin, *Uncaria cordata*

Abstrak

Dalam meneruskan minat kami terhadap genus ini, satu kajian fitokimia ke atas *Uncaria cordata* var. *ferruginea* yang diambil dari Hutan Pasir Raja, Malaysia telah dijalankan. Dua flavonol dikenali sebagai quercetin dan kaempferol telah diasingkan daripada ekstrak metanol bahagian batang tumbuhan ini bersama sebatian fenolik lain dan terpena. Kedua-dua flavonol ini dilaporkan buat pertama kali daripada spesies ini. Struktur sebatian telah dielusidasi berdasarkan data spektroskopi, terutamanya 1D-NMR, 2D-NMR dan juga perbandingan dengan kajian literatur.

Kata kunci: flavonoid, flavonol, kaempferol, quercetin, *Uncaria cordata*

Introduction

The genus *Uncaria* (Rubiaceae) is well known for centuries among medicinal practitioners due to its medicinal properties and ability in healing various diseases such as diarrhea, dysentery, fevers, diabetes and others. Many studies have been carried out scientifically for its pharmacological activities on *Uncaria* species [1]. For example, *Uncaria tomentosa* which is widely explored has been proven to have anticancer, anti-inflammatory and other biological properties. A biological study on five species of Malaysian *Uncaria* including *Uncaria longiflora* var. *pteropoda, Uncaria acida, Uncaria lucida, Uncaria callophylla* and *Uncaria cordata* have indicated that they are rich sources of antioxidants and potential anti-diabetic agents which may be used in the prevention and control of type II diabetes [2].

Uncaria is amongst the genera known for its alkaloid content. Previously, we have reported the isolation of two new heteroyohimbine-type oxindole alkaloids, namely rauniticine-*allo*-oxindole B and rauniticinic-*allo* acid B along with five of their stereoisomers including four pentacyclic oxindole alkaloids, isopteropodine, pteropodine, uncarine F and isopteropodic acid from Malaysian *Uncaria longiflora* var. *pteropoda* [3 – 5]. In contrast, the non-alkaloid constituents have not been widely reported from *Uncaria* genus. Lately, the isolation of flavonoids and other chemical constituents present in *Uncaria* have gained more interest. The flavonoids reported from the genus are mostly isolated from *Uncaria gambir* particularly flavane derivatives including flavan-3-ols and their dimers [6]. Recently, we have reported the isolation of a novel flavonoid, (-)-2*R*, 3*R*-3,5,4'-trihydoxyflavan-[6,7:5",6"]-2"-pyranone named uncariechin, along with (-)-*epi*afzelechin and (-)-*epi*catechin from the methanol extract of the leaves of *Uncaria longiflora* var. *pteropoda* [7]. Therefore, continuing our interest on the phytochemicals from *Uncaria*, the isolation of two flavonols, quercetin (**1**) and kaempferol (**2**) from the stems of Malaysian *Uncaria cordata* var. *ferruginea* was reported in this study.

Materials and Methods

General

Column chromatography packed with Sephadex LH-20 was carried out and flavonoids were detected on thin layer chromatography (TLC) stained with aluminium chloride ($AlCl_3$) reagent. A positive result was indicated by the observation of yellow spots visualized under UV light at 365 nm. Mass spectra were measured on an Agilent 1100 Series Technologies HPLC-TOF LC/MS, where the analysis for compound **1** was run in the positive mode, while compound **2** was analysed in the negative mode. The ultraviolet (UV) spectra were obtained in methanol on a Shimadzu UV-Vis 160i. The infrared (IR) data was recorded on a Perkin Elmer model FT-IR spectrometer as KBr disks. ^{1}H and ^{13}C-NMR data for compound **1** was obtained in acetone-d_6 on Bruker 600 Ultrashield NMR spectrometer measured at 600 and 150 MHz, respectively while ^{1}H-NMR and ^{13}C-NMR data for compound **2** was obtained in MeOD on Bruker 500 Ultrashield NMR spectrometer measured at 500 and 125 MHz, respectively.

Plant material

Stems of *Uncaria cordata* var. *ferruginea* was collected from Hutan Pasir Raja, Terengganu in December 2011 and was identified by Dr. Shamsul Khamis (Universiti Putra Malaysia). The voucher specimens were deposited at the Herbarium of Institute of Bioscience, Universiti Putra Malaysia.

Extraction and isolation of compounds

Stems of Malaysian *Uncaria cordata* var. *ferruginea* were cut into small pieces, air-dried and ground into fine powder. The finely ground stems were then weighed and soaked in methanol for 72 hours at room temperature. The solvent was evaporated off under reduced pressure by using a rotary evaporator. Then the extract was dissolved with methanol and water (1:1) before being subjected to liquid-liquid partitioning using chloroform and ethyl acetate. The ethyl acetate fraction (9.8 g) was further fractionated using a column packed with Sephadex LH-20 employing $CHCl_3$: MeOH (9:1) as the solvent system to give four sub-fractions. Based on their TLC profiles, flavonoids were detected in sub-fractions f2 and f4 by using aluminium chloride reagent. Repeated column chromatography of these two sub-fractions using Sephadex LH-20 successfully yielded compound **1** and compound **2**.

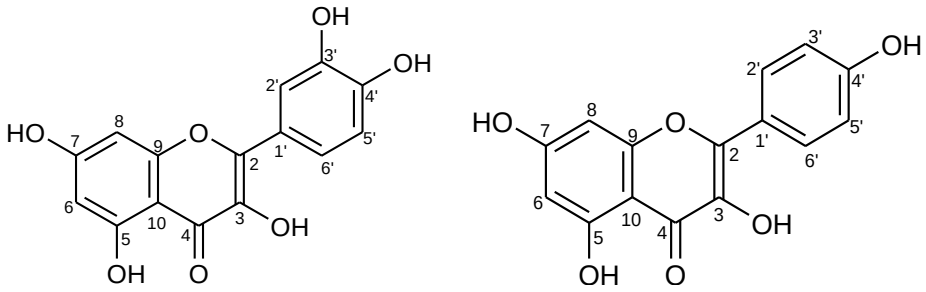
Results and Discussion

Compound **1** was isolated as a yellow amorphous solid with melting point 316 °C. The mass spectrum of this compound showed a molecular ion $[M+H]^+$ peak at m/z 303 which corresponded to the molecular formula $C_{15}H_{10}O_7$. Its UV absorptions maxima at 295, 338 and 385 nm were found to be in agreement with a flavonol-type compound [7]. The IR spectrum displayed absorption bands at 3411, 1665 and 1615 cm^{-1} indicating the presence of functional groups of OH, C=O and C=C aromatic, respectively. The ^{1}H NMR spectrum of compound **1** showed the characteristic signals of flavonoid-type compound with ABX system. In A-ring system, two doublet peaks of *meta*-coupled aromatic protons present at δ 6.28 (1H, d, J = 2.4 Hz) and at δ 6.54 (1H, d, J = 2.4 Hz) were assigned as H-6 and H-8, respectively. The rest of proton signals belonging to the ring-B system appeared at δ 7.01 (1H, d, J = 8.4 Hz, H-5'), 7.72 (1H, dd, J = 8.4, 2.4 Hz, H-6') and 7.85 (1H, d, J = 2.4 Hz, H-2'). Its COSY spectrum showed the H-H correlation indicating H-5' and H-6' to be neighbouring protons. Its ^{13}C NMR spectrum showed the presence of 15 carbon signals which were typical of a flavonol skeleton. The most downfield signal at δ 175.67 was attributed

to carbonyl C-4 due to electron withdrawing oxygen and anisotropic effects. In addition, five oxyaryl carbons observed at δ 135.85, 144.97, 147.51, 161.45 and 164.16 were attributed to C-3, C-3', C-4', C-5, and C-7. Four quaternary carbons at δ 103.23, 122.86, 146.05 and 156.90 were assigned as C-10, C-1', C-2 and C-9, respectively. The rest of the signals at δ 93.57, 98.29, 114.87, 115.34 and 120.56 were subsequently determined as aromatic methine carbons C-8, C-6, C-2', C-5' and C-6', respectively which are confirmed by HMQC correlations. All carbon assignments were further confirmed by HMBC and NOESY correlations. In short, the characterization of compound **1** is given below.

Pale yellow amorphous solid, wt: 3.2 mg; MS *m/z* = 303 $[M+H]^+$, $C_{15}H_{10}O_7$; UV (MeOH) λ_{max} nm: 295, 338, 385; IR (KBr) υ_{max} cm^{-1}: 3411 (free OH), 1665 (C=O), 1615 (C=C aromatic); ^1H NMR (Acetone-d_6, 600 MHz) δ ppm : 12.19 (1H, br s, OH), 7.85 (1H, d, *J* = 2.0 Hz, H-2'), 7.72 (1H, dd, *J* = 8.5, 2.0 Hz, H-6'), 7.01 (1H, d, *J* = 8.5 Hz, H-5'), 6.54 (1H, d, 2.0 Hz, H-8), 6.28 (1H, d, 2.0 Hz, H-6); ^{13}C NMR (Acetone-d_6, 150 MHz) δ ppm : 175.67 (C=O), 164.16 (C-7), 161.45 (C-5), 156.90 (C-9), 147.51 (C-4'), 146.05 (C-2), 144.97 (C-3'), 135.85 (C-3), 122.86 (C-1'), 120.56 (C-6'), 115.34 (C-5'), 114.87 (C-2'), 103.23 (C-10), 98.29 (C-6), 93.57 (C-8). Thus, based on the 1D and 2D NMR spectral data, as well as comparison with the literature [8], compound **1** was identified as quercetin.

Compound **2** was isolated as yellow amorphous powder with melting point 277°C. Its mass spectrum showed a molecular ion $[M-H]^-$ peak at *m/z* 285 which corresponds to the molecular formula $C_{15}H_{10}O_6$. Its UV absorptions at 310 and 380 nm were indicative of a flavonol-type compound. The IR spectrum displayed absorption bands at 3324, 1660 and 1614 cm^{-1}which were due to the functional groups of OH, C=O, and C=C aromatic, respectively. The ^1H NMR spectrum of this compound showed proton signals of a typical flavonol-type compound with ABX system (6-8 ppm). For the A-ring protons, two doublet peaks observed at δ 6.18 (1H, d, *J* = 2 Hz) and at δ 6.39 (1H, d, *J* = 2 Hz) were assigned as H-6 and H-8, respectively. Both of these protons were *meta*-coupled as indicated by their coupling constant value. In the B-ring system, proton signals appeared as a pair of doublet of doublets at δ 6.90 (2H, dd, *J* = 7, 2 Hz, H-3', H-5') and at δ 8.09 (2H, dd, *J* = 7, 2 Hz, H-2', H-6'). These protons were *ortho*-coupled based on their *J* values and were adjacent to each other as was evident from the COSY spectrum. Its ^{13}C NMR spectrum exhibited 13 carbons signal attributed to 15 carbons with the peak at δ 129.27 representing equivalent carbons C-2' and C-6' and the peak at δ 114.89 representing equivalent carbons C-3' and C-5'. A very downfield signal at δ 175.95 was attributed to carbonyl C-4 due to electron withdrawing oxygen and anisotropic effect. In addition, four oxyaryl carbons observed at δ 135.72, 159.13, 161.10 and 164.17 were attributed to C-3, C-4', C-5 and C-7, respectively. Four quaternary carbons at δ 103.14, 122.33, 146.62 and 156.84 were then assigned as C-10, C-1', C-2 and C-9, respectively. The rest of the carbon signals observed at δ 93.07 (C-8), 97.86 (C-6), 114.89 (C-3', C-5'), and 129.27 (C-2', C-6') were methine carbons. The carbon assignments were confirmed by HMQC and HMBC data. The characterization of compound **2** is given below.



Pale yellow amorphous solid, wt: 1.3 mg; MS *m/z* = 285 $[M-H]^-$, $C_{15}H_{10}O_7$; UV (MeOH) λ_{max} nm: 310, 380; IR (KBr) υ_{max} cm^{-1}: 3324 (free OH), 1660 (C=O) 1614 (C=C aromatic);^1H NMR (MeOD, 500 MHz) δ ppm : 8.09 (2H, dd, *J* = 8.9, 2.0 Hz, H-2',H-6'), 6.90 (2H, dd, *J* = 8.9, 2.0 Hz, H-3', H-5'), 6.39 (1H, d, *J* = 2.0 Hz, H-8), 6.18 (1H, d, *J* = 2.0 Hz, H-6); ^{13}C NMR (MeOD, 150 MHz) δ ppm : 175.95 (C=O), 164.17 (C-7), 161.10 (C-5), 159.13 (C-4'), 156.84 (C-9), 146.62 (C-2), 135.72 (C-3), 129.27 (C-2', C-6'), 122.33 (C-1'), 114.89 (C-3', C-5'), 103.14 (C-10), 97.86 (C-6), 93.07 (C-8). On the basis of spectral data and comparison with literature [9], compound **2** was identified as 3,4',5,7-tetrahydroxyflavone or kaempferol.

Table 1 shows the ^{13}C NMR data compounds **1** and **2** along with literature values. Figure 1 shows the structure of the flavonoids.

Figure 1. Structure of flavonols isolated from the stems of Malaysian *Uncaria cordata* var. *ferruginea*: (**1**) Quercetin, (**2**) Kaempferol

Conclusion

Phytochemical study of the methanolic stem extract of Malaysian *Uncaria cordata* var. *ferruginea* has led to the isolation of two flavonols, quercetin and kaempferol along with other phenolic compounds and terpenes. The structure of the compounds was elucidated on the basis of spectroscopic data. The presence of other non-alkaloidal constituents should be further explored in order to justify their chemotaxonomic significance in the *Uncaria* genus.

Abstract

Hemicelluloses from oil palm empty fruit bunches were extracted using alkaline extraction and fractionated by ethanol precipitation. Extraction of hemicellulose from oil palm empty fruit bunches were carried out with different KOH concentration (1 M, 3 M, 5 M), temperature (30 °C, 40 °C, 50 °C) and time (2 hours, 4 hours, 6 hours). The alkaline extraction produced two hemicellulosic fractions namely precipitate (HA) and alkali soluble hemicelluloses (HB). The alkali soluble hemicelluloses were then sub-fractionated by precipitation in 0.2 and 4 volumes ethanol for obtaining HB1 and HB2, respectively. Three hemicellulosic fractions (HA, HB1 and HB2) were further characterized in the form of total sugar, monosaccharides and Klason Lignin content. The optimal alkaline extraction was obtained at temperature of 40 °C, 3 M KOH concentration and extraction time 4 hrs. It was found that the alkaline extraction and ethanol precipitation is the suitable method to maximize the hemicelluloses yield.

Keywords: oil palm empty fruit bunches, alkaline extraction, hemicellulose

Abstrak

Hemisellulosa daripada tandan kosong kelapa sawit telah dieskstrak menggunakan pengesktrakan alkali dan terpisah oleh pemendakan etanol. Pengesktratan hemisellulosa daripada tandan buah kepala sawit dijalankan dengan pelbagai kepekatan KOH (1 M, 3 M, 5 M), suhu (30 °C, 40 °C, 50 °C) dan masa (2 jam, 4 jam, 6 jam). Pengesktrakan alkali menghasilkan dua pecahan hemisellulosa iaitu mendakan (HA) dan hemisellulosa yang larut alkali (HB). Hemisellulosa yang larut alkali masing- masing kemudiannya di sub-pisahkan oleh pemendakan dalam isipadu etanol 0.2 dan 4 masing-masing bagi menghasilkan HB1 dan HB2. Tiga pecahan hemisellulosa (HA, HB1 dan HB2) selanjutnya dicirikan oleh jumlah gula, kandungan monosakarida dan Klason Lignin. Pengesktrakan alkali optimum telah diperolehi pada suhu 40 °C, KOH 3 M dan masa 4 jam. Secara kesimpulannya pengesktrakan alkali dan pemendakan etanol merupakan kaedah yang sesuai untuk memaksimumkan hasil hemisellulosa.

Kata kunci: tandan kosong kelapa sawit, pengesktratan alkali, hemisellulosa

Introduction

Oil palm (*Elaeis guineensis)* were originated from West Africa and currently is one of the leading perennial oleaginous food crops cultivated widely in Malaysia, Indonesia and Thailand [1, 2]. Malaysia alone produce 47 %

oil palm which can be considered as second largest producer and exporter of oil plam. According to Idris et al. [3] oil palm cultivation in Malaysia covered more than 3.88 million hectares of land and operates more than 368 palm mills. Eventhough, palm oil industry has boosted the national economy in Malaysia, it also generated abundant of by-products. For every tonne of palm oil produced from fresh fruit bunch (FFB), approximately 1 tonne of oil palm empty fruit bunch (EFB), 0.7 tonnes of palm fibers, 0.3 tonnes of palm kernels and 0.3 tonnes of palm shells were generated in palm oil mills during the processing of palm oil from FFB [4]. Out of these by-products, EFB considered the biggest biomass waste and if not handled properly, would pose a severe environmental menace. Part of EFB is either incinerated for burn ash or recyled back to the plantation as mulching or used as solid fuel in the boilers to generate steam and electricity for the mills [5]. Increasing the utilization of this biomass is necessary and one such possibility would be to extract hemicelluloses to convert them to highly value-added products such as biodegradable film. The EFB biomass contains cellulose, hemicelluloses and lignin. It is estimated that EFB biomass comprised of 24 % hemicellulose which known as a valuable in pulp additives [6] and natural barrier for packaging film [7].

Hemicelluloses are the second most abundant polysaccharides in nature. Hemicelluloses, which are found in wood together with cellulose and lignin, give the best combination of mechanical support and transport properties. It is difficult to separate hemicelluloses from cellulose and lignins due to the component in lignocelluloses are bound tightly together without significant modification to its structure [8]. This could be among the main explanation why the material properties of hemicelluloses have not been exploited. Many treatments have been done to extract hemicelluloses from the plant such as steam explosion and ultra-filtration, heat treatment, classical alkaline extraction, ultrasound extract assistant and organosolv process. But among this processes, alkaline extraction has been the most promising method to accomplish complete utilization of lignocelluloses with minimal harm to the environment [9].

The purpose of the present work is to optimize the alkaline extraction conditions and ethanol precipitation of EFB on the yield of hemicelluloses. The effect of KOH concentration, temperature and time on hemicelluloses yield was investigated. The chemical properties of hemicelluloses fractions were examined in detail by means of sugar analysis and Klason Lignin. Furthermore, FT-IR was used to determine the chemical structure of sample.

Materials and Methods

Material

Oil palm EFB was obtained from a local palm oil factory in Johor, Malaysia. It was first soaked with distilled water overnight to remove dirt. Then EFB was oven-dried at 105 °C overnight to avoid fungus growth. Finally, dried EFB were ground to pass a 0.08 mm size screen using a mill blade. The samples were stored in the plastic bag prior to use. All chemicals used were of analytical grade unless otherwise stated. Xylose, glucose and arabinose were used as a standard for monosaccharide determination.

Hemicelluloses extraction

The extraction of hemicelluloses was carried out according to the method reported by Anis [10] with some modification. Oil palms EFB were soaked in different concentrations (1 – 5 M) KOH solution for different soaking time (2 – 6 hours) and at different temperatures (30 – 50 °C) with solid liquid ratio of 1:10. After extraction, the crude hemicelluloses was collected by filtration, acidified with 50 % acetic acid until pH 4.7 – 5.0 and allowed to stand for 24 hours at 4°C. The mixture was centrifuged at 3000 rpm for 15 min and the precipitates were washed with 95 % ethanol to remove the residual acid. The precipitate was dried in an oven at 60 °C for 24 hours to evaporate the ethanol and was designated as hemicelluloses (HA). The supernatant were successively sub-fractionated by graded ethanol volume solutions of 0.2V and 4V. Then both supernatant were centrifuged at 3000 rpm for 15 min. After centrifuged, the precipitates were dried in an oven at 60 °C for 24 hours to evaporate the ethanol. The precipitate obtained from the supernatant was designated as hemicelluloses B1 (0.2 volumes) and B2 (4 volumes). Hemicelluloses yield in solid extract were quantified by determining the total sugar content.

Hemicellulose characterization

Total sugar content was measured according to phenol-sulphuric acid method [11]. The total sugar content was evaluated using UV-Vis spectrophotometer (Perkin Elmer, USA) at 480 nm. Deionized water was used as a blank.

Klason lignin content in the hemicellulosic fractions was determined following TAPPI method T222. The monosaccharides content of hemicellulose fraction analysis was performed by acid hydrolysis. The hemicelluloses fraction was pre-hydrolyzed with 1.5 mL of 72 % H_2SO_4, before diluting the samples with 40 mL of distilled water and autoclaving them at 121°C for 1 hour. The samples were neutralized using $CaCO_3$ to pH 5.5 – 6.0.

The monosaccharides sugar was determined by high performance liquid chromatography (HPLC) (Agilent Technologies 1200 Series, Germany) using Aminex HPX 87P column (300 mm x 7.8 mm). The HPLC was equipped with a refractive index detector (G 1362A, Agilent Technologies 1200 Series, Germany) and column oven (Agilent Technologies 1200 Series, Germany). The sample was filtered through a 0.20 µm nylon syringe filter (Minisart, Sartorius AG, Germany) prior directly injected to the HPLC system. The sample was eluted using deionised water as the mobile phase at temperature of 80 °C with a flow rate of 0.5 mL/min [12]. The FT-IR spectra were obtained at a resolution of $4cm^{-1}$ using potassium bromide (KBr) pellet technique. The spectra were recorded between 500 and 4000 cm^{-1}.

Statistical analysis
Statistical analyses were performed using the software SPSS 16.0 program, via one way analysis of variance (ANOVA). Tukey's multiple range test was applied to determine the significantly different ($P < 0.05$) samples.

Results and Discussion

Effect of concentration of KOH on the hemicelluloses yield
To investigate the effect of KOH concentration on hemicelluloses yield, different KOH concentration (1 M, 3 M and 5 M) were used for extraction at 40 °C for 4 hours. Alkali extraction was found to have the most efficient method for isolating large amounts of hemicellulose polysaccharides. Hydroxyl ions cause swelling of cellulose, hydrolysis of ester linkage and disruption of storage linkages, such as intermolecular hydrogen bonds between hemicelluloses and cellulose, bring a portion of hemicellulose material into solution [13]. As shown in Figure 1a, the yield of hemicelluloses; HA (3.46 % to 4.67 %), HB1 (8.97 % to 7.43 %) and HB2 (17.32 % to 29.37 %) increased from 1 M to 3 M. Hemicelluloses yield increased with increasing of KOH concentration, however up to 5M KOH, the yield of all hemicelluloses fractions decreased indicating that appreciable amounts of hemicelluloses were leached out. It was found that HB2 has higher hemicelluloses yield compared to HA and HB1. Therefore, 3 M KOH was chosen for the following experiments.

Effect of temperature on the hemicelluloses yield
The hemicelluloses yield obtained at different temperature are shown in Figure 1b. It was observed that all hemicelluloses fractions increased after temperature 30 °C. The yields of hemicelluloses increased from 2.3 % to 4.7 %, 13.7 % to 24.4 % and 10.9 % to 29.4 % for HA, HB1 and HB2 respectively. Hemicellulose has a finite solubility in cold alkaline temperatures, but presumably, warm alkaline solutions lead to enhance hemicelluloses degradation; above 40 °C further extraction was occurred. It shows that high temperature is necessary for extracting hemicellulose in order to help the process of penetrating the lignified cell wall [14]. However at 50 °C, hemicellulose yield for HA (4.7 % to 2.6 %), HB1 (24.4 % to 8.5 %) and HB2 (29.3 % to 26.9 %) were decreased. Hemicellulose yield decreased at 50 °C due to degradation of hemicellulose by end-wise peeling reactions [15]. Therefore, a reaction temperature of 40 °C was considered as an optimum temperature for all hemicelluloses fractions.

Effect of time on the hemicelluloses yield
The effect of time on hemicelluloses yield during alkaline extraction was examined after an ideal concentration and temperature were obtained. Extraction periods of 2, 4 and 6 hrs were used at 40 °C and 3 M KOH. As observed from Fig. 1c), an increasing of extraction time from 2 hours to 4 hours, the hemicellulose yield were increased for HA and HB2. Both hemicellulosic fractions, HA and HB2 have higher hemicelluloses yield at 4 hours extraction. The results indicated that increasing extraction time may enhance the yield of hemicellulose. This is in accordance with other research finding [16]. Hydrolytic cleavage may degrade polysaccharides and induces the change of polysaccharides molecule structure at elevated time [17]. Therefore, the period of time 4 hours was chosen as an ideal time for the following experiments to save time and energy.

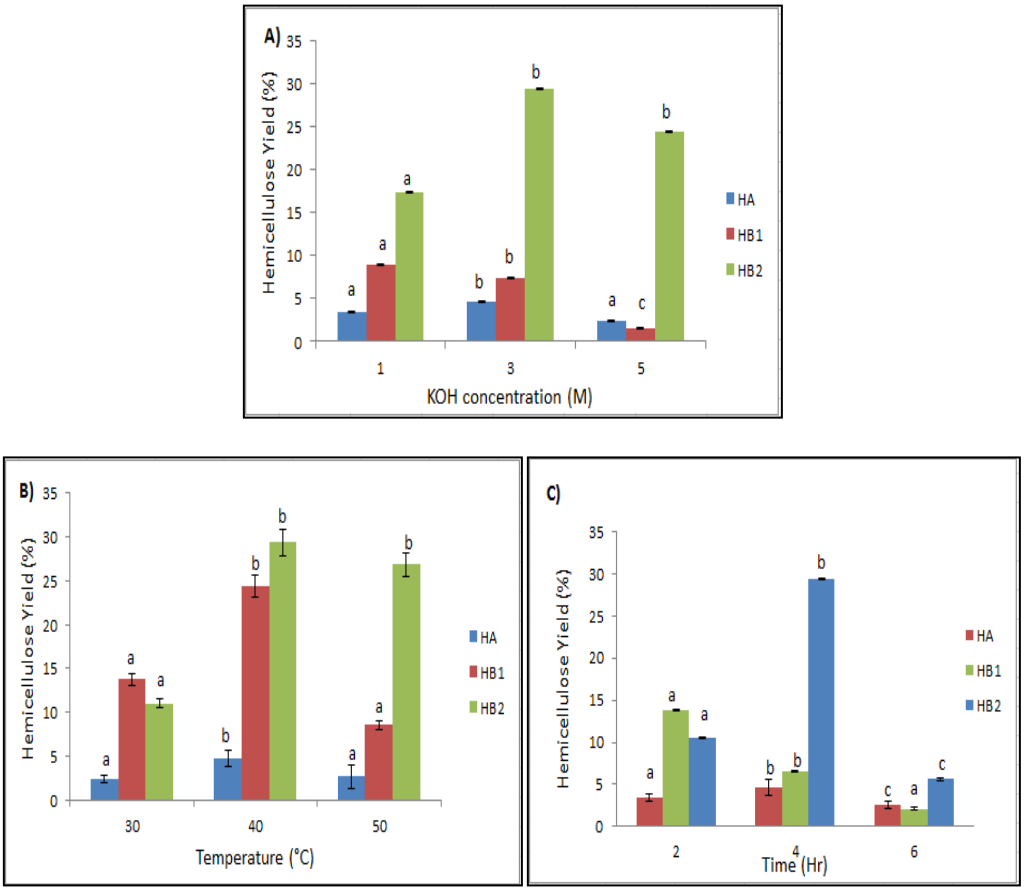

Figure 1. Effect of KOH concentration (a), temperature (b) and time (c) on the hemicelluloses yield (%). Letters (a - c) represent statistical comparisons made between different samples (HA, HB1 and HB2). Means with different letters indicate statistically significant difference from each other ($p < 0.05$).

Characterization:

Fourier transform infrared analysis

Figure 2 displays the FTIR spectra of untreated EFB, HA1, HB1 and HB2, recorded as the transmittance (%) versus wavenumber in the range of 500-4000 cm^{-1}. The O-H and aliphatic C-H stretching frequencies can be seen in region from 4000 to 1900 cm^{-1} [18]. Stretching band at 3440 cm^{-1} is attributed for O-H stretching band which corresponds to hydroxyl groups on anhydrogalactose bonds, this band showed a decrease in the intensity of HA spectra with alkaline treatment. This is due to the removal of –OH groups by reaction with KOH. HB1 and HB2 showed similar characteristics because they were also subjected to alkaline treatment. The band at 2941 cm^{-1} is attributed to C-H stretching vibration in cellulose and hemicellulose. The absorption at 1575 – 1665 cm^{-1} in all spectra is associated with water, since the hemicelluloses has strong affinity for water [19]. Untreated EFB has characteristic of ring vibrations overlapped with stretching vibrations of C-OH side groups and the C-O-C glycosidic bond vibration band at 1200 – 1000 cm^{-1} [20]. The disappearance peak observes at 1277 cm^{-1} in HA, HB1 and HB2 sample suggested that lignin was removed during alkaline extraction. This peak represents C-O linkage in guiacyl aromatic methoxy groups [21]. Combination of deformation of syringyl and cellulose was assigned at 1165 cm^{-1} band. The decrease in intensity at wavenumber 1165 cm^{-1} was greater than that at wavenumber 1277 cm^{-1} after alkaline extraction. This suggests that syringyl was more solubilized by alkaline extraction than guaicyllignin [22]. Band at ~1035 cm^{-1} is responsible for typical of xylan-rich polysaccharides which indicated a dominant xylan of the hemicellulosic

fractions [23]. Bands at 1420, 1360 and 1052 cm^{-1} are indication of hemicelluloses existence in the sample. In addition with band at 900 $cm^{-1}$is a characteristic of β-glycosidic linkage between the monosaccharide units, indicating β-linked hemicelluloses [23]. These spectral changes are characteristics of hemicellulose, which further demonstrates the removal of lignin.

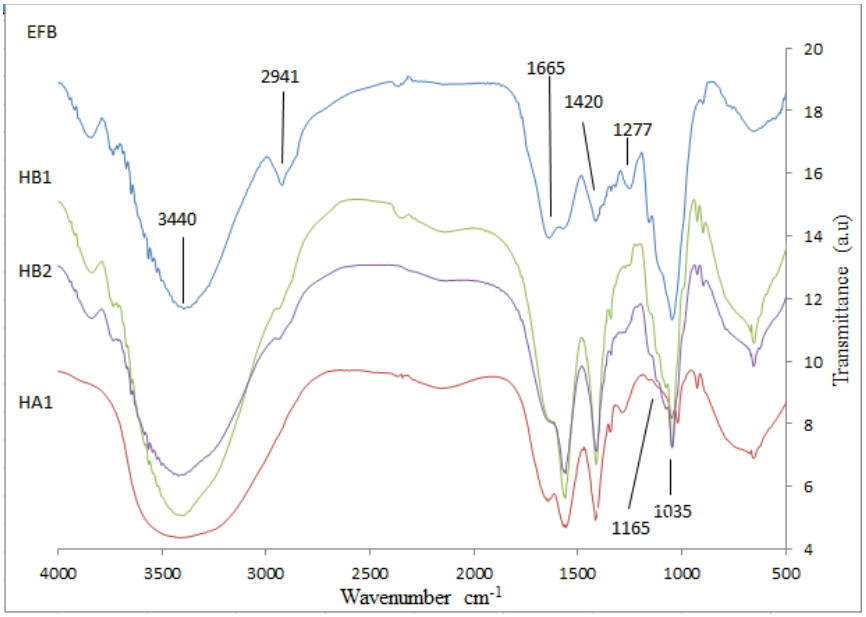

Figure 2. FTIR spectra of EFB, HA, HB1 and HB2

Klason lignin content

It was observed that a significant reduction in lignin content of HA has been achieved as compared to the original untreated OPEFB through the alkaline extraction process (Table 1). Treatment using KOH permitted the swelling of the particles that resulted in easy lignin degradation. It proved that alkaline extraction can significantly breaks the bonds between lignin and hemicelluloses [24]. After alkali extraction, the lignin content of HB1 and HB2 were decreased. This is in accordance with the finding reported by Zhao et al. [25].

Table 1. Monosaccharide compositions and lignin content in untreated EFB and hemicellulosic fractions

Sample	Monosaccharide Compositions (mg/ml)				Lignin Content (%)
	Glucose	Xylose	Arabinose	Ratio Xyl/Ara	
Untreated EFB	-	-	-	-	24.50 ± 0.01
HA	0.051 ± 0.033	0.490 ± 0.017	0.142 ± 0.027	3.456	12.06 ± 0.05
HB1	nd	0.546 ± 0.105	0.119 ± 0.004	4.591	8.96 ± 0.05
HB2	0.277 ± 0.043	1.130 ± 0.042	4.131 ± 0.023	0.273	6.08 ± 0.03

nd = not detected. Each data point were average at least two replicate measurements

Monosaccharide analysis by HPLC

The neutral monosaccharides composition content of the three precipitated hemicellulosic fractions; HA, HB1 and HB2 are shown in Table 1. Sugar analysis of hemicellulosic fractions showed that the two predominant monosaccharides in EFB were xylose and arabinose. It is suggested that the fraction may be a mixture of xylan with a small amount of arabinoxylans-type polysaccharides [26, 27]. The degrees of linearity or branching of hemicellulosic polymers were indicated by the ratio of xylose to arabinose (Xyl/Ara). A low Xyl/Ara ratio suggest that a short-chain polymer with a large amount of branching with other monosaccharide constituents. As shown in the Table 1, the ratio of Xyl/Ara gradually increased from 3.456 to 4.591. These result indicated that the hemicellulosic fractions released in alkaline extraction and ethanol precipitation has more linear structures [28].

Conclusion

This study presented extraction of hemicellulose from empty fruit bunches with various conditions. The hemicelluloses yield of HB2 was found to be higher than HA and HB1. As conclusion, alkaline extraction and ethanol precipitation are suitable methods for extracting hemicelluloses from oil palm empty fruit bunches.

Abstract

A commonly known weakness of homogeneous catalysts is the difficulty to recover the active catalyst from the product. Due to the disadvantage, the designing of supported catalyst has been approached to overcome the separation difficulty of the palladium-based homogeneous catalyst. New polymer supported N_2O_2 metal complex was successfully immobilized by mixing of poly(4-vinylpyridine) with palladium(II) complex in the presence of ethyl acetate as solvent. Then, the reaction was stirred for 72 hours at room temperature to form corresponding P_4VP-Pd catalyst. The properties of immobilized catalyst were characterized by various techniques such as fourier transform infrared (FTIR), thermogravimetric (TGA), X-ray diffraction (XRD), scanning electron microscopy/energy dispersive X-ray (SEM/EDX) and inductively coupled plasma-optical emission (ICP-OES) spectroscopy.

Keywords: immobilized catalyst, palladium(II) complex, poly(4-vinylpyridine)

Abstrak

Satu kelemahan penggunaan mangkin homogen adalah umum diketahui bahawa kesukaran untuk memperoleh kembali mangkin yang aktif daripada hasil produk. Oleh kerana kelemahan ini, reka bentuk mangkin berpenyokong telah diperkenalkan untuk mengatasi kesukaran pemisahan mangkin homogen berasaskan logam paladium. Kompleks logam N_2O_2 berpenyokong polimer baru telah berjaya dipegunkan dengan mencampurkan poli(4-vinilpiridina) dengan kompleks paladium(II) dengan kehadiran etil asetat sebagai pelarut. Kemudian, campuran tindak balas dikacau selama 72 jam pada suhu bilik untuk menghasilkan mangkin P_4VP-Pd. Sifat – sifat mangkin yang berjaya dipegunkan telah dicirikan dengan pelbagai teknik spektroskopi antaranya infra merah transformasi fourier (FTIR), analisis termogravimetrik (TGA), pembelauan sinar-X (XRD), mikroskopi elektron imbasan/ sinar-X tenaga tersebar (SEM/EDX) dan spektroskopi pancaran optik-aruhan (ICP-OES).

Kata kunci: mangkin terpegun, kompleks paladium(II), poli(4-vinilpiridina)

Introduction

Historically, the homogeneous catalysts have been developed to be used in industry earlier than heterogeneous catalyst. Homogeneous catalyst offered a several number of advantages to the researchers. It was found the homogeneous catalyst having transition metal complexes exhibited high selectivity and activity [1]. Despite of its advantages, the homogeneous catalyst is not commonly used as heterogeneous catalyst due to its difficulties to recover. These was proven when Dunnewijk et al. [2] reported that homogeneous catalyst is not widely used in chemical industry because the catalyst is difficult to recover and the catalysts also suffer from corrosion problems and product contamination [2]. Moreover, the homogeneous metal catalyst such as palladium is expansive to afford, toxic and suffered from prohibited drawbacks deactivation of poor conversion [3] Therefore, due to these reason there is a need to use the most applicable catalyst which is heterogeneous catalyst where the metal is heterogenized on a polymer support [4]. Other than that, heterogeneous catalyst offered easy recovery of catalyst from the reaction mixture by simple filtration and can be reused for several times [5].

One of the reasons palladium is commonly used in research because palladium is one of the most versatile of the transition metals and can formed coordination with electron donor atoms such as nitrogen and oxygen [6]. Due to these reason, Evangelisti et al. [7] discovered that the development of heterogeneous Schiff base a phosphine-free palladium catalyst which is economic and its environmental points of view have been done [7]. Schiff base is a compound which consists of nitrogen analogue of an aldehyde or ketone in which carbonyl group (C=O) have been replaced with an imine or azomethine group. The Schiff base compounds or also known as azomethines are very easy to be prepared from relatively inexpensive material and these selective ligands are sensitive towards most of the metal ions [8 – 10].

Polymers have been widely explored as immobilised material for supported catalyst [11]. In this research, poly(4-vinylpyridine) (P_4VP) has emerged as an interesting approach for catalyst support to the Schiff base metal complex. P_4VP has gained interest due to its stability towards high temperature resistance, hardness, impact strength, and its transparency can be precisely controlled through the metallocene structure.

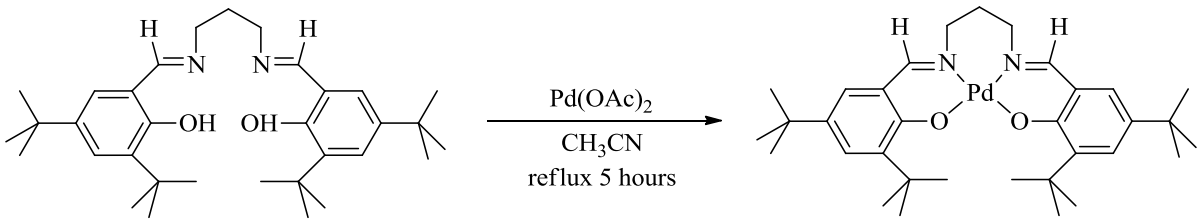
In this present paper, the synthesis and characterization of the poly(4-vinylpyridine) supported palladium(II)-Schiff base complex which highly potential as heterogeneous catalyst for carbon-carbon bond formation were reported.

Materials and Methods

Materials

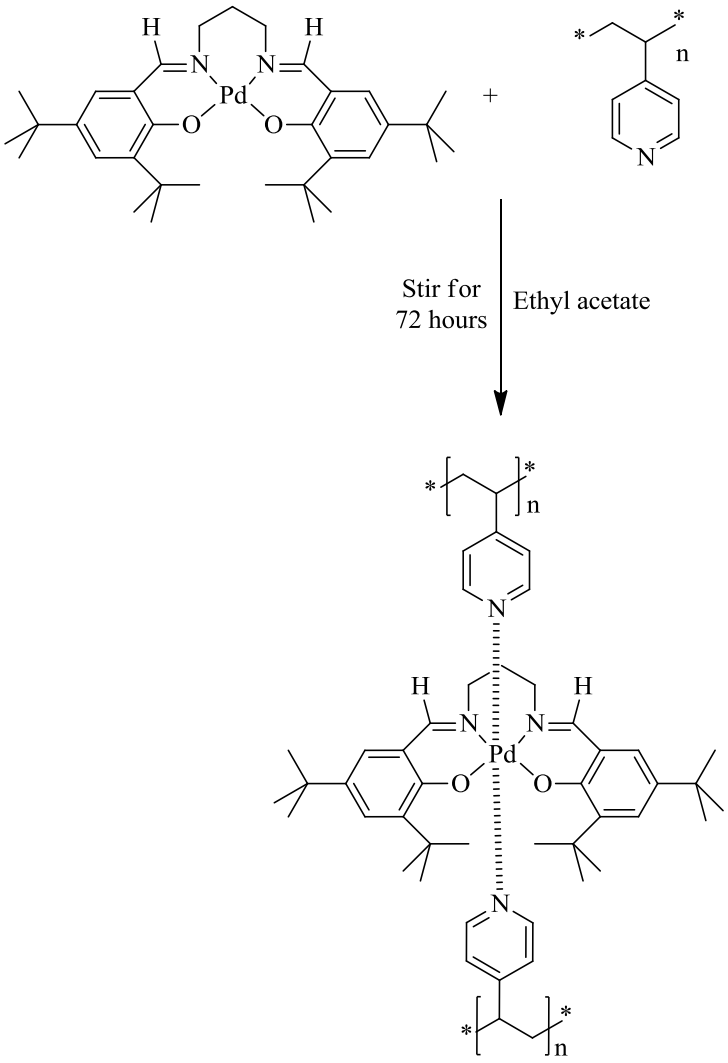
All of the reagents which included chemicals, materials and solvent are analytical grade and commercially purchased from standard suppliers (Aldrich and Fluka) were used without further purification. All reactions were carried out under an ambient atmosphere and no special precaution was taken to exclude air or moisture during synthesis work-up.

Synthesis of N,N'-bis(3,5-di-tert-butylsalicylidene)-propane-1,3-diamine



The N_2O_2-Schiff base ligand was synthesized according to the literature methods [12, 13]. The spectroscopic characterizations of these ligands were in agreement with literature values.

Synthesis of N,N'-bis(3,5-di-tert-butylsalicylidene)-propane-1,3-diaminepalladium(II) complex



The Pd(II) complex (Scheme 1) was synthesized following standard method [14]. The complex was prepared by treating an equivalent molar amount of the corresponding ligand with $Pd(OAc)_2$ in acetonitrile. The spectroscopic data (^1H, ^{13}C NMR and FTIR) of this complex are in agreement with those reported recently by Soh et al. [15] .Yield: 88%. Melting point: 375-376 °C. CHN elemental analysis (%): Experimental: C, 55.60; H, 6.53; N, 3.82. Calculated for $C_{33}H_{48}N_2O_2Pd$ requires: C, 64.85; H, 7.92; N, 4.58

Synthesis of Poly(4-vinylpyridine) supported Pd(II) complex

The poly(4-vinylpyridine) (0.8 g) was loaded into round bottom flask containing complex (0.8 g) with ethyl acetate as a solvent. The solution was stirred for 72 hours at room temperature (Scheme 2). The resultant solid catalyst was filtered off and washed with ethyl acetate two times followed by acetone. The residue was dried in air for 24 hours.

Scheme 1. Synthesis of N,N'-bis(3,5-di-tert-butylsalicylidene)-propane-1,3-diaminepalladium

Scheme 2. Synthesis of poly(4-vinylpyridine) supported Pd(II) complex

Results and Discussion

Synthesis of N_2O_2 Schiff Base ligand and Palladium(II) complex

The Schiff base ligand N,N'-bis(3,5-di-tert-butylsalicylidene)-propane-1,3-diamine was obtained yellow solid in high yield through condensation reaction between 3,5-di-tert-butyl-2-hydroxybenzaldehyde with 1,3-diaminopropane. The resulting ligand was further treated with palladium(II) acetate in order to form metal complex. The synthesis of the Schiff base palladium(II) complex is shown in Scheme 1.

Synthesis of Poly(4-vinylpyridine) supported Pd(II) complex

The outline for synthesizing of P_4VP-Pd(II) complex was presented in Scheme 2. The N_2O_2 palladium(II) complex was then immobilized onto poly(4-vinylpyridine) solid support in order to obtain heterogeneous catalyst of P_4VP-Pd(II) complex. The immobilized P4VP-Pd(II) complex was well characterized by FTIR, TGA, XRD, SEM-EDX and ICP-OES. The amount of metal present determined by ICP-OES suggested 0.361 mmol/g palladium loading onto supported palladium complex.

FTIR spectrum (Figure 1) showed the important bands of P_4VP-Pd(II) complex are located at 1610.73 cm^{-1}, 3401.29 cm^{-1}, and 1456.16 cm^{-1} due to stretching vibration of ν(C=N), ν(N-H) and ν(C=C). The thermal stability curves of P_4VP and its supported Pd(II) complex are presented in Figure 2 were carried out at a heating rate of 10 °C min^{-1} in nitrogen over a temperature range of 30-700 °C. TGA data demonstrated that P_4VP and P_4VP-Pd(II) complex degraded at considerably high temperature. P_4VP-Pd(II) complex was stable up to 330 °C and above this temperature it undergo decomposition process.

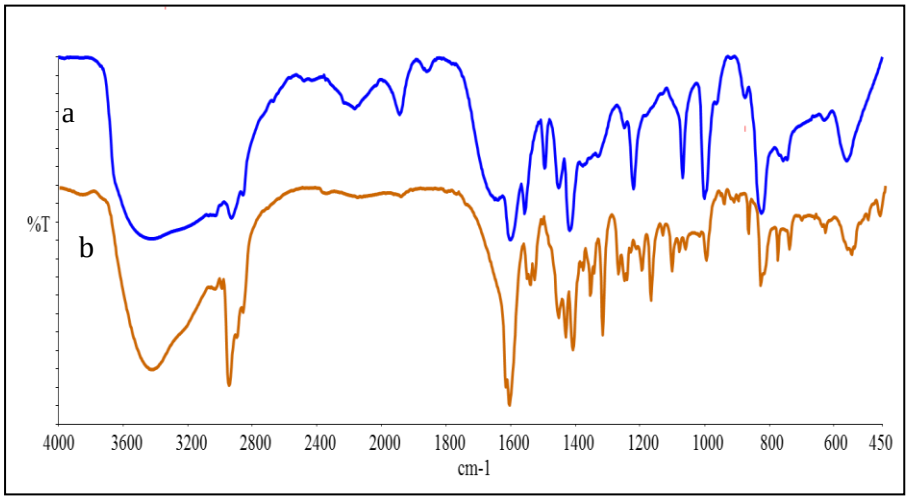


Figure 1. The FTIR spectrum for (a) P_4VP and (b) P_4VP Pd(II) complex

The surface morphological features of each sample of P_4VP and P_4VP-Pd(II) complex were observed using SEM (Figure 3) equipped with energy dispersive X-ray spectroscopy (EDX) (Figure 3). The morphology of P_4VP shows as compact and lumps surface. Meanwhile, the morphology of P_4VP-Pd(II) complex has changed and small like particles are observable through the specimen. This could be due to the existence of palladium crystallite. The EDX data (Figure 4) clearly supported the presence of palladium metal on the surface of polymeric chain of poly(4-vinylpyridine).

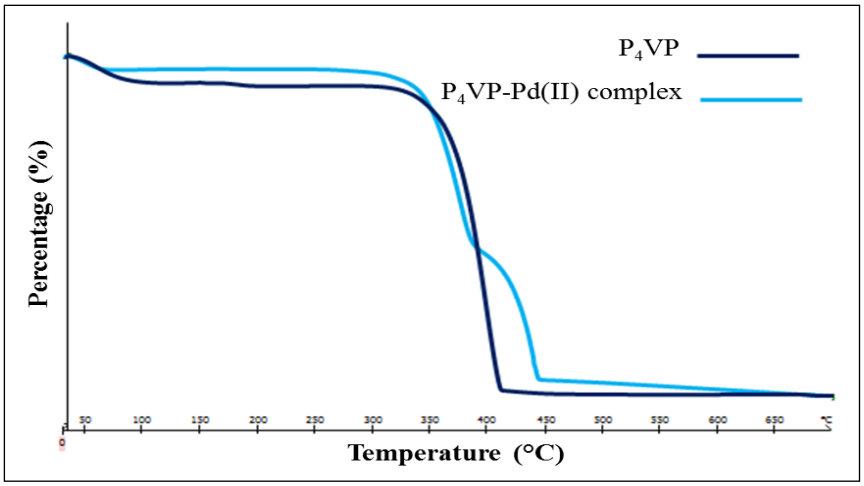

Figure 2. The TGA curves of the supported catalysts and free P_4VP

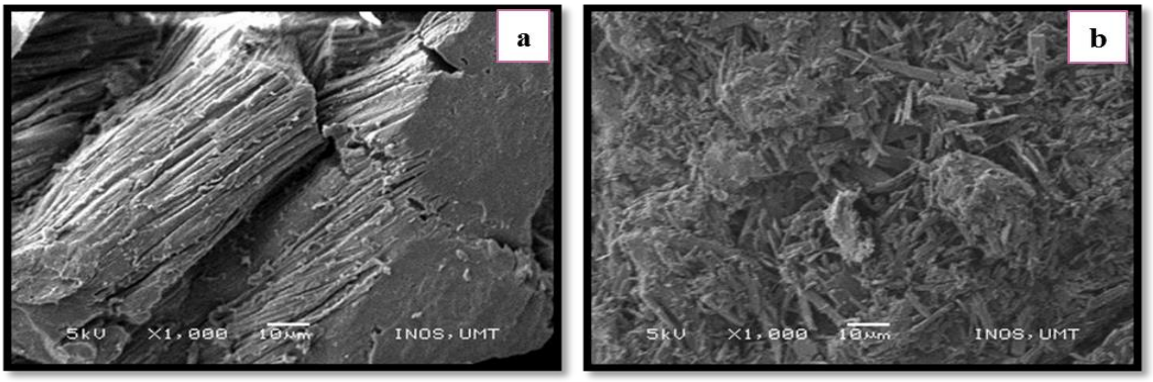

Figure 3. SEM image of the (a) P_4VP and (b) P_4VP-Pd(II) complex

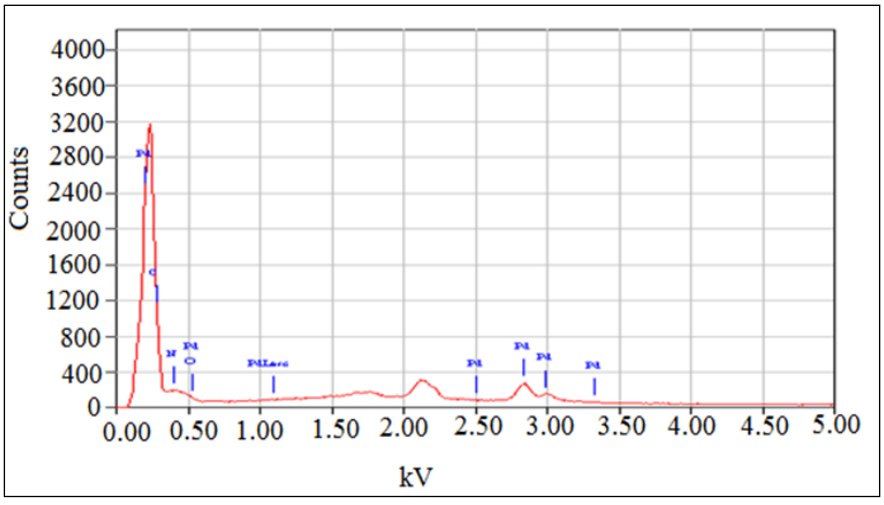

Figure 4. The EDS profile for supported P_4VP-Pd(II) complex

Powdered X-ray diffraction study is regularly used to assess the quality and structural ordering of P_4VP and supported catalyst (Figure 5). XRD pattern showed that the P_4VP support is amorphous nature with no characteristic XRD peaks is observed. The diffractogram of P_4VP-Pd(II) complex showed dramatic changes compared to P_4VP structure due to the represent of crystalline phase and indicated that the palladium complex which is incorporated with P_4VP matrix.

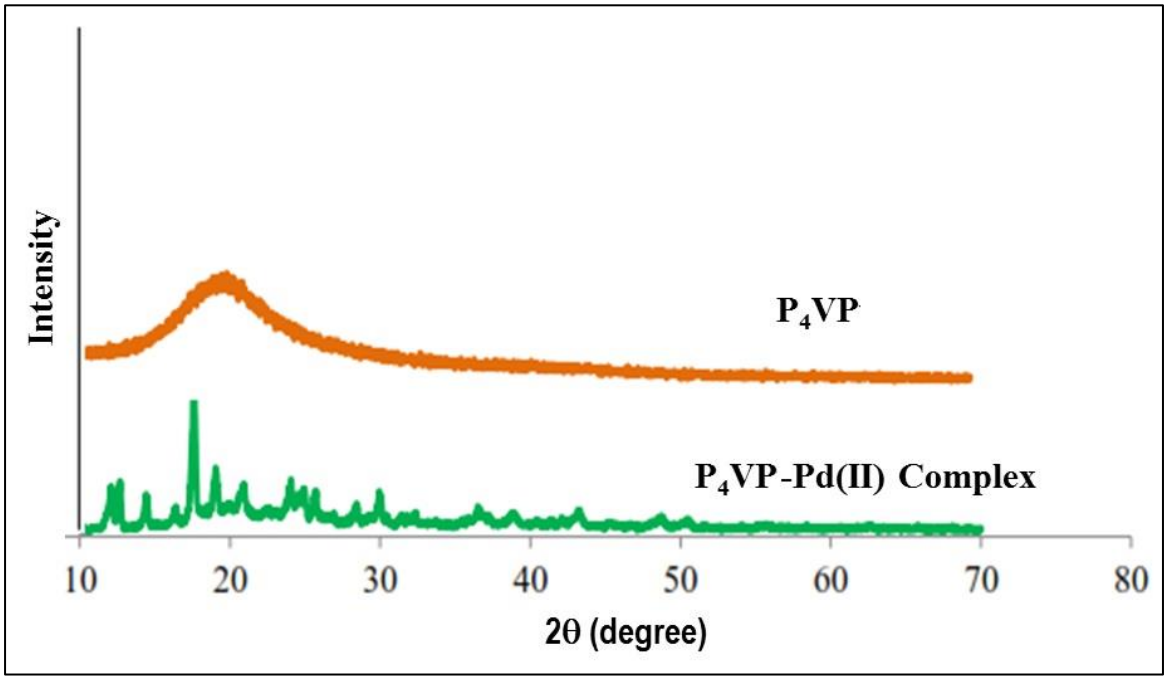

Figure 5. The XRD pattern for free P_4VP and its supported P_4VP-Pd(II) catalyst

Conclusion

In conclusion, Pd(II) complex was successfully immobilized onto P_4VP solid support and characterized via several of spectroscopic and analytical technique. The ease and simple preparation, stability towards air and moisture will make this immobilized catalyst as an ideal supported catalyst for C-C bond formation.

Abstract

Ozone is known as an important secondary pollutant in the atmosphere. The aim of this study is to find the best fit distribution for calculating exceedance and return period of ozone based on suburban areas; Perak (AMS1) and Pulau Pinang (AMS2). Three distributions namely Gamma, Rayleigh and Laplace were used to fit 2 years ozone data (2010 and 2011). The parameters were estimated by using Maximum Likelihood Estimation (MLE) in order to plot probability distribution function (PDF) and cumulative distribution function (CDF). Four performance indicators were used to find the best distribution namely, normalized absolute error (NAE), prediction accuracy (PA), coefficient of determination (R^2) and root mean square error (RMSE). The best distribution to represent ozone concentration at both sites in 2010 and 2011 is Gamma distribution with the smallest error measure (NAE and RMSE) and the highest adequacy measure (PA and R^2). For the 2010 data, AMS1 was predicted to exceed 0.1 ppm for 2 days in 2011 with a return period of one occurrence per 179 days. However, AMS2 do not exceed MAAQG limit (0.1 ppm) based on both 2010 and 2011. From the results, the exceedance and return period can be used as a guidance to overcome future air pollution problem.

Keywords: ozone, performance indicators, probability distribution function, return period, cumulative distribution function

Abstrak

Ozon dikenali sebagai pencemar sekunder yang paling penting di atmosfera. Matlamat kajian ini adalah untuk mengenalpasti taburan yang terbaik dalam mengira jumlah kepekatan yang melepasi had yang ditetapkan dan tempoh kembali untuk ozon berdasarkan kawasan sub-bandar; Perak (AMS1) dan Pulau Pinang (AMS2). Pembolehubah-pembolehubah telah dianggarkan melalui penggunaan penganggar kebolehjadian maksimum (MLE) untuk plot fungsi taburan kebarangkalian (PDF) dan fungsi taburan kumulatif (CDF). 4 penunjuk prestasi telah digunakan untuk mencari taburan terbaik antaranya, ralat mutlak dinormalkan (NAE), kejituan ramalan (PA), pekali penentuan (R^2) dan punca min ralat kuasa dua (RMSE). Taburan terbaik yang mewakili kepekatan ozon di kedua-dua tempat adalah taburan Gamma dengan nilai ukuran ralat yang terkecil (NAE dan RMSE) dan nilai ukur kadaran yang terbesar (PA dan R^2). Data bagi tahun 2010, AMS1 dijangkakan akan melepasi had 0.1 ppm dalam masa 2 hari pada tahun 2011 dengan tempoh kembali satu kejadian dalam masa 179 hari. Walaubagaimanapun, AMS2 tidak melebihi had MAAQG (0.01 ppm) untuk kedua-dua tahun 2010 dan 2011. Berdasarkan hasil kajian, didapati jumlah kepekatan yang melepasi had yang ditetapkan dan tempoh kembali boleh digunakan sebagai panduan untuk mengatasi masalah pencemaran udara pada masa akan datang.

Kata kunci: ozon, penunjuk prestasi, fungsi taburan kebarangkalian, fungsi taburan kumulatif, tempoh kembali

Introduction

Owing to the burgeoning development of infrastructure in all areas in Malaysia including suburban areas, surface ozone occurrence is very likely. The higher entropic emissions such as heating emission from building and the unfavourable dispersion conditions can initiate the temperate climate of high air pollution [1]. The precursors of surface ozone are contributed by anthropogenic and natural sources. Anthropogenic sources such as deforestation, logging, fuel combustion, biomass burning, industrial causes and marine emission [2]. The examples of natural sources are nitrogen cycle, sea salt aerosol, cud-chewing animal waste and atmospheric lightning [2]. The ozone (O_3) can irritate lung airways and cause inflammation much like sunburn [3]. In Malaysia, many studies applied statistical distribution on particulate matter (PM_{10}) but less in ozone (O_3). Most of the studies on ozone use different method which are multiple linear regressions (MLR), variation and correlation between parameters such as reported in previous studies [4, 5], but there are lack of studies applying statistical distribution on ozone.

The aim of this study is to find the best fit distribution for determining exceedance and return period of ozone in AMS1 and AMS2 via statistical distribution. Three distributions namely Gamma, Rayleigh and Laplace were used to fit 2 years ozone data (2010 and 2011).

Materials and Methods

Study area

Both sites selected in this study were shown in Figure 1. The coordinate of AMS1 is 3°41’17.00’’ N and 101°31’11.79’’ E. AMS1 situated at Tanjung Malim district. Surrounded by many residential and construction areas, contained partly of Lebuhraya Utara-Selatan (main highway in Malaysia) can catalyse the ozone formation. The coordinate of AMS2 is 5°21’38.12’’ N and 100°17’55.74’’ E. AMS2 located at an education based centre in Pulau Pinang and congested with resident areas and traffics including Pulau Pinang bridge which is connected with the mainland.

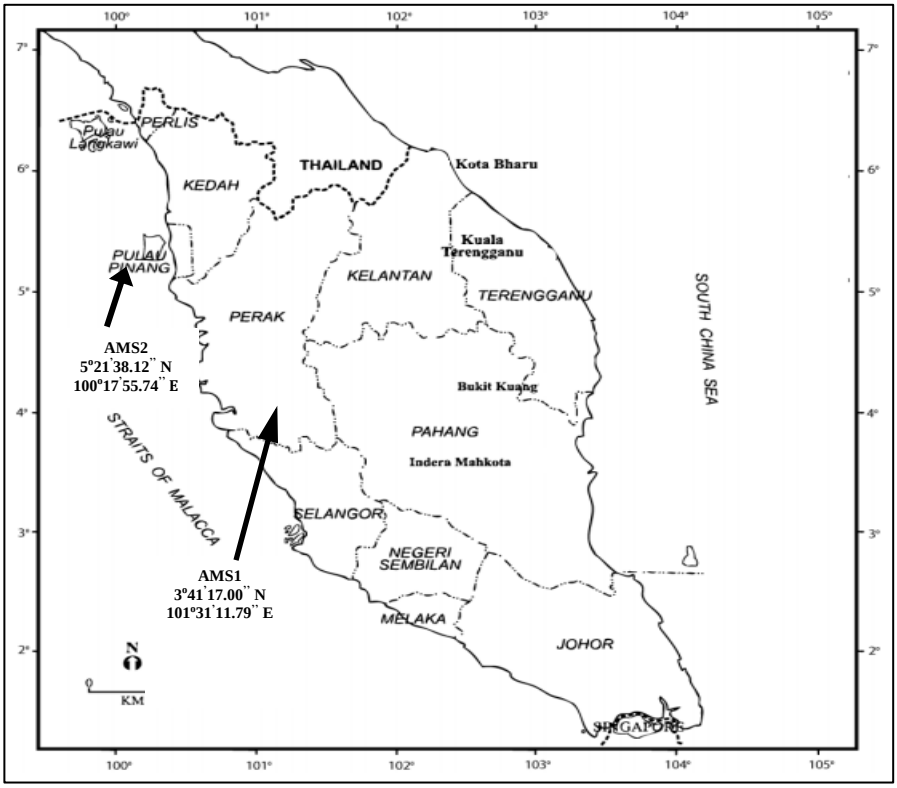

Figure 1. Map of Malaysia Peninsula (site location and its description [6])

Instrumentation and data collection

The hourly O_3 data is procured from both sites in year 2010 and 2011 which were owned from Department of Environment Malaysia (DoE) and managed by Alam Sekitar Sdn. Bhd (ASMA). The data are subjected to standard quality control processes and quality assurance procedures [7]. ASMA applied Beer-Lambert law to measure low range surface ozone concentration by using Teledyne Ozone Analyzer Model 400E UV Absorption [7]. Those best fit distribution, best distribution, exceedance and return period were obtained by analysing selected distributions via MATLAB R2014a. Statistical Package for Social Science version 19 (SPSS) was implemented to identify descriptive statistics for both stations.

Probability distribution and performance indicator

The parameters for the distributions were estimated by maximum likelihood estimation (MLE). The Gamma distribution is comprised of Chi-Squared, Erlang and Exponential distribution. It has scale and shape parameter in which growing rate of shape parameter signifies the large dataset [8]. Laplace distribution is known as double exponential distribution because of its CDF pattern [8]. It has location and scale parameter in which increasing number of scale parameter epitomizes heavier tail and lower kurtosis in PDF figure. Rayleigh distribution has scale parameter only which is simplified from Weibull distribution [8]. The formulas are as shown in Table 1. The formulas for the performance indicators are tabulated in Table 2.

Table 1. Each distribution with respective probability distribution function (PDF), cumulative distribution function (CDF) and maximum likelihood estimation (MLE)

Distribution	PDF and CDF	MLE parameter
Gamma	PDF: $f\left(x; a, B\right) = \frac{1}{\Gamma(a)B^a} x^{a-1}\exp\left(-x/B\right)$ (1) CDF: $\frac{1}{\Gamma(a)}\gamma(a, \frac{x}{B})$ $a > 0, B > 0$ (3)	Scale Parameter: $\hat{a} = \bar{x}/\hat{B}$ (2) Shape Parameter : $log\hat{a} - \varphi(\hat{a}) = \left[\bar{x}/(\prod_{i=1}^{n} x_i)\,\hat{}\,\frac{1}{n}\right]$ (4)
Rayleigh	PDF: $f(x; a) = \frac{x}{a^2} e^{\frac{-x^2}{2a^2}}$ (5) CDF: $1 - e^{\frac{-x^2}{2a^2}}$ $a > 0$ (7)	Scale Parameter : $a = \left(\left(\frac{1}{2n}\sum_{i=1}^{n} x_i^2\right)\right)\hat{}\,\frac{1}{2}$ (6)
Laplace	PDF: $f(x; \mu, \lambda) = \frac{1}{2\lambda} e\left(-\frac{\lvert x-\mu\rvert}{\lambda}\right)$ (8) CDF: $\begin{cases} \frac{1}{2} e\left(\frac{x-\mu}{\lambda}\right) \; if \; x < \mu \\ 1 - \frac{1}{2} e\left(\frac{-x-\mu}{\lambda}\right) \; if \; x \geq \mu \end{cases}$ (10)	Scale Parameter: $\frac{1}{n}\sum_{i=1}^{n}\lvert x_i - \mu\rvert$ (9) Location Parameter: Median (11)

Notation: μ is the scale parameter for Laplace distribution, a is the scale parameter for Gamma and Rayleigh distribution, λ is the location parameter and B is the shape parameter [8].

Table 2. The formula and best value for each performance indicator

Type	Performance Indicator	Formula	Best Value
Error Measure	Normalized Absolute Error (NAE)	$NAE = \frac{1}{\sum_{i=1}^{N}(O_i)}\sum_{i=1}^{N}\lvert P_i - O_i\rvert$ (12)	Near 0
	Root Mean Square Error (RMSE)	$RMSE = \sqrt{\left(\frac{1}{N-1}\right)\sum_{i=1}^{N}(P_i - O_i)\hat{}2}$ (13)	Near 0
Adequacy Measure	Prediction Accuracy (PA)	$PA = \sum_{i=1}^{N}\left[\frac{(P_i-\bar{P})(O_i-\bar{O})}{(N-1)\sigma_P\sigma_O}\right]$ (14)	Near 1
	Coefficient of Determination (R^2)	$R^2 = \left[\frac{1}{N}\frac{\sum_{i=1}^{N}(P_i-\bar{P})(O_i-\bar{O})}{\sigma_P\sigma_O}\right]$ (15)	Near 1

Exceedance and return period

Actual exceedance can be obtained by calculating the cases number exceeding the threshold of Malaysia Ambient Air Quality Guideline (MAAQG) limit and dividing this number by the number of available data [12]. Predicted exceedance can be determined by using the data collected from both actual and previous years [12]. Thus, the formula of exceedance is written in equation 16 below [9].

Exceedance: $P\{X > 0.1\} = 1 - P\{X \leq 0.1\} = 1 - F(0.1)$ (16)

Return period is a time period to calculate how many days the ozone data exceed the standard. The formula of return period is stated as below [9].

Return Period: $\frac{1}{P\{X>0.1\}} \times 365\ days$ (17)

Results and Discussion

The description statistic for AMS1 and AMS2 were shown in Table 3. The skewness showed positive numbers that define the occurrence of extreme events and high ozone emissions. These results showed that the ozone distributions are skewed to the right represent most data is concentrated on the left of the PDF plots with few high values. The mean, median, skewness and kurtosis were increasing for both sites from 2010 until 2011, indicating growing air pollution problem.

Table 3. The descriptive statistic for both sites

Data parameters	AMS1		AMS2	
	2010	2011	2010	2011
Maximum	0.127	0.165	0.086	0.089
Mean	0.018	0.019	0.019	0.020
Standard Deviation	0.018	0.021	0.014	0.015
Median	0.011	0.012	0.015	0.017
Skewness	1.13	1.6	0.9	1.005
Kurtosis	3.76	6.03	3.18	3.55

Table 4 shows that the parameter estimates are different when dissimilar statistical distributions models were applied via Maximum Likelihood Estimation (MLE). All shape parameter (a) in Gamma and Rayleigh distribution and scale parameter (λ) in Laplace distribution were less than 0.5 for both sites in 2 years. These showed that the PDF plot for all distributions had high and sharp central peak (represent high ozone concentration) and the tails are long and fat (represent few high values). The scale parameters (B) were greater than shape parameters (a) in Gamma distribution. The scale parameters (λ) were larger than location parameter (μ) in Laplace distribution. From the results, these parameters showed higher concentration for both sites in 2011 compared to 2010.

Table 4. MLE parameter estimates for both sites

Data parameters for distributions	AMS1		AMS2	
	2010	2011	2010	2011
Gamma	a=0.019 B=0.95	a=0.017 B=1.12	a=0.019 B=0.994	a=0.013 B=1.656
Rayleigh	a=0.018	a=0.020	a=0.017	a=0.018
Laplace	μ=0.011 λ=0.014	μ=0.011 λ=0.015	μ=0.015 λ=0.011	μ=0.017 λ=0.012

From the parameter estimates, CDF and PDF for Gamma, Rayleigh and Laplace distribution were plotted. Among these distributions, Gamma was the best fitted distribution as shown in Figure 2 for both sites from 2010 until 2011. PDF plots for both sites in 2010 and 2011 are positively skewed and the densities were lower meaning that ozone concentration had risen. Long tail recorded in both PDF plots indicated the presence of extreme value. The CDF plot was used to indicate the best distribution that fit the ozone concentration data. Observational line in CDF plot for AMS1 in 2010 fit at 0.044 ppm with theoretical line. Meanwhile, for AMS1 in 2011, the observational line fit at 0.02 ppm. The observational line in CDF plot for AMS2 in 2010 fitted to theoretical line at 0.04 ppm and for AMS2 in 2011, most of ozone concentration data fit to the theoretical line.

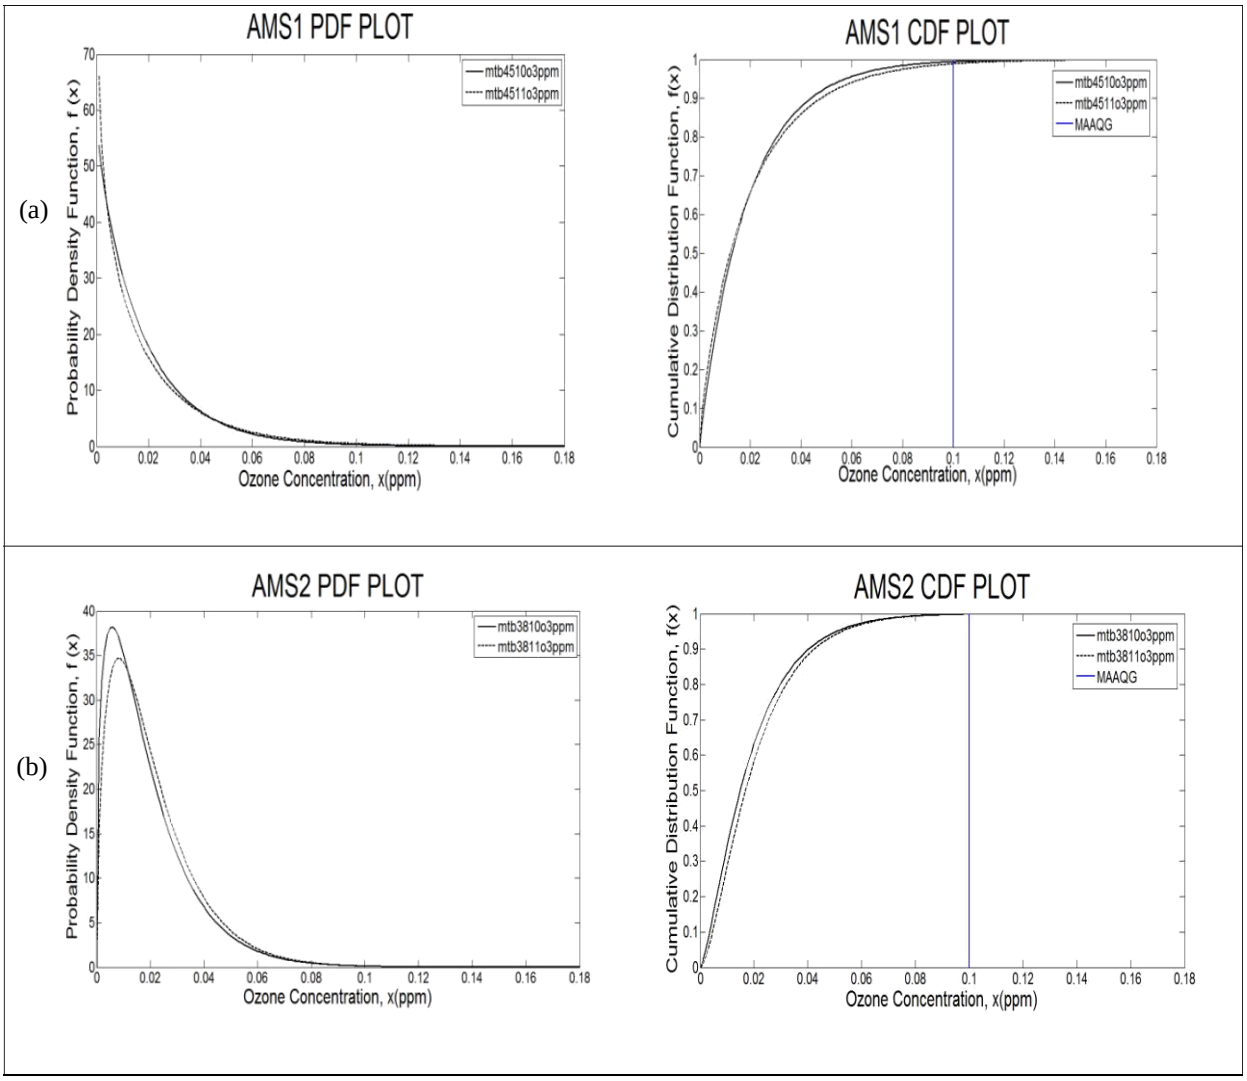

Figure 2. Gamma distribution PDF and CDF plots for both sites in 2010 and 2011 with MAAQG limit

The role of performance indicator is to determine the best fit distribution. NAE and RMSE were in error measure category which decides the smallest value gives the best fit. The R^2 and PA were categorized in adequacy measure which indicates the closer value to 1 gives the best fit. The result shows that the Gamma distribution is the best for both sites from 2010 to 2011 as shown in Table 5.

Table 5. The performance indicators for ozone concentration in both sites

Performance Indicator	Sites (Year)	Gamma Distribution	Rayleigh Distribution	Laplace Distribution	Best Distribution
NAE (near to 0)	AMS1 (2010)	0.151	0.405	0.361	Gamma
	AMS1 (2011)	0.181	0.496	0.410	
	AMS2 (2010)	0.150	0.223	0.206	
	AMS2 (2011)	0.054	0.198	0.197	
RMSE (near to 0)	AMS1 (2010)	0.005	0.009	0.008	Gamma
	AMS1 (2011)	0.006	0.011	0.008	
	AMS2 (2010)	0.004	0.005	0.012	
	AMS2 (2011)	0.002	0.005	0.013	
R^2 (near to 1)	AMS1 (2010)	0.950	0.939	0.790	Gamma
	AMS1 (2011)	0.989	0.919	0.784	
	AMS2 (2010)	0.943	0.980	0.851	
	AMS2 (2011)	0.982	0.980	0.858	
PA (near to 1)	AMS1 (2010)	0.975	0.969	0.889	Gamma
	AMS1 (2011)	0.994	0.959	0.886	
	AMS2 (2010)	0.971	0.990	0.923	
	AMS2 (2011)	0.991	0.990	0.926	

Table 6 shows that the predicted exceedances were underestimated for AMS1 from 2010 to 2011. However, the differences between predicted and actual days were small for both years. The gap of more than 1-day difference for AMS1 which is surrounded by residential areas showed that there was a few of consistent high hourly ozone detection in 2010. For 2011, the gap was below 1-day difference showed that there was detection of greater amount of consistent high hourly ozone concentration. From the result, the decreasing of difference between predicted and actual exceedances showed that the ozone concentration had become worsen from 2010 to 2011.

Table 6. The exceedance probability and return period of AMS1 for 2010 and 2011

	Elements	AMS1	
		2010	2011
	Probability ≤ 0.1 ppm	0.9944	0.9938
	Exceedance Probability > 0.1 ppm	5.6×10^{-3}	6.2×10^{-3}
Return Period	Predicted Exceedances (day)	2	2.3
	Actual Exceedances (day)	0.3	2.7
	Difference of predicted and actual exceedances (day)	1.7	0.4

Conclusion

This study shows Gamma distribution is the best fit distribution for both suburban-based sites in 2010 and 2011. Both sites show the mean are greater than median indicating the observation data are positively skewed in all three distributions. For the 2010 data, AMS1 was expected to surpass 0.1 ppm for 2 days in 2011 with a return period of one occurrence per 179 days. For the 2011 data, AMS1 was expected to surpass 0.1 ppm for 2.3 days in 2012 with a return period of one occurrence per 159 days. The results showed the ozone concentration at AMS1 became worsen from 2010 to 2011. AMS2 do not have data that exceed 0.1 ppm for both years, therefore no exceedance and return period need to be considered.

Abstract

The wide-ranging biological activities of 4-hydroxycoumarin have stimulated considerable interest in this class of compounds, and various biscoumarin derivatives have been synthesized. Recently, a number of methods have been reported for the synthesis of biscoumarin by the reaction of 4-hydroxycoumarin and various aldehydes in the presence of catalysts. In the present study, a new series of biscoumarin and benzopyrano dicoumarin were synthesized and physically characterized by nuclear magnetic resonane (^{1}H and ^{13}C NMR), fourier transform infrared spectroscopy (FTIR), mass spectrometry (MS) and melting point.

Keywords: synthesis, 4-hydroxycoumarin, biscoumarin, benzopyrano, nuclear magnetic resonane

Abstrak

Aktiviti biologi yang meluas daripada 4-hydroksikumarin telah merangsang minat yang besar di dalam kelas sebatian ini dan pelbagai terbitan biskumarin telah disintesis. Baru-baru ini, beberapa kaedah telah dilaporkan bagi sintesis biskumarin melalui tindak balas 4-hidroksikumarin dan pelbagai aldehid dengan kehadiran pemangkin. Dalam kajian ini, satu siri baru biskumarin dan benzopyrano dikumarin telah disintesis dan telah dicirikan secara fizikal oleh resonans magnet nukleus (^{1}H dan ^{13}C NMR), spektroskopi infra merah transformasi Fourier (FTIR), spektrometri jisim (MS) dan pengukuran takat lebur .

Kata kunci: sintesis, 4-hidroksikumarin, biskumarin, benzopirano, resonans magnet nukleus

Introduction

Significant properties and wide-ranging biological activities of 4-hydroxycoumarin have stimulated considerable interest in this class of compounds, and various biscoumarin derivatives have been synthesized. Biscoumarin, the bridge substituted dimers of 4-hydroxycoumarin, have enormous potential as anticoagulants [1, 2], antidiabetic [3], urease inhibitors [4], anticancer [5], antibacterial [6]. A number of biscoumarin have also been found to significantly inhibit c-Met phosphorylation in BaF3/TPR-Met and EBC-1 NSCLC cell lines [7]. Recently, a number of methods have been reported for the synthesis of biscoumarin by reaction of 4-hydroxycoumarin and various aldehydes in the presence of various catalysts such as tetrabutylammonium bromide [8], molecular iodine [9], [bmin] BF4 [10], SO_3H-functionalized ionic liquid [11], sodium dodecyl sulfate [12], piperidine [4], n-dodecylbenzene sulfonic acid (DBSA) [13], nano silica chloride [14], ruthenium (III) chloride hydrate [15] and Zn (proline)2 [16]. Benzopyrano dicoumarin are a derivative of biscoumarin resulting from the removal of a water

molecule. Both compounds are reported to possess versatile activities through chemical modifications (different substituents on the aromatic ring) [4,17].

Therefore, in the present study a new series of biscoumarin and benzopyrano dicoumarin were synthesized and physically characterized by Nuclear Magnetic Resonane (^{1}H and ^{13}C NMR), Fourier Transform Infrared Spectroscopy (FTIR), Mass Spectrometry (MS) and measurement of melting point.

Materials and Methods

Instrumentation

Infrared spectra were recorded on a Spectrum One FTIR Spectrometer (Perkin Elmer), using KBr discs and values were signified in cm^{-1}. The ^{1}H NMR and ^{13}C NMR spectra were measured on Bruker 500 Ultrashield Plus NMR (500 MHz) in DMSO-*d*6 as solvent, using tetramethylsilane (TMS) as an internal standard, and chemical shifts are expressed as ppm. HR-ESI-MS were determined on Agilent 6224 TOF-LC/MS using negative mode at Faculty of Pharmacy, UiTM Puncak Alam, Malaysia.

General procedure for the synthesis of compounds 1 – 18

Biscoumarin analogs 1 – 16 and benzopyrano dicoumarin 17 – 18 were synthesized by stirring the mixture of 6-Cl-4-hydroxycoumarin (1 mmol) and substituted aromatic aldehyde (0.5 mmol) in water and 10 mmol triethyl ammonium bromide (TEAB) [3]. The reaction mixture was refluxed for 24 hours. Completion of reaction was monitored by periodic TLC. After completion of reaction, the product was filtered and then washed with distilled water affording a pure product in high yields. The structures of compounds 1 – 18 were characterized by using different spectroscopic techniques namely Nuclear Magnetic Resonanes (^{1}H and ^{13}C NMR), Fourier Transform Infrared Spectroscopy (FTIR), Mass Spectrometry (MS) and melting point.

Results and Discussion

Characterization study: 3,3'-(o-tolylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (1)

Yield; 0.23g (84%). m.p. 227 °C. IR(KBr) (ν_{max}, cm^{-1}): 3076, 1668, 1610, 1560, 1115, 1175. ^{1}H NMR (500 MHz, DMSO) δ 7.77 (d, *J* = 2.5 Hz, 2H), 7.54 (dd, *J* = 8.8, 2.5 Hz, 2H), 7.32 (d, *J* = 8.8 Hz, 2H), 7.25 (d, *J* = 4.0 Hz, 1H), 7.19 (t, *J* = 5.5 Hz, 1H), 7.02 (s, 2H), 6.08 (s, 1H, Ar_3CH), 2.08 (s, 3H, CH_3). ^{13}C NMR (126 MHz, DMSO) δ 166.5, 164.0, 151.4, 140.6, 136.1, 131.1, 130.6, 128.6, 127.7, 125.9, 125.4, 123.6, 121.4, 118.2, 104.4, 36.12. EI-MS: 493.0255 (M^-, 1).

3,3'-((2-chlorophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (2)

Yield; 0.24g (86%). m.p. 225 °C. IR(KBr) (ν_{max}, cm^{-1}): 3277, 1668, 1618, 1567, 1176, 1116. ^{1}H NMR (500 MHz, DMSO) δ 7.77 (d, *J* = 2.5 Hz, 2H), 7.63 (d, *J* = 8.0 Hz, 1H), 7.54 (dd, *J* = 8.7, 2.6 Hz, 2H), 7.37 (d, *J* = 7.5 Hz, 1H), 7.32 (d, *J* = 8.7 Hz, 2H), 7.27 (dd, *J* = 7.5, 1.3 Hz, 1H), 7.25 – 7.09 (m, 2H), 6.13 (s, 1H, Ar_3CH). ^{13}C NMR (126 MHz, DMSO) δ 166.3, 163.8, 151.4, 139.9, 133.1, 131.2, 130.7, 129.9, 127.8, 127.8, 126.6, 123.6, 121.4, 118.2, 104.0, 36.7. EI-MS: 512.9706 (M^-, 1).

3,3'-(p-tolylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (3)

Yield; 0.23g (84%). m.p. 280°C. IR(KBr) (ν_{max}, cm^{-1}): 3026, 1671, 1619, 1567, 1177. ^{1}H NMR (500 MHz, DMSO) δ 7.76 (d, *J* = 2.6 Hz, 2H), 7.56 (dd, *J* = 8.7, 2.6 Hz, 2H), 7.34 (d, *J* = 8.8 Hz, 2H), 6.98 (s, 4H), 6.21 (s, 1H, Ar_3CH), 2.23 (s, 3H, CH_3). ^{13}C NMR (126 MHz, DMSO) δ 166.3, 164.6, 151.5, 138.5, 134.4, 131.3, 128.9, 127.7, 127.0, 123.6, 121.4, 118.2, 104.8, 36.3, 21.0. EI-MS: 493.0252 (M^-, 1).

3,3'-((3-hydroxyphenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (4)

Yield (0.24 g) 86%. m.p. 292 °C. IR(KBr) (ν_{max}, cm^{-1}): 3077, 1657, 1618, 1564, 1169. ^{1}H NMR (500 MHz, DMSO) δ 7.77 (d, *J* = 2.4 Hz, 2H), 7.55 (dd, *J* = 8.7, 2.4 Hz, 2H), 7.41 (dd, *J* = 13.1, 5.3 Hz, 1H), 7.32 (d, *J* = 8.7 Hz, 2H), 7.25 (t, *J* = 7.9 Hz, 1H), 7.17 (dd, *J* = 12.8, 6.4 Hz, 1H), 7.03 (t, *J* = 7.4 Hz, 1H), 6.98 (dd, *J* = 10.6, 8.6 Hz, 1H), 6.30 (s, 1H, Ar_3CH). ^{13}C NMR (126 MHz, DMSO) δ 166.5, 163.9, 151.4, 131.2, 130.3, 127.7, 123.8, 123.7, 121.5, 118.2, 115.5, 115.3, 103.8, 32.5. HR-EI-MS: 495.0043 (M^-, 1).

3,3'-(m-tolylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (5)
Yield (0.23 g) 84%. m.p. 243 °C. IR(KBr) (ν_{max}, cm^{-1}): 3014, 1668, 1618, 1565, 1181. ^{1}H NMR (500 MHz, DMSO) δ 7.76 (d, *J* = 2.4 Hz, 2H), 7.55 (dd, *J* = 8.7, 2.5 Hz, 2H), 7.33 (d, *J* = 8.7 Hz, 2H), 7.06 (t, *J* = 7.7 Hz, 1H), 6.90 (m, 3H), 6.22 (s, 1H, Ar_3CH), 2.19 (s, 3H, CH_3). ^{13}C NMR (126 MHz, DMSO) δ 166.5, 164.6, 151.5, 141.8, 137.1, 131.2, 128.2, 127.7, 127.7, 126.3, 124.3, 123.7, 121.6, 118.2, 104.7, 36.6, 21.7. EI-MS: 493.0257 (M^-, 1).

3,3'-((2-nitrophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (6)
Yield (0.20 g) 78%. m.p. 244°C. IR(KBr) (ν_{max}, cm^{-1}): 3084, 1676, 1616, 1563, 1479, 1440, 1367, 1257, 1176, 1119, 1070. ^{1}H NMR (500 MHz, DMSO) δ 7.71 (d, *J* = 2.5 Hz, 2H), 7.57 (d, *J* = 7.9 Hz, 1H), 7.55 (dd, *J* = 8.8, 2.6 Hz, 2H), 7.51 (td, *J* = 8.0, 1.0 Hz, 1H), 7.37 (dd, *J* = 15.2, 7.8 Hz, 2H), 7.32 (d, *J* = 8.7 Hz, 2H), 6.45 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 166.7, 163.5, 151.5, 150.0, 135.0, 132.1, 131.3, 130.0, 127.7, 127.3, 124.4, 123.6, 121.2, 118.3, 103.3, 34.5. HR-EI-MS: 523.9945 (M^-, 1).

3,3'-((2-fluorophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (7)
Yield (0.24 g) 86%. m.p. 201°C. IR(KBr) (ν_{max}, cm^{-1}): 3080, 1660, 1615, 1565, 1489, 1452, 1253, 1116, 977, 760. ^{1}H NMR (500 MHz, DMSO) δ 7.77 (d, *J* = 2.4 Hz, 2H), 7.55 (dd, *J* = 8.7, 2.4 Hz, 2H), 7.32 (d, *J* = 8.7 Hz, 2H), 7.25 (t, *J* = 7.9 Hz, 1H), 7.17 (dd, *J* = 12.8, 6.4 Hz, 1H), 7.03 (t, *J* = 7.4 Hz, 1H), 6.98 (dd, *J* = 10.6, 8.6 Hz, 1H), 6.30 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 166.5, 163.9, 151.4, 131.2, 130.3, 127.7, 123.8, 123.6, 121.5, 118.2, 115.5, 115.3, 103.8, 32.5. HR-EI-MS: 497.0005 (M^-, 1).

3,3'-(pyridin-2-ylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (8)
Yield (0.21 g) 80%. m.p. 309°C. IR(KBr) (ν_{max}, cm^{-1}): 3155, 2837, 1648, 1606, 1534, 1455, 1349, 1205, 1168, 1032, 947, 765. ^{1}H NMR (500 MHz, DMSO) δ 8.62 (d, *J* = 5.4 Hz, 1H), 8.42 (t, *J* = 7.6 Hz, 1H), 7.90 (d, *J* = 8.1 Hz, 1H), 7.85 (dd, *J* = 6.6, 5.0 Hz, 1H), 7.74 (d, *J* = 2.5 Hz, 2H), 7.61 (dd, *J* = 8.8, 2.5 Hz, 2H), 7.39 (d, *J* = 8.8 Hz, 2H), 6.48 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 167.7, 163.9, 151.8, 131.9, 127.9, 123.9, 121.3, 118.5, 101.6, 37.2. HR-EI-MS: 480.0047 (M^-, 1).

3,3'-((3-chlorophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (9)
Yield (0.24 g) 86%. m.p. 222°C. IR(KBr) (ν_{max}, cm^{-1}): 3079, 1654, 1614, 1563, 1475, 1440, 1341, 1298, 1253, 1181, 1071, 978, 785. ^{1}H NMR (500 MHz, DMSO) δ 7.78 (s, 2H), 7.56 (dd, *J* = 8.7, 2.5 Hz, 2H), 7.34 (d, *J* = 8.8 Hz, 2H), 7.20 (dd, *J* = 21.6, 7.9 Hz, 2H), 7.08 (d, *J* = 5.3 Hz, 2H), 6.25 (s, 1H).^{13}C NMR (126 MHz, DMSO) δ 166.6, 164.5, 151.5, 134.6, 133.3, 131.4, 130.2, 127.8, 126.8, 126.0, 125.7, 123.7, 121.3, 118.3, 104.1, 36.6. HR-EI-MS: 512.9709 (M^-, 1).

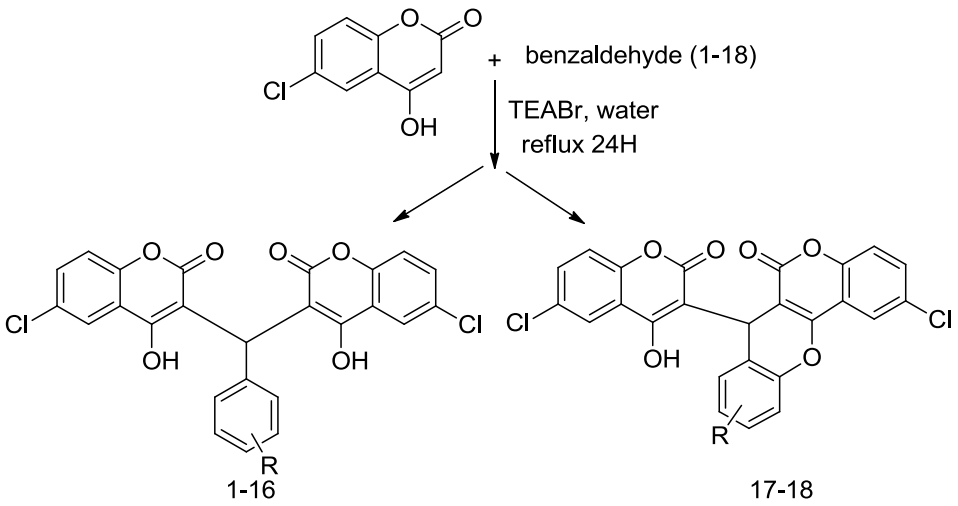
3,3'-((3-fluorophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (10)
Yield (0.26 g) 90%. m.p. 238°C. IR(KBr) (ν_{max}, cm^{-1}): 3079, 1654, 1615, 1563, 1485, 1440, 1256, 1183, 1104, 1072, 813, 789. ^{1}H NMR (500 MHz, DMSO) δ 7.77 (d, *J* = 2.0 Hz, 2H), 7.56 (dd, *J* = 8.7, 1.9 Hz, 2H), 7.34 (d, *J* = 8.7 Hz, 2H), 7.22 (dd, *J* = 14.6, 7.5 Hz, 1H), 6.91 (dd, *J* = 28.3, 17.6 Hz, 2H), 6.83 (s, 1H), 6.25 (s, 1H).^{13}C NMR (126 MHz, DMSO) δ 166.7, 164.4, 151.5, 131.3, 127.7, 123.7, 123.2, 121.5, 118.3, 104.2, 36.7. HR-EI-MS: 497.0006 (M^-, 1).

3,3'-((3-nitrophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (11)
Yield (0.25 g) 88%. m.p. 248°C. IR(KBr) (ν_{max}, cm^{-1}): 3075, 1657, 1611, 1563, 1529, 1348, 1104, 977, 818, 793. ^{1}H NMR (500 MHz, DMSO) δ 8.01 (d, *J* = 7.5 Hz, 1H), 7.88 (s, 1H), 7.76 (d, *J* = 2.4 Hz, 2H), 7.65 – 7.53 (m, 3H), 7.51 (t, *J* = 7.9 Hz, 1H), 7.36 (d, *J* = 8.7 Hz, 2H), 6.33 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 167.0, 164.3, 151.6, 134.2, 131.5, 129.9, 127.8, 123.7, 121.5, 121.5, 121.0, 118.3, 103.7, 36.9. HR-EI-MS: 523.9949 (M^-, 1).

3,3'-(pyridin-3-ylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (12)
Yield (0.21 g) 80%. m.p. 376°C. IR(KBr) (ν_{max}, cm^{-1}): 3446, 3062, 2594, 2147, 1685, 1610, 1537, 1389, 1179, 1123, 1012, 815. ^{1}H NMR (500 MHz, DMSO) δ 8.78 – 8.61 (m, 2H), 8.37 (d, *J* = 8.1 Hz, 1H), 7.93 (dd, *J* = 7.9, 5.9 Hz, 1H), 7.74 (d, *J* = 2.5 Hz, 2H), 7.59 (dd, *J* = 8.7, 2.6 Hz, 2H), 7.36 (d, *J* = 8.8 Hz, 2H), 6.38 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 167.2, 164.0, 151.7, 145.1, 142.5, 140.9, 139.8, 131.6, 127.8, 127.1, 123.7, 121.4, 118.4, 102.7, 35.2. HR-EI-MS: 480.0049 (M^-, 1).

3,3'-((4-chlorophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (13)
Yield (0.22 g) 82%. m.p. 277°C. IR(KBr) (ν_{max}, cm^{-1}): 2929, 1668, 1566, 1492, 1340, 1302, 1252, 1179, 1117, 1097, 1071, 821, 789, 758. ^{1}H NMR (500 MHz, DMSO) δ 7.75 (d, *J* = 2.1 Hz, 2H), 7.55 (dd, *J* = 8.7, 2.3 Hz, 2H), 7.33 (d, *J* = 8.7 Hz, 2H), 7.22 (d, *J* = 8.3 Hz, 2H), 7.10 (d, *J* = 8.2 Hz, 2H), 6.21 (s, 1H).
^{13}C NMR (126 MHz, DMSO) δ 166.7, 164.5, 151.5, 140.9, 131.3, 130.2, 129.0, 128.2, 127.8, 123.7, 121.5, 118.2, 104.3, 36.3. HR-EI-MS: 512.9709 (M^-, 1).

3,3'-((4-nitrophenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (14)
Yield (0.24 g) 86%. m.p. 285°C. IR(KBr) (ν_{max}, cm^{-1}): 3067, 1644, 1570, 1512, 1483, 1440, 1331, 1252, 1118.^{1}H NMR (500 MHz, DMSO) δ 8.06 (d, *J* = 8.8 Hz, 2H), 7.75 (d, *J* = 2.5 Hz, 2H), 7.57 (dd, *J* = 8.8, 2.6 Hz, 2H), 7.36 (dd, *J* = 10.9, 8.9 Hz, 4H), 6.32 (s, 1H).^{13}C NMR (126 MHz, DMSO) δ 167.0, 164.3, 151.6, 151.0, 145.9, 131.4, 128.4, 127.8, 123.7, 123.6, 121.5, 118.3, 103.8, 37.3. HR-EI-MS: 523.9953 (M^-, 1).



3,3'-((4-hydroxyphenyl)methylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (15)
Yield (0.21 g) 80%. m.p. 358°C. IR(KBr) (ν_{max}, cm^{-1}): 3083, 1717, 1663, 1614, 1564, 1299, 1241, 1177, 1118. ^{1}H NMR (500 MHz, DMSO) δ 7.76 (d, *J* = 2.5 Hz, 2H), 7.54 (dd, *J* = 8.7, 2.5 Hz, 2H), 7.32 (d, *J* = 8.7 Hz, 2H), 6.88 (d, *J* = 8.3 Hz, 2H), 6.57 (d, *J* = 8.5 Hz, 2H), 6.15 (s, 1H). ^{13}C NMR (126 MHz, DMSO) δ 166.3, 164.6, 155.3, 151.4, 131.6, 131.1, 128.0, 127.7, 123.6, 121.6, 118.2, 115.1, 105.0, 35.9. HR-EI-MS: 495.0046 (M^-, 1).

3,3'-(pyridin-4-ylmethylene)bis(6-chloro-4-hydroxy-2H-chromen-2-one) (16)
Yield (0.25 g) 88%. m.p. 349°C. IR(KBr) (ν_{max}, cm^{-1}): 3446, 1673, 1608, 1390, 1246, 1205, 1124, 1052. ^{1}H NMR (500 MHz, DMSO) δ 8.66 (d, *J* = 4.7 Hz, 2H), 7.80 (d, *J* = 4.7 Hz, 2H), 7.74 (s, 2H), 7.60 (d, *J* = 7.9 Hz, 2H), 7.38 (d, *J* = 8.5 Hz, 2H), 6.41 (s, 1H).^{13}C NMR (126 MHz, DMSO) δ 167.32, 164.08, 151.75, 141.88, 131.75, 127.87, 125.57, 123.78, 121.33, 118.44, 102.51, 38.15. HR-EI-MS: 480.0050 (M^-, 1).

2-chloro-7-(6-chloro-4-hydroxy-2-oxo-2H-chromen-3-yl)-10,11-dihydroxychromeno[4,3-b]chromen-6(7H) -one (17)
Yield (0.24 g) 86%. m.p. 375°C. IR(KBr) (ν_{max}, cm^{-1}): 3291, 1676, 1608, 1568, 1488, 1422, 1371, 1199. ^{1}H NMR (500 MHz, DMSO) δ 9.32 (s, 1H), 9.14 (s, 1H), 8.58 (d, *J* = 2.4 Hz, 1H), 8.03 (s, 1H), 7.73 (dd, *J* = 8.8, 2.5 Hz, 1H), 7.63 (dd, *J* = 8.8, 2.2 Hz, 1H), 7.48 (d, *J* = 8.8 Hz, 1H), 7.36 (d, *J* = 8.7 Hz, 1H), 6.57 (d, *J* = 8.3 Hz, 1H), 6.45 (d, *J* = 8.2 Hz, 1H), 5.64 (bs, 1H). ^{13}C NMR (126 MHz, DMSO) δ 160.6, 151.3, 151.2, 146.2, 133.5, 132.5, 132.1, 130.4, 129.1, 128.7, 128.5, 123.3, 118.9, 118.8, 118.4, 117.9, 116.0, 113.0, 27.3. HR-EI-MS: 508.9840 (M^-, 1).

2-chloro-7-(6-chloro-4-hydroxy-2-oxo-2H-chromen-3-yl)-9-hydroxychromeno[4,3-b]chromen-6(7H)-one (18)
Yield (0.23 g) 84%. m.p. 310°C. IR(KBr) (ν_{max}, cm^{-1}): 3306, 1695, 1614, 1568, 1473, 1423, 1386, 1206. ^{1}H NMR (500 MHz, DMSO) δ 9.79 (s, 1H), 8.12 (d, *J* = 2.4 Hz, 1H), 8.04 (d, *J* = 1.1 Hz, 1H), 7.74 (dd, *J* = 8.8, 2.5 Hz, 1H), 7.64 (dd, *J* = 8.8, 2.3 Hz, 1H), 7.50 (d, *J* = 8.8 Hz, 1H), 7.37 (d, *J* = 8.7 Hz, 1H), 6.98 (d, *J* = 8.4 Hz, 1H), 6.77 (d, *J* = 2.2 Hz, 1H), 6.59 (dd, *J* = 8.4, 2.3 Hz, 1H), 5.62 (bs, 1H). ^{13}C NMR (126 MHz, DMSO) δ 160.51, 157.87, 155.73, 151.25, 151.03, 150.10, 132.58, 132.18, 129.56, 129.17, 128.51, 122.4, 119.0, 118.8, 118.3, 115.8, 113.6, 103.4, 28.7. HR-EI-MS: 492.9892 (M^-, 1).

In this work, a new series of biscoumarin and benzopyrano dicoumarincoumarin were synthesized (Scheme 1) in moderately good yields by Claisen condensation according to a previous report [3]. The formation of biscoumarin 1–16 were prompted with aldol condensation of 6-Cl-4-hydroxycoumarin (2 mmol) and substituted aromatic aldehydes linker (1 mmol) followed by dehydration of the aldol product to give a chromone. Subsequent *in situ* reaction of the chromone with another 6-Cl-4-hydroxycoumarin present in excess gave dimeric coumarin derivatives 1–16 bearing an aryl substituent in the central methylene linker [6]. In contrast, the chromone derivatives containing an *ortho*-substituted phenyl moiety gave fused benzopyrano dicoumarin 17-18 under spontaneous cyclization and removal of water. The structures of compounds 1 – 18 (Table 1) were characterized by using different spectroscopic techniques such as ^{1}H, ^{13}C NMR, FTIR, Mass Spectroscopy and melting point.

6		12		18	

The ^{1}H NMR spectra of biscoumarin derivatives 1 – 16 showed characteristic of sharp singlet peak at δ 6.08–6.48 assigned to a methine proton, a bridge substituted dimers of 4-hydroxycoumarin. In the ^{13}C NMR spectra, this methine carbon appeared at δ 38.2 – 32.5. The hydroxyl protons of 4-hydroxycoumarin were not observed in the ^{1}H NMR spectra. Benzopyrano dicoumarin of compound 17 – 18 were form when benzaldehyde having 2-hydroxy substituent was allowed to react with 4-hydroxycoumarin under the same reaction conditions. In the ^{1}H NMR spectra, the methine was shifted to a more upfield region (δ 5.62 – 5.64) and appeared as a broad singlet peak compared to methine of biscoumarin. We thus turned our attempt to characterize this compound by means of other spectroscopic methods. The mass spectra of both compounds showed a molecular ion peak at m/z 508.9840 and 492.9892, respectively, which is in accordance with a cyclization reaction by the removal of one water molecule from the corresponding biscoumarin. However, IR spectra of both compounds showed similar characteristic absorption bands at 1600 – 1700 cm^{-1} and 2900 – 3500 cm^{-1} due to carbonyl and OH group, respectively.

Conclusion

In conclusion, a series of new 6-chloro-4-hydroxy substituted biscoumarin and benzopyrano dicoumarin derivatives of compound (1-18**)** were synthesized in moderately good yield and characterized by using different spectroscopic techniques such as ^{1}H, ^{13}C Nuclear Magnetic Resonanes (NMR), fourier transform infrared spectroscopy (IR), mass spectrometry (MS) and melting point. A further study to investigate the potential pharmacological activity is in progress.

Abstract

An air-breathing stack for a direct formic acid fuel cell (DFAFC) was designed, fabricated and evaluated. The DFAFC stack consisted of six cells arranged in a hexagonal arrangement and each single cell contained a pair of stainless steel current collectors, a membrane electrode assembly (MEA) and a cathode end-plate. A fuel reservoir was located at the center which supplied formic acid supply to the anode of each cell. The effects of fuel concentration, palladium (Pd) loading at the anode and activation on DFAFC performance and long term operation were evaluated. DFAFC stack performance increased with increasing fuel concentration and a stable power up to 200 mW at 2.4 V was achieved for passive and ambient conditions at a 7 M fuel concentration. Catalyst loading had a slight effect on DFAFC performance, where 4 mg cm^{-2} Pd loading was best for 7 M fuel operation. During long-term operation, the DFAFC stack could be operated for 27 hours without adding more fuel and less than a 20 % reduction in performance during operation. MEA reactivation with deionized water technique was required for immediate recovery of stack performance.

Keywords: stack, activation, passive direct formic acid fuel cell, membrane electrode assembly

Abstrak

Tindanan pasif udara bagi sel bahan api asid formik langsung (DFAFC) direka bentuk, difabrikasi dan diuji. Tindanan DFAFC mengandungi enam sel yang dibentuk secara susunan heksagon. Setiap sel mempunyai sepasang pengumpul arus, himpunan membran elektrod (MEA) dan plat penghujung katod. Takungan bahan api ditempatkan di tengah yang mana akan membekalkan asid formik ke setiap sel. Kesan kepekatan bahan api, kandungan palladium (Pd) di anod dan pengaktifan terhadap prestasi dan jangka masa panjang DFAFC dikaji. Prestasi tindanan DFAFC meningkat dengan peningkatan kepekatan bahan api dan kuasa yang stabil sehingga 200 mW dicapai pada 2.4 V dan 7 M kepekatan bahan api dalam keadaan pasif dan persekitaran. Kandungan mangkin mempunyai kesan minimum terhadap prestasi DFAFC yang mana kandungan Pd 4 mg cm^{-2} merupakan kandungan terbaik bagi pengoperasian 7 M kepekatan asid formik. Sepanjang pengoperasian jangka masa panjang, tindanan DFAFC boleh beroperasi selama 27 jam tanpa menambah bahan api di dalam takungan dan kurang daripada 20 % pengurangan prestasi tindanan. Pengaktifan MEA menggunakan teknik nyahion air diperlukan bagi pemulihan segera prestasi tindanan DFAFC.

Kata kunci: tindanan, pengaktifan, sel bahan api asid formik langsung pasif, himpunan membran elektrod

Introduction

With respect to direct liquid fuel cells (DLFCs), a direct formic acid fuel cell (DFAFC) is a promising alternative to direct methanol fuel cell (DMFC) and direct ethanol fuel cell (DEFC) cells. The main advantages of DFAFC are a relatively high electro-catalytic oxidation rate [1, 2] and low crossover rate for the fuel [3 – 5] and has the potential to replace batteries in electronic devices [6]. Based on previous work, a Pd-based catalyst was used as the DFAFC anode due to better cell performance compared to other precious metals such as platinum (Pt). However, a disadvantage of electro-catalytic anodes is their activity decreases or they are rapidly deactivated with operation time. To address these issues, Zhu et al. reported a palladium DFAFC anode which could be recovered by applying a potential of 1.2V versus dynamic hydrogen electrode (DHE) to the anode for a few seconds [1], while Tsujiguchi et al. used a water-wash technique to reactivate the electrode [7].

Furthermore, one of the major issues for a DFAFC is the mass transport limitation of the anode electrode due to the hygroscopic characteristic of formic acid. Then, it would affect the hydrophobicity; for better gas transport, or even hydrophilicity characteristics in the electrode, specifically in diffusion layer. Therefore, the electro-structure of the anode electrode requires proper design with respect to Teflon or Nafion content as well as carbon or catalyst loading. Currently, there are a lot of studies focusing on the optimizing the MEA for the fuel cell [8 – 10]. Rice et al. discussed the constraints to formic acid mass transport to the anode side might be due to Nafion ® within the catalyst layer, Teflon on carbon cloth, or both [11]. Oedegaard et al. showed that without Teflon-loading, the membrane electrode assembly (MEA) had a maximum current density of 173 mA cm^{-2}, while at 15 wt. % and 30 wt. % Teflon-loading, 137 mA cm^{-2} and 125 mA cm^{-2} were observed, respectively [12]. Kim et al. reported that higher catalyst loading was needed at lower temperatures (i.e. 30 ^{o}C), while low catalyst loading was suitable for high-temperature operation, (i.e. 70 ^{o}C) [13]. These data indicated the anode side of the DFAFC has significant mass transfer limitations depending on the anode media diffusion properties and operating parameters such as temperature and fuel concentrations.

Review of published literature indicates researchers have focused on a single cell DFAFC either in passive, semi-passive or active modes in order to improve performance. However, little has been published on the development of a DFAFC stack [6, 14]. In reality, passive-mode DFAFCs are more attractive, since they eliminate auxiliary devices such pumps for feeding fuel or a blower to supply air, and a simplified stack configuration for a passive DFAFC is highly desirable for portable applications.

In this study, an air-breathing stack for a direct formic acid fuel cell (DFAFC) was designed, fabricated and evaluated. The effects of catalyst loading, fuel concentrations, and MEA reactivation will be addressed on the basis of stack performance.

Materials and Methods

DFAFC stack design

The DFAFC fuel cell stack consisted of six single cells, and each single fuel cell consisted of current collector plates, gaskets, membrane electrode assembly (MEA) and the end plate. Six single cells were combined to form a hexagon with the fuel reservoir located in the center of the stack, which allowed the formic acid fuel to be supplied passively to each cell (Figure 1). The dimensions of the polycarbonate stack holder, including fuel reservoir, were 143 mm x 124 mm x 30 mm stainless steel (SS, 316L), 1 mm in thickness was used as the current collector plate. Polycarbonate (5 mm thickness) was used as the end plate for each cell and silicone rubber was used as a gasket. At the top of the stack, the cover and holder were constructed from acrylic material (3 mm), and two 3.0 mm circular holes were located in the cover to release any CO_2 formed by the anode reaction. The plate had 12 small 3.1 mm holes which allowed passage of stainless steel bolts used to hold the cell components together. The overall weight of the stack was 560 g, without formic acid fuel.

MEA fabrication

A membrane electrode assembly (MEA) with an active area of 2.0 cm^2 was fabricated using the conventional brush painting technique. Commercial carbon fibre paper (E-TEK, USA) was used as a backing layer with a 2.0 mg cm^{-2} of carbon black loading serving as a diffusion layer at the anode and cathode. Pd-black and Pt-black (Johnson-

Matthey) were used as the catalyst at the anode and cathode, respectively. These catalysts were mixed with isopropyl alcohol and a Nafion solution 5 wt% (Wako Pure Chemical Industries, Ltd.) to produce catalyst ink which was used to prepare the catalyst layer for the anode and cathode electrodes. Catalyst loading was fixed at 10 mg cm^{-2} for the cathode, while loading was 6, 8 and 10 mg cm^{-2} at the anode. The MEA was assembled by sandwiching the NRE 212 electrolyte membrane (DuPont™) between the anode and the cathode and hot pressing at 135°C and 4 MPa for 3 min.

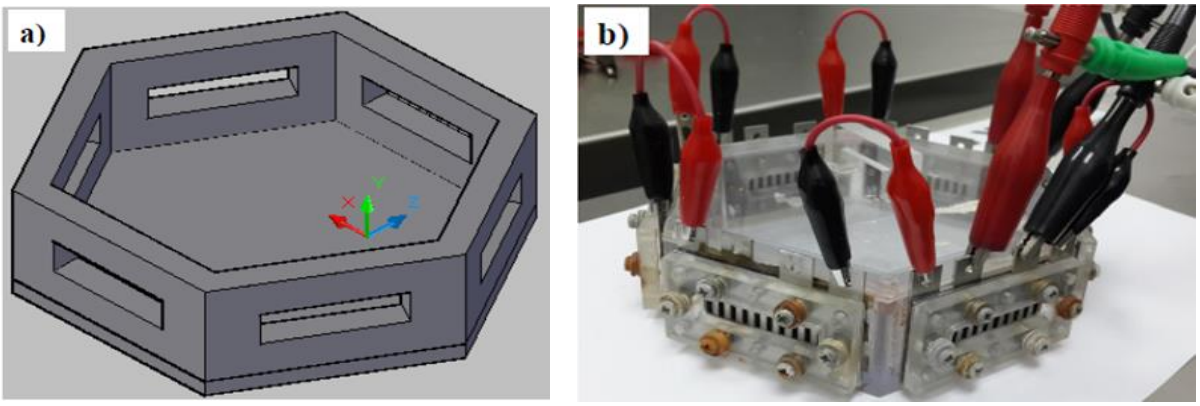

Figure 1. DFAFC fuel cell stack developed in this study: (a) stack holder and (b) fuel reservoir of the DFAFC stack during performance testing

DFAFC stack operation and long term performance

To activate the MEAs, the stack was flushed with pure hydrogen (H_2) gas at 500 ml min^{-1} for one hour (pre-treatment mode). The DFAFC stack was then operated at ambient room conditions at various fuel concentrations and Pd loadings (for the MEA). Formic acid solution (2 to 10 M, 150 mL) was added to the reservoir and the cathode exposed to ambient air. Each cell (1 – 6) was connected in series in order to measure the performance of stack during operation and power generation was conducted at a 2.4 V for 2 hours. The electrochemical performance of the cell was measured using a Potentiostat/Galvanostat WMPG1000 model (WonATech, Korea) though only one cell of cell 1 could be measured due to a limited channel to measure the electrochemical performance and will be represented the performance profile for each single cell. Long-term performance testing (over 24 hours) was also conducted and after a certain time (nearly 27 hours), the cell was refueled, with or without reactivation of the MEAs by the water-washing technique. During washing, the cell or stack was washed several times (more than three times) using deionized water to eliminate or reduce adsorption of any impurities (such as carbon monoxide, CO).

Results and Discussion

Power profiles and effect of fuel concentration on performance

Figure 2 shows the power profiles obtained over 120 min for cell 1, while Figure 3 shows the power profiles for the direct formic acid fuel cell (DFAFC) using 10 mg cm^{-2} Pd loading at the anode and formic acid concentrations varying from 2M to 10M. For all the cases in Figure 2 and Figure 3 (single cell or stack), at the beginning of cell operation, power values were unstable with largely decreasing from initial by two or three times larger than a stable power obtained before became nearly stable with time.

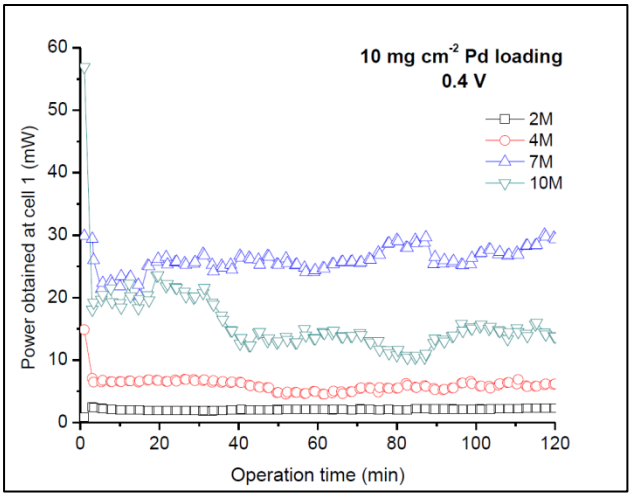

Figure 2. DFAFC power profiles for cell 1 at 10 mg cm^{-2} Pd loading at anode and different formic acid concentrations

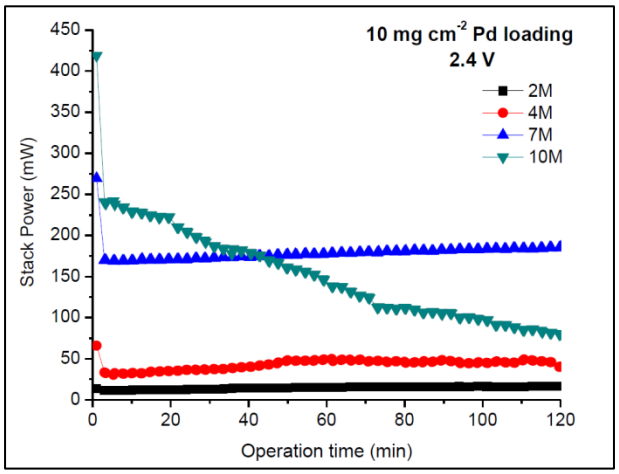

Figure 3. DFAFC power profiles for stack at 10 mg cm^{-2} Pd loading at anode and different formic acid concentrations

The unstable power could be related to the conditions of cell 1 and due to mass transport limitations at the anode or water flooding at the cathode at high concentrations (7 M and 10 M). When fueled with 10 M formic acid, the power profile for the DFAFC stack rapidly decreased over 120 min from 240.8 mW to 80.5 mW. This could be due to high formic acid crossover from the anode to the cathode which directly affected the electrochemical DFAFC reaction, and decreased stack performance.

The power values measured at 60 min (Figures 2 and 3) are summarized in Table 1. The power obtained either from cell 1 or the stack increased as the formic acid concentration in the reservoir was increased from 2 M up to 7 M giving power values of 15.03 mW, 49.36 mW and 178.06 mW at 2M, 4M and 7M formic acid, respectively. These data indicated the 7 M concentration yielded the highest output, while operation at 10 M decreased stack performance (150.85 mW). This trend of increased DFAFC performance as formic acid concentrations increased (to a certain concentration limit) was similar to previous studies [1, 4]. Increasing fuel concentration could enhance

formic acid mass transfer in terms of flux from the diffusion layer into the anode catalyst layer. For example, at a low formic acid concentration, mass transfer of formic acid was slow and directly can be influenced to no sufficient formic acid flux to maintain a stable electron movement for formic acid oxidation at anode.

Table 1. Stable power obtained at 60 min for cell 1 and stack using different formic acid concentrations

Formic Acid Concentration (M)	Stable power at 60 min operation (mW)	
	Cell 1	Stack
2	2.08	15.03
4	4.52	49.06
7	24.64	178.06
10	14.33	150.85

Moreover, the trend could have contributed to the thermal effect of the stack. In general, fuel crossover increased as the fuel concentration increased, which contributed to increasing stack temperature due to the direct cathode reaction. Therefore, the electrochemical reaction at the anode would be improved with increased stack temperature (Table 1) at 7 M formic acid. Furthermore, at high concentrations (such as 10 M), mass transfer of formic acid was not the rate-controlling power generation step, though it could be controlled by the electrode reaction due to high formic acid crossover from the anode to the cathode rather than fuel supply to the anode.

Effect of anode catalyst loading on stack performance

To ensure the relationship between fuel mass transports and stack performance, membrane electrode assemblies (MEAs) with different Pd catalyst loadings at the anode layer were tested in the DFAFC stack. Figure 4 shows the DFAFC stack power output capacity profile at different catalyst loadings when 7M formic acid was used as fuel. For all the cases shown in Figure 4, the power profiles were similar to each other and similar to the trend seen in Figure 3.

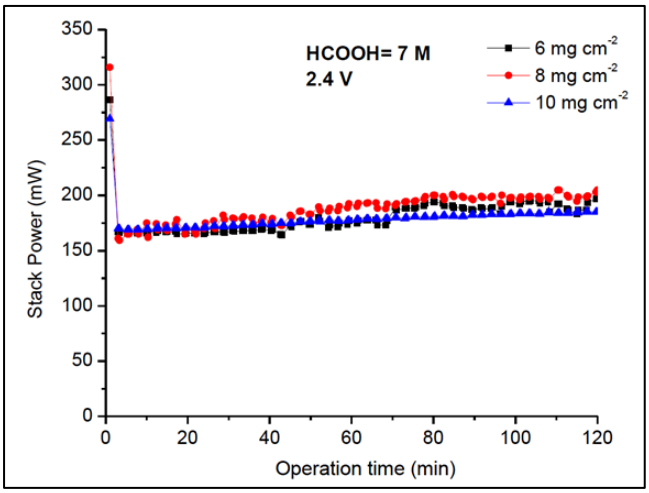

Figure 4. DFAFC power profiles at different anode catalyst loadings using a 7M concentration of formic acid

The power values obtained at 60 min are summarized in Figure 5, and additional data obtained from measurements at 2 M, 4 M and 10 M formic acid and 6, 8 and 10 mg cm^{-2} Pd loadings at the anode are presented. For all Pd loadings, the power increased linearly with increasing formic acid concentrations up to 7 M and decreased when

using 10 M, which were due to the rate controlling step (fuel mass transfer) at the anode. Meanwhile, the trend differed when Pd loading was compared to operation at different fuel concentrations. For an example, at 6 mg cm^{-2} Pd loading, the power obtained over during stable 60 min was always lower or similar to that 8 and 10 mg cm^{-2}, respectively.

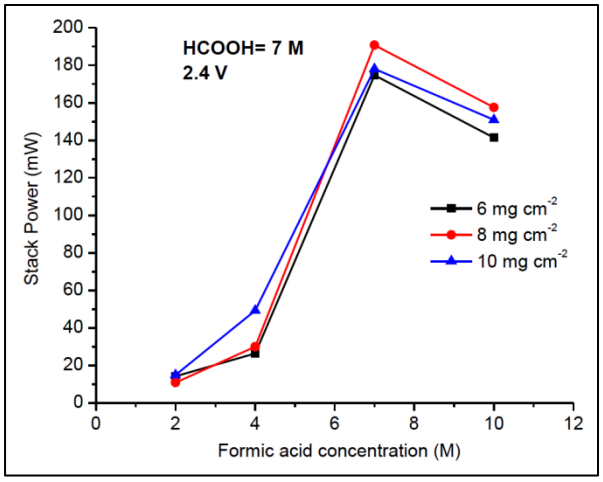

Figure 5. Stable power for the DFAFC stack at 1 h operation at various anode catalyst loadings using different concentrations of formic acid

For the power obtained at low concentrations (2 M and 4 M), high Pd loading (10 mg cm^{-2}) was dominant, while 8 mg cm^{-2} was dominant at 7 M and 10 M formic acid concentrations. These profiles could be related to the limitations in proton transfer through the electrolyte membrane. Kim et al. also linked the effect of catalyst layer thickness to proton transport through the Nafion membrane [13]. In this study, high catalyst loading would have resulted in increasing the thickness of the catalyst layer, and protons would need to be transported a greater distance (compared to the shorter distance at a low catalyst loading), which directly affected power generation. At this stage, design and optimization of the Nafion content of the catalyst layer at the anode could be important for proton transport. These results indicated the essential role of proper catalyst loading, as well as the importance of optimizing anode electrode fabrication, to enhancing anode mass transfer limitations.

Long term operation with and without reactivation

To explore the long-term operation of a DFAFC stack and the effect of reactivation by the water-washing technique, the stack was operated in two modes. Figure 6 shows the long-term performance testing for a DFAFC stack using 7 M formic acid with/without reactivation of the MEA with deionized water. In the first stage, the stack was operated nearly 27 hours after pre-treatment of MEAs (using pure H_2), while in second stage, fresh fuel (7M) was added to the fuel reservoir after the reactivation (or not) of MEA.

During the first stage (first 27 hours of operation) (Figure 6), stack power generation was similar and these data were good for comparison between first and second stages regions. The data showed that decreasing stack power over time (during the first 27 hours) was due to dilution of the formic acid fuel (i.e. fuel consumption for anode reaction). By focusing on the first stage region, the power produced by the DFAFC stack was nearly stable over the 27 hours of operation and the calculated reduction in performance was 20 %. These data suggested the DFAFC stack evaluated in this study had good stability for over a one-day period in a free-air breathing environment and could be used to power very low power electronic devices.

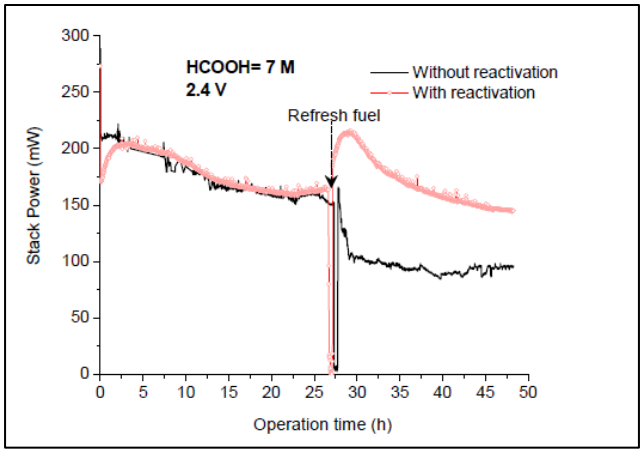

Figure 6. Long-term performance testing of the DFAFC stack using a 7 M concentration of formic acid, with and without membrane electrode assembly (MEA) reactivation with deionized water

In the second stage, when the MEAs were reactivated, the profiles and the magnitude of power produced were similar to the first stage. Without reactivation, the power increased slightly within five minutes of operation before significantly dropping to 80 mW and becoming stable, which could be due to deactivation of the Pd catalyst at the anode. Based on a literature review, deactivation of the Pd catalyst is due to adsorbed intermediates which form during the oxidation of formic acid at the anode (especially CO species) [3, 7]. Using a simple water-washing technique for MEA reactivation could eliminate or remove the poisoning species present at the anode catalyst layer. Therefore, MEA reactivation was an important step for DFAFC to recover their performance.

Conclusion

An air-breathing DFAFC stack with six cells was developed and evaluated in this study. The effect of formic acid concentration was investigated and 7 M formic acid yielded the best performance. The stable power achieved by the DFAFC stack was 200 mW and 2.4 V (16.7 mW cm^{-2}) using the optimum concentration. Catalyst loading indicated optimization of electrode fabrication was important to power generation. Proper catalyst loading (8 mg cm^{-2}) was achieved when the stack was operated at the optimum concentration (7 M) of formic acid. Furthermore, MEA reactivation was needed for long term operation to recover the electro-activity of the catalyst layer, while the performance and stability of DFAFC could be maintained by refueling with formic acid, and a high energy density could be achieved.

Abstract

In this work, proton exchange membranes (PEMs) based on chitosan (CS) and cellulose (CL) have been prepared using a solution-casting technique with sulfosuccinic acid (SSA) as an ionic cross linker. The characteristics of these CS-CL biocomposite membranes were studied using scanning electron microscopy (SEM), Fourier transform infrared spectroscopy (FTIR), electrochemical impedance spectroscopy (EIS) in addition to the measurement of the water uptake rate (WUR) and the ion exchange capacity (IEC). The results indicate that the amount of SSA used in this study played a significant role in the proton conduction of the membrane. The proton conductivity of a cross-linked CS-CL membrane was on the order of 10^{-5} S cm^{-1}, which is greater than the proton conductivity of a pure CS membrane.

Keywords: proton exchange membranes, chitosan, cellulose, biocomposite, membrane

Abstrak

Dalam kajian ini, membran penukaran proton (PEM) berasaskan kitosan (CS) dan selulosa (CL) telah disediakan dengan menggunakan teknik tuangan larutan bersama dengan asid sulfosusinik (SSA) yang berfungsi sebagai pemaut silang ion. Sifat membran biokomposit CS-CL ini dikaji menggunakan mikroskopik pengimbas elektron (SEM), spektroskopi inframerah transformasi Fourier (FTIR), spektrometer elektrokimia impedans (EIS) sebagai tambahan kepada pengukuran kadar penyerapan air (WUR) dan kapasiti penukaran ion (IEC). Keputusan menunjukkan bahawa jumlah SSA digunakan dalam kajian ini memainkan peranan penting dalam pengangkutan proton di dalam membran. Kekonduksian proton untuk CS-CL bertaut silang membran yang diperoleh adalah di dalam lingkungan 10^{-5} S cm^{-1}, iaitu lebih tinggi berbanding dengan kekonduksian proton membran CS tulen.

Introduction

Recently, fuel cells have been recognised as a prime candidate for new energy resources and have been extensively studied as an alternative to limited fossil fuel resources. Fuel cells have received attention, as they are efficient, clean and eco-friendly power sources [1, 2]. Extensive research has been undertaken to develop and prepare a new membrane to prevent a deficiency in currently used perfluorinated membranes (Nafion). This effort includes an expanded search of natural polymers that could produce biopolymer and biocomposite membranes with valuable properties. The use of natural polymer-based membranes became a focus when environmental concerns motivated

the use of renewable resources for producing clean energy and sustainable consumption and production with the goal to maintain or even improve quality of life [3, 4].

Among all natural polymers, chitosan (CS) and cellulose (CL) are the most important and abundantly available renewable resources on the earth. CS and CL possess many attractive properties such as biodegradable, biocompatible and non-toxic [5, 6]. Both CS and CL have similar molecular structure except for the group attached to the C2 atom. In this configuration CS has a primary amine ($-NH_2$) group, whereas CL has a hydroxyl (-OH) group that can be modify [7].

In this study, CS-CL biocomposites with various amount of sulfosuccinic acid (SSA) were prepared using the casting method to improve their properties as well as the conductivity of the membrane. The main purpose of this research was to develop the biopolymer material for electrolyte membrane.

Materials and Methods

The following chemicals were reagent grade and obtained from Sigma-Aldrich: chitosan (CS) powder (low molecular weight), α-cellulose (CL) powder, acetic acid (glacial 100 % anhydrous for analysis), dimethyl sulfoxide (DMSO) ($H_2O \leq 0.005\%$), and sulfosuccinic acid (SSA) (70 wt. % in H_2O). Deionised water was used during the preparation of the acetic acid solution.

Pre-weighed CS powder was added to 1.0 wt. % aqueous acetic acid solution and was stirred vigorously to form a 1.0 wt. % CS solution. CL (0.18 g) was dissolved in the DMSO using an ultrasonic stirrer. Both the CS and CL solutions were mix together at a weight ratio of 1: 0.18 and were stirred vigorously using a magnetic stirrer for several hours at room temperature. The CS-CL solutions were mixed with various amounts of SSA (0.05 and 0.10 M SSA, labelled as CA05 and CA10, respectively. The mixtures were then continuously stirred and were poured into a petri dish and left to dry at room temperature for 48 hours to form a thin membrane layer. Finally, the biocomposite membranes were dried in an oven at 70 °C for several hours to remove the solvents. The membrane thickness was in the range of 25 – 26 µm.

The surface morphology of the CS-CL biocomposite membranes was characterised using SEM with Carl Zeiss EVO MA10 model at a voltage of 15 kV. The membranes were freeze-fractured with liquid nitrogen to expose the edge of the membrane and sputter coated with a thin layer of gold before SEM analysis. The infrared spectra of the membranes were recorded with a model Nicolet 6700 Thermo FTIR spectrophotometer in the wavenumber range of 400 to 4000 cm^{-1} at a resolution of 4 cm^{-1}.

The water uptake rate of the CS-CL membranes was measured by immersing the membrane samples into deionised water at various temperatures (25, 50, 70, and 90 °C) for 2 hours. Then, the membranes were bolted dry with tissue paper and were immediately weighted to determine the initial wet weight. The samples were then maintained in an oven at 120 °C for 2 hours. The procedure was repeated three times until satisfactory reproducibility was obtained. The water uptake values were calculated according to Equation 1:

$$\text{Water uptake } (\%) = \frac{(\text{Wwet} - \text{Wdry})}{\text{Wdry}} \times 100 \quad (1)$$

where W_{wet} and W_{dry} are the wet weight and the dry weight of the membrane, respectively [8].

The IEC values of the membrane sample were determined using a titration method. The sample were immersed in a 1.0 M NaCl solution for 2 hours followed by titration with a 0.01 M NaOH solution using phenolphthalein as an indicator [9]. The IEC values were calculated from the titration data using Equation 2:

$$\text{IEC } (\text{mmol g}^{-1}) = \frac{(\text{VNaOH} \times \text{MNaOH})}{\text{Wdry}} \times 10 \quad (2)$$

where V_{NaOH} and M_{NaOH} are the consumed volume (mL) and molar concentration of the NaOH solution, respectively. W_{dry} is the weight of the dry membrane.

The proton conductivity of the CS-CL membranes was measured using electrochemical impedance spectroscopy between 10^{-1} to 10^{5} Hz using a Metrohm Autolab potentiostat (PGSTAT128N) equipped with a FRA2 module. The type of cell configuration used in this test is two-electrode AV impedance method in ambient air with relative humidity. The proton conductivity, σ, was calculated using the Equation 3:

$$\sigma = \frac{L}{R\ X\ A} \tag{3}$$

where σ (S cm^{-1}) is the membrane conductivity, L (cm) is the thickness of the membrane inside the conductivity cell, A (cm^2) is the geometric area of the membrane, and R (Ω) is the bulk resistance calculated from the high-frequency intercept on the real axis of the complex impedance plot [10].

Results and Discussion

The morphology of the CS-CL membranes is shown in Figure 1 and represents the cross-sections and the surface of the biocomposite membranes. The cross-sectional micrographs (a) and (b) display the two-phase separation. The CL fibres were visible but well distributed at the bottom of the membranes. These observations provide evidence that the CL fibres were deposited at the bottom layer of the dried membrane after the homogenised biocomposite solution was cast into the petri dish and allowed to dry completely. The phase separation of CS and CL was apparent for all blends indicating that a non-homogenous membrane was obtained. Both biopolymer membranes were brittle. Where, the CS-Cl blend in this study has demonstrated poor miscibility between CS and CL in the samples. Therefore, in this study, CL acted as the filler in the CS membrane used to improve the mechanical strength of the biocomposite membrane. The surface structure of the polymeric blend membranes has a rough structure compared with the morphology of the CS blend membranes reported by Khan et al. [11]. According to his report, CL appeared as shiny white dots in the CS, which could correspond to transverse sections of the CL.

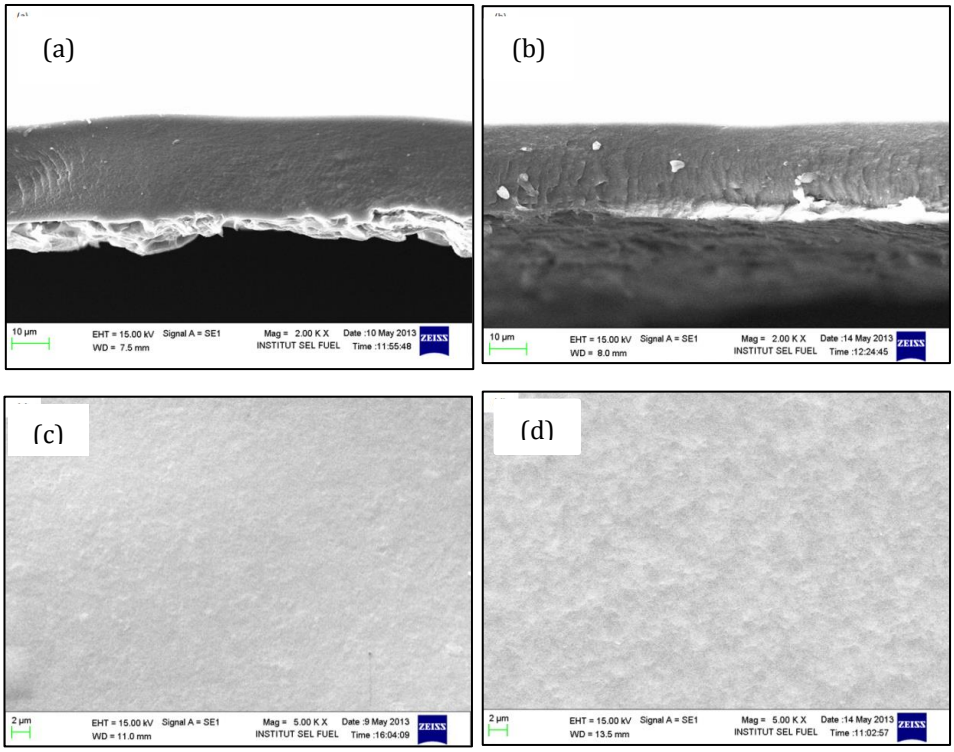

Figure 1. SEM images of the cross section (a) CA05, (b) CA10, and the surface of (c) CA05, (d) CA10 biocomposite membranes.

The FTIR spectrum (Figure 2) of CS, CL and the biocomposite CS-CL membranes with different amount of SSA were compared to investigate the interconnected structural network formed from linking the functional groups in the membranes. For the CS and CL spectrums, which act as the "control"; there are peaks similar to peaks reported by different authors in the literature [12 – 14]. The CS spectrum showed the presence of absorption bands at 3355, 2874, 1650, 1587, 1429, 1376, 1150 and 1069 cm^{-1}. The band observed at 3355 cm^{-1} is due to O-H stretching, which overlaps with the NH- stretching in the same region [11, 14]. The peaks at 2874 cm^{-1} correspond to C-H stretching. The absorption bands at 1429 cm^{-1} and 1376 cm^{-1} could be assigned to the C-H and O-H vibration and CH_3-bending vibrations. The characteristic bands of CS and CL were observed in the spectra of the biocomposite membranes. The spectrum of both the CL and CS showed similar bands with the exception of the absorption bands at 1650 and 1587 cm^{-1}, which correspond to characteristic of –C=O stretching (amide I) and –NH bending (amide II), respectively, as shown in the structure of CS.

The same absorption bands can also be seen from the CA05 and CA10 membranes with slightly significant differences at 1650 to 1646 cm^{-1} and at 1585 to 1579 cm^{-1}. The basic characteristics of CS were also shown in the CA05 and CA10 membranes, which had bands at 1154 cm^{-1} and 1155 cm^{-1} due to the anti-symmetric stretching of the C-O-C bridge. The bands at 1022 and 1029 cm^{-1} were the skeletal vibrations involving C-O stretching. Indeed, a band observed in that region is assigned to the amide group of the CS polysaccharide structure [15]. From the CA05 and CA10 spectra, a new band was being observed in the range from 1350 to 1000 cm^{-1}, which represents C-N interactions. Moreover, the absorption bands near 1250 cm^{-1} indicate the presence of the sulfonic acid group caused by the introduction of SSA. Therefore, from the FTIR spectrum of the samples, the cross linking reaction occurs primarily between the amine group in the chitosan and the carboxylic group in the SSA [16]. There was likely no interaction occurs between CS and CL functional group. These interactions are more towards a physical interaction rather than chemical interactions.

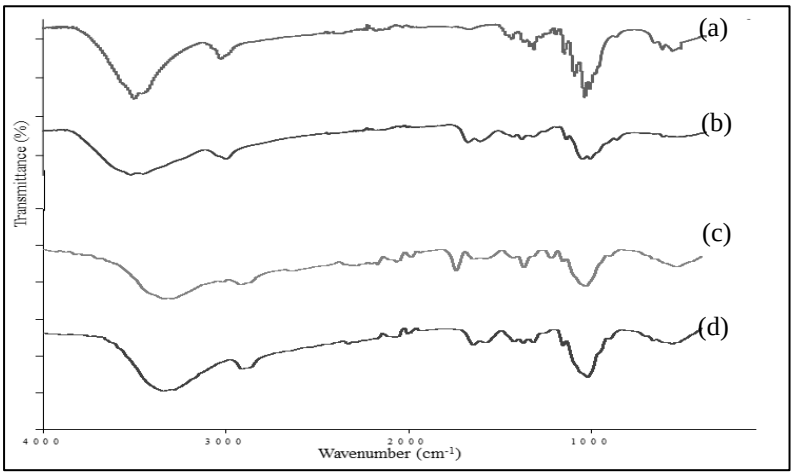

Figure 2. The IR spectra of (a) cellulose (b) chitosan (c) CA05 and (d) CA10.

Table 1 shows the results of water uptake for Nafion 212, CA05 and CA10 membranes. When considering the water uptake properties, the transport of protons in the sulfonated polymer membranes is greatly affected by the presence of water molecules [17]. The membrane water uptake has been determined at four different temperatures. Table 1 shows the trend that the water uptake of the biocomposite membranes increased with an increased temperature, which is similar to the Nafion membrane. As a result, water uptake of the cross-linked CS-CL was found to be multiple times greater than the Nafion 212 in the temperature range between 25 and 90 °C. The CA05 and CA10 membranes possessed greater hydrophilic characteristic compared with the Nafion membrane due to the presence of three polar functional groups. CS is highly capable of forming a hydrogen bond with water and trapping water in its

structure [8]. This result is in contrast with the Nafion membranes, which have both hydrophilic and hydrophobic zones and contain polar hydrophobic (C-F bonds) and polar functional groups (C-O-C linkages). The concentration of the cross-linking agent also influenced the water uptake capacity of the membranes. The CS-CL membrane that contained 0.05 M SSA exhibited greater water uptake than the membranes that contained 0.10 M SSA. With an increase in the concentration of SSA, the membranes became more rigid and structurally compact, and this may have caused the free volume of water molecules retain in the structure to decrease.

Table 1. The water uptake rate of membranes in various temperatures

Temperature (°C)	Water uptake (%)		
	Nafion 212	CA05	CA10
25	9.0	64	34
50	11.8	71	54
70	16.0	87	61
90	16.3	104	78

Table 2 shows the IEC values of Nafion and the CS-CL biocomposite membranes. The IEC value is the opposite of the water uptake results. The IEC values for Nafion 212 and CA10 membranes decreased due to an increase in the condition temperature. Rhim et al. has reported that at low operating temperature resulted in more cation exchangeable sites due to the unreacted carboxylic acid groups in the SSA [16]. Conversely, the CA05 membrane, IEC increased with an increase in the temperature. This result could be attributed to the increment of charge carriers and closely related to the rigidity of the molecule structure. An increase in the IEC values (interpreted as an increase in the number of sulfonic acid groups within the polymer matrix) will not necessarily increase the water uptake values. Therefore, the amount of cross linker added to a polymer electrolyte membrane is not a dominant factor of the increase in the proton conductivity [16]. It can be concluded that the degree of cross linking in the membranes affected significantly their proton conductivities.

The proton conductivity measurements were carried out to study the effect of cross-linking and the temperature of the operating system on the electrical properties of the CS-CL membranes. The conductivity of the CS-CL membranes has shown in Table 3. As seen in Table 2 and Table 3, the conductivity of the membranes followed a similar trend with the IEC, as it is believed that increasing the amount of SSA in the membrane could lead to significant improvement in the proton conductivity of the membrane due to the increase in proton carriers by the sulfonic acid group ($-SO_3^-H^+$). Even though the conductivity of the CS-CL membranes in this study has a lower value than other membranes, the conductivity is still an improvement compared with a pure CS membrane. There is potential to obtain greater proton conductivity through modification of the CS structure.

Table 2 The ion exchange capacity of the membranes in various temperatures.

Temperature (°C)	Ion exchange capacity (mmol/g)		
	Nafion 212	CA05	CA10
25	1.57	0.49	2.00
50	1.47	0.69	2.04

Table 3. Ionic conductivity of the membranes at room temperature condition

Membranes	**Proton conductivity (S cm^{-1})**
Nafion 212	5.96×10^{-3}
CA05	2.30×10^{-5}
CA10	4.73×10^{-5}

Conclusion

CS-CL biocomposite polymers cross-linked with various amount of SSA have been prepared and evaluated as a potential polymer electrolyte membrane for fuel cell applications. CL has been shown to be filler that strenghthens biocomposite membrane. Further study will be focusing on conductivity using different types of ionic crosslinker agent. Specifically, SSA has improved the proton conductivity of the CS membrane from ~10^{-9} to ~10^{-5} by introducing a cross linking agent and an ionic carrier in the biocomposite membrane. The proton conductivity was found to be dependent on the concentration of the ionic cross linker.

Abstract

Various modifications of the titanium dioxide thin films have been done in fulfilling the photoelectrode requirements for photoelectrochemical water splitting reaction. In this study, surface passivation of TiO_2 by hematite-Fe_2O_3 was reported. Electrodeposition technique was used to deposit the Fe_2O_3 onto the TiO_2/FTO film with variation of time. X-ray diffraction (XRD), Scanning Electron Microscope (SEM) and UV-Vis spectroscopic analyses were used to characterize the electrode. Plane-wave-based pseudopotential density functional theory (DFT) calculations were used to analyze the electronic structure and charge potential at the surface of the electrode. The photocurrent measurement showed that current density of TiO_2/Fe_2O_3 electrode was higher than the TiO_2/FTO under the same illumination intensity of 100 $mWcm^{-2}$. The highest current density was produced by 5 minutes electrodeposition of Fe_2O_3, which also shifted the absorption to visible region at the threshold wavelength of 518 nm.

Keywords : titanium dioxide, iron(III) oxide, passivation layer, band gap

Abstrak

Pelbagai pengubahsuaian titanium dioksida filem nipis telah dilakukan untuk memenuhi keperluan fotoelektrod bagi tindak balas fotoelektrokimia pembelahan molekul air. Dalam kajian ini, dilaporkan pempasifan permukaan TiO_2 dengan bijih besi-Fe_2O_3. Teknik pengelektroenapan digunakan untuk mendepositkan Fe_2O_3 ke TiO_2/FTO filem dengan pelbagai masa pengelektroenapan. Analisis XRD, SEM dan UV-Vis spektroskopi telah digunakan untuk mencirikan elektrod. pengiraan teori fungsi ketumpatan (DFT) berasaskan planar gelombang pseudopotential telah digunakan untuk menganalisis struktur elektronik dan potensi caj di permukaan elektrod. Pengukuran arusfoto menunjukkan bahawa ketumpatan arus TiO_2/Fe_2O_3 elektrod adalah lebih tinggi daripada TiO_2/FTO bawah keamatan pencahayaan yang sama, 100 $mWcm^{-2}$. Ketumpatan semasa tertinggi dihasilkan oleh 5 minit pengelektroenapan Fe_2O_3, yang mana penyerapan beralih ke kawasan yang boleh dilihat pada panjang gelombang ambang 518 nm.

Kata kunci: titanium dioksida, ferum (III) oksida, lapisan pasif, sela jalur

Introduction

Hydrogen has been considered as an alternative fuel to replace fossil fuels for many years. It is used in fuel cell technology to generate electricity where water molecule is the only byproduct [1]. Hydrogen is plentiful in the universe, obtained via extraction off water molecule, an element, which is abundant and cheap; however requires a lot of energy to extract it. One of the promising method to produce hydrogen from water molecule is through photoelectrochemical (PEC) reaction that utilizes sunlight energy [2]. The system uses inexpensive metal oxide photoelectrode without the expense of electrolyzer, which leads to a further reduction in the cost of hydrogen delivery. The concept was first demonstrated by Honda and Fujishima in 1972 and since then, its science has influenced many followers [3].

PEC cell is a type of an electrolytic cell, where the sunlight is absorbed by the photoelectrode to generate current that is used to drive an electrochemical reaction. Generally, photoelectrode is an n or a p-type semiconductor electrode, which flows the electrons generated by the light induced chemical reactions initiated at its surface. Several photoelectrode requirements that must be fulfilled for direct PEC water splitting to occur are listed in Table 1. The band gap of photoelectrode semiconductor must be at least 1.5 eV, higher than the effective redox potential of water, which is about 1.23 – 1.4 eV [4,5].

Table 1. Main PEC water-splitting requirements [4]

Condition	**Requirement**
PEC water-splitting	$H_2O_{(liquid)} + 2h\upsilon \rightarrow ½O_{2(gas)} + H_{2(gas)}$
Minimum potential	$E°_{H_2O}(25\ °C)_{min} = 1.229$ eV
Practical potential (+overpotential & losses)	$E°_{H_2O}(25\ °C)_{prac} = 1.6 - 2.0$ eV $E_{bandgap} > E°_{H_2O}$
Utilization of sunlight	UV > hυ (Vis) > IR $h\upsilon \geq E_{bandgap}$
Bandedges	$C_{band\ edge} < E°_{H2/H^+}$ $V_{band\ edge} > E°_{O2/H2O}$

Concurrently, the semiconductor's conduction band (CB) must be higher than the reduction potential of water, whle its valence level (VB) must be lower than the oxidation potential of water. The focus of recent PEC research are mostly on developing photoelectrode materials that meet with the criteria besides high efficiencies, low-cost, long-term usages and non-photocorrosion of materials [3].

Titanium dioxide (TiO_2) is reported as the most promising photoelectrode [6]. This material has several advantages for photochemistry and photo-electrochemistry including low cost, widely available, non-photocorrosion and nontoxic. However, TiO_2 photocatalytic has large band gaps that limit its absorption of solar radiation to just 4 %, which is of UV spectrum. Numerous attempts have been made to expand the TiO_2 photoanode absorption spectrum to longer wavelengths: through doping TiO_2 with various metals and anions, use a dye-sensitizer molecule [7] and also morphology modifications of nano-scaled TiO_2, namely spheres, wires, rods and tubes [8, 9]. Significant experimental results are also observed by a surface passivation layer of TiO_2 with various metal oxide [10, 11]. Surface passivation layers electrode is a type of junction electrode, which comprises two or more layers of semiconductors. The surface passivation layers provide an alternative low energy route for charge transfer through catalytically active sites. In addition, surface passivation layers can reduce corrosion and improve chemical or photochemical stability of photoelectrode when immersed in an electrolyte [3,12].

In designing the passivation layer, it is important to consider the band positions of the metal oxides (Figure 1). For wide band gap semiconductor, TiO_2 should be combined with a narrow band gap metal oxide: WO_3 [13], Cu_2O

[14], CdTe [15] and CdS [16], that can absorb visible light. Here, investigation TiO_2 passivated by hematite-Fe_2O_3 is reported. Fe_2O_3 is one of prospective material for PEC. It is a photoactive material and absorbs visible light, however is poor in conductivity and has a CB energy below the reduction potential of hydrogen ion [11].

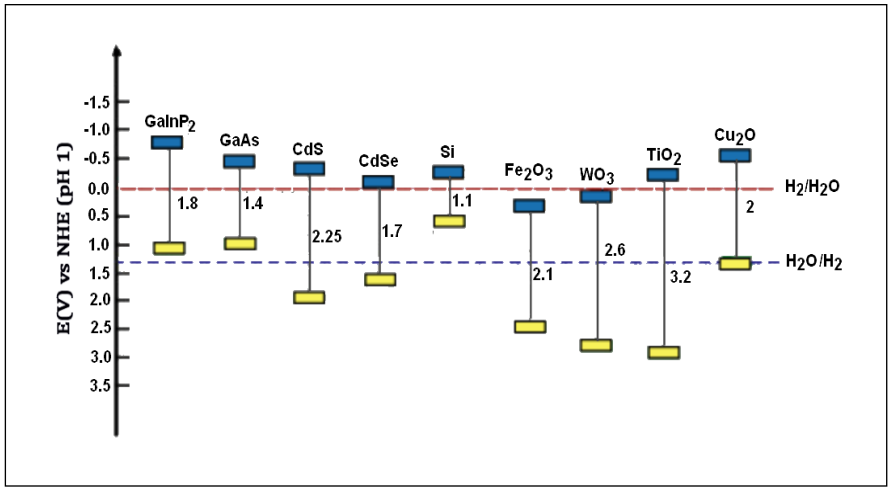

Figure 1. Bandgap and band edges of some semiconductor materials compared with a redox potential of water molecules

In this study, the Fe_2O_3 was electrodeposited on the TiO_2/ FTO thin film by variation of time. The Fe_2O_3/TiO_2/FTO multilayer film system was characterized by X-ray diffraction (XRD), Scanning Electron Microscope (SEM) and Uv-vis spectroscopy. PEC performance was measured by calculating its I-V under UV–vis light illumination.

Materials and Methods

Photoelectrode preparation

The TiO_2 electrodes were prepared using commercial colloidal TiO_2 powder (Degussa P25) by doctor-blading onto fluorine-doped tin oxide (FTO) glass plates. The 1 g TiO_2 powder was ground with 1 ml dipolyethylene glycol 300 (Merck), Triton-X and double-distilled water to form homogenous paste. The paste was smeared onto a clean FTO glass. Then, the TiO_2/FTO was dried at room temperature for a few minutes and was heated in a furnace at 450 ^oC for 2 hours with ramping rate of 5 $^oC\ s^{-1}$. Afterward, the Fe_2O_3 was deposited onto the TiO_2/FTO using electrodeposition method for 5 minutes, in which the iron sulfate ($FeSO_4$) was used as the starting material. The process was carried out using a potentiostat (VersaSTAT 4, Ametek), connected to a working electrode (TiO_2/FTO), counter electrode (Pt) and reference electrode (Saturated Calomel Electrode, SCE). The samples were calcined in a furnace at 500 ^oC for 60 minutes with heating rate of 1 $^oC\ s^{-1}$. Characterization of thin films was done using X-Ray diffraction (Bruker D8 Advance) via Cu Kα radiation. Morphology of the thin film was characterized using scanning electron microscopy (Zeiss AM10).

Photoelectrochemical analysis

The PEC analysis was conducted based on previous study [17]. The analyses were carried out using Ametek Versastat 4 on the TiO_2 and TiO_2 deposited by Fe_2O_3 at different times. The 450 W full arc Xenon light source at an intensity of 100 $mWcm^{-2}$ was used to irradiate the electrodes. The electrolyte in this experiment was 0.5 M Na_2SO_4, and it was purged with nitrogen gas for 30 min before the tests. The scan rate was set to 0.01 $V\ s^{-1}$.

Computational method

Density functional theory (DFT) calculations were carried out using the $DMol^3$ code in Materials Studio 5.5 from Accelrys. Geometry of the bulk molecule was optimized in a double-numeric-plus polarization (DNP) basis, set

using three different functional methods: PWC, PW91 and PBE. Self-consistent field (SCF) method was used for calculating the electronic structure; all core electrons were treated as being polarizable and Hartree-Folk (RHF) spin-restricted mode. TDDFT calculations were conducted on the ground state in spin-restricted mode.

Results and Discussion

X-ray diffraction (XRD) patterns of the TiO_2 and TiO_2/Fe_2O_3 on the FTO films are shown in Figure 2. The TiO_2 anatase (101) phase was observed at 25.35°, while rutile (110) phase appered at 27.40° (Figure 2b). The peaks for α-Fe_2O_3 (104) appeared at 33.50°, while α-Fe_2O_3(110) at 35.50° (Figure 2c) (JCPDS file no. 01-077-9926). All TiO_2 and Fe_2O_3 peaks were observed at TiO_2/Fe_2O_3 composite pattern (Figure 2d). Diffractogram pattern of the TiO_2 produced is similar with TiO_2 pattern that was reported by Vlasa et al. [18].

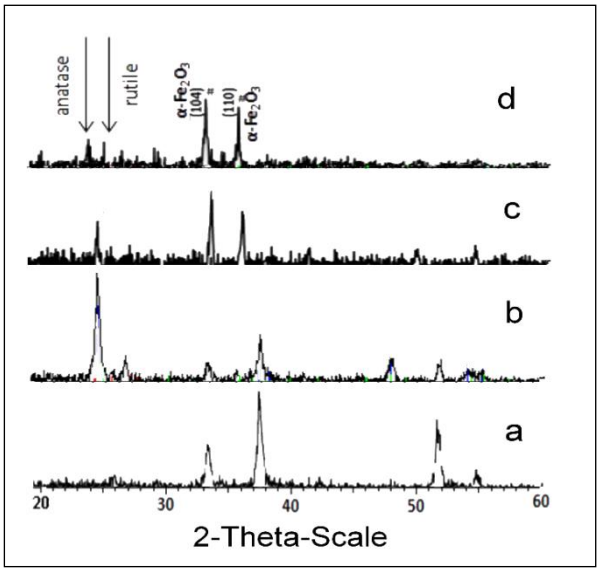

Figure 2. X-ray diffraction for (a) FTO (b) TiO_2 and (c) Fe_2O_3 and (d) TiO_2/Fe_2O_3

The surface morphology by scanning electron microscopic (SEM) image of TiO_2/Fe_2O_3 on an FTO glass substrate is shown in Figure 3. The image clearly shows flower-like shape on the surface of TiO_2 substrate (B), which is similar to a previous study [19]. The duration of deposition time changed the shape of Fe_2O_3; at 3 minutes, the flower-like shape changed to a spiny and globular structure (C) and then turned to fine particles that scattered randomly onto TiO_2 surface at 5 minutes (D). The presence of Fe was confirmed by EDX analysis (Table 2). The number of Fe did not automatically increased with time of deposition; however, the shape of Fe was: at 5 minutes of deposition time, the Fe shape became clotted and the TiO_2 surface became exposed. The thickness of TiO_2/Fe_2O_3 layer on the FTO substrate based on SEM images was obtained around 10-15 μm.

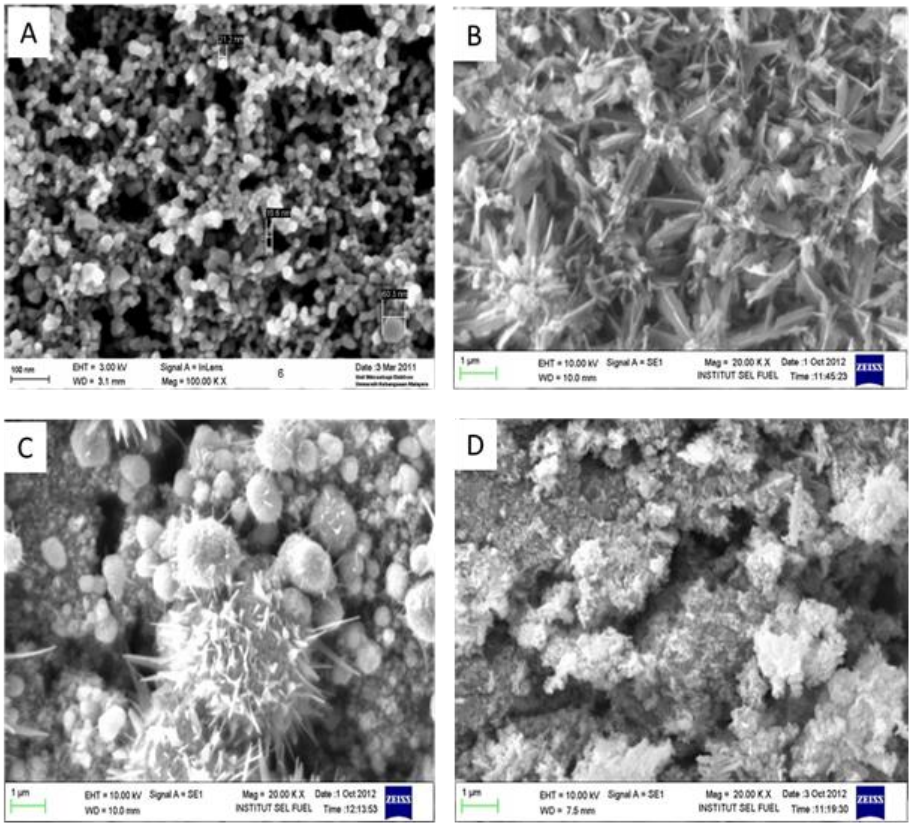

Figure 3. Surface morphology of (a) TiO_2 and (b) TiO_2/Fe_2O_3 on FTO films

Table 2. Element percentage of Fe, Ti and O based on EDX analysis

Element	Percentage (%) of element		
	TiO_2-Fe_2O_3 (1 min)	**TiO_2-Fe_2O_3 (3 min)**	**TiO_2-Fe_2O_3 (5 min)**
Ferrum (Fe)	57.0	29.8	16.3
Titanium (Ti)	55.6	42.8	18.6
Oxygen (O)	28.2	27.4	24.4

The optical characterizations of TiO_2 and TiO_2 doped Fe_2O_3 are shown in Figure 4. The band gaps were determined from reflectance spectra of the films using the following formula equation 1[5]:

$$E_g\ (eV) = 1240/\lambda_g\ (nm) \quad (1)$$

where, E_g and λ_g are the band gap energy and the absorption wavelength threshold of the doping material, respectively. In Figure 4, the band gap of TiO_2 was found to be 3.44 eV with the threshold wavelength at 360 nm. On the other hand, band gap of the TiO_2 doped with Fe_2O_3 was 2.39 eV with the threshold wavelength at 518 nm. The TiO_2/Fe_2O_3 film absorption was shifted to visible light, caused by excitation of electrons in the 3d shell of Fe to conduction band of TiO_2 [20].

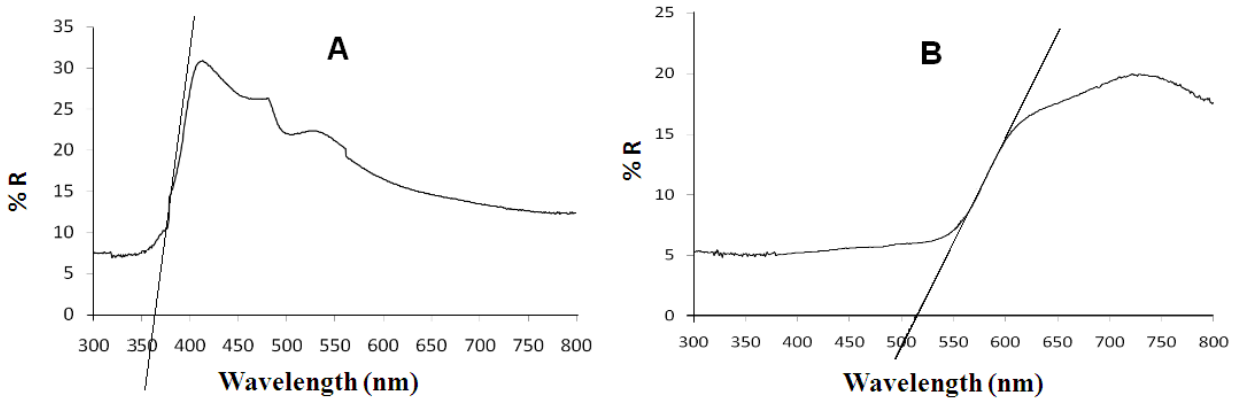

Figure 4. Reflection (R) spectra of TiO_2 (**A**) and TiO_2 doped Fe_2O_3 (5 min) (**B**) electrodes

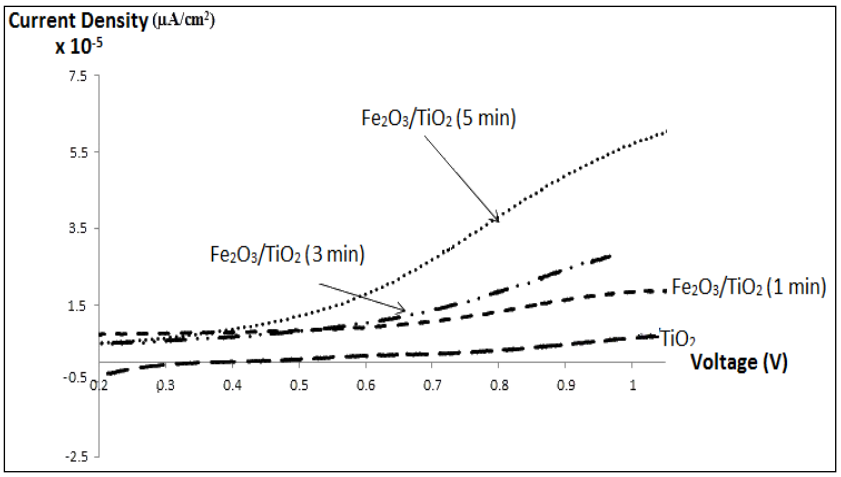

Figure 5. Current density-voltage (V/SCE) characteristics for Fe_2O_3/TiO_2 at different duration of electrodeposition proses

Photocurrent density was measured using three electrodes in 0.5 M Na_2SO_4 electrolyte under a Xenon lamp (100 mW cm^{-2}) irradiation. The applied voltage bias was measured againts SCE as the reference, and the values of photocurrent are shown in Figure 5. The current density of undoped TiO_2 was low compared with TiO_2 doped with Fe_2O_3. In addition, the deposition time of Fe_2O_3 onto TiO_2 surface contributed to the increase of current density. The highest photocurrent was measured at 5 minutes deposition of Fe_2O_3, which was about 55 µA cm^{-2} at 1.0 V bias potential. The current density of TiO_2 without Fe_2O_3 is 7 µAcm^{-2} and TiO_2/Fe_2O_3 at 1 and 3 minutes are 28 µAcm^{-2} and 29 µAcm^{-2}, respectively. This is probably due to the reduction of electron-hole recombination on TiO_2 doped with Fe_2O_3. Kim et al. found similar result, where the passivation layer of TiO_2 with Fe_2O_3 as photo-absorber on FTO film showed 3.5 times higher photocurrent densities for water splitting under UV-vis light illumination than the Fe_2O_3/FTO or TiO_2/FTO films [11].

Theoretical investigation started with the optimization of the bulk structure of TiO_2 and Fe_2O_3 in three kinds of functional methods. The average length of Ti-O and Fe-O are shown in Table 3. Calculated bond length of the Ti-O in these three methods gave similar results, which was about 1.92 Å. The calculated bond length of the Fe-O in

PWC was about 0.03 Å smaller than the calculated PW91 and PBE, which was about 1.96 Å. All calculated bond lengths of the Ti-O and Fe-O were in normal range [16]. The band gap of TiO_2 and Fe_2O_3 in these three methods were similar at about 0.076 Ha (2.06 eV) and 0.03 Ha (0.81 eV), respectively (Figure 6). Although the calculated band gaps were smaller than the experimental data, it is aceptable since the calculations were in atomic level.

Table 3. Bond length (Å) of the optimized structure in three different functional method calculation.

Bulk	**LDA-PWC**	**GGA-PW91**	**GGA-PBE**
Ti-O	1,923	1,927	1,927
Fe-O	1,939	1,960	1,960

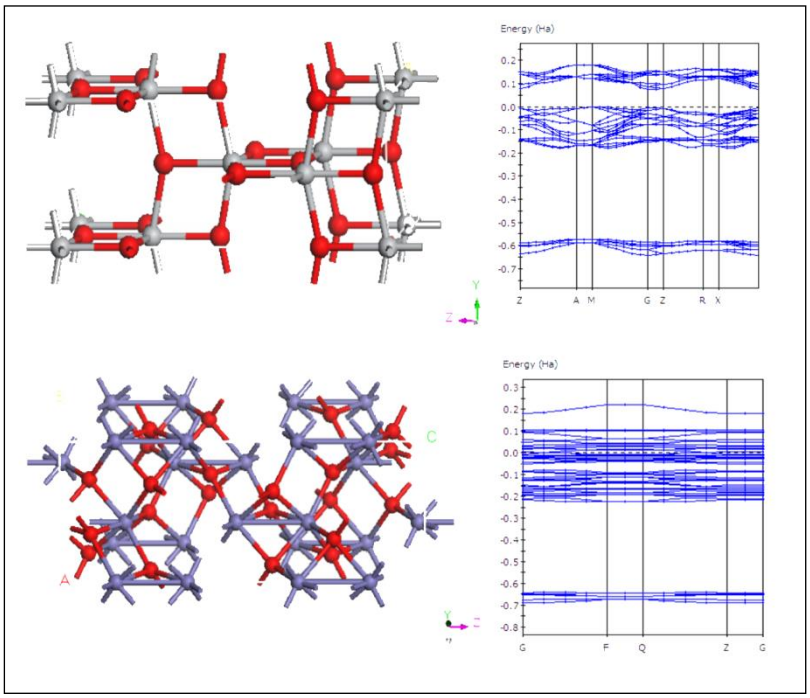

Figure 6. Molecular structure and electronic structure of TiO_2 (101), Fe_2O_3 (104) and composite TiO_2/Fe_2O_3

The optimized bulk structures of TiO_2 and Fe_2O_3 were used to form TiO_2 (101) and Fe_2O_3 (104) phases, which were then re-optimized further. The molecular structure of TiO_2 (101)/Fe_2O_3 (104) bilayer is shown in Figure 7. The electronic structure of the bilayer can not be determined easily since the increasing atomic number causes overlapping of the electronic orbitals. Nevertheless, band gap of the composite can be determined from the calculation of HOMO-LUMO energy gaps (0.70 eV), which is smaller than the monolayer oxides bad gaps; an indication of the charge transfer improvement in the system. Also shown in Figure 7 the potential electrophilic charge of the composite surface, where the potential of both oxides are similar. The more positive charge was found around Fe atoms, where supposedly the location of oxygen atom oxidation.

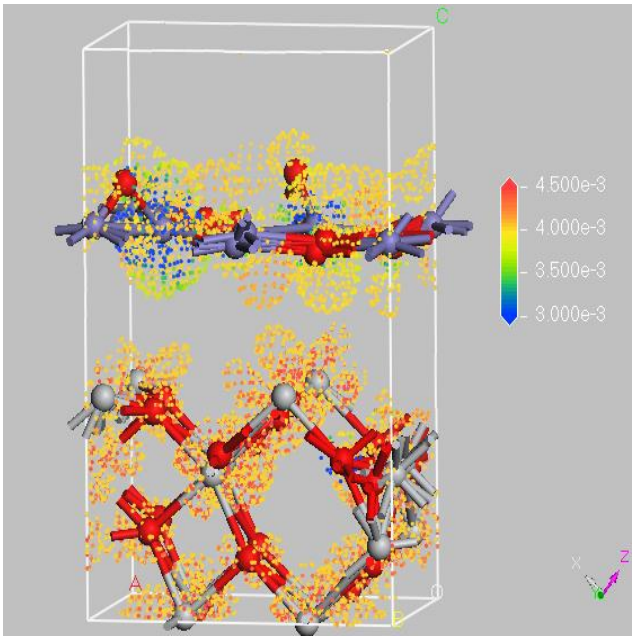

Figure 7. Molecular structure and electrophilic charge of TiO_2 (101)/Fe_2O_3 (104) composite

Conclusion

Surface passivation layer of TiO_2/Fe_2O_3 for use in the PEC water splitting application was successfully fabricated. $FeSO_4$ was used as the starting material and electrodeposition technique was used to deposit the iron molecule onto TiO_2 thin film. The measurements from photocurrent and reflection spectrum showed that Fe_2O_3 increased the performance of TiO_2 electrode. The maximum photocurrent was obtained from 5 minutes electrodeposition of Fe_2O_3 on TiO_2/FTO film. The TiO_2/Fe_2O_3 composite structure was built based on DFT calculations. The potential charges of the composite surface were successfully determined.

Abstract

Efficient operation results from a proper control strategy. In the operation and performance of a Proton Exchange Membrane Fuel Cell (PEMFC), the hydrogen gas flow rate is one of the most essential control parameter in addition to operating pressure, water management, temperature and humidity. This is because of the high cost and amount of energy are required to produce the purity hydrogen gas. In this paper, a Proportional Integral Derivative (PID) feedback control system is used to control the hydrogen flow rate. A strategy is adapted to balance the hydrogen use based on the loading requirements, especially during start-ups and sudden power demands. This system is implemented using National Instrument (NI) devices powered by the LabVIEW program. This is due to its simplicity and customization flexibility for measuring, processing and recording data. Designed structure allows the real-time implementation of a robust control law that is able to address the related nonlinearities and uncertainties without incurring a heavy computational load for the controller algorithm. While it facilitating a fast sampling rate according to the needs of the power system. Test results from the controller show that the new fuel control system provides good performance by reducing the amount of wasted hydrogen gas compared with that of the previous open loop system by 30 % to over 80 % saved by the varied load. This improvement is beneficial for any PEMFC that experiences fluctuating power demand, especially for vehicle applications.

Abstrak

Operasi yang cekap terhasil dari strategi kawalan yang baik. Dalam operasi dan prestasi Fuel Cell Membran Penukaran Proton (PEMFC), kadar aliran gas hidrogen adalah salah satu parameter kawalan yang paling penting selain dari tekanan operasi, pengurusan air, suhu dan kelembapan. Ini kerana kos yang tinggi dan jumlah tenaga dikehendaki untuk menghasilkan gas hidrogen berketulenan tinggi. Dalam kertas kerja ini, sistem kawalan Perkadaran, Kamiran dan Perbezaan (PID) suap balik digunakan untuk mengawal kadar aliran hidrogen. Strategi disesuaikan untuk mengimbangi penggunaan hidrogen berdasarkan keperluan bebanan, terutamanya pada permulaan dan permintaan kuasa secara tiba-tiba. Sistem ini dilaksanakan dengan menggunakan peranti instrumen nasional (NI) yang dikuasakan oleh program LabVIEW. Ini kerana ia ringkas dan fleksibel untuk mengukur, pemprosesan dan rakaman data. Struktur yang direka bentuk membolehkan pelaksanaan masa sebenar hukum kawalan yang mantap yang mampu menangani keadaan yang tidak linear dan tidak menentu tanpa memerlukan pengiraan yang sukar untuk algoritma pengawal. Sambil itu, ia memudahkan kadar pensampelan yang cepat mengikut keperluan sistem kuasa. Hasil ujian dari pengawal menunjukkan bahawa sistem kawalan sel fuel yang baru memberikan prestasi yang baik dengan

mengurangkan jumlah gas hidrogen yang terbazir berbanding sistem gelung terbuka dengan pengurangan sebanyak dari 30 % hingga 80 % pada variasi beban. Peningkatan ini memberi manfaat kepada mana-mana PEMFC yang mengalami permintaan kuasa turun naik, terutama untuk aplikasi kenderaan.

Introduction

The proton exchange membrane fuel cell (PEMFC) generates energy from chemical sources to produce electrical energy efficiently and directly via an electrochemical reaction between the hydrogen and oxidant as the reactant. It has drawn enormous Research and Development (R&D) interest because its high energy density makes it the most viable candidate for use in the transportation, stationary power and portable device sectors [1]. PEMFC have the characteristics of low operating temperature, low noise, low weight, low corrosion, small volume and fast start-up capability, thus resulting in high energy density and quick start features.

However, the commercialization of this technology is still hampered by many challenges such as cutting costs, improving performance and increasing durability. Although those issues could be solved primarily by material selection, PEMFC performance relies mostly on design and operation of a fuel cell system. That includes a balance of plant, power converters and their control systems. System that commonly use are the humidity, reactant pressure, reactant flow rate, water, temperature and power electronics management systems [2, 3]. Every system plays a role in the design that will determine the correct amount of material that must be supplied for proper function and better electricity generation.

In this paper, study will focus on reactant system where the parameter should be considered for high performance; pressure, flow rate and stoichiometric ratio. To supply the reactant source three mode can be used; the dead-end mode, the flow-through mode and the recycling mode [4]. For the pressure factor, the amount supplied is depending on the size of stack. A higher value can increase the kinetics reaction in the electrochemical process. Thus, result in a higher power density and greater stack efficiency. Even so too high pressure will cause damage on the membrane electrode assembly (MEA) components. In the other hand, at low supplied pressure may result in a lower net available power. Therefore, its value should be sufficient in order to produce a required power and maintain the durability of fuel cell [5, 6]. Danzer et al. [7] prevent starvation issue of their stack operated at transient condition. They adjust the oxidant fuel by designing a controller that supplied a minimum pressure.

The flow rate and stoichiometric ratio are closely related. Higher flow rates cause the stoichiometric ratio and power production to become high as well because additional reactants are available for the reaction. However, this will reduce the energy production efficiency because more reactants are supplied but did not react and are wasted. Usually this happen when the fuel is supplied at a fixed and high stoichiometric ratio in orders to maintain the desired current density [8, 9]. But if the stoichiometric ratio is too low, will result in low performance [10, 11]. But problems often arise when the imposed loading varies and the supplied reactants are insufficient to produce the needed power. Zhou et al. [12] studies the behavior of fuel cell under fuel starvation condition. At different stoiciometric ratio and loading variation, they observe after unsatisfactory condition, the carbon corrosion issues arise.

This problem requires serious attention, especially in vehicle and load variation applications, because this complex phenomenon may cause a transient power issue that leads to performance degradation, damage to the electrode and electrolyte surface and shorter fuel cell life [13]. To solve this problem, a reactant controller should be implemented to control the flow rate supplied to the fuel cell stack. This is done to ensure an educate supply of reactant can be consume by fuel cell and generate the required power needed in both normal and transient operation mode. Flow control chosen to be control since it is critical parameter at uncertainties. This overview shows that a more efficient hydrogen-air supply management system is required for better PEMFC system operation to increase the efficiency of the reactant used.

In this paper, we focus on implementing a hydrogen fuel controller in which the design of a feedback control system using the PID controller was carried out to manipulate the supply to the fuel cell. But the fan speeds are maintained at a specific power for reduction of system complexity. A sufficient flow rate based on performance is determined to obtain the required reactant supply and to prevent excessive fuel consumption. This implementation can be broadly used in many applications that address load variation, such as electric vehicles in which the power demand is impulsive rather than constant.

Materials and Methods

System setup

PEMFC stack from Horizon Fuel Cell Technologies was used in this study. The open cathode stack was supplied with 99.99 % pure hydrogen gas that stored in compressed gas cylinder. The hydrogen gas flows inside the stack using a dead-end mode; every 10 seconds, the end valve was opened to release the existing gas for purging action. An axial fan are used to supply the oxygen source (air) using the flow-through mode. The overall setup tables for the experiment shown in Figure 1. This fuel cell can generate a variable power demand with a maximum rated value of 100 W (±14.4 V at ±7.2 A) and consists of 24 MEA cells with a total electrode area of 45 cm². The measurement of the stack performances are being varied using the DC electronic load and recorded by the NI data logger and LabVIEW program.

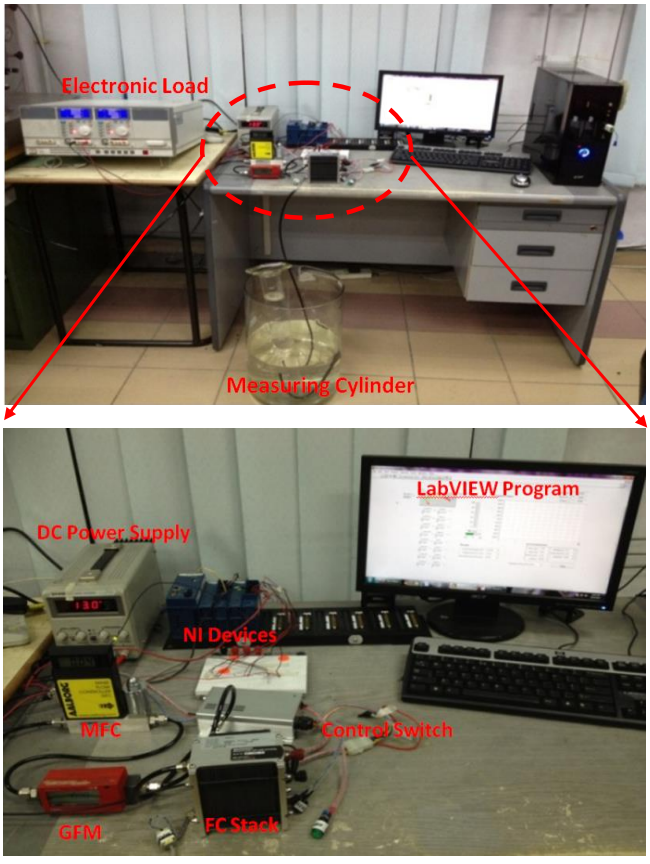

Figure 1. Overall table setup for testing PEMFC commercial stack

Fuel cells often use open loop system (OLS) shown Figure 2. In which hydrogen was supplied directly to the stack from compressed hydrogen gas stored in a cylinder tank in which the pressure are manually controlled with a pressure regulator. The procedures to operate the commercial stack with the OLS are based on flow diagram as in Figure 3. In this situation we need to make sure that the source of reactant are sufficient by supplying the flow rate in excess amount to avoid starvation problem.

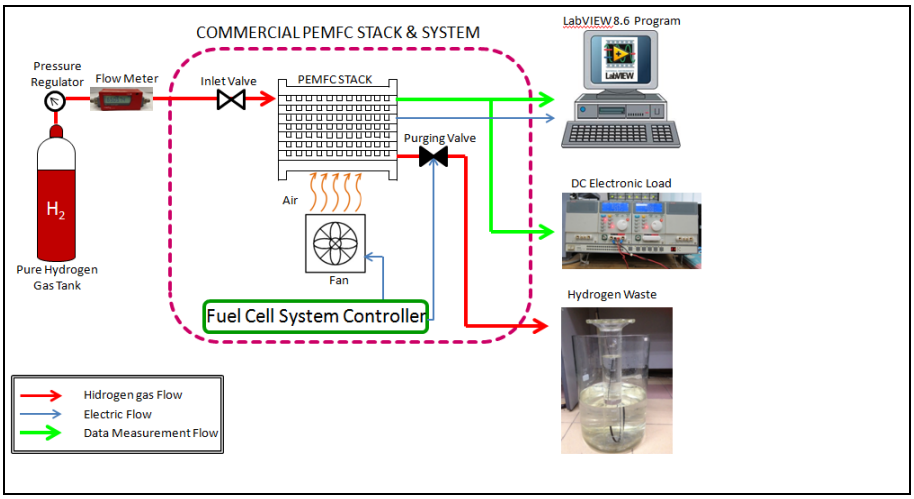

Figure 2. Flow diagram of operating the fuel cell stack using an Open Loop System (OLS)

However, the OLS system has the disadvantage where it will lead to starvation or waste of resources reactant when the flow rate is not controlled. Therefore, a hydrogen control system using PID control is built to reduce this problem. The application of controller functions in a manner similar to an automatic control system known as closed loop system (CLS). To see the hydrogen consumption difference for both systems; OLS without any modification and CLS with PID controller implemented used to manage the hydrogen flow rate when PEMFC generating the power.

An electrical circuit diagram build for the hydrogen flow rate control system shown in Figure 4. Electrical connection is made between 100 W commercial fuel cell stack, the DC power supply to turn on electronic equipment, mass flow controller (MFC) for the determination of the output and input current to change the flow rate of hydrogen, NI device (CFP-AIO-600) as connective reaction programmed in LabVIEW software and DC electronic load to monitor the voltage and power produce and also applied current load.

Control techniques

The PID controllers are used to improve fuel cell performance by regulating the amount of hydrogen using control element that exists in the LabVIEW program. The controller can provide control actions designed for the specific process requirements. The general form of PID is express as equation 1:

$$u(t) = K_p e(t) + K_I \int e(t)dt + K_D \frac{d}{dt} e(t) \quad (1)$$

where the signal input (u) of the controller is equivalent to the increase in the proportion of (K_P) times the magnitude of the error plus the integral increase (K_i) times the integral of the error plus the increase in the difference (K_d) times the error difference.

For CLS, specific amounts of hydrogen are adjusted to a sufficient value by increasing and decreasing the delivery via a current control mode. This mode is based on the power required to maintain the stack output voltage, and this concept is vital to providing an efficient amount of power output and reducing hydrogen waste. To control this process, the signal must be subjected to these algorithms. The process begins by measuring the fuel cell system voltage output using a compact field point (cFP) hardware tool (read signal). The control program built using LabVIEW was used to measure the parameters, log the data, record the outputs and analyze the data to be applied to the fuel cell stack on a real-time basis. The results were subsequently passed to the cFP hardware tool (write signal) for implementation. A programmable electronic load was used to generate a pulse current load profile. These sequences were maintained and continued as the signal was sent out (control) and received (feedback) to analyze the system power.

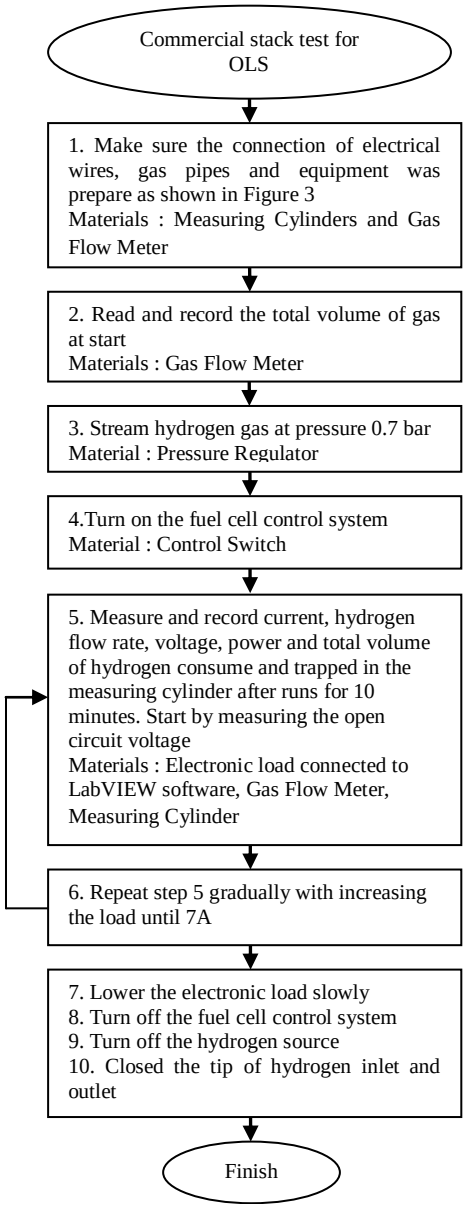

Figure 3. Flow chart of operating OLS

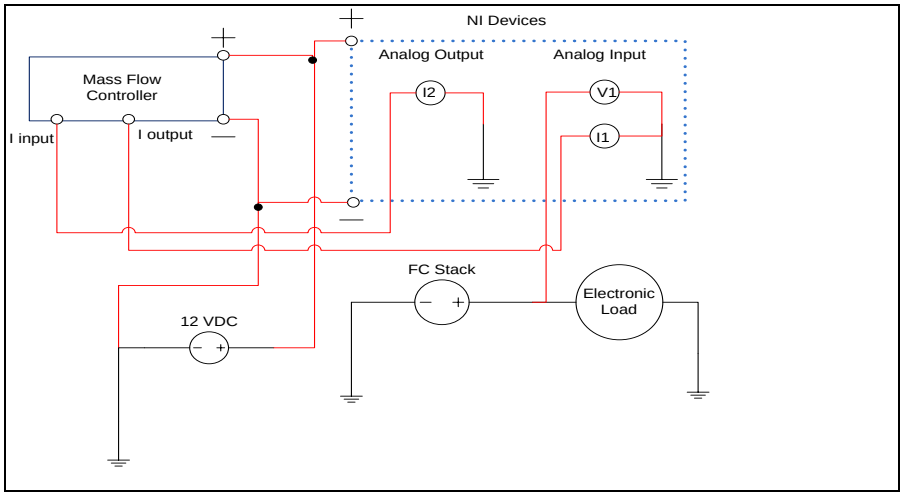

Figure 4. Hydrogen control system electrical circuit

In the CLS, adjustments are enacted using a hydrogen mass flow controller (MFC) functions to control the amount of hydrogen flow. The MFC is controlled by measurement and supply of a signal through the NI devices (cFP-AIO-600) based on the program built using LabVIEW. The setup of the system is shown in Figure 5.

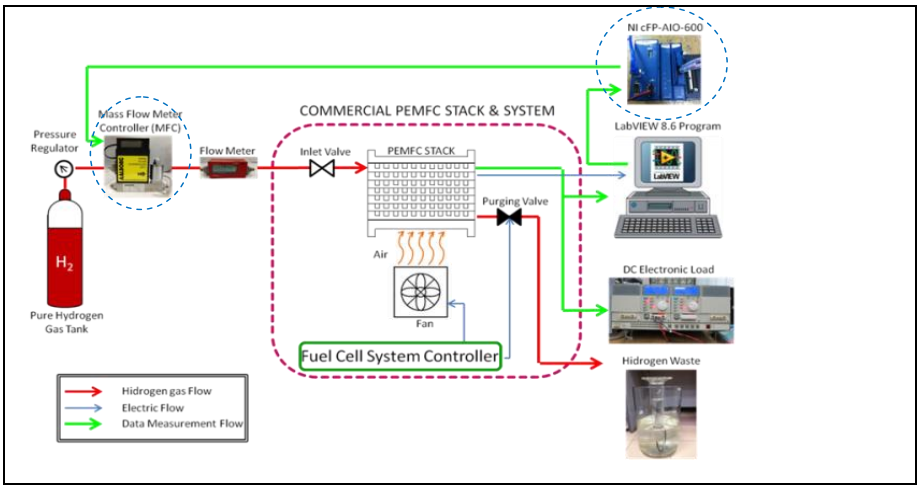

Figure 5. Flow diagram of the CLS

The NI module was placed between the fuel cell system and the computer (LabVIEW) to convert the analog input to a digital output for cFP measurements and control actions. A voltage range between 14 V (minimum voltage) up to 24 V (open circuit voltage) was determined to maintain suitable flow rates. The voltage was measured and the signal was logged using the NI analog input and subsequently sent to the LabVIEW controller program for processing. The required flow rate was automatically chosen using the PID program. The signal was sent back using the NI analog output current to control the MFC valve flow rate. The program reactions are based on PID changes that produce an operating signal that manipulates the flow rate of the hydrogen reactant to maintain the stack output voltage.

The flow rates required were determined from the OLS results and aimed to conserve hydrogen based on the loading demand to maintain the fuel cell stack voltage. Eight sets of voltage ranges were fixed to comply with the different flow rates at the transient conditions. The detailed voltage ranges, flow rates and MFC output currents are listed in Table 1. The procedures to operate the CLS are also listed as in Figure 6. The developed PID controller program details structure are shown in the block diagram in Figure 7.

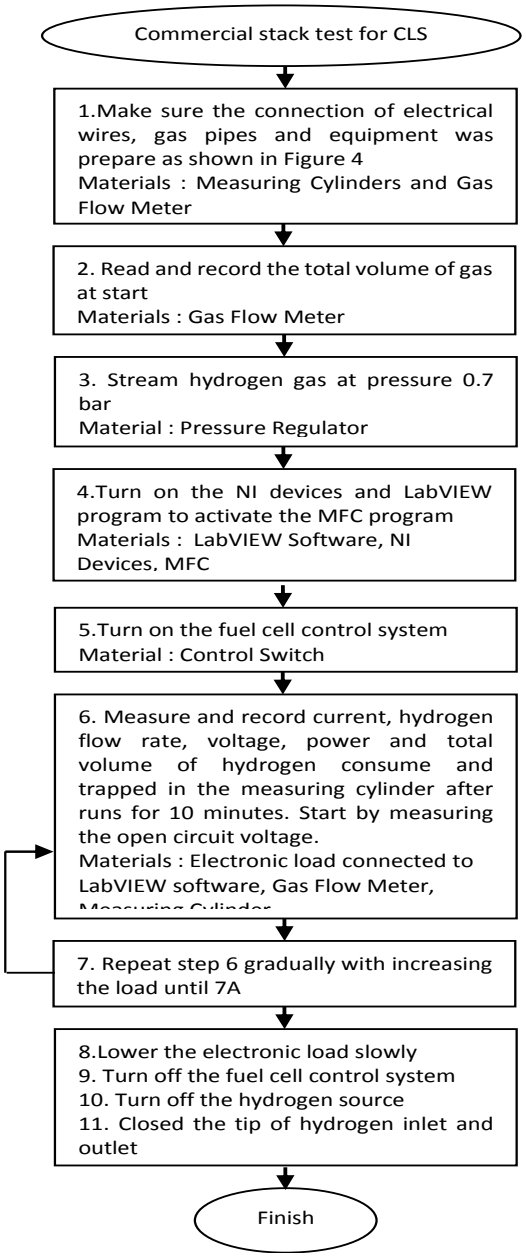

Figure 6. Flow diagram of the CLS

Table 1. Voltage range options at different hydrogen flow rates for controller calibration

Range Option	Stack Voltage Range (V)	Hydrogen Flow Rates (l/min)	cFP AIO 600 Output Current to MFC (A)

Results and Discussion

Stack performance in different systems

As the main part of this study, a flow rate controller was implemented for more reliable operation using CLS. The strategies used then were compared with the OLS and controller used by Kim et al. [14]. Kim et al. using a PEM fuel cell stack can power up to 150-W and implement a closed-loop method controller. The effects on the fuel cell system performance in response to hydrogen reactant control were analyzed. Figure 8 shows the performance comparison between them, where Figure 8a indicates that the implementations of controlled hydrogen flow rates are able to satisfy the power demand.

The performance response at different loadings shows the values of the hydrogen consumption rates are affected. Where, as the power stack demand is increasing, the hydrogen flow rates consumed also increase, but the value consumed different depends on the system used. In Figure 8b, can be observe that the demand of hydrogen are lower request by the CLS compared to the two other system. Therefore, it is necessary to consider hydrogen control management in the fuel cell design in order to reduce hydrogen usage. After ensuring control of the hydrogen supply does not affects the power performance, the impact of hydrogen consumption and wasted (purged out) will further studied for both the OLS and CLS processes.

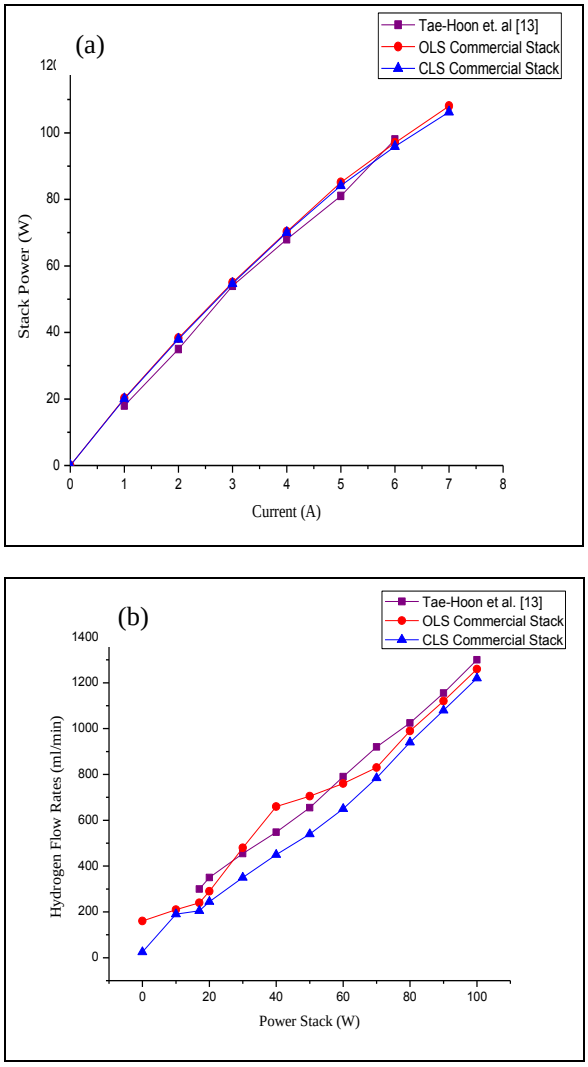

Figure 8. Characteristics of (a) stack power and (b) hydrogen flow rate under various loading values at different stack conditions

Control system impact in hydrogen consumption

The data of overall performance shows that the amount of hydrogen consumes are directly proportional to the load demand. Figures 9 indicate that the volumes of hydrogen that flowed into the stack were consumed and were subsequently purged out of the fuel cells every 10 minutes differed with respect to the loading value.

An increase in loading also increased the amount of hydrogen that entered the fuel cell; for the OLS in Figure 9, almost 2 liters of hydrogen was wasted at low currents from the OCV until a current of 4 A was reached because of the purging condition. However, the amount of wasted hydrogen decreased as the loading increased, which indicates that additional hydrogen reacts at a higher demand. Between 5 A and 7 A, the purging value increased to greater than 2 liters. The CLS showed an almost identical pattern to that previously discussed for the OLS. The load and hydrogen influx were positively correlated, but the influx was limited by the controller. Thus, the purged amounts of hydrogen were smaller compared with those of the OLS, and thus, the CLS constitutes an improvement by gradually and appropriately allowing hydrogen to enter the fuel cell. Hydrogen purged out recorded between 30% to over 80% have been successfully saved depends on the applied load.

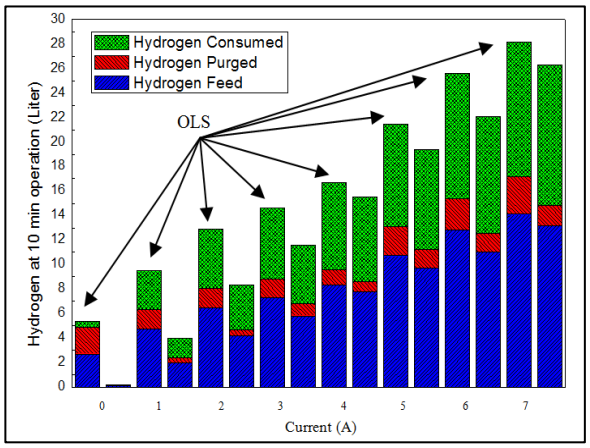

Figure 9. Total hydrogen consumption for OLS and CLS configuration

Transient loading effect

The study continues with an application of a variable load to observe the effect on the performance and use of hydrogen flow control and to determine whether it can produce effective results for the active load current changes. The load current for this stack can vary depending on the load demand, from 0 A to 7 A, and the changes cover all of the stack operations. In this implementation, the patterns in the current changes are set to distinguish the results from the system used. Figure 10 shows the change in current fluctuations applied manually via an electronic load. These changes cover nearly the entire fuel cell stack operating conditions.

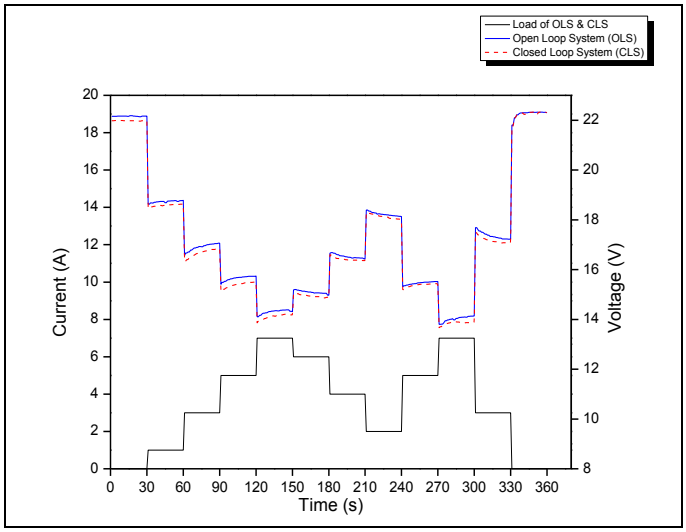

Figure 10. Stack performance at variation loading for OLS and CLS vs. time

The performance of load variation at both conditions operate at 360 second can be observed in Figure 10. The amount of hydrogen flow used by the commercial stack for the OLS is 4.90 liters with 1.30 liters wasted. However, for the CLS condition, only 4.20 liters were used and 0.67 liters were released into the atmosphere. This result shows that almost 50% of the hydrogen waste has been eliminated. The designed controller produced more optimal

power efficiency in terms of fuel consumption. This result shows that the new system improved the fuel cell system efficiency in terms of fuel consumption and cost effectiveness by reducing the waste of hydrogen resources released into the atmosphere.

Conclusion

The impact of hydrogen consumption in both the open-loop and closed-loop operations was compared to validate the proposed design. The controlled flow rates mimicked those of the OLS, and this system was most beneficial at the purging condition. The power performance of the CLS control system result was the same as that of the previously established OLS. The implementation effectively controlled the hydrogen flow rate under active current load variations such that minimal amounts of hydrogen were wasted while accommodating the needs of the reaction. Although this experiment used small-scale and commercialized fuel cells, with short time of operation indicated that the CLS improved the fuel cell hydrogen efficiency and cost effectiveness by reducing waste, which constitutes a significant benefit to the commercial fuel industry. The newly proposed fuel cell control system is also able to accommodate transient load demands. A sufficient hydrogen supply maintains fuel cell performance, reduces fuel waste and prevents MEA damage. If this condition is applied to higher power fuel cells or is implemented for longer durations, additional hydrogen can be conserved.

Abstract

In this study, we are interested in the effect of long time exposure of the microbial fuel cells (MFCs) to air on the electrochemical performance. Here, MFCs enriched using an effluent from a MFC operated for about eight months. After 30 days, the condition of these systems was reversed from aerobic to anaerobic and vice versa, and their effects were observed for 11 days. The results show that for anaerobic MFCs, power generation was reduced when the anodes were exposed to dissolved oxygen of 7.5 ppm. The long exposure of anodic biofilm to air led to poor electrochemical performance. The power generation recovered fully when air supply stopped entering the anode compartment with a reduction of internal resistance up to 53%. The study was able to show that mixed facultative microorganism able to strive through the aerobic condition for about a month at 7.5 ppm oxygen or less. The anaerobic condition was able to turn these microbes into exoelectrogen, producing considerable power in relative to their aerobic state.

Keywords: microbial fuel cell, aerobic, oxygen exposure, wastewater

Abstrak

Dalam kajian ini, kami berminat untuk mengesan prestasi elektrokimia sel bahan api mikrob (MFC) terhadap pendedahan jangka masa panjang kepada udara. Di sini, MFC diperkaya menggunakan efluen daripada MFC yang telah beroperasi selama kira – kira lapan bulan. Selepas 30 hari, keadaan sistem ini telah diterbalikkan dari aerobik untuk anaerobik dan sebaliknya, dan kesannya diperhatikan selama 11 hari. Keputusan menunjukkan bahawa untuk MFC anaerobik, penjanaan kuasa telah berkurangan apabila anod terkena oksigen terlarut 7.5 ppm. Pendedahan jangka masa panjang biofilem anod kepada udara membawa kepada prestasi elektrokimia yang rendah. Penjanaan kuasa pulih sepenuhnya apabila bekalan udara berhenti memasuki ruangan anod dengan pengurangan rintangan sehingga 53 %. Kajian ini dapat menunjukkan bahawa mikroorganisma fakultatif campuran dapat hidup melalui keadaan aerobik selama sebulan pada 7.5 ppm oksigen atau kurang. Keadaan anaerobik mampu mengubah mikrob ini kepada eksoelektrogen, seterusnya menghasilkan kuasa yang tinggi berbanding dengan apabila berada di dalam keadaan aerobik.

Introduction

A microbial fuel cell (MFC) system is a bioenergy converter that utilizes bacteria to generate electricity through bacterial metabolic pathway [1]. These bacteria are known as exoelectrogens and could transfer electrons to anode electrode. Oxygen and nitrate are preferred electron acceptor over the anode reducing power generation in their presence in the anolyte. Tests on the impact of oxygen in air on anaerobic MFCs had been done on both single cell culture, such as from the genus *Shewanella* [2, 3], *Escherichia coli (E. coli)* [4] and mixed bacterial cultures from anaerobic wastewater treatment streams [5, 6]. It was shown that the dissolved oxygen in anolyte reduces the capability of certain bacteria to transfer electrons to external anode. Kim et al. [7] in their research on biosensor, found that *Shewanella putrefaciens* completely loss its electrochemical activity within three hours of exposure to air, while Biffinger et al. [8] found that *Shewanella oneidensis* work well as exoelectrogen in the presence of oxygen. Wang et al. [4] discovered that *E. coli* had about 61- 68 % decreased in capability to reduce external mediator, hexacyanidoferrate (III) $[Fe(CN)_6]^{3-}$ in anaerobic MFC when oxygen is presence. In the case of mixed culture, Liu et al. [5] found that the diffusion of oxygen to the anolyte from the catholyte would lead to 21- 50 % loss of substrate to aerobic oxidation by bacteria, which translates as the loss of generated electricity through the MFC.

A more detail work was done by Li et al. [3] on the response of *Shewanella decolorationis* with oxygen within six days of changing the flowing of argon gas and air into the MFCs to create alternate condition of aerobic and anaerobic. They discovered that in contact with oxygen, *S. decolorationis* reduced more NAD to NADH, which in turns increase in charge production. However, the dissolved oxygen (DO) in the anolyte increased aerobic respiration and biomass production that leads to current reduction in MFCs. There are not many studies reported on aerobic effect towards the anodic biofilm of MFCs [9]. Though available findings pointed out the short term adverse effect of oxygen on generation of current by bacteria in MFCs, to our knowledge there are no reports that show long term oxygen exposure on anolyte in MFC.

Therefore, this study aims to analyse the effect of long-duration exposure towards oxygen on the electrochemical performance of enriched multi-cultured bacteria in MFCs. In this work, effluent from an air-cathode MFC operated for about eight months was used as inocula for aerobic and anaerobic MFCs. After 30 days, the conditions of the system were changed by swapping between the nitrogen and air. This turned the aerobic into anaerobic and anaerobic into aerobic and were let to acclimatize in their new condition for 11 days. The electrochemical performance of the MFCs before and after the gas swapping were compared in view of maximum power density (P_{max}), current density (I_{max}) at P_{max} and internal resistance (R_{int}) accomplished within the systems.

Materials and Methods

Chemicals

Chemicals were of analytical grade. Peptone was purchased from Merck (Darmstadt, Germany). Yeast extract was purchased from Scharlau (Barcelona, Spain). Ammonium chloride (NH_4Cl) and sodium acetate anhydrous (CH_3.COONa) was purchased from AnalaR®, BDH Laboratory Supplies (Poole, England). Di-sodium hydrogen orthophosphate anhydrous (Na_2HPO_4) and potassium chloride (KCl) were purchased from Fisher Scientific UK Ltd. (Leicestershire, UK). Sodium dihydrogen orthosphosphate ($NaH_2PO_4.H_2O$) was purchased from LabServTM, Biolab (Aust) Ltd. (Victoria, Australia). All analytical solution was made using distilled water unless otherwise stated.

Inoculum, buffers, reagents and media

Effluent from an air cathode MFC inoculated with sludge collected from Bromley Wastewater treatment plant and operated about eight months using acetate as the electron donor was used to inoculate air-cathode MFCs used in this study. The basal medium was prepared by dissolving 0.31 g/L NH_4Cl, 3.12 g/L $NaH_2PO_4 \cdot 2H_20$, 4.58 g/L Na_2HPO_4, and 0.13 g/L KCl in phosphate buffer (50 mM, pH 7.0) [10, 11]. The acetate medium was made by dissolving 1 g/ L CH_3 COONa, 1 g/ L peptone of casein and 2 g/ L yeast extract in the basal medium [12]. The medium was autoclaved at 121 ^oC for 15 min prior to use.

MFC air-cathode construction

The study utilized single chambered air-cathode MFCs as described in Weld & Singh [13]. The reactor was constructed using three machined polycarbonate pieces with O-rings and steel bolts. The internal volume was 19.2 mL (Figure 1). The middle polycarbonate had its top equipped with three holes: two big holes of ø 1.8 cm and ø 1.0 cm for batch mode feeding and reference electrode respectively and one small hole of ø 0.4 cm for gas inlet. The anode chamber was separated from an air cathode by using cation exchange membrane (Ultrex) from BASF Fuel Cell Inc. (Somerset, NJ. USA).

The air-cathode and the anode were 4 cm × 4 cm of 10% Pt-carbon cloth (Fuel Cell Earth LLC, Stoneham, MA) covered with a layer of 4 cm × 4 cm plain carbon cloth (Fuel Cell Earth LLC, Stoneham, MA) and 4 cm × 4 cm plain carbon cloth respectively. The cathode was fastened to the exterior wall of the Ultrex membrane with a nickel strip, acted as current collector and also used to grip the anode.

Operation

Here, 2 % (v/v) of anolyte (OD_{600} of 2.85) from an eight month old MFC was incubated in acetate media for 24 h at 150 rpm and 24 °C. Each six new MFCs were filled with 0.4 mL of the incubated culture and topped up with acetate media. Two of the MFCs were bubbled with nitrogen to create anaerobic condition, the other two were bubbled with air to create aerobic condition, while two more were made as control, free from flowing of gas to create natural anaerobic condition. Except for the controlled MFCs, the anodes of gassed MFCs were poised at potential of +200 mV (vs. Ag/AgCl) for seven days and operated in controlled temperature of 28 °C. From the eighth day onwards, the anode poising was discontinued and the MFCs were connected to external resistors of 1,000 Ω.

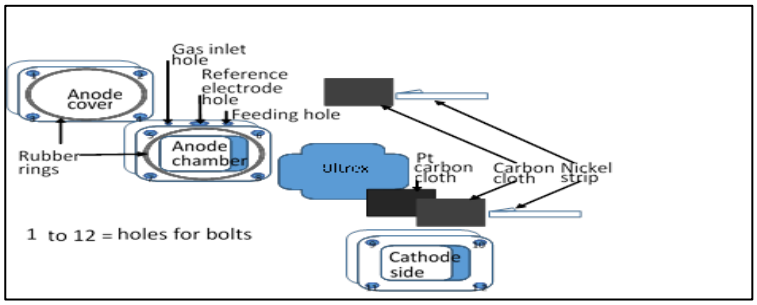

Figure 1. MFC used in this study

Analytical methods and calculation

Cell voltage (*E*) across the external resistor and cell current generated from the anode fixed potential poised were measured every twice a day using a Digitech QM 1326 multimeter or every 30 s to 30 min using a four channel Quadstat 164 potentiostat (eDAQ Pty Ltd, NSW, Australia) and continuous recording using an e-corder 1621 (eDAQ Pty Ltd, NSW, Australia) data acquisition system. Current (*I*) and power (*P*) were calculated using the Ohm's law (Equation 1 and 2):

$$I = \frac{E}{Rext} \quad , \; I_{density} = \frac{I}{Anode\ area} \tag{1}$$

$$P = I\ x\ E \quad , P_{density} = \frac{P}{Anode\ area} \tag{2}$$

where *E* represents circuit's potential and R_{ext} represents circuit external resistance, with the current density, $I_{density}$ and power density, $P_{density}$ normalized by the projected area of the anode [14].

Dissolved oxygen concentration in the anolyte was determined before the gas swapping activity from the aerobic MFCs as 7.5 ppm, using HQ40d portable multi-parameter meter (pH/ conductivity/ dissolved oxygen/ ORP/ ISE)

(Hach Company, Colorado, US). The polarization curve and the power density curves were produced by using method in Luo et al. [14] and Watson and Logan, [15] to obtain the open circuit voltage (OCV), P_{max}, I_{max} and R_{int} of the system. In this study, the polarization curves were obtained using multiple resistors (820 kΩ to 18 kΩ), with each resistance changed in decreasing order after every pseudo steady-state achieved or not more than 20 min intervals (which ever comes first) over a complete fed batch cycle. Analysis was conducted once the voltage output was stabilised after replenishing the media. The analysis was done for two consecutive cycles to ensure that the voltage response was unchanged with successive cycles.

Results and Discussion

Current density shows that once the anode poising was discontinued, only anaerobic MFCs show high current density with total daily average from day-8 till day-25 of 38.26 ± 0.13 mA/ m^2 and lowest by aerobic MFCs of 2.08 ± 0.01 mA/ m^2 while the control gave an average of 20.65 ± 0.28 mA/ m^2 (Figure 2). As soon as the MFC characterisation started (day 23, 24 and 25), the aerobic MFCs began to show significant in current density (t-test, $p<0.05$), which is higher than anaerobic MFCs with total daily average from day-26 till day-30 of 70.93 ± 0.19 and 67.49 ± 0.32 mA/ m^2 respectively. For the control system, there was not much increase in current density recorded after day-26, 30.69 ± 0.68 mA/ m^2.

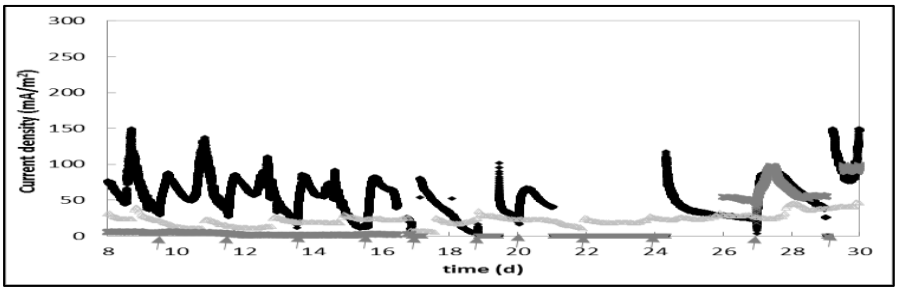

Figure 2. Biocatalytic current generation compared between aerobic and anaerobic environment.The air-cathode MFCs: anode chamber bubbled with nitrogen (◆), anode chamber bubbled with air (x) and control (▲). The frequency of batch feeding mode was in daily average (represented by ↑)(n=2).

The poising of the anode was to allow consistent control of the biofilm electrode potential, by making the electrode as the sole electron acceptor [16]. The reason of nitrogen bubbling into the anode compartment was to accelerate the anaerobic condition in the system simultaneously increase the MFC electrochemical performance. The control MFCs were solely depending on the bacteria in the anode chamber to create anaerobic environment by gradually consuming the soluble oxygen in the anolyte [17]. The current density generated by the control MFCs was almost 2-fold less than that generated by nitrogen bubbled MFCs. The high mass of bacteria inoculated in the anode compartment of the control MFCs, capable to consume oxygen available in the chamber for a short time. When the condition became suitable for anaerobic bacteria to survive and perform anodophilic transfer, then only current density started to gain pace. A similar situation was observed by Hutchinson et al. [18], who stated the importance of having the anode compartment free of diffused oxygen from the cathode esspecially during startup. In this study, feeding was done manually through a designated cavity at the top of the MFC reactor. This action might allow air to seep into the control MFCs, while for the anaerobic MFCs, the pressure created by the nitrogen bubbled MFC kept the air out during feeding. Therefore, the nitrogen bubbled MFCs could generate high current without the interference of air. In contrast, air bubbled MFCs remained at much lower current density than the control MFCs during the gassing period.

The characterisation of the MFCs for power and polarization curves, appeared to increase the current intensity of the aerobic and the anaerobic MFCs. From the Ohm's law in equation 1, new voltage at the electrodes can be obtained through changing the R_{ext}. During the characterisation analysis, the R_{ext} applied had values larger than the fixed R_{ext} used for the MFCs' operation. The large R_{ext} values were necessary to obtain the standard MFC characterisation and

polarization curves. This might attributed to the moment surged in current intensity once the MFC characterisation was stopped and the system were again connected to the fixed $R_{ext,}$ which had much lower value. Similar incident was experienced by Aelterman et al. [19], in their studies on the effect of R_{ext} ranges towards MFCs current generation. They found that the current intensity of their MFCs increased by 3.29-fold when they changed the R_{ext} from 50 to 10.5 Ω. However, further study is necessary to identify reason on how the aerobic increased in current density by one fold more than the anaerobic after characterisation analysis was done.

The switching of gasses between air and nitrogen began on day-33 until day 44. The total daily average current calculated for the 11 days after gas swapping did not show any significant in current density (t-test, p >0.05) between before (day-26 to 30) and after gas swapping for each MFC conditions (day-33 to 44): 49.89 ± 0.19 mA/ m^2(nitrogen gassed MFCs) and 74.81 ± 0.18 mA/ m^2 (aerated MFCs) (Figure 3).

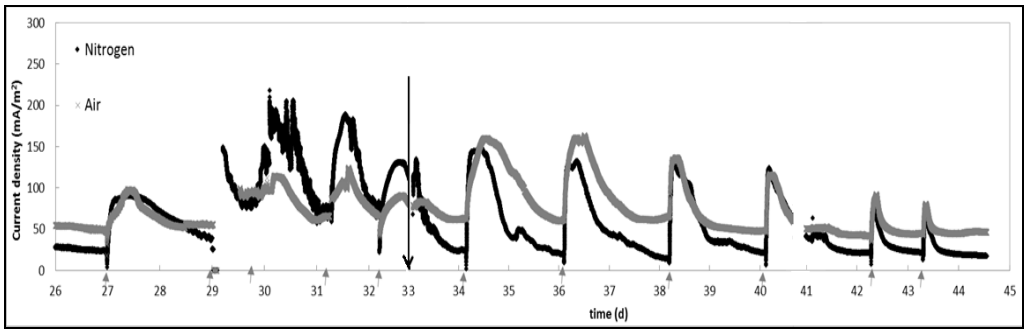

Figure 3. Effect of gas swapping (↓) between the aerobic and anaerobic MFCs. The frequency of batch feeding mode was in average every two days (represented by ↑)(n=2)

However, when looking at the individual daily average in current density (Table 1), there seems to be clear decreasing trend for the anaerobic MFCs from the beginning of the swapping till day-43. For aerobic MFCs, the effect of nitrogen bubble seems evidenced within the first four days after gas swapping and the anaerobic effect slowly became reduced and stabilized at about 50 mA/ m^2. Further study would need to be carried out to understand this phenomenon.

The impact of the gas swapping before and after can be observed through the polarization and the power curves. Comparisons done on the OCV from the polarization curves between the aerobic and anaerobic MFCs before and after the gas swapping (Figure 4a), which was about 20 days apart and the control, shows that the aerobic MFCs possessed 2.3 fold higher OCV than before the gas swapping (150 mV, vs. Ag/ AgCl), and 1.2 fold higher OCV than both the anaerobic (before and after gas swapping) and the control MFCs (300 mV, vs. Ag/ AgCl)(Figure 4a). The OCV zone is known as the activation loss zone and refers to the electron transfers reaction at the electrode surface. The OCV is the highest voltage produced in an MFC, measured in the absence of current and take into consideration various potential losses as follows (Equation 3 and 4)[20, 21].

$$OCV = E_{cell} + IR_{int} \tag{3}$$

$$E_{cell} = E_{emf} - (\sum \eta_a + |\sum \eta_c| + IR_{\Omega}) \tag{4}$$

where the E_{cell} is the measured cell voltage, IR_{int} is the sum of all internal losses of the MFC, $\sum \eta_a$ and $|\sum \eta_c|$ represents the overpotentials of the anode and cathode respectively. The overpotential of the anode and cathode reflect the influence of slow kinetics of heterogenous electron transfer, which is the movement of electrons between a chemical species and a solid-state electrode, together with ohmic resistance and concentration

gradients [22]. E_{emf} is the cell electromotive force from the differece of cathode potential, E_{cat} to anode potential, E_{an} , and IR_{Ω} represents the sum of all ohmic losses.

Table 1. Daily average current calculated after gas swapping (± standard error of mean) (n=2)

Day	**Anaerobic MFCs bubbled with air (mA/ m^2)**	**Aerobic MFCs bubbled with nitrogen (mA/ m^2)**

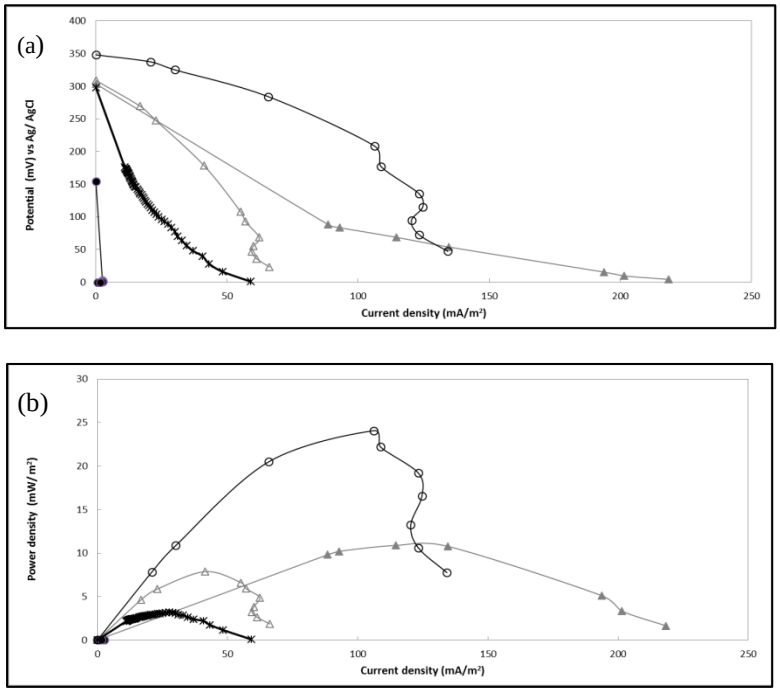

Figure 4. Polarization (a) and power density (b) curves recorded. Symbols in the figure represent anaerobic MFCs before (△) and after (△) gas switching and aerobic MFCs before (●) and after (○) gas switching as well as controls (x)(n=2).

Hence, apart from the low concentraiton of oxygen in air (ca. 21%), the reduced in OCV could be attributed to factors, such as potential generated by the exoelectrogen that formed the anodic biofilm, diffused oxygen into the anode compartment that interrupts the anodic biofilm and inefficient oxygen reduction reaction (ORR) occurs at the cathode site [23]. Ideally, an OCV of an air-cathode MFC should be around +621 mV (vs. Ag/AgCl) (+820 mV, vs. SHE) when pure oxygen is used. The 820 mV is based on the potential of redox couple between pure oxygen and water (½ O2/ H_2O, $2e^-$) [24]. However when air is used at the cathode side, OCV obtained are much lower than the ideal. In an MFC study done by Li et al. [25] using anaerobic wastewater as inoculum in a 75.6 mL dual chambered MFC with air bubbled in deionized catholyte, OCV was within the range of +419 to +489 mV (vs. Ag/ AgCl). In other study done by Khan et al. [26] using anaerobic digester from palm oil waste as inoculum in 20 mL single chamber air-cathode, found that the OCV also dependent on the catalyst applied onto the cathode, which could ranged from +385 to +626 mV (vs. Ag/ ACl). In this study, however, the high OCV recorded for the aerobic MFCs after the anolyte was continously bubbled with nitrogen for 11 days, might have increased the population of the exoelectrogens in the anode compartment, thus reduce the overpotential of the anode and the internal losses in the MFC.

From the MFC characterisations (Table 2), positive changed were seen on the aerobic MFCs where the P_{max} increased by more than 1,000- fold, increased in I_{max} by 42-fold, once the air in the anolyte was replaced with nitrogen. The change in the anaerobic MFCs after the nitrogen bubble replaced with air was small, about 1.4- fold of decreased in P_{max} along with a slight decreased in I_{max} by 2.8-fold. This increase in both I_{max} and P_{max} for the aerobic MFCs after the gas swapping shows that when MFCs were in the aerobic state, the exoelectrogens were already there, and these became active once the environment turned to anaerobic. Exoelectrogens are believed to be facultative bacteria that could survive in both conditions, aerobic and anaerobic [27]. In the air bubbling anode chamber, the small number of exoelectrogenic bacteria near the anode still survive because concentration of oxygen lessen with the increasing depth of biofilm; while the centre is already anaerobic [28]. Diffused oxygen is consumed in the outer layers of biofilm, providing favourable conditions for growth of facultative and strict anaerobes in the deep layers of the biofilm [29]. Similar to oxygen, substrate diffusion also decrease with the increase of biofilm mass depth from bulk fluid to the interior biofilm [30].

Table 2. Details obtained from MFC electrochemical characterizations

MFC	P_{max} **(mW/ m^2)**	I_{max} **(mA/ m^2)**	R_{int} **(kΩ)**
Anaerobic- before gas swap	10.88 ± 8.33	114.61 ± 49.97	30.55 ± 0.00
Anaerobic- after gas swap (aerobic condition)	7.87 ± 2.13	41.29 ± 5.35	226.40 ± 2.45
Aerobic- before gas swap	0.02 ± 0.02	2.50 ± 2.25	50.92 ± 0.00
Aerobic- after gas swap (anaerobic condition)	24.07 ± 4.06	106.22 ± 11.20	107.79 ± 3.89
Control	2.91 ± 2.52	31.09 ± 17.94	2.41 ± 0.00

Although both the P_{max} and the I_{max} showed expected results with the swapping of gasses, the R_{int} for aerobic MFCs showed an increment of 2.1-fold after the gas swapping. Comparison between the R_{int} of aerobic and anaerobic MFCs after the gas swapping however shows that the nitrogen replacing the air in aerobic MFCs, reduced its R_{int} lower than that of anaerobic MFCs. This effect can be seen clearly in the power curves where the curve of aerobic MFCs after the swapping was not symmetrical as the power curve of the anaerobic MFCs (Figure 4b). Based on Logan et al. [20], the symmetric nature of the power density curve obtained from the MFC characterisation analysis, which was also seen in this study represents a high R_{int} in an MFC mostly due to the ohmic resistance (R_{Ω}) at the point of P_{max}. R_{Ω} is derived from any material that creates resistance in the system, such as substrates, bacteria, gap between electrodes, loose contacts between components, and low ionic conductivity in the substrate. The continuous air bubbling in the anode chamber probably helped with the growth of aerobic microbes due to a direct reduction of

oxygen in the cell to increase biomass production. Although increase in biomass means increase in the NADH production, which leads to increase in electrons production, most of these electrons however will be consumed for biomass before able to generate electricity [3]. This could be the reason for the high R_{int} observed from aerobic MFCs before the gas swapping with very poor I_{max} and P_{max} [24].

Although this study was able to culture exoelectrogen from aerobic sludge originated from trickling filter, the electrochemical performance was way too low from results that have been reported in other publications, which is no less than 100 mW/m^2. According to Rahimnejad et al. and Haslett et al [31, 32], the performance of MFCs are commmonly associated with the following: 1) Substrates oxidation in the anode compartment, 2) Microorganism used for inoculum, 3) Mediator, 4) Permeabililty of cation exchange membrane (if any), 5) Electrode material and their surface area, 6) Electron acceptor at the cathode chamber, 7) Electron trasport pathway to anode surface, 8) Overpotential at the electrodes, 9) External load applied, 10) Distance between electrodes, 11) Mass transport, and 12) Operational temperature [31, 32]. For instance Feng et al. [33] analysed the effect of acid modified carbon fiber brush in 28 mL air-cathode MFC having 20% inoculum from domestic wastewater with external load of 1 kΩ, achieved P_{max} of 1,370 mW/ m^2. Watson and Logan [15] adapted similar MFC design with an increased of inoculum concentration upto 50%, different type of microorganism and used a non modified carbon fiber brush, had achieved 1.6 fold lower P_{max} than the later. Santoro et al. [34] on the other hand with completely different MFC design, used 4.6 fold more volume and non modified carbon cloth for anode and cathode, only achieved 268 mW/m^2 of P_{max}. To identify the reason of poor electrochemical performance in this study and to reduce such high R_{int}, the variables affecting the performance of MFCs listed above need to be analyzed and compare them with those having similar MFC designs.

Conclusion

The goal of this study was to analyse the effect of long-duration exposure towards oxygen in air through gas swapping on the electrochemical performance of enriched multi-cultured bacteria in air-cathode MFCs. The results showed that prolong exposure in 7.5 mg/L (ppm) of dissolved oxygen MFCs for a month on the enriched multi-cultured bacteria culture, makes the bacteria electrochemically inactive and produced low power and current generation. This however is not permanent since it could easily and quickly be rectified with improvements up to 100 % in P_{max} and I_{max} and a reduction in R_{int} of up to 53 %, when introduced into an anaerobic environment. Future studies could be carried out to gain a more in-depth understanding on electrochemical performance of MFCs before and after gas swapping, and also understanding of its effect on microbial community in the biofilm and half-wave redox potential ($E_{1/2}$). Further research can also be carried out on electrode polarization and the effect of different oxygen concentration ranges on MFC performance.

Abstract

Different compositions of Fe-doped tungsten trioxide thin films were synthesized on fluorine-doped tin oxide (FTO) glass substrate by sol-gel method, with ferrocene and tungstic acid as starting materials. The synthesized thin films was characterized with X-ray diffraction (XRD), scanning electron microscope (SEM), UV/Vis spectrophotometer and photoelectrochemical (PEC) analysis. The results show that the surface morphology of the thin films became rough and the grain size increased along with the concentration of Fe. Monoclinic structure of tungsten trioxide was obtained for all doped and undoped WO_3 and red-shift can be observed from UV-vis spectrum. Band gap reduced from 2.74 eV of undoped WO_3 thin films to 2.60 eV of 20 % Fe-doped WO_3 thin films. Photoactivities of all Fe-doped WO_3 are higher than undoped thin films. The highest photoactivities contributed by 5 % Fe-doped WO_3 films with photocurrent densities measured was 0.148 mA/cm^2, which is 3 times higher compared to undoped WO_3.

Keywords: Fe-doped WO_3, direct water splitting, photoelectrochemical cell, photoanode

Abstrak

Filem nipis tungsten trioksida terdop Fe berbagai komposisi telah disediakan di atas kaca substrat FTO (fluorine-doped tin oxide) dengan kaedah sol-gel, dengan menggunakan ferosin dan asid tingstik sebagai bahan pemula. Filem nipis yang terhasil kemudiannya dicirikan dengan pembelauan sinar X (XRD), mikroskopi elektron pengimbasan (SEM), UV/Vis spektrofotometer dan analisis fotoelektrokimia. Keputusan menunjukkan bahawa morfologi permukaan filem nipis menjadi kasar dan saiz butiran bertambah dengan penambahan kepekatan Fe. Tungsten trioksida yang berstruktur monoklinik telah dihasilkan dan anjakan merah telah diperhatikan di dalam spectrum UV-vis. Jurang tenaga telah berkurang dari 2.74 eV (WO_3 tulen) kepada 2.60 eV (20 % Fe-dop WO_3). Fotoaktiviti WO_3 terdop Fe adalah lebih tinggi berbanding WO_3 tulen. Fotoaktiviti yang tertinggi dicatatkan oleh filem 5 % WO_3 terdop Fe dengan ketumpatan fotoarus 0.148 mA/cm^2. Ia adalah 3 kali ganda lebih tinggi berbanding WO_3 tulen.

Introduction

Hydrogen is a potential energy replacing current used of fossil fuel because it is renewable and environmentally friendly energy where the product of its consumption is only water and heat compared to fossil fuel which emit

carbon based gases. Thus, hydrogen is a promising future energy [1, 2]. However, most of hydrogen production is via steam reforming which also consumes fossil fuels. In 1972, Fujishima and Honda first reported photocatalytic water splitting using semiconductor material TiO_2 in 1972 [3]. Since then, photocatalytic water splitting using semiconductor catalysts received much interest from scientific community due to its potential to convert sunlight energy into chemical energy (hydrogen gas). The process of water splitting involves the excitation of electrons from the valence band during illumination. The excited electrons then moved to conduction band leaving holes in valence band. The holes on the semiconductor catalyst surface will oxidize water to produce oxygen gas and hydrogen ions while the excited electrons in conduction band moves towards the cathode to reduce the hydrogen ions into hydrogen gas [4]. The energy in excess of the band gap energy will be dissipated as heat. In practice, a semiconductor with a band gap of 1.70 eV [5] which is greater than the energy required for water splitting reaction (1.23 eV), can utilize maximum absorption of energy for PEC reactions [6,7]. There are several important criteria to be considered in selecting the semiconductor catalyst such as (1) favorable band edge position, (2) stability in harsh environments, (3) small band gap, and (4) photocorrosion resistance. However semiconductor catalyst that satisfy all of these criterial has yet to be found. Therefore several modifications on this photocatalyst was introduced such as fabrication of nanostructures, layered/junction, noble metal loading, and doping (anion or cation) [8-10]. In this paper, doping are our main interests because it is an alternatives approach to decrease the bandgap of semiconductor materials [11].

Tungsten trioxide (WO_3) is a good candidate in electrochromic, photochromic and sensoring applications [12 -17] and is one of the semiconductors which have the potential in water splitting when induced by sunlight. However, WO_3 has a large band gap of 2.8 eV where it can only absorb < 450 nm wavelength in the solar spectrum. In order to reduce the band gap, WO_3 was synthesized via different methods [18-21]. The narrow band gap of 2.20 - 2.80 eV helps in absorption of ultraviolet region and blue region of visible light in solar spectrum [22-25]. Furthermore, WO_3 has been investigated with the aim of improving catalyst activity and stability in the irradiated aqueous environment [26-29]. Tungsten trioxide powders prepared from various W precursors has been studied by Bamwenda and Arakawa [30]. They found that the WO_3 using tungstic acid as precursor has the lowest light absorption in long wavelength region, but it has the highest crystallinity level and photoactivity. On the other hand, iron nitrate has been used as dopant for Fe-doped TiO_2 thin film [31] and Fe-doped WO_3 powder photocatalyst [32]. Band gap of Fe-doped TiO_2 reduced from 3.30 eV to 2.89 eV when 0.2 at. % of Fe is added. Photocurrent density of 0.2 at.% Fe-doped TiO_2 is much higher than undoped TiO_2. The 10 % Fe-doped WO_3 photocatalyst is able to evolve more hydrogen gas under laser illumination compared to undoped WO_3. Apart from the nitrate salt, ferrocene is another Fe source that has been studied in various applications. Saremi Yarahmadi et al. [33] found that the thin films prepared using ferrocene has increased the optical absorption due to higher packing density, and improved the measured photocurrent density.

In this paper, we aim to prepare Fe-doped WO_3 photoelectrodes with ferrocene as the Fe source and tungstic acid as the WO_3 precursor. Photoactivity performance of the thin film photoanode was studied as well. The film properties are discussed herein.

Materials and Methods

Fe-doped WO_3 was fabricated via sol-gel method on the fluorine-doped tin oxide (FTO) glass using starting material made of Tungstic acid, H_2WO_4 (Sigma-Aldrich), ammonia aqueous (Merck, 28-30%), ferrocene (Sigma-Aldrich) and PEG 300 (Merck). Other chemicals involved in this fabrication were of analytic purity grades and distilled de-ionized water. The starting material was prepared by adding the tungstic acid into aqueous ammonia which formed 0.4 M ammonium tungstate solution. The excess ammonia from the solution was eliminated by heating. The ferrocene and PEG 300 were then added into the ammonium tungstate solution which resulted in the desired ratio of W to Fe (W:Fe = x:1-x, where x = 1, 0.95, 0.9, 0.85 or 0.8). Before the fabrication process, the FTO glass was cleaned using ultrasonic cleaner by immersing the FTO glass into three different beakers containing acetone, ethanol, and iso-propanol for 5 minutes in each beaker sequentially. The cleaned FTO glass was then coated with ferrocene-ammonium tungstate solution by doctor blading method, which formed thin films on the FTO glass. The as-deposited thin films were calcined and sintered in furnace at 500°C for 30 minutes with constant heating rate of 5 $^{o}Cs^{-1}$.

The calcined thin films were characterized using X-ray diffraction measurement, XRD (Bruker D8 Advance diffractometer) with CuKα radiation, to determine the structure and crystalinity of thin films, scanning electron microscope, SEM (Zeiss AM10) to determine its morphology, grain size and thickness of the thin films, and UV-Vis spectrophotometer (PerkinElmer Lambda 35) to measure the absorption of the thin films. Meanwhile, the band gaps of the thin films were estimated from the UV-Vis absorption spectrum and by utilizing the Tauc formula. Photoelectrodes were prepared by attaching copper wire to the FTO glass as described by Minggu et al. [34]. The photoelectrochemical (PEC) tests of the photoelectrodes prepared was carried out in a conventional three electrodes system, which consists of working electrode (photoelectrode), counter electrode (platinum wire), and reference electrode (SCE) whereas, 0.5 M Na_2SO_4 was used as the electrolyte. Prior to PEC analysis, the electrolyte was purged with nitrogen gas for 30 minutes. The scan rate was set to be 0.01 Vs^{-1}. The photoelectrochemical (PEC) analyses were carried out by using Ametek Versastat 4 with 450W full arc Xenon lamp source.

Results and Discussion

SEM analysis

Figure 1 shows SEM micrographs of undoped WO_3 and Fe-doped WO_3 on FTO glass. The morphology of undoped WO_3 is different from the WO_3 thin film prepared by Yagi et al. [35] using similar method. In their study, tungstic acid was dissolved in ammonia aqueous and PEG was added but the film produced was covered with micro-scale plates. This morphological difference might be caused by the much higher molecular weight of PEG they used (PEG 20000 was used in their study). This plate-like feature can also be observed in WO_3 thin film produced from tungstic hexaethoxide/PEG annealed in 300°C [36]. The organic residue causes the degradation in porosity and finally it forms plate. Therefore, spherical surface feature observed in this paper suggested that the organic compounds used were successfully eliminated. Morphological differences among the doped WO_3 thin films can be noticed by comparing the micrographs in Figure 1.

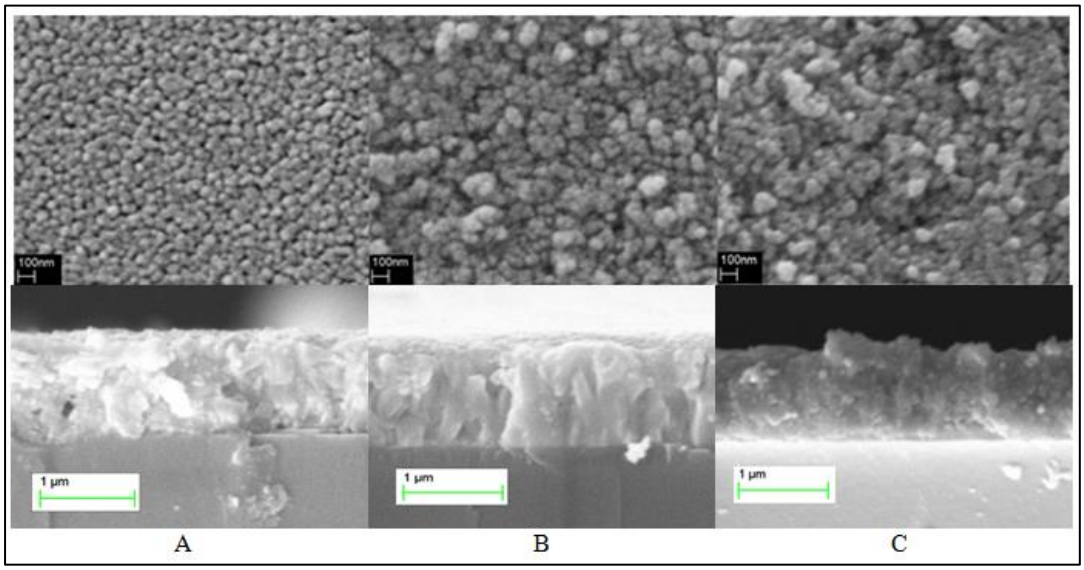

Figure 1. SEM image of (A) undoped, (B) 10% and (C) 20% Fe-doped WO_3 thin films

By comparing Fe-doped WO_3 with the undoped WO_3 thin films, it is noticed that surface of the Fe-doped WO_3 is rough. The presence of Fe would lead to agglomeration of the WO_3 particles. Therefore, the grain size of the Fe-doped WO_3 is increasing as the Fe content increases [37]. From cross section, the thickness of the films are approximately 1 µm. Taking account of the fluorine-tin oxide layer 900 nm, the actual thickness of undoped and Fe-doped WO_3 is around 100 nm.

XRD analysis

All thin films of different Fe concentration of Fe-doped WO_3 and undoped WO_3 thin films were subjected to X-ray diffraction measurement. The XRD pattern in Figure 2, which are in agreement with the Joint Committee on Powder Diffraction Standards (JCPDS) file no. 01-083-0950, displayed strongest peak at 24.4º, which corresponding to (2 0 0) plane of the annealed WO_3 thin films. This peak shows that the thin films were all of monoclinic, polycrystalline WO_3 structure. The XRD pattern of each thin films was coincident with undoped WO_3, which suggested well incorporation of Fe into WO_3 lattice. Furthermore, additional peaks that were not detected from the patterns shown, indicates that the crystalline structure of WO_3 thin films was not affected by Fe-doping with various concentration. Besides, the increment in intensity of the WO_3 peaks can also be observed. This suggested that the crystallinity of WO_3 is improved as the crystal defects disappear when Fe particle was added to the WO_3 crystal lattice [30]. The increased in crystallinity is due to reduce nucleation centre density which favors crystal grains growth [38]. High crystalline WO_3 was obtained for 20% Fe-doped WO_3 and this effect can also be observed on Fe-doped TiO_2 [31]. The main peak was shifted to lower lattice parameters due to the size of ionic radii of Fe^{2+} (0.064 nm) [39], which was larger than W^{6+} (0.060) [40]. The shifted peak also suggested that Fe^{2+} had successfully replaced some of the W^{6+} in bulk WO_3 lattice and thus, Fe-doped WO_3 was successfully synthesized.

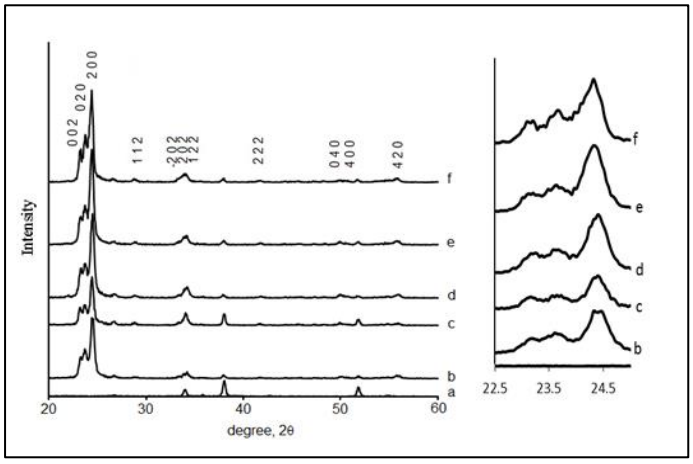

Figure 2. XRD pattern of (a) FTO, (b) undoped, (c) 5%, (d) 10%, (e) 15% and (f) 20% Fe-doped WO_3 thin films

The average crystallite size of each thin films was estimated using the Scherrer equation by referring to the XRD pattern. The crystallite size of undoped WO_3 was found to be 17 nm, estimated based on (200) peak, which is in agreement with previous study [34]. The crystallite size remains almost the same for all the doped thin films of 5 %, 10 %, 15 %, and 20 % Fe-doped WO_3. However, from the SEM measurement, the particle size is found to be larger, which is due to the agglomeration of the particle with only slight growth of crystal [41]. This indicates that the doping of Fe to WO_3 does not alter the crystallite size.

Optical charaterization

Figure 3 shows the UV-vis absorption spectra of the undoped and Fe-doped WO_3 thin films. From the Figure, it is observed that the spectrums are shifted to higher wavelength, which is also known as the red-shift in light absorption. The red shift shows that the band gap of Fe-doped WO_3 thin films was reduced compared to the undoped sample. To estimate the optical band gap, E_g of the thin films, equation (1) and (2) below were used [42]

$$T = e^{-\alpha d} \quad (1)$$

$$\alpha h\nu = B(h\nu - E_g)^n \quad (2)$$

From equation (1), α is the optical absorption coefficient, T is measured spectral transmittance, and d is thickness of the film (cm). Meanwhile from equation (2), B is a constant, n is the exponent where, n = 1/2, 3/2, 2, and 3 when the transition is direct allowed, direct forbidden, indirect allowed and indirect forbidden, respectively for crystalline semiconductors. The band gap of the thin films was estimated by plotting $(-InT)^{1/2}$ against energy (hν) for undoped and Fe-doped WO_3 thin films, assuming the materials are indirect semiconductors. The band gap of the undoped WO_3 is 2.74 eV and it is in agreement with previous studies [22-26]. Meanwhile, the band gap of the doped thin films was decreased to 2.60 eV as the concentration of Fe increased up to 20%. This band gap reduction was attributed to the doping of Fe into the WO_3 lattice, as shown in XRD pattern.

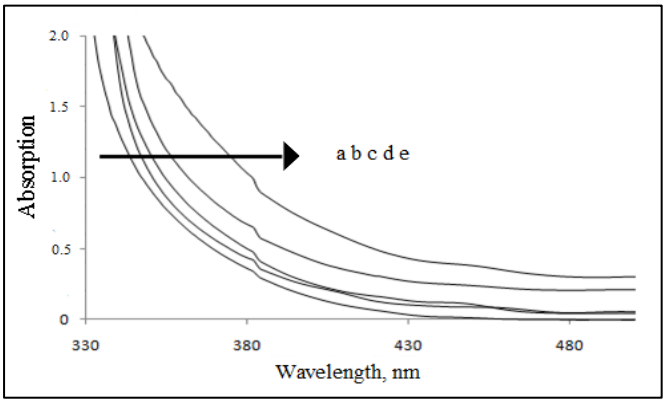

Figure 3. UV-Vis spectrum of (a) undoped, (b) 5%, (c) 10%, (d) 15% and (e) 20% Fe-doped WO_3 thin films

PEC analysis

The photocatalyst of undoped and Fe-doped WO_3 thin film performance was studied by measuring the photocurrent densities by applying potential (0 V to 1.5 V) in 0.5 M Na_2SO_4 as electrolyte, under full arc xenon lamp irradiation (100 $mWcm^{-2}$). The photocurrents are calculated by subtracting the measured currents under light irradiation with the respective dark currents. Figure 4 shows the photocurrent density of undoped and Fe-doped WO_3 thin films.

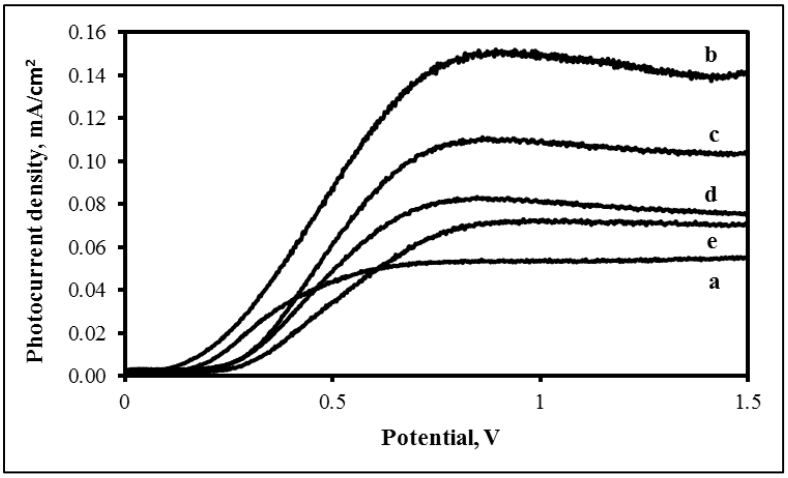

Figure 4. PEC analysis of (a) undoped, (b) 5%, (c) 10%, (d) 15% and (e) 20% Fe-doped WO_3 thin films

Figure 4 shows that the photocurrents produced by Fe-doped WO_3 photoelectrodes are higher compared to the undoped WO_3 under the same bias potential of 0.8 V. This indicates that under the same irradiation of 100 $mWcm^{-2}$ with the same bias potential of 0.8 V, the flow of photoexcited electrons of Fe-doped WO_3 electrode are more than the electron flow of the undoped WO_3 electrode via external circuit towards the cathode. As the electron leaving, the photoexcited holes remains at the surface of the photoelectrodes, which eventually drives the oxidation reaction. The high photoactivity with Fe-doped electrode was due to the Fe particles in WO_3 lattice act as electron acceptors, which helps in charge separation and thus, contributes to the improvement of photocurrent in Fe-doped WO_3. However, we observed that the photocurrent saturation potential of Fe-doped WO_3 were higher than the undoped WO_3. A high potential was needed to achieve the highest photocurrent production. This might be due to the rapid recombination rate in iron oxide as it has short carrier diffusion length of 2-4 nm [21].

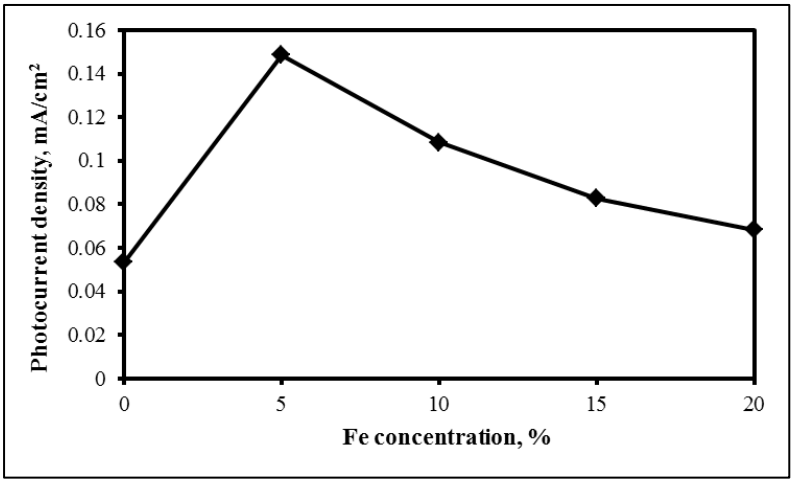

Figure 5. Photocurrent density versus Fe concentration of 0 %, 5 %, 10 %, 15 % and 20 % at 0.8 V vs SCE

The photogenerated charges (electron-holes) are easily separated by supplying bias to the PEC system and the reduction and oxidation reaction (process of splitting of water and generation of hydrogen) occurs at physically different electrode. Hence, surface recombination is not the main contribution of photogenerated charges recombination. However, the main contribution is from the recombination that occurs during the electron flows through photocatalyst films and the movement of holes towards the electrode-water interface which is known as volume recombination [43]. Comparing among the Fe-doped WO_3 thin films, the photocurrent density of the sample with 5% of Fe is the highest and it is decreasing with the increase in concentration of Fe in the thin films (Figure 5). This is because of the grain size of the sample increases as the concentration of Fe increases, causing the volume recombination of electron-hole pair increases. Therefore, in this study, 5% fe-doped WO_3 electrode exhibits the best water splitting capability than the others under xenon light irradiation.

Conclusion

In this paper, we have described the fabrication of WO_3 doped with different concentration of Fe and undoped WO_3 thin films via sol-gel method, using ferrocene and tungstic acid as starting materials. The XRD result of thin films with different Fe concentration has shown that all WO_3 thin films are in monoclinic form and also shows the Fe particles are successfully incorporated into WO_3 lattice. The Fe-doped WO_3 thin films show red-shift in UV-vis absorption spectra which corresponding to band gap reduction. Also, photoelectrohemical analysis shows that thin films of 5 % Fe-doped WO_3 produce the highest photocurrent under the full arc xenon lamp irradiation. The photocurrent of 5 % Fe-doped WO_3 is 3 times higher compared to undoped WO_3.

Abstract

This paper presented the transformation of a golf cart system powered lead acid battery into an environmental friendly hybrid vehicle. The design developed by using an advantage contributes by the uprising alternative power source candidate which is Proton Exchange Membrane Fuel Cell (PEMFC) and the maintenance free energy storage device, a supercapacitor (SC). The fuel cell (FC) stack was an in house manufactured with 450 W (36 V, 12.5 A) power, while the SC was from Maxwell Technologies (48 V, 165 F). This two power sources were controlled by the mechanical relay, meanwhile the reactant (hydrogen) are control by mass flow controller (MFC) both signaled by a National Instrument (NI) devices. The power management controller are programmed in the LabVIEW environment and then downloaded to the NI devices. The experimental result of the power trend was compared before and after the transformation with the same route to validate the effectiveness of the proposed power management strategy. The power management successfully controls the power sharing between power sources and satisfies the load transient. While the reactant control managed to vary the hydrogen mass flow rate feed according to the load demand in vehicular applications.

Keywords: proton exchange membrane fuel cell, supercapacitor, hybrid, power management strategy

Abstrak

Kertas kerja ini membentangkan tentang transformasi sistem kereta golf dikuasakan oleh bateri asid plumbum kepada kenderaan hibrid yang mesra alam. Reka bentuk ini dibangunkan dengan menggunakan kelebihan yang disumbangkan oleh sumber kuasa alternatif iaitu Sel Bahan Api Membran Penukaran Proton (PEMFC) bersama peranti penyimpanan tenaga tanpa penyelenggaraan, Superkapasitor (SC). Tindanan Sel Bahan Api (FC) telah dibina sendiri dengan kuasa 450 W (36 V, 12.5A) manakala SC adalah dari Teknologi Maxwell (48V, 165F). Kedua-dua sumber kuasa ini dikawal menggunakan geganti mekanikal, sementara itu bahan tindak balas (hidrogen) dikawal menggunakan meter pengawal aliran (MFC) yang kedua-dua diisyaratkan dengan menggunakan peranti Instrumen Nasional (NI). Pengawal pengurusan kuasa diprogramkan di dalam persekitaran LabVIEW dan kemudiannya dimuat turun kepada peranti NI. Hasil eksperimen trend kuasa telah dibandingkan sebelum dan selepas transformasi dengan laluan yang sama untuk mengesahkan keberkesanan strategi pengurusan tenaga yang dicadangkan. Pengurusan kuasa ini berjaya mengawal perkongsian kuasa di antara sumber kuasa dan memenuhi kehendak beban fana. Manakala kawalan bahan tindak balas berjaya mengurus kadar aliran hidrogen mengikut permintaan beban dalam aplikasi kenderaan.

Kata kunci: sel bahan api membran penukaran proton, superkapasitor, hibrid, strategi pengurusan kuasa

Introduction

Today, with increasing number of vehicles on the road that used internal combustion engine (ICE), concerns about the inability to supply sufficient fossil fuels is increasing because the failure to discover new oil sites and the impact of pollution produced are more serious [1]. As a consequence, much interest in new solutions to replace ICEs powered vehicles has increased steadily [2].

Nowadays the hybrid system technology becoming new phenomena in transportation area. These technologies are developed to help reduce the pollution made by ICEs vehicles. The interest in the hybrid vehicle has open new aspects to optimize its performance. The component of hybrid power sources are such as petrol, diesel engines, electric motor/generator units, batteries (BTs), SCs and FCs. The first commercial hybrid vehicle was introduced by Toyota in 1997 named Prius, and many more coming to the market from other vehicle manufactured throughout the world such as Honda, Hyundai, Lexus, BMW, Mercedes-Benz and many more. This type of vehicle used BT as the auxiliary source. However, BT has its own limitation. When the life time of BT depend on the reactant material and electrodes. Moreover, once energy stored is depleted, the BT needs to be recharged and if the performance degrades, the BT will be replaced with new ones. So, using BT produce wastage that involve time and cost.

Currently, the world is seeking for a more reliable power source where FC as an alternative energy is one of the best candidates. This technology offer variety of advantages over existing power sources and based on its specific characteristics where the reactants source is not limited, efficient energy, light in weight, fuel flexibility, and ability to provide power to the range of diverse applications [3-5]. FC technology generates power through an electrochemical reaction between hydrogen and oxygen. The process emitting zero pollutants gases, greenhouse gases, and hazardous waste make it an environmentally friendly, quiet and considered a green energy source of power generator [6, 7]. There are various types of FCs, one of it is Proton Exchange Membrane Fuel Cell (PEMFC). This type of FC is the most popular choice and highly sought after development of this technology in recent years. It is much more compatible towards vehicle, portable and stationary applications. This is evidenced by some of the world's great enterprises were using or developing this technologies such as Horizon Fuel Cell, Ballard Power Systems, Power Energy, Daimler-Chrysler, General Motors, Honda, Toyota and many more.

Many interest to build a FC car since it is a green car with zero pollutants as the result of an electrochemical process in FC that produces electric with only water and heat as byproduct compared to conventional ICE automobiles that emit carbon dioxide and volatile organic compounds that do not burn. However, FC is known to have a slow dynamic response to load changes that many have agreed FCs alone might not be sufficient to satisfy the load demands in vehicular applications [8-11]. The slow dynamic response of FC will lead to more serious problem like permanent cell damage, system stall, or reduced the cell lifetime. This is due to fast load demand that cause fuel starvation where it happen when a high voltage is drop in a short time. The hybridization of FC with energy storage devices that is SC or also known as Ultracapacitor (UC) are claim much helpful by the researchers where it minimize the size of this power generator and increase it efficiency by storing the regenerative braking energy from the vehicle [7, 11-19]. SCs are well known with it characteristic of fast charge and fast discharge without damaging its structure. SC also have more life cycle compare to BT, thus less wastage.

However, due to it fast discharge characteristic, this device need to combine with power generator (such as ICE or FC) before it can apply to vehicle. This combination (hybrid) SCs and FCs are being examine by several researchers with various control strategy to support FCs [9, 12, 16, 20, 21]. Eren et al. [21] studied fuzzy logic based supervisory controller of FC/UC hybrid for vehicular power system. Lin and Weng [16] studied the adaptive optimal-control method of a FC/UC hybrid power system. While Ates et al. [12] studied the energy management based on combined neural network-wavelet transform of FC/UC hybrid for vehicular application. Thounthong et al. studied the energy management based on differential flatness control of FC/SC hybrid sources [17] and a DC link voltage regulation FC/SCs hybrid power sources for vehicular application. Erdinc et al. [22] studied the wavelet-fuzzy logic based load sharing and control algorithm of FC/UC hybrid for vehicular application. In contrary to the

other positive results achieved in the literature of PEMFC with SC/UC vehicles hybridization, reference in [14, 19] claims that this combination are rarely used because of the high power train cost.

Another characteristic of FC are the current produced fluctuate due to the change in load and input reactants [23, 24]. Reviews from various studies indicate that the performance of PEMFC is very dependent on the conditions of operation, in which the voltage generation depending on the dependent variable to be controlled. Among the important factors for power generation from the FC is design of balance of plant (BOP). BOP works to supply the right amount of power to the right place and at the time required. BOP can improve the electrochemical reaction in PEMFC and ensure operational stability even in times of uncertainty interrupt its capability. Therefore, it will improve the performance and durability of PEMFC [25, 26]. The BOP often built in PEMFC based on humidity system, water management, operating temperature, pressure and the appropriate flow rate response [27-33]. Every parameter plays their own role where the design will determine the correct amount need to be supply function to result in better generation of electricity. Here, the focus is the reactant mass flow rates where the hydrogen amount to be supply are the biggest concern for power generation. The fuel management is design with the controller to prevent the occurrence of unsatisfactory fuel supply that will limit the ability of FC to deliver the power being request from load.

With nearby growing era of FCs in transportation sector, it is very important to understand this technology in its applications. In this paper, development, manufacturing and car assembly of the PEMFC as a power generator are done with hybridization with SC as the secondary power supply. To avoid the high cost and complex control system, golf cart are used as a prototype FC car using DC 3 kW electric motor. The power management of this hybrid FC car and reactant control system are done using LabVIEW program and applied using NI devices.

Materials and Methods

Fabrication of PEMFC stack

Two stacks with 40 cells each built consists of end plates, current collectors, bipolar plates, gas diffusion layer, membrane electrode assemblies (MEA), and sealants that are sandwiched together. Bipolar plates used instead of single plates in this stack to reduce the FC size. The flow fields are engraved using a computer numerical control (CNC) machine. The stacks built are connected in series to obtain higher voltage value. Flow field pattern and size of the bipolar plate (anode and cathode) are designed and produce an output power of 450 W at 36 VDC. The PEMFC stack is designed based on the FC open cathode system with air as cooling system. For the anode side, the flow shape build with the serpentine flow but for cathode, straight flow are engraved. The size of both plate are 30 cm length and 11 cm width, with the plate area 330 cm^2. The material of bipolar plate is a mixture of graphite and carbon materials.

The MEA as the heart of FC consists of three main components namely gas diffusion layer (GDL), membrane and catalyst layer. The performance of FC is much depends on the good electrode and electrolyte (MEA) composition and research to improve the performance of both materials are necessary for the successful manufacturing process. A fabrication, characterization and performance tests of nano catalyst platinum-ruthenium-nickel/carbon (Pt-Ru-Ni/C) done to improve the performance of MEA. Nano materials are potential for increasing performance of FC through the nano impact. Production of Pt-Ru-Ni/C catalyst in this research is expected to increase carbon monoxide (CO) tolerance caused by the oxidation of CO or low CO adsorption process. Developments are focus on the design and manipulation of materials structures at the atomic or molecular level to provide a more effective catalyst. This composite can be used to overcome problems such as high production costs, corrosion and CO poisoning of the electrode, thus can improve the durability, stability and performance of the FC. For electrode, the anode and cathode electrodes used carbon fiber paper as gas absorption distribution layer and catalyst platinum/carbon (Pt/C) as an electrochemical reaction layer. GDL are made from carbon paper, while for the membrane, Nafion^{TM} being used as a proton exchange membrane. Method of manufacturing GDL and catalyst layer are by spraying method. The main ingredient of catalyst is Pt/C with 0.3 mg cm^{-2}. The three components are pressed at 350°C for three minutes before merge to become MEA. The thickness of each MEA produced was around 0.23 mm. Figure 1 shows the PEMFC stack built.

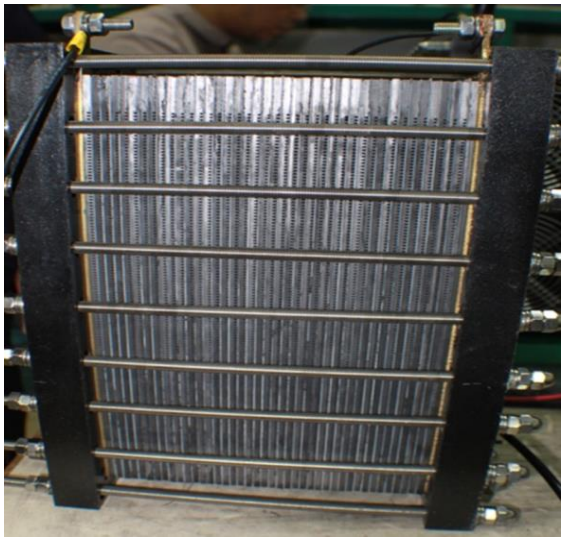

Figure 1. Fabrication of single stack open cathode PEMFC

Balance of plant (BOP)

The PEMFC performance relies mainly on the design and operation of a FC system that includes the BOP and power converters as well as their control systems. The complexity of the FC requires many studies on the design and operation of these units. This PEMFC system used pure hydrogen that stored in cylindrical pressurized tank with 7.2 m³ capacity flowed in FC stack with pressure control using a pressure regulator. The hydrogen flow are using continuous mode, but it supplied based on request load. The reactant control system build [34] are used to ensure the gases entering the stack is sufficient with the amount of power produced. Otherwise for oxygen in cathode sides, fans are used to blow source of oxygen from the air. Eight fans powered with 24 V, 0.5 A each is used and the fan speed applied at the maximum rate to ensure the air flow is sufficient for the reaction at the cathode as well as to cool the stack. The flow diagram of reactant controller is shown in Figure 2.

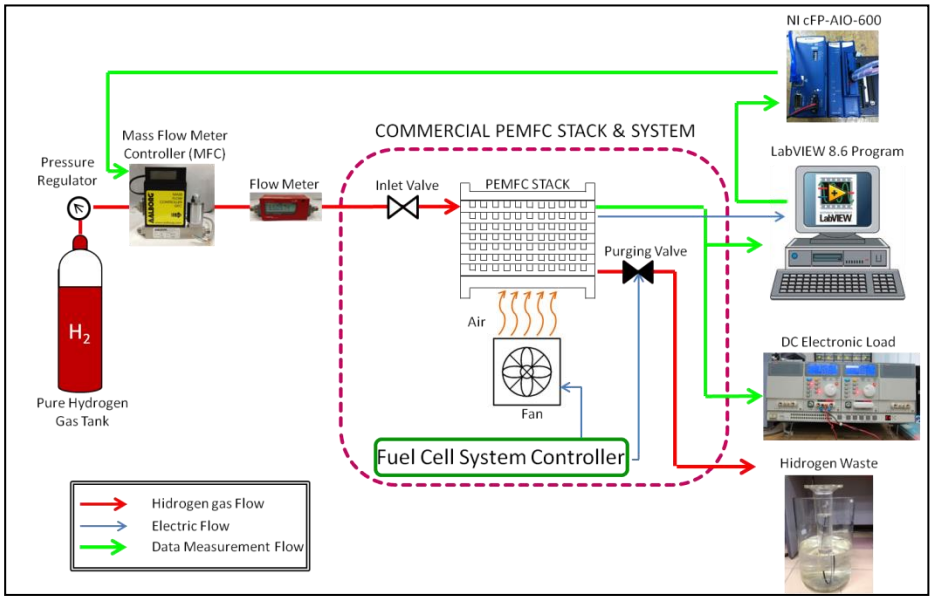

Figure 2. Flow diagram reactant controller of PEMFC stack

NI-cFP-AIO-600 is one of standard products from NI that provides precise data acquisition. It used in this experiment to measure and monitor the input voltage, current, power and to control the gas flow via the output current. It consists of four analog voltage or current input channels with 11 input ranges up to ±36 V or ±24 mA and four analog current output channels ranging from 0 to 20 or 4 to 20 mA without over-ranging. The NI module placed between FC system and a computer (LabVIEW) to convert the analog input to a digital output for the cFP measurements and controlling actions. Voltage ranges to maintain suitable flow rates was determined. This voltage measured and the signal logged using the NI analog input (NI-cFP-AIO-600 – voltage input-channel 1) and sent to LabVIEW controller program to be processed. The required flow rate will automatically choose using the PID program. The signal then sent back using the NI analog output current (NI-cFP-AIO-600 - current output-channel 3) to control the MFC valve flow rate. The program react are based on the PID changes that can produce an operating signal that manipulates the flow rate of the hydrogen reactant to maintain stack output voltage. The PID controller program developed as shown in the front panel on Figure 3 and the detail of the structure is shown in the block diagram in Figure 4.

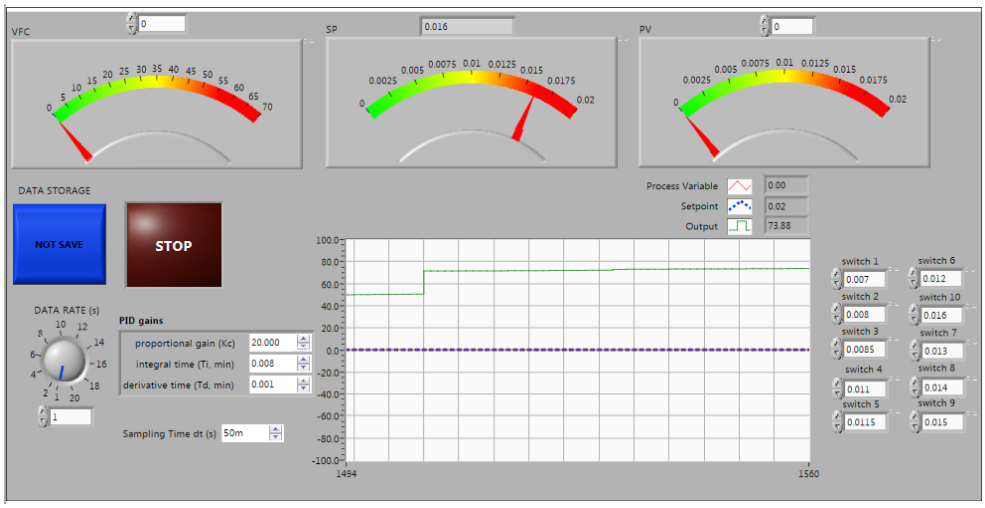

Figure 3. Front panel interface of PID control system for reactant control

Golf Cart specification after transformation

A golf cart serves as the vehicle prototype. Originally, the BTs used in the golf cart as the power generator, then it was replaced with FC and SC. The space required are to place the hydrogen storage tanks, FC stack, SC, and power management system. Figure 5 showed the modification done to the golf cart during this study. Power management system unit is designed for 3 kW power to control the golf cart motor. This unit are integrated with a FC system that control the amount of hydrogen into the FC stack conducted in accordance with the power requirements. The Global Positioning System (GPS) and collection or storage of data is designed and installed in this prototype car using seagull devices, NI devices and LabVIEW program.

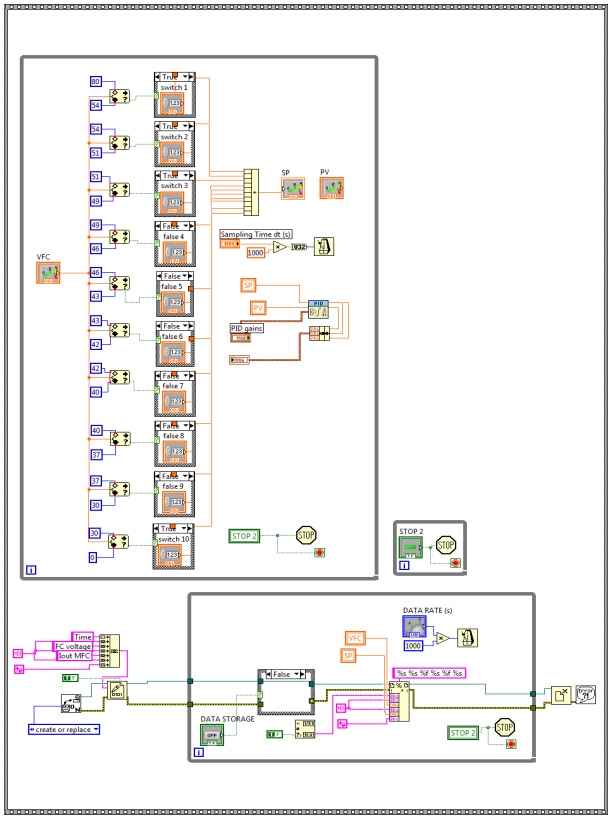

Figure 4. Block diagram interface of PID control system for reactant control

Figure 5. Prototype golf cart after modification

The SC model BMOD0165 from Maxwell Technologies used as the auxiliary power source in this hybrid system are with a rated voltage of 48 V and rated capacitance of 165 F. Its features are compact, rugged, fully enclosed splash proof design was the main points that make this SC the primary choice. The benefit of choosing SC rather than BTs was because it provide over 1,000,000 duty cycles which is a thousand times more than average BTs.

All components built are assembled and tested on a golf cart, and the system was constructed and equipped with manual and automatic hydrogen flow valve functions. The manual function was prepared as a safety precaution to avoid severe circumstances that could occur during testing, and also used as the start-up function for the electronic components in the cart. After all required electronic parts are functioning, the valve switch to automatic valve to control the hidrogen mass flow rate during speed changing or load demand, and changes in the stack voltage reading will vary the hydrogen flow rate according to the programmed control structure. The flow diagram for hydrogen is displayed in Figure 6.

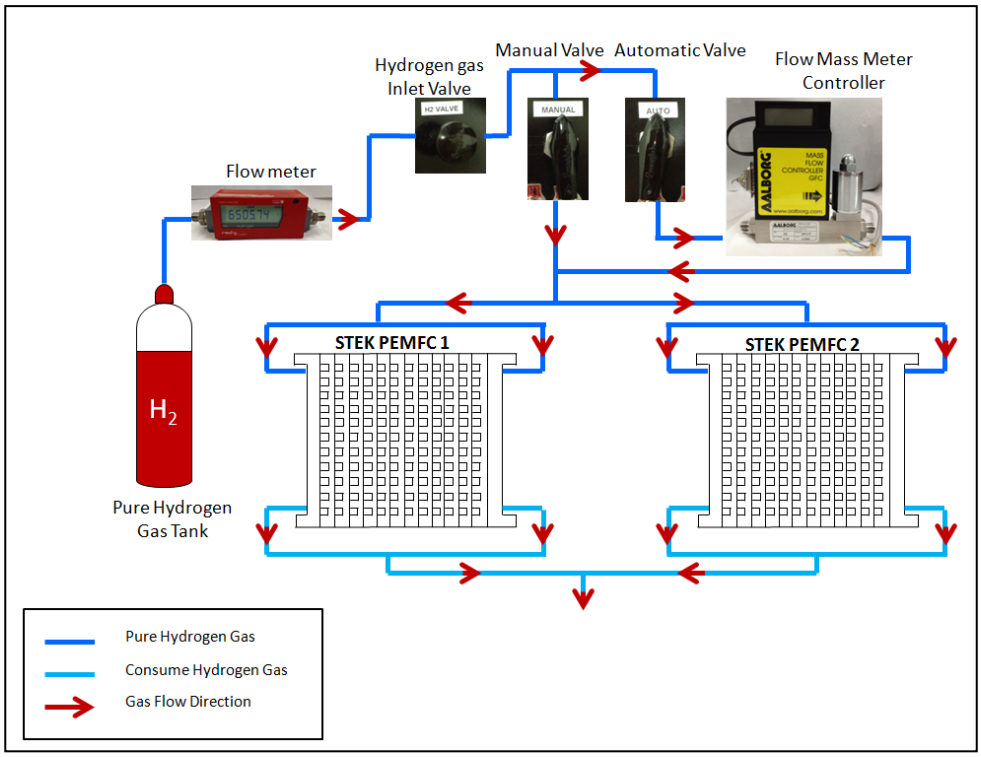

Figure 6. The flow diagram of hydrogen on a golf cart

Power management strategies of hybrid vehicle

The hybrid system combines the FC and the SC to run the golf cart. The FC in this system serves as the primary power source to satisfy the load and to charge the SC. In contrast, the SC acts as the auxiliary power source to supply any load amount that exceeds the capability of the FC. This power management system contains two components, one of which is the controller circuit unit and the other is the power controller device. These two components are related to one another through the controller circuit, which carries out the power management strategy programmed in the power controller device.

The focuses of this study are design and developed the controller circuit unit. This unit includes power relays, recovery diodes, and a DC/DC converter. This system uses the power relay as a switch to allow power flow for discharging or charging the SC. The power relay required a supply of 12 V voltage and 417 mA current to function.

The relay chosen was model G9EA1B from OMRON, which is capable of allowing a 100 A maximum switching current suitable for the golf cart system. The recovery diode is a 150UR series from International Rectifier and functions as a blocking device to ensure that the current flows only in one direction, as directed by the diode. The objective is to decide when to charge and when to discharge the SC as programmed in the controller. The DC/DC converter is a voltage stabilizer device. As the load demand increase, the FC output voltage will decrease. This phenomenon is well understood as a characteristic of FC technologies, but application devices will not tolerate this situation because they require a stable operating voltage within a certain tolerance. The golf cart must be supplied with 48 V, which is also the output voltage of DC/DC converter used in this system and the input voltage for converter are from FC.

The power management strategy is programmed in the LabVIEW software that will be integrated with the cFP device. In this application, extensive palette of functions and tools connected by strings are used to meet the strategy objective. The block diagram of the power management strategy are shown in Figure 7. The power management strategy used in the golf cart is based on voltage regulation, and the control strategy is described below:

1) If the load voltage is greater than 48 V and the SC voltage is greater than or equal to 48 V, the excess power from the FC will be supplied directly to the motor.
2) If the load voltage is greater than 48 V and the SC voltage is less than 48V, the excess FC power will charge the SC.
3) If the load voltage is less than 48 V, the SC will discharge to meet the load power demand.

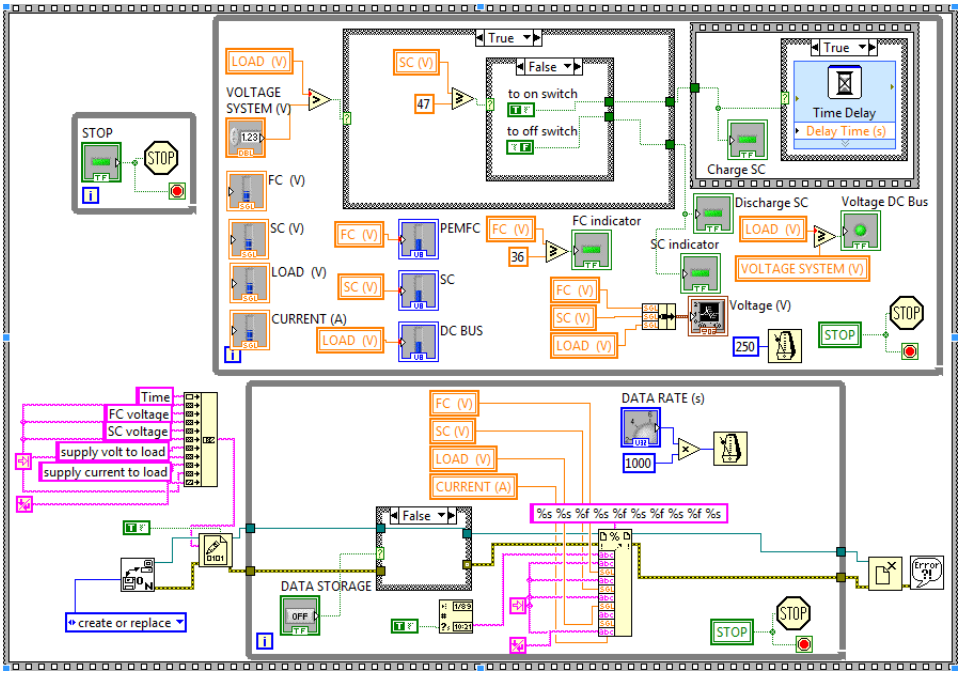

Figure 7. Block diagram of power management program

Results and Discussion

Performance test of the prototype FC hybrid cars done in and outside the laboratory. FC system performance testing in the laboratory will use the FC system performance test. For test outside the laboratory, prototype FC cars are designed and manufactured with equipment to be able to record and store the data needed for doing performance test.

Electric golf cart – before transformation

The performance test of the golf cart before transformation was done on a route around UKM in the Figure 8. The test was done to check the performance of the golf cart with BT system. The speed, current drawn from BT, voltage of the system and the resultant power of the golf cart are recorded during the route. This result (Figure 9) was a benchmark to compare with the new hybrid system proposed. The golf cart power requirement and the capability of golf cart are discovering during this test. The highest altitude the golf cart climb was around 110 m above sea level, the maximum speed of the golf cart can be move by this motor are around 20 km/h throughout the test. The highest current draws are 77.13 A during climbing up slopes. The voltage are fluctuates from 44 V to 54 V maximum due to discharge and charge of BTs during the course, but the average voltage of 48 V are required to run the golf car motor that being set by the motor controller. The power consumption extract from this test was not more than 4 kW.

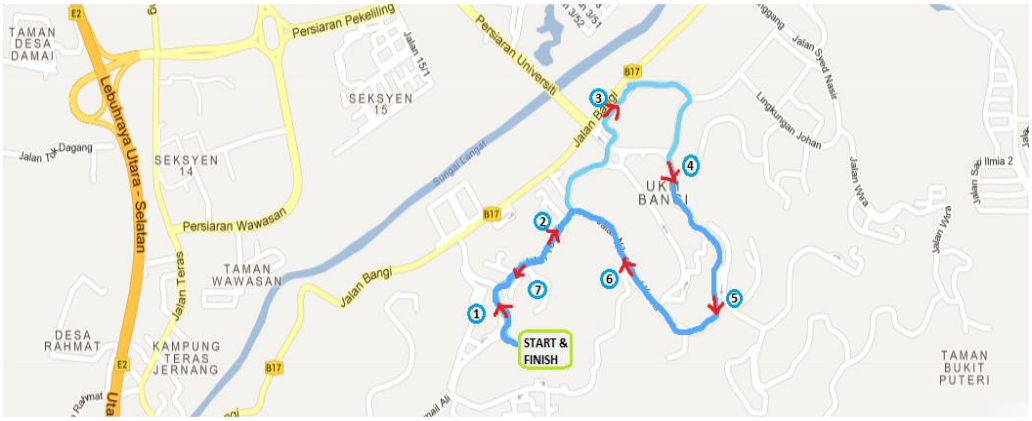

Figure 8. Route map of on road test

Hybrid golf cart – after transformation

In laboratory testing

The development of the reactant system was applied towards the stack as in Figure 2 and the system was tested in the laboratory using electronic load 3311D to change the value of the load variations. Test results are shown in the Figure 10 where the polarization curve plotted shows that the highest amount of power can be drawn from the FC stack is around 380 W. The flow rate of hydrogen change with the increasing load in Figure 11, this prove that controlling of hydrogen flow rate amount are essential in order to supply sufficient reactant amount to have a good power performance. In Figure 12, the graph show the voltage fluctuation as the test done resultant form the LabVIEW program measurement, the setpoint current programmed function well as the voltage change to satisfy the current output getting from the controller.

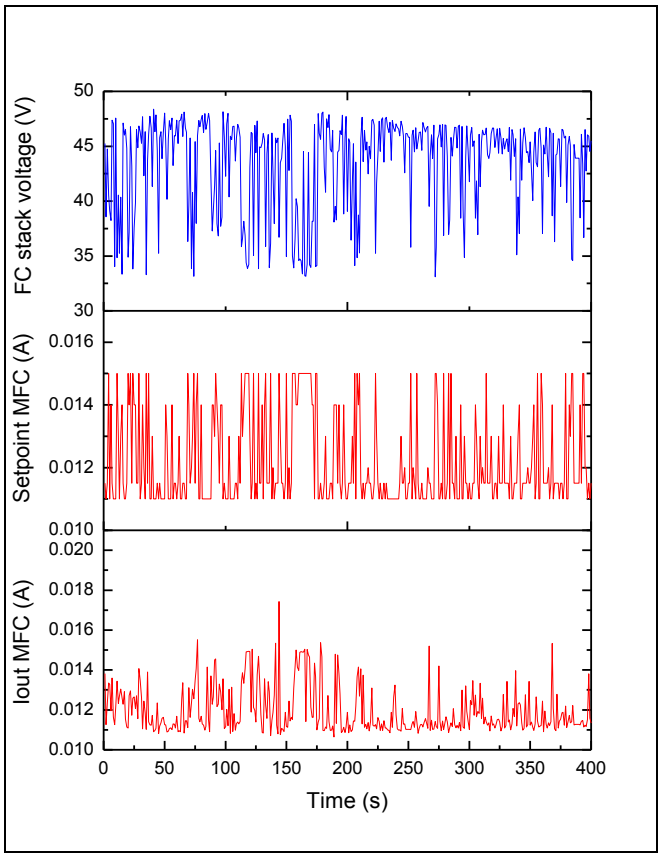

Figure 12. Measurement of voltage variation with change response of current setpoint andoutput form mass flow controller

On road testing

For on road tests, the reactant control system built was applied to the FC stack, and FC are as the primary source and the power management system used to control the FC stack and SC for golf cart to replace the six pieces of 8 V lead-acid BTs connected in series before. The on road tests after transformation are done with the same route before. The test objective was to make sure the hybrid system work and the power management system flow are working as they are programmed. This new power management system was working as programmed but due to existence of slope in the route, the SC discharge rapidly and worst depleted. The speeds are maintaining not more than 15 km/h so it can sustain throughout the test. The new hybrid golf car was worked successfully with the power sources helping each other to serve the load demand. Due to reduce in weight of golf cart as described in Table 1, the current consumption drawn also reduced. Their average currents are 17 A. The resultant powers are also decrease and there are not fluctuate so much as before. The results are shown as in Figure 13.

Table 1. Weight and volume comparison of the transformation of the FC/SC hybrid system with the BT system

		BT	**FC/SC hybrid**
BT (6 unit)	Weight (kg)	174	-
	Volume (m^3)	0.0809	-
FC (2 stack)	Weight (kg)	-	26
	Volume (m^3)	-	0.0441
SC	Weight (kg)	-	14.2
	Volume (m^3)	-	0.0152
Total	Weight (kg)	174	40.2
	Volume (m^3)	0.0809	0.0593

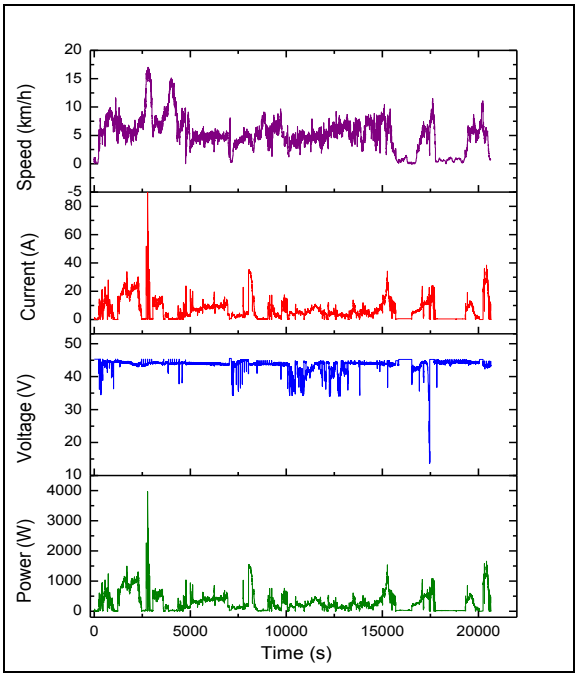

Figure 13. Measurement of speed, current, voltage and power response during on road testing using FC and SC as power generator

From Figure 14, the voltages of the golf cart power source are shown. The FC stacks are successfully maintaining the operating voltage with the help from DC/DC converter. As we can see from the second graph, SC voltage begin to depleted at 700 s. FC voltage from 700 s onward fluctuations rapidly as it try to charge the SC. The SC voltage begins to increase at 1500 s and the FC voltage fluctuation reduces a bit. The graph proves that the power management is working as the strategyprogram in LabVIEW. Moreover, the last graph shows the resultant voltage from FC and SC. A SC can advance the load, following the characteristics of the main sources by providing a stronger power response to the changes in system load. During essential steps in the load, the SC provides the energy balance needed during load transition periods. Adding energy storage (SC) to the power generator (FC) systems improves power quality and efficiency. The graphs clearly proof the function of having SC as the auxiliary power source.

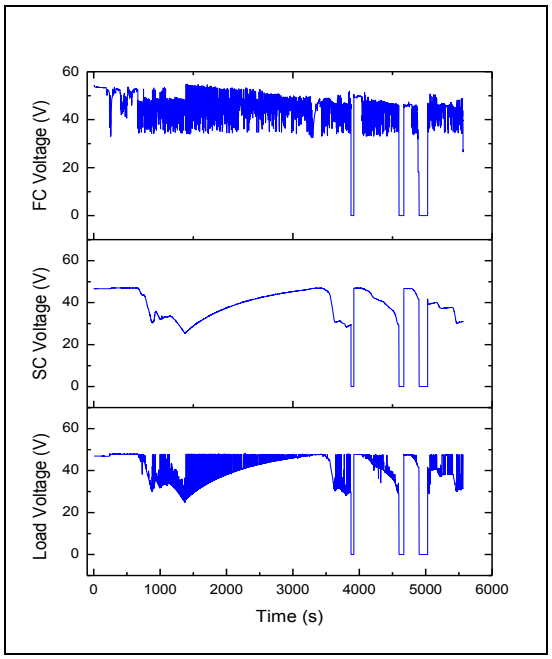

Figure 14. Measurement of FC, SC and load voltage

Conclusion

The transformation of the commercialize electric golf cart powered by the conventional lead acid BT done by replacing the power generator to more environment friendly power source that is PEMFC and SC. This hybrid vehicle development includes from the PEMFC manufacturing process, to the reactant controller of the FC stack, as well as the hybrid power management controller. The PEMFC build consist of two stacks connected in series to add up their equivalent voltage to be sufficient with the motor. The reactant controller is focus on the flow rate of the hydrogen supply to adjust with the requested load power in order to meet the reaction requirement and reduce from excess waste to atmosphere. The power management controller manages the power flow of the FC and SC to meet the load demand. The controller program work successfully and satisfy the required load and the use of PEMFC and SC in hybrid vehicle appear to be environmentally benign and sustainable option to overcome the environment pollution made by ICE vehicles.

Abstract

A potential dye sensitizer material for solar cell composed of a ruthenium-(4, 4'dimethyl-2, 2′-bipyridine)-isothiocyanato-tungsten-[bis-(phenyl-1, 2-ethilenodithiolenic)] bimetallic complex structure was successfully developed using Density Functional Theory (DFT) calculations. The optimal structure was realized by calculations using the generalized gradient approximation (GGA) framework in a double numeric plus polarization (DNP) basis set using the following three functional methods: Becke-Pardew (BP), Becke-Lee-Yang-Parr (BLYP) and Perdew-Burke-Ernzerhof (PBE). The PBE calculation gave a structure with bond lengths and angles that approximated the experimental data. The restricted-spin calculation of PBE found that BM has 339 molecular orbitals in which the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) are located at orbital numbers 312 and 313, respectively. The HOMO was delocalized over the $W(S_2C_2)$ ring, the ruthenium metal center and the thiocyanate bridging ligand. In contrast, the LUMO was found mainly at the bipyridyl ligand with a small contribution from the ruthenium metal center. Electron excitation from the HOMO → LUMO occurred at 2964 nm with an excitation energy of 0.42 eV, which is depicted by the charge transfer from one metal to another (intervalence charge transfer, IVCT) or as a manifestation of the NCS bridging ligand.

Keywords: density functional theory, bimetallic, thiocyanate, bridging ligand

Abstrak

Pembangunan struktur molekul kompleks dwilogam rutenium-(4,4'dimetil-2,2′-bipiridina)-isotiosianat-tungsten[bis-(fenil-1,2-etilenoditiolena)] (BM) telah dilakukan menggunakan kaedah pengkomputeran Teori Fungsi Ketumpatan (DFT) berdasarkan data yang diperoleh dari eksperimen. Untuk mendapatkan struktur yang optimum, pengiraan telah dilakukan dengan menggunakan pendekatan gradien menyeluruh (GGA) dengan set asas pengutuban tambahan gandaan angka (DNP) pada tiga kaedah fungsian; Becke-Pardew (BP), Becke-Lee-Yang-Parr (BLYP) dan Perdew–Burke–Ernzerhof (PBE). Pengiraan menggunakan fungsian PBE menghasilkan struktur dengan panjang dan sudut ikatan yang paling mendekati nilai eksperimen. Hasil pengiraan spin terhad dengan PBE mendapati bahawa kompleks BM memiliki 339 orbital molekul, di mana orbital molekul berisi tertinggi (HOMO) dan orbital molekul tak berisi terendah (LUMO) masing-masing berada pada orbital molekul 312 dan 313. Orbital HOMO kompleks dwilogam BM didapati dinyah setempat pada gelang $W(S_2C_2)$, logam pusat Ru serta ligan penghubung NCS. Sebaliknya, orbital LUMO sebahagian besarnya berada pada ligan bipiridil dengan sedikit sumbangan dari logam pusat Ru. Tenaga pengujaan elektron dari HOMO → LUMO wujud sebagai puncak penyerapan pada 2964 nm

dengan tenaga pengujaan 0.42 eV yang berpadanan dengan peralihan cas daripada logam kepada logam (peralihan cas antara velensi, IVCT) yang menyokong peranan NCS sebagai ligan titian.

Kata kunci: teori fungsi ketumpatan, kompleks dwilogam, thiosianat, ligan penghubung

Introduction

Computational chemistry investigations have been used in many fields, such as in solar cell material development [1], batteries [2], sensors [3] and thermoelectric materials [4]. The investigation can be used to identify the structure and properties of the crystal and bulk molecule as well as the thin film surface; it can also be used to model the chemical reactions on the structure surface for a more detailed understanding [5, 6]. The computational chemistry methods and the ability of each method to analyze the structure and predict the properties of molecules have been widely discussed, including the density functional theory (DFT) method. The DFT method has been used to successfully and accurately study various properties of molecules in the ground state, including transition metal complex molecules.

The ruthenium-(4,4'dimethyl-2,2′-bipyridine)-isothiocyanato-tungsten-[bis-(phenyl-1,2-ethilenodithiolenic)] bimetallic complex, abbreviated BM, was successfully synthesized, and its properties were investigated as a potential dye sensitizer molecule for TiO_2 [7, 8]. Because the acquisition of a suitable BM single crystal for X-ray diffraction studies has been unsuccessful, in this study, the theoretical development of the BM molecular structure was investigated. DFT analysis used for in-depth studies was performed on the optimized molecular structure. The development of the molecular structure using a theoretical calculation is similar in principal to the X-ray diffraction refinement of a single crystal molecule, which defines the most stable structure at the lowest energy or stationary state. The molecular orbital configuration and the optical properties of the lowest energy BM structure were reported for various parameter calculations.

Materials and Methods

Computational details

The molecular structure and density functional theory (DFT) calculations were performed using Microsoft visualizer and the $DMol^3$ module in Bolivia Materials Studio 7.0 software. All of the calculations were performed using the self-consistent field (SCF) method on a spin polarization system with the multiplicity set to auto for all of the core electron treatments. The SCF is a repetition of Hatree Fock calculations on all of the electrons until the effective electrostatic field does not further change or converges. For the DFT calculation, an approximation should be performed because an energy function is not precisely known. In this study, the generalized gradient approximation (GGA) was used with varying correlation functional methods, such as Pardew Backe (BP), Beckie (B), gradient-corrected correlation of Lee-Yang-Parr (LYP) and the exchange correlation Perdew-Burke-Ernzerhof (PBE) [9,10,11]. Double numerical plus polarization (DNP), which is comparable to 6-31G ** of the Gaussian basis set was used [12]. The entire geometry optimization process in this study was performed with fine quality. The geometry optimization was reiterated until the structure reached its lowest energy state.

Vibrational frequency analysis was used to confirm the energy state of the structure in every geometry optimization process. The absence of imaginary frequencies in the optimization results indicates that the structures are already in a stationary state [13]. In addition, the comparison results of vibration frequency analysis calculations with experimental FTIR analysis results were used as supplementary information for the confirmation of the molecular structure. The result was quality examined by comparing the bond lengths and angles of the calculation results with a similar molecular structure that has been reported. Analysis of the molecular orbital calculations and the optical properties was performed on the optimized structures of the molecule using the time dependence of the density functional theory (TD-DFT) method [14].

Results and Discussion

Molecular structure

The molecular structure of BM was constructed from two octahedral precursors. The molecular structures of the precursors were derived from X-ray single crystal data of similar molecules with ligand modification (Figure 1). Both of the precursor structures were optimized to the stationary state and placed adjacent to each other with the

thiocyanate ligands of ruthenium-[bis(4,4'-dimethyl-2,2′-bipyridyl)-isothiocyanato], abbreviated as M1 complex, and the carbonyl ligands of the tungsten dithiolene carbonyl complex $[W(S_2C_2Ph_2)_2(CO)_2]$ (M2) facing each other. The carbonyl ligands of complex M2 were then removed, and each S atom on the –NCS– ligands of complex M1 was connected to the tungsten atom of complex M2, forming double –NCS– bridging ligands. The bond lengths of W–S and S–Ru were arranged to approach normal lengths. The BM structure was then optimized several times until no imaginary frequencies were found using various parameters.

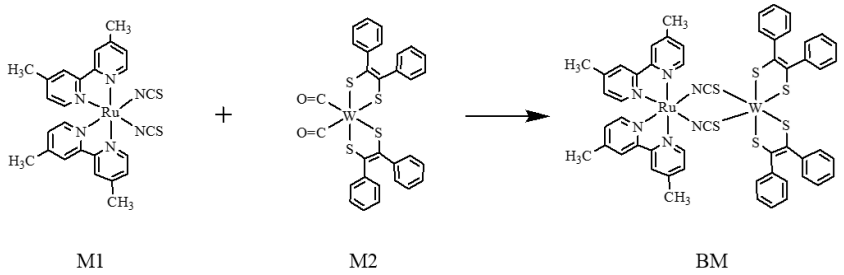

Figure 1. The reaction scheme for preparation of BM

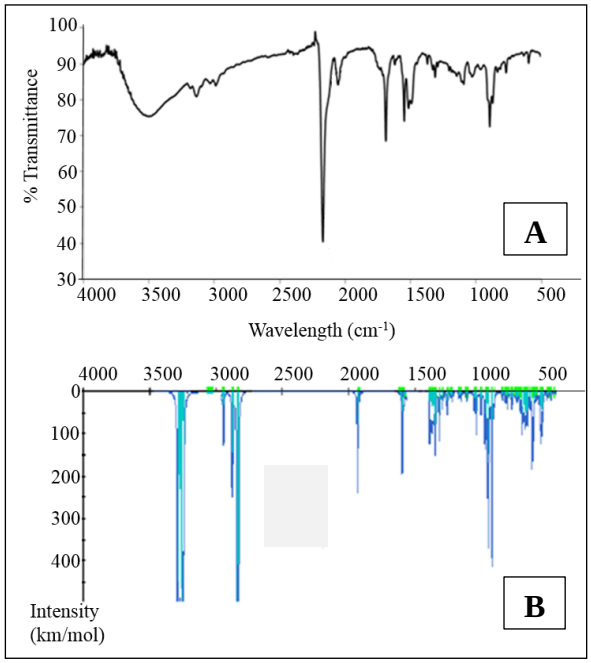
To ensure that the complex structure agreed with the experimental data, the frequency vibration spectra were compared with FTIR experimental data (Figure 2). Although the peaks of the harmonic vibration frequency spectra calculation and those from the FTIR experiment were not exactly in the same position, the important peaks, such as N–H, C–C aromatic, and –NCS, among others, were present in both of the spectra. Most of the peaks of the spectrum calculation appeared at a lower energy of approximately 200 cm^{-1} compared with the FTIR experimental peak frequencies. This result is because the environmental factors of the experiment cannot be perfectly modeled, such as the presence of residual solvent molecules that might affect the experimental spectrum. In this study, the optimization calculation was processed under vacuum conditions. The optimized structure of BM is similar to the bimetallic complex with the double thiocyanate ligand structure reported by Eran et al. [15]. Eran has reported a homobimetallic complex of Pt connected to double thiocyanate ligands in which each Pt was connected to –S and N– of the thiocyanate.



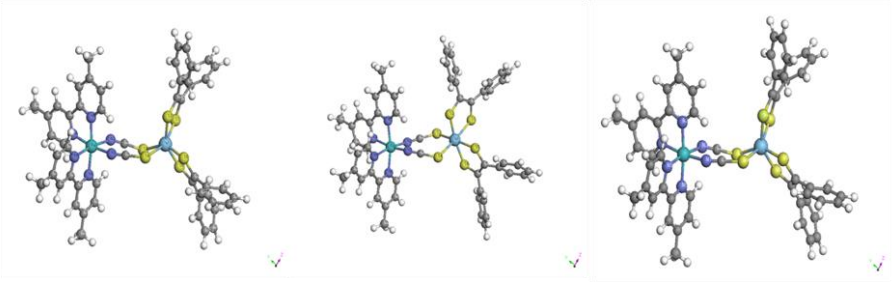


Figure 2. Comparison of FTIR experiment (A) and harmonic vibrational frequencies spectrum (B) of BM

The BM was optimized using three different GGA functionals, which produced a slightly different geometrical structure (Figure 3). The total energy consumption during the optimization process and the band gap energy produced are listed in Table 1. All of the optimized structures have two metals in the center of the perpendicular plane. All of the bipyridine and dithiolene ligands chelated each metal center, which distorted the octahedral structure. The optimized structure of BM using BLYP and PBE resulted in a similar structure in which the geometry of the W metal center was more closely distorted to trigonal prismatic. The W-S bond length of the BLYP calculation result was generally longer than that of the BP and PBE results. All of the bond length and angle calculation results are summarized in Table 2.

BLYP BP PBE

The bond angle of S–W–S in the chelating ligands from the BLYP calculation is 79.25º and 79.92º, and the bond angle of S–W–S on the NCS bridging ligands is 78.22° to 174.56°, while the bond angle of S–W–S between the 5-membered ring WS_2C_2 is 92.44º. Overall, the distorted octahedron of the tungsten metal is between 5.4° and 11.78°. The double bridging ligands –SCN– that connect the tungsten and ruthenium metals form an 8-membered W–$(SCN)_2$–Ru ring, with a W–S bond length of 2.388 Å and 2.432 Å. Umakoshi et al. have reported the molecule structure of the tungsten bimetallic complex, which is connected to a sulfur atom with a W–S bond length of 2.329 Å to 2.322 Å [16]. Meanwhile, the C–S bond length in the bridging ligand is 1.703 and 1.752 Å, which is shorter than the C–S bond length in the WS_2C_2 rings. However, both of the C–S bonds have lengths in normal range [17]. The two bipyridyl ligands and the two thiocyanate ligands that connect to the ruthenium metal center result in a distorted octahedral geometry with a distorted angle of 5.89 - 8.23°. Both of the bipyridyl ligands are perpendicular to the main plane of the eight-membered rings of W-$(SCN)_2$-Ru. The Ru–N bond length calculation result is between 2.123-2.138 Å, which is 3.8% longer than the experimental result reported [17]. Meanwhile, the N–Ru–N angle calculation result is between 77.30° and 81.19°.

The molecular structure from the PBE functional calculation results obtained was similar to the BLYP structure; however, the bond lengths and angles are more uniform and closer to the experimental results that have been reported. The W-S bond length is 2.399 - 2.414 Å, and the bond length of the W–S of bridging ligands is 2.602 and 2.617 Å. The S–W–S bond angles of PBE are similar to those obtained with the BLYP calculation results. The Ru–N bond lengths of PBE are shorter than the BLYP calculation result, with the average bond length of 2.09 Å, which is approximately 2% longer than the experimental results [18].

Moreover, the calculations with the BP functional method resulted in a structure with longer bond lengths than the PBE calculation results but slightly shorter than those in the BLYP. The distorted octahedral geometry of the BP calculation result is smallest compared with the BLYP and PBE calculation results. Overall, the PBE method result is considered closest to the experimental value compared with BLYP and BP. For further study, the characterization calculation is only performed with the PBE functional method.

Orbital molecular configuration

Most of the orbital configurations of the monometallic complex molecules have been well described, such as the complex of cis-bis(4,4'-dicarboxylate-2,2'-bipyridine)diisothiocyianate-ruthenium (II) (N3), whose HOMO comes from the Ru metal and isothiocyanate ligand, while its LUMO is mostly derived from bipyridine aromatic rings [19]. In contrast to monometallic complexes, the electronic distribution and molecular orbital configuration of bimetallic complexes have seldom been reported because there are many molecular orbitals involved in the bimetallic complex, causing the orbitals to become irregular and creating difficulty in defining the position of the HOMO and LUMO. Recently, the use of the DFT method, which can describe the molecular orbital configuration of a molecule composed of more than 500 atoms, has led to the successful description of the molecular orbital configuration of large complexes, which contributes to the knowledge of these compounds.

The molecular orbital configuration of the BM bimetallic complex with the PBE calculation results is displayed in Figure 4. There are 339 molecular orbitals involved in the BM bimetallic complex in which the HOMO and LUMO are located at the orbital numbers of 312 and 313, respectively. The HOMO of the BM bimetallic complex is located along the $W(S_2C_2)$ ring with a portion at the ruthenium metal and the –NCS– bridging ligands. The LUMO is located in the bipyridyl and ruthenium metal. The BM complex has overlap energies, as shown in Fig. 4, in which HOMO and HOMO-1, HOMO-2 and HOMO-3, HOMO-4 and HOMO-5, as well as LUMO and LUMO+1, among others, lie at the same energies. This phenomenon always occurs at the *C1* molecular symmetry due to the repetitive unit and dimeric nature of the complex [20]. The molecular orbital of LUMO+1 up to LUMO+4 also fully lies in the bipyridine ligands and the ruthenium metal center, while all of LUMO+5 and LUMO+6 lies at the tungsten metal and the SCN bridging ligands. Meanwhile, HOMO-1 to HOMO+4 are primarily spread over the tungsten metal, along with the dithiolene ligand with some at ruthenium and the NCS bridging ligands, while HOMO-5 and HOMO-6 lie along the two metal centers and the bridging ligands.

The LUMO to LUMO+2 band gap energy is smaller than that of HOMO to HOMO-2, indicating that it is easier to reduce than to oxidize the BM complex. Furthermore, oxidation occurs more easily on tungsten metal because the HOMO and HOMO-1 are mostly lying at the tungsten and the dithiolene ligands. Reduction occurs more easily at bipyridine and the ruthenium metal. This result is compatible with the cyclic voltammetry analysis results that have been previously reported [7]. The HOMO-LUMO band gap energy calculation using PBE (0.383 eV) was found as the smallest compared with the band gap energy from the BLYP (0.402 eV) and BP (1.339 eV) methods.

Optical properties

The optical properties of the bimetallic complex were studied from the TD-DFT calculation using the PBE functional of the GGA method. Using this technique, the optical properties, which are difficult to identify experimentally, could be easily solved. Table 3 summarizes the 12 lowest singlet and triplet excitations under vacuum. The lowest excitation energy of the singlet state is the excitation of an electron from the HOMO to the LUMO, which lies at the 312 $\rightarrow$ 313 molecular orbital. This excitation appears as an absorption peak at 2964 nm with an energy of 0.42 eV, which is absorption of ^{1}MMCT. This absorption is wider than that of the two constituent complexes. The highest oscillator strength is the excitation of the 310 $\rightarrow$ 314 orbitals (HOMO-3 $\rightarrow$ LUMO), which is the excitation of ^{1}MLCT at an absorption wavelength of 847 nm with a 1.46 eV excitation energy. While at the triplet state (^{3}MMCT), the electron excitation of HOMO $\rightarrow$ LUMO occurs at a lower energy wavelength, with an energy of 0.39 eV. Table 3 shows that the twelfth position of excitation of the lowest singlet and triplet in the bimetallic complex molecular excitation is derived from metal to metal and metal to ligand. The calculations results show that the BM absorbs light energy up to the near IR region. These results also agree with the experimental results in which the absorption of light of the bimetallic complex BM was higher than the monometallic complexes (M1 & M2) and N3 commercial sensitizer [7].

Conclusion

The geometrical structure of the BM bimetallic complex was successfully modeled using the DFT calculation technique with the DMol^3 Material Studio software package. This technique can be used to build the molecular structure, although it was unsuccessful at growing a quality crystal for X-ray single crystal analysis. The bond lengths and angles of the calculation results using the PBE functional of the GGA method had the most similar appearance to the experimental data. From the calculation result, 339 molecular orbitals were involved in the complex in which the HOMO and LUMO orbitals were located at orbital numbers 312 and 313, respectively. The band gap energy between the HOMO and LUMO was 0.383 eV. The HOMO of the complex was mostly derived from the W(S_2C_2) rings with a portion from the Ru metal and the NCS bridging ligands. The LUMO was primarily derived from the bipyridyl ligands and the Ru metal. The optical properties of the complex analysis from the TD-DFT calculation shows that the electronic absorption of the complex can reach up to 2964 nm and is wider compared with the absorption area of the monometallic complex starting materials, which is 902 nm for *cis*-$W(S_2C_2Ph_2)_2(CO)_2$ (M2) and 1652 nm for *cis*-[$Ru(dmbpy)_2NCS_2$] (M1).

Abstract

A proton exchange membrane (PEM) fuel cells (FCs) with ultracapacitor (UC) and battery (BT) hybrid system has fast transient response compare to stand alone FCs. This hybrid system is promising candidates for environmentally friendly alternative energy sources. An energy management system design and control strategy was introduced in this study. The energy management strategy FC/UC/BT hybrid system model has been developed and the control strategy was programmed in the LabVIEW™ environment and implemented using National Instrument (NI) devices. The energy management strategy is able to manage the energy flow between the main power source (FCs) and auxiliary sources (UC and BT). To control the hybrid system and achieved proper performance, a controller circuit was developed with the three energy sources aligned in parallel to deliver the requested power. The developed model demonstrates the proportion power from the FC, UC and BT under various load demand. Experimental results demonstrate that FC/UC/BT hybrid system operated automatically with the varying load condition. The experimental results are presented; showing that the proposed strategy utilized the characteristic of both energy storage devices thus satisfies the load requirement.

Keywords: proton exchange membrane fuel cell, ultracapacitor, battery, hybrid energy system, energy management strategy

Abstrak

Sistem hibrid sel bahan api (FC) membran penukaran proton (PEM) dengan ultrakapasitor (UC) dan bateri (BT) mempunyai tindak balas yang lebih cepat berbanding FC sahaja. Sistem hibrid adalah salah satu sumber tenaga alternatif mesra alam yang amat berpotensi. Satu reka bentuk sistem pengurusan tenaga dan strategi kawalan telah diperkenalkan dalam kajian ini. Model strategi pengurusan tenaga sistem hibrid FC/UC/BT telah dibangunkan dan strategi kawalan telah diprogramkan dalam perisian LabVIEW™ dan dilaksanakan dengan menggunakan peranti instrument Nasional (NI). Strategi pengurusan tenaga ini mampu untuk menguruskan aliran tenaga di antara sumber kuasa utama (FC) dan sumber kuasa tambahan lain (UC dan BT). Untuk mengawal sistem hibrid dan mencapai prestasi yang sewajarnya, litar pengawal telah dibangunkan dengan tiga sumber tenaga sejajar selari untuk menyediakan permintaan kuasa. Model yang dibangunkan menunjukkan keseimbangan jumlah kuasa daripada FC, UC dan BT di bawah pelbagai permintaan beban. Keputusan eksperimen menunjukkan bahawa sistem hibrid FC/UC/BT beroperasi secara automatik dengan keadaan beban yang berbeza-beza. Keputusan eksperimen dibentangkan,

menunjukkan bahawa strategi yang dicadangkan memanfaatkan ciri kedua-dua sumber kuasa tambahan dengan itu memenuhi keperluan beban.

Kata kunci: Sel bahan api membran penukaran proton, ultrakapasitor, bateri, sistem tenaga hibrid, strategi pengurusan tenaga

Introduction

Research in the field of alternative/renewable energy sources increasingly become the focus of many researchers, in an attempt to find a novel and environmentally friendly energy source that does not rely on fossil fuels, to replace internal combustion engines for use in vehicles. This research, besides ensuring energy supplies for the future, it may also reduce the pollution caused by fossil fuels. As an alternative to the internal combustion engine, fuel cell technology has advantages in many aspects that make it the preferred choice of researchers [1-5]. PEMFC is one that has been applied widely, from a stand-alone system and a hybrid system, especially in vehicle applications, power units, and electronic devices mobile. A stand-alone PEMFC system unfortunately cannot satisfy the sudden load variation in vehicles due to its slow dynamic response. The voltage decreases drastically and this situation evidently harmful to the PEMFC [6]. Most electronic devices and vehicles require a stabilized power source and fast transient response. Combining a PEMFC with an auxiliary power source would improve the operational efficiency and dynamic response of the system and extend the PEMFC lifetime. The auxiliary energy source usually uses an energy storage device that can store the excess energy from the PEMFC (charge) and support the load demand when needed (discharge). This system includes power electronics and a controller for the energy management system. The concept of hybrid technology was widely embraced for the conventional internal combustion engine (ICE) to minimize the peak power possible for acceleration, allow for optimal operational efficiency [7], recapture kinetic energy when braking (regenerative braking), and, more importantly, conserve fuel. In the literature [8-11], the preferred energy storage devices for PEMFCs are BTs and UCs because they have their own unique characteristics. BTs can charge rapidly and have excellent energy density [12] and a higher specific energy than UCs, thus supplying extra power for a longer period of time. And the key advantage of UCs is their ability to charge and discharge for almost an unlimited number of cycles, have relatively high power densities and long lifetimes, are cheaper and environmentally safe, can be operated at high or low temperatures without maintenance, and can deliver high power/currents in a short time without incurring structural damage [12].

The energy management strategy and controller are important factors in hybridizing PEMFCs and energy storage devices. In the past, researchers extensively studied hybrid system technologies using various control strategies to manage the energy distribution between the FC and auxiliary energy source. The strategy for each system, which can affect the system performance, was developed based on a certain objective (for example, the fuel consumption) within the constraints of the device used (BT state of charge limits, power limits, etc.) [13]. Hybrid systems capture the best features of each energy resource and can provide stable and quality electricity.

Materials and Methods

Basically, in active hybrid, several configurations can be used to achieve power sharing in PEMFC hybrid systems. Uzunoglu and Alam developed the simplest parallel operating structure for vehicle applications, which was direct integration by Honda [14]. The auxiliary power source is directly connected in line between the FC and the load as shown in Figure 1. This configuration is quite attractive because it does not require a high-power DC/DC converter, and thus, the complexity, cost, weight, and volume of the system are significantly reduced. Therefore, we modified the direct integration configuration to include three energy sources.

After choosing an appropriate system configuration, the components should be selected carefully. Our objective was to design a low-cost system with a simple configuration that did not involve a complex mathematical algorithm and that had an easy-to-follow circuit arrangement. The system uses an active hybrid with one buck DC/DC converter directly integrated into the system. The power demand of the electronic load is satisfied by the combination of the FC, UC and BT. The resultant load current and output power can be expressed in equation 1 and 2 as given below:

$$I_L = I_{FC} + I_{UC} + I_{BT} \quad (1)$$

$$P_L = V_L I_L \quad (2)$$

where I_L is load current, I_{FC} is FC current, I_{UC} is UC current and I_{BT} is BT current. While P_L is load power and V_L is load voltage respectively.

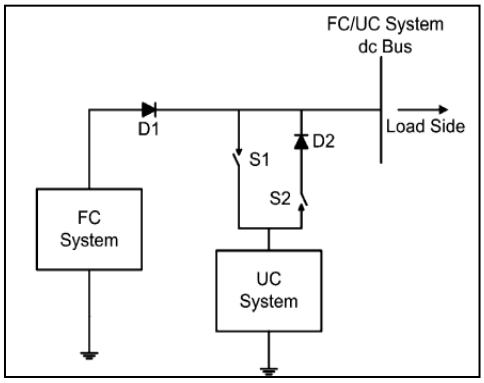

Figure 1. PEMFC/UC hybrid power system [14]

Energy management system controller

National Instruments Compact Field Point (cFP) is the energy management system controller. The power control is based on the output voltage from each energy source and the resulting load voltage. The strategy is programmed using the LabVIEW™ software and then implemented using the cFP devices combined with the controller circuit. The input and output modules used in this work were cFP-RLY-425 (relay module) and cFP-AI-102 (analog input module for the voltage). This relay module was used to control the power of the mechanical relay in the controller circuit. Approximately 5 W were required to turn on the mechanical relay in the controller circuit with a rated voltage of 12 V and a rated current of 417 mA. The cFP-AI-102 module on the other hand acts as a voltage indicator to the controller program in LabVIEW™. The PEMFC, BT, UC, and load voltages and currents were also measured using this device.

Controller circuit

The controller circuit (Figure 2) is the electrical board that links the energy sources, controller device, and electronic devices to the load. To give the specific load requirements for this study, the DC electronic load is employed. The controller circuit consists of four mechanical relays, three diodes, four DC buses, and a 12 V DC/DC converter. The mechanical relay serves as the switch to allow power to flow from the UC and/or BT to support the FC or to charge and discharge the UC and BT. The diode acts as a blocking device to prevent the power from flowing in the wrong direction. The voltage drop from the diode is only 0.7 V, which is negligible. Moreover, the DC bus is a connecting bar where all the power sources connect to the DC/DC converter for ease of plugging into and out of the power source. The DC/DC converter is the voltage regulator that maintains the voltage output from the DC bus at 12 V. This controller circuit manages the power transfer between these three power sources.

Energy storage device

UC and BT energy storage devices are used in the proposed hybrid system. These two energy sources are combined with a PEMFC to be in line with the power generator unit. In this study, we use 350 F, 2.5 V Boostcap UCs from Maxwell Technologies. For the experiment, a nominal voltage of 12 V is required; therefore, six single 350 F, 2.5 V Boostcap UCs are connected in series. The equivalent series capacitance is 58.333 F. As the UCs discharge, their voltage drops. To manage the UC charging, the voltage limits for the controller circuit program were set to 12 V, as suggested by the manufacturer.

A 12 V, 5A H nanogel BT (model YTZ5S-BS, Koyoko) are used for the second energy storage device. It is a plug-and-play product, meaning no acid or BT water needs to be added. The manufacturer suggests that the BT voltage remain at 12.5V or higher to maintain its excellent mode operation. The charging settings are 13 V – 15 V and 0.8 A - 1.2 A. In this work, the BT is charged by the power output from the DC/DC converter, which is limited to a maximum of 12 V.

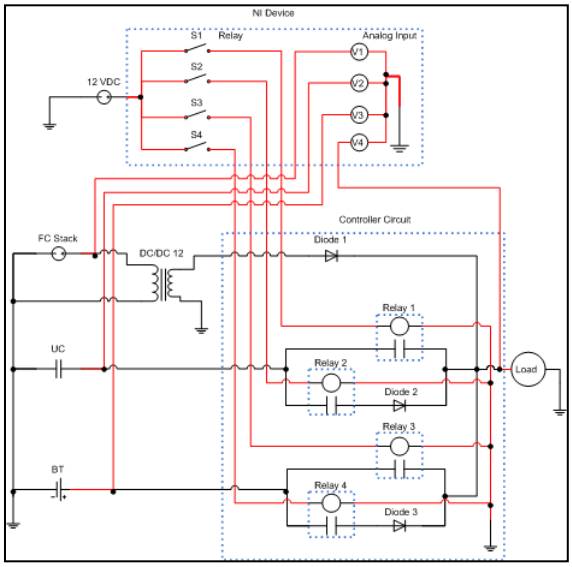

Figure 2. Controller's electrical circuit of the energy management system

PEMFC stack

The advantages of using PEMFC are the simplicity, high efficiency, lightweight design, smaller size, ease of integration and use, few peripherals, and good reliability. In this work, a model H-100 PEMFC manufactured by Horizon Technology is used. This PEMFC is an open-cathode FC with 24 cells stacked together. The nominal voltage capacity of the PEMFC stack is 14.4 V at a current of approximately 7.2 A and typically capable of producing 100 W at a rated power. The stack efficiency at 14.4 V is 40%, as stated in the manufacturer's manual.

Energy management strategy

Currently, energy management is an absolute necessity. FCs sometimes supplies more energy than necessary, and the excess energy should be used to charge the auxiliary energy source. Occasionally, the FC does not supply enough energy. Then, the auxiliary energy source is partially depleted, but the power demand is high, making it necessary to satisfy the load demand rather than charge the auxiliary energy source. The energy management strategy proposed in this paper is described below and was based on voltage regulation:

a) The system measures the load voltage. If the load voltage is greater than 12 V, then the system measures the UC voltage to determine if it is also greater than 12 V. The system charges the UC if the voltage is below 12 V. If the UC voltage is 12 V or higher, the system checks the BT voltage and charges the BT if its voltage is below 12 V. If all voltages are at least 12 V, the excess energy is delivered to the load only.
b) If the measured load voltage is less than 10 V, both the UC and BT switches are opened to supply the needed energy. Otherwise, if the load voltage is between 10 V and 12 V, only the UC switch is opened because the UC can charge and discharge quickly.

Test bench

The test bench setup as in Figure 3 consists of the three energy sources (PEMFC, UC and BT), controller device, and circuit described previously. The controller device requires a computer to monitor the performance of the hybrid system and the DC electronic load, which is the load demand. The electronic load was programmed to act as the current load to replicate the current required on most application devices. The load profile used in this study is based on one from the literature [15] to prove that this configuration and energy management strategy can satisfy the load profile.

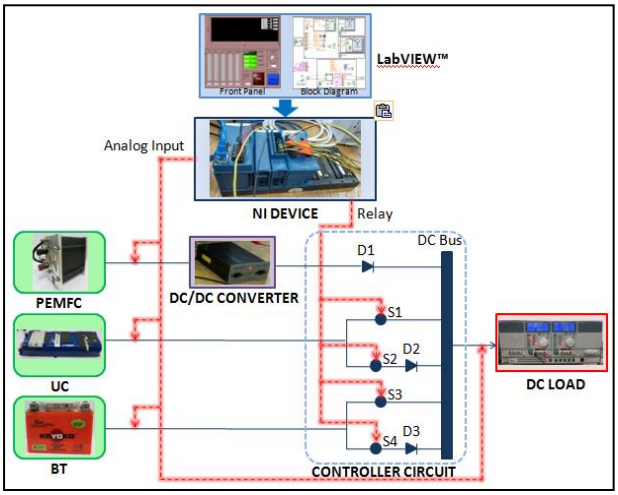

Figure 3. Diagram of the PEMFC/UC/BT hybrid energy management system.

Results and Discussion

In this study, the load profile used is a series of step signals to represent the load-required power presented in Figure 4a. The load profile can be used to represent the power consumed in most electronic applications. The controller is then manage the load sharing between FC, UC and BT. Initially, the step power starts at 1.1 W, which is the power required to start most electronic devices. The power increases to 3.3 W at 31 s and rises to 43 W at 61 s, then decreases to 22 W at 91 s. At 121 s, the power increases again to 43 W. The system begins to overload at 151 s when the power increases to 60 W, and the peak power of about 65 W is reached at 153 s. The power slowly decreases to 53 W at 211 s and further decreases to 37 W at 241 s. Then, the system increases the power demand to 43 W at 271 s and to 57 W at 301 s. The power then decreases to 6.7 W at 331 s and goes to 1.1 W at 361 s. The performance of the developed energy management strategy of PEMFC/UC/BT hybrid system, FC, UC, BT and load power, voltage and current as a function of time are illustrated in Figure 4 until Figure 6.

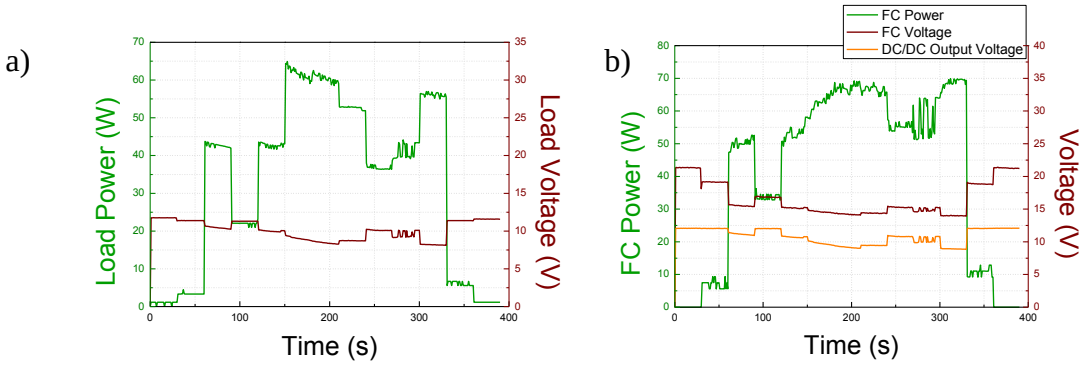

Figure 4. Power and voltage of a) Load and b) Fuel Cell

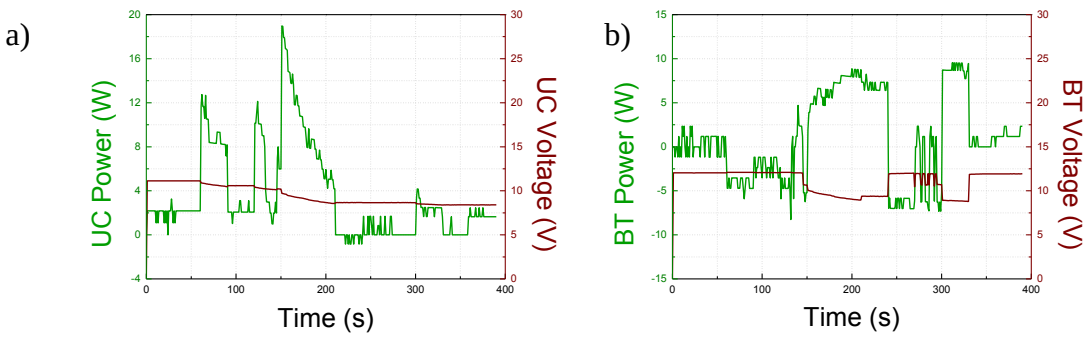

Figure 5. Power and voltage of a) Ultracapasitor and b) Battery

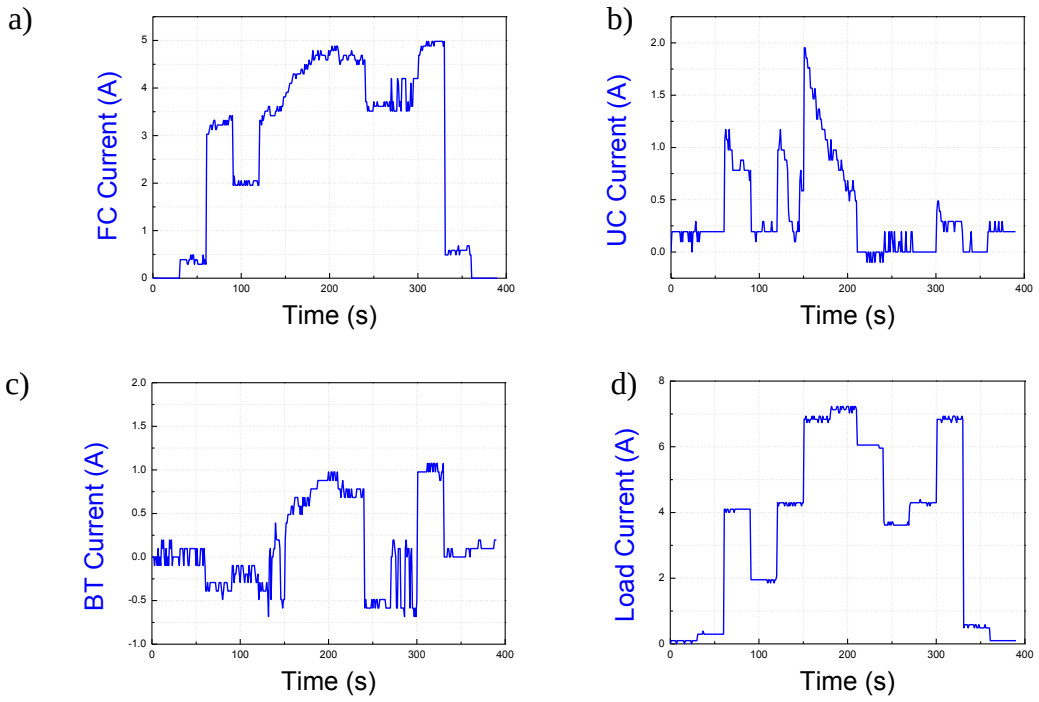

Figure 6. Current of a) Fuel Cell; b) Ultracapasitor; c) battery and d) Load

The FC, however, needs to be regulated by the DC/DC converter to ensure that the output power was constant at 12 V. The efficiency of the FC power was reduced by 15 % due to the DC/DC converter, and the input voltage is between 14 V and 24 V. If the FC voltage is lower than 14 V, the DC/DC converter output is considerably less than 12 V, and the UC or BT is required to supply the remaining needed power. The FC system successfully maintained the output voltage above 14 V, but due to the high load demand between 151 to 240 s and between 301 to 330 s illustrate in Figure 6a where the current draw from FC are near to 5 A, the system voltage at the DC bus fell below 10 V. The resulting FC voltage decreases as the power increases, as shown in Figure 4b is due to the basic characteristic of FC. However, its support the load demand base portion without facing a crucial transient changes.

The maximum power generated by the FC is approximately 69 W when the load at peak power about 60 W. On contrarily, the load profile used in literatures [12, 14] research are based on urban dynamometer driving schedule (UDDS) drive cycle. Thus, the power demand varied all the time. Both research are in hybrid system for FC, only differ with the energy storage unit. In [12] the energy storage unit are the same with this paper, which combine UC and BT. While in study reported by Uzunoglu and Alam [14], it used only UC as the energy storage unit. In Figure 7a and 7b show the FC output power of both system and clearly present that the combination of UC and BT greatly reduce the transient power demand face by FC.

The energy stored in the UC is depleted between 151 s to 390 s, as shown by the decrease in the voltage during this period in Figure 5a. The energy strategy dictates that the UC provide the necessary energy to the system by discharging and high current draw from UC as in Figure 6b. The UC then starts to charge for a short while then discharge until end of experiment (as mentioned before, UC only can support power for a short time) after 241 s. In contrast, the BT begins to discharge at 141 s. In the meantime, the BT charges and discharges as the current demand changes and support FC longer to satisfied the load, this utilize the BT characteristic of high energy densities. The details are presented in Figure 5b for BT power and voltage while in Figure 6c the current draw presented. This result provides good advantages in commercializing FC with the help of hybrid system. While decreasing the size and cost of the FC, the hybrid system also prevent the FC from operate in fuel starvation situation.

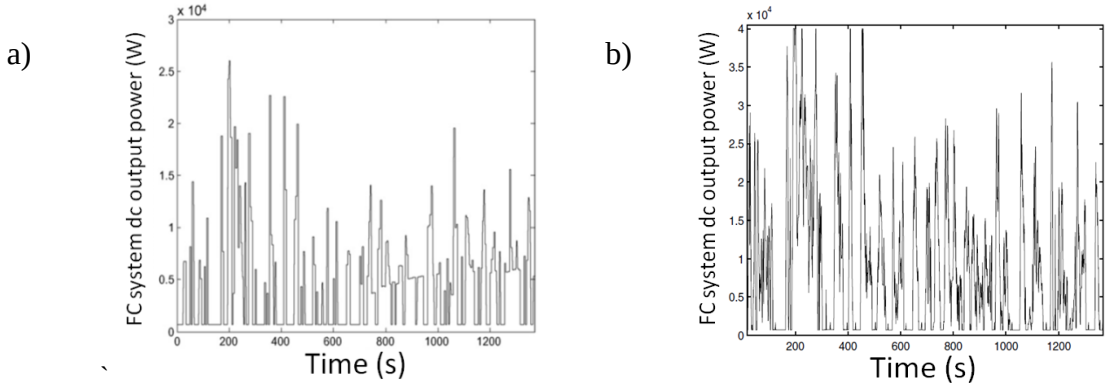

Figure 7. The FC output power variation according to UDDS of a) FC/UC/BT hybrid system [12] and b) FC/UC hybrid system [14].

The hybrid energy management system directs the flow of energy from the energy source to the load system successfully. As shown by the resulting current of the hybrid system in Figure 6d. The system on the other hand did not maintain the operating voltage at 12 V (Figure 4a). The single DC/DC converter however was not sufficient for this system, and an additional DC/DC converter is needed to stabilize the UC and/or BT voltage output, making the system more costly.

The test was continued further by increasing the current step by 0.5 A for every 30 s to determine the maximum operating current of this system. The objective of development a PEMFC/UC/BT hybrid system was to develop a system that utilizes a PEMFC as the primary energy source to supply DC power to electronic devices. Accordingly, the output of the PEMFC/UC/BT hybrid system is recorded at the DC bus. The system was predicted to supply a constant 12 V voltage despite the changing current. The current step profile used for this test is shown in Figure 8a. The current was increased by 0.5 A every 30 s. Figure 8b shows the DC bus voltage output of the system, which was a constant 12 V for 180 s. This system is thus a good working supply system for the operation of electronic devices. This test demonstrates that the PEMFC/UC/BT hybrid energy management system can handle up to a 2.5 A current load. However, the DC bus output begins to decrease after 180 s because of the DC/DC converter used. The 12 V DC/DC converters can receive an input voltage between 14 V and 24 V to produce a constant 12 V voltage with an efficiency of approximately 90%. Lower input values result in a much lower voltage because the efficiency

of the DC/DC converter can drop to 30%. The output power of this hybrid system is also shown in Figure 8b and demonstrates that this system can provide up to 30 W for an electronic application.

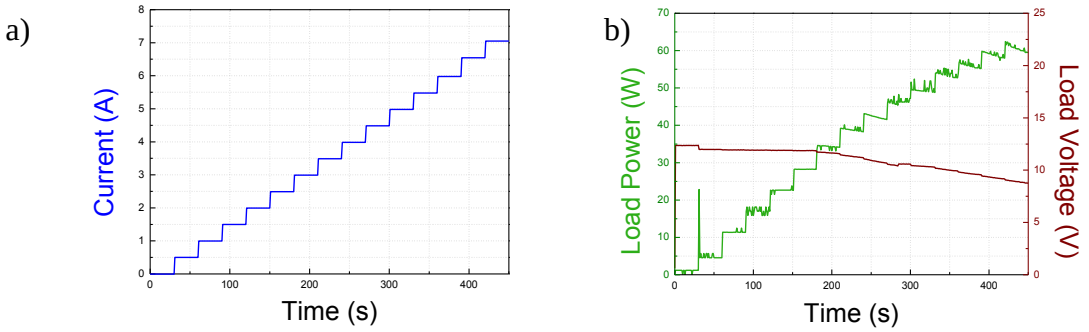

Figure 8. Result of step load for a) current and b) power and voltage

These results indicate that this hybrid energy source is an environmentally friendly energy source that can supply a constant, stable 12 V voltage up until 2.5 A current load compare to 1.5 A in literature [15]. Yan Zhang et al. [15] who also developed an energy management strategy but using only BT as the energy storage unit. Despite using an in-house manufacturing PEMFC, their energy management system, which utilized a simulation developed with the Simulink software, worked well up to a current of 1.5 A, as shown in Figure 9. Due to the unstable voltage output shown in Figure 10a and the limitations of the FC output voltage, the portable PEMFC-BT power system did not produce more than 18 W of power (Figure 10b). The results presented here show that the PEMFC/UC/BT hybrid energy management system is more capable of supplying power and stable than the PEMFC-BT or PEMFC/UC hybrid system.

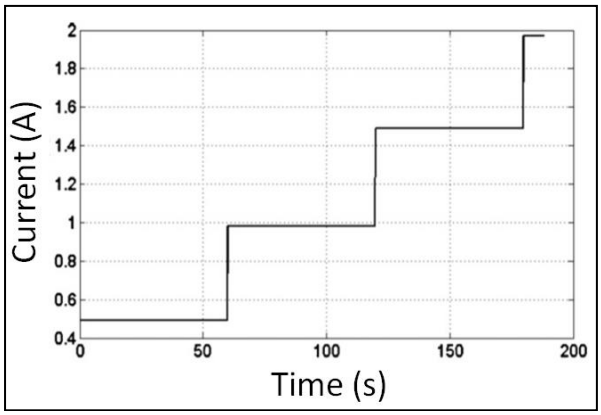

Figure 9. Current step input in PEMFC-BT hybrid system study [15]

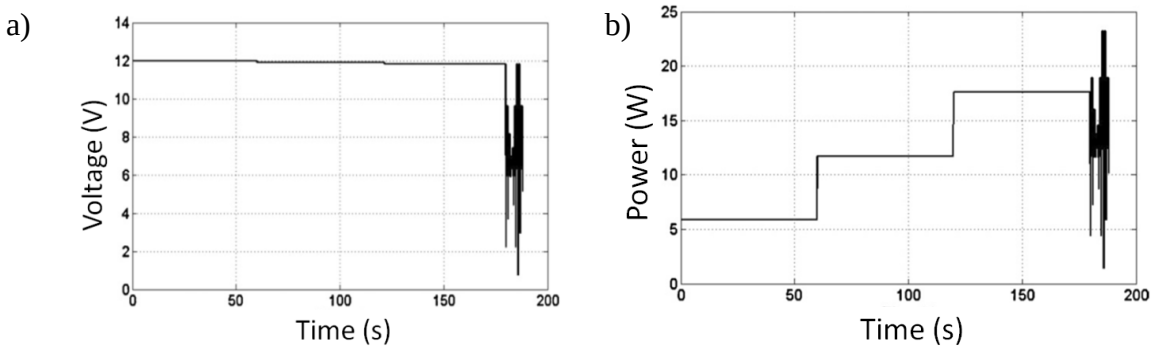

Figure 10. a) Voltage and b) power output of PEMFC-BT hybrid system [15]

Conclusion

The results of this research convincingly show the benefits of PEMFC hybrid systems. The energy management strategy successfully fulfilled the system requirements during peak power demand, charging and discharging the auxiliary energy sources. This new energy controller is easy to develop, low-cost with few electronic components and employ in the management of the energy sources. This hybrid system did not require full FC power to meet the load demand; the UC and BT helped to reduce the requirements on the FC. In other words, the FC stack is more cost-effective when used in a hybrid system. The transient response of the hybrid system was improved because the auxiliary energy source overcame the limitations of the FC. This system is also more portable compared to that in an electric vehicle because the BT in an electric vehicle must be charged by plugging it into an external energy source, while in hybrid system used FC.

Abstract

Density functional theory (DFT) computations were performed on the optimized geometric and electronic properties of reduced graphene oxide/polypyrrole (rGO/PPy) composite in comparison with pure graphene and graphene oxide structures. Incorporation of both reduced GO (rGO) and PPy will form a good composite which have advantages from both materials such as good mechanical strength and excellent electrical conductivity. These composite would be very suitable in fabrication of methanol sensor in direct methanol fuel cell (DMFC). The HOMO-LUMO energy (eV) was also calculated. These computational calculations provide a theoretical explanation for the good performance of rGO/PPy composite as electrode materials in methanol sensor.

Keywords: graphene, structure, polypyrrole, direct methanol fuel cell, density functional theory

Abstrak

Pengiraan teori fungsi ketumpatan (DFT) telah dilakukan ke atas ciri-ciri optimum geometri dan elektronik oksida komposit grafin terturun/polipirol (rGO/PPy) berbanding dengan grafin tulen dan grafin oksida. Gabungan kedua-dua GO terturun (rGO) dan PPy akan membentuk komposit yang baik yang mempunyai kelebihan dari kedua-dua bahan seperti kekuatan mekanikal dan kekonduksian elektrik yang sangat baik. Komposit ini menjadi sangat sesuai dalam pembuatan sensor metanol dalam sel bahan api metanol langsung (DMFC). Tenaga HOMO-LUMO (eV) juga telah dikira. Pengiraan ini memberikan penjelasan teori untuk prestasi baik rGO/PPy komposit sebagai bahan elektrod dalam sensor metanol.

Introduction

Direct Methanol Fuel Cell (DMFC) is a potential device as a source of mobile power which provides advantages such as high energy density, low pollution, fast starting time, lightweight and more compact compare to rechargeable battery and other types of fuel cells. It is also easy to use. DMFC is capable of converting chemical energy directly between the reaction of methanol and oxidant (air or oxygen) into electrical energy [1, 2]. The overall reaction for methanol oxidation is given as Eq. 1 below [3]:

$$CH_3OH + H_2O \longrightarrow CO_2 + 6e^- + 6H^+ \text{ (anode)} \quad (1)$$

The reaction for the fuel-cell-based sensor expressed as Eq. 2 below:

$$5O_2 + 6e^- + 6H^+ \longrightarrow 3H_2O \text{ (cathode)} \quad (2)$$

A constraint to the fuel cell is the fuel cell performance itself in terms of efficiency and low power density due to the low electro-catalyst activity. In addition, the constrains faced by toxicity in the anode as a result of the absorption of the intermediate products, such as carbon monoxide and high methanol crossover through Nafion membranes [4]. The objective of this paper is to investigate the optimized rGO and graphene structure as well as to determining their energy bands.

Polymer composites have showed significant potentials in development of various application areas like electronic devices, supercapacitor, rechargeable electrode and sensors. The usage of carbon based materials such as graphene, carbon black, single wall carbon nanotubes, carbon nanofibres instead of silicate compound layer or synthetic clay are states to be useful in enhancing the electrical and thermal conductivity [5 – 7].

Graphene oxide (GO) is one of the member in carbon based materials. GO is chemically modified form of graphene that contains oxygen functional groups such as epoxides, alcohols, and carboxylic acids which contributes to more reactive GO. Sharing the same atomically thin structural framework as graphene, it provide alternative for graphene which is complicated to produce. It recently emerged as a solution-processable material for large-area electronics because it can be deposited readily and uniformly on a variety of substrates. GO contains saturated sp3 carbon atoms bound to oxygen, which makes it an insulator. Transition to a semiconductor through chemical or thermal removal of oxygen allows it to be reduced incrementally so that the electrical conductivity can be tuned over several orders of magnitude [8].

While, conducting polymers such as polypyrrole (PPy) have high conductivity, are lightweight, low in cost, flexible and environmentally friendly but, as electrode materials, the degradation during cycling might happened where the volume of the polymer changes due to the insertion/deinsertion of counter ions [9]. Incorporation of graphene oxide in a conducting polymer matrix leads to the formation of nanocomposites which own advantages from both components. This advantages would be every useful in fabricating the methanol sensor in DMFC. The rGO/PPy composite electrode shows larger specific capacitance, higher rate performance, and better charge–discharge stability [10]. The rGO/PPy composite also provide large surface area which increases the binding sites [11]. According to Chandra and Kim, the PPy component of the composite is effectively lessen the swelling/shrinkage of polymer chains which solve the problem of the usage of PPy.

In this paper, the density functional theory (DFT) is applied to study on optimizing the structure of rGO/PPy composite and to examine the effect on incorporating the PPy as a composite with rGO. The energy of graphene, GO and rGO/PPy in applying the composite as methanol sensor electrode are also compared.

Materials and Methods

Calculation details

The spin-restricted DFT calculation was performed using DMol3 package. All results were obtained by PBE functional the exchange -correlation function within the generalized gradient approximation (GGA). In terms of numerical basis sets, double numerical plus polarization (DNP) was chosen within DFT semi-core pseudopots due to its reasonable accuracy in energy calculation. A lateral 5x3 cell was selected as the pure graphene. In the geometrical optimization, all structures were relaxed until the total energy were converged to 1.0×10^{-4} Hatree. The maximum force converged to less than 2×10^{-2} Hartree/Å, and the maximum displacement convergence was 5×10^{-2} Å. All structures were fully optimized without any symmetry constraint. Figure 1 show the structures of graphene and rGO of Min and Chang et al. [12] and Bagri et al. [13] respectively.

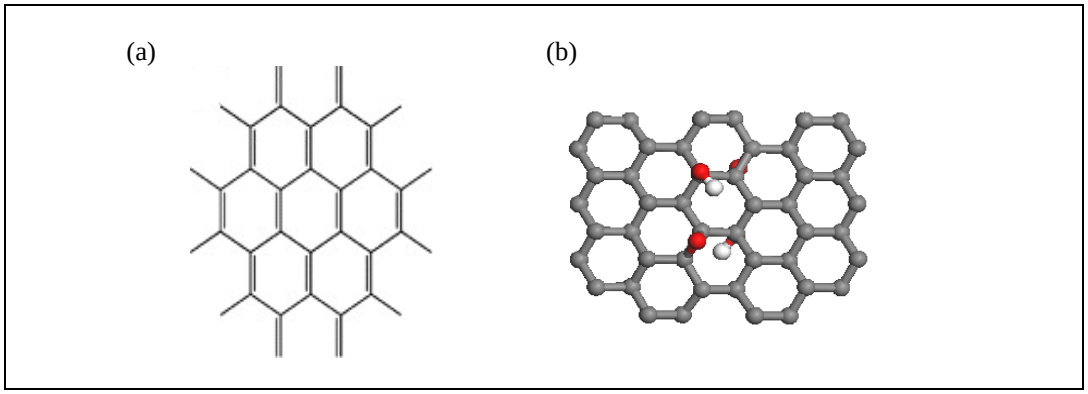

Figure 1. Min and Chang model structure of graphene (a) and Bagri et al. structure of graphene oxide (b)

Results and Discussion

Figure 2 shows the optimized structure of pure graphene based on structure proposed by Min and Chang. It consists of 42 atoms of carbon. The use of hydrogen atoms in terminating the boundaries of graphite cluster model is a good choice for simulation purposes [14].

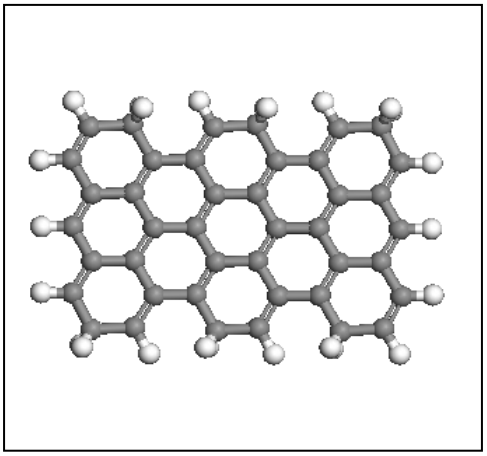

Figure 2. The modelled optimized structure of graphene

For graphene, the calculation is done in two different basis set, DSPP and all-electron basis set to determine which give the lowest value. The calculated value of DSPP, which is -1597.89 Ha is taken into consideration due to diverging that occur when using all-electron basis set. The optimized rGO is shown in Figure 3. The calculated properties of optimized rGO structure were compared with the graphene structure. The total energy of optimized rGO is -2051.3074 Ha.

From Table 1, the both value were compared. The optimized rGO have lower total energy than graphene. This proves that optimized rGO is more stable than graphene. Liu et al. [15] stated that the edge defects arising from the epoxide and carbonyl groups caused the electrical conductivity of functionalized graphene oxide is several orders of magnitude lower than graphene. The electronic properties of rGO, the highest occupied molecular orbital (HOMO)

and lowest unoccupied molecular orbital (LUMO) were also calculated. Result shows that, rGO also has lower HOMO-LUMO energy. This showed that graphene has higher binding energy compared to rGO.

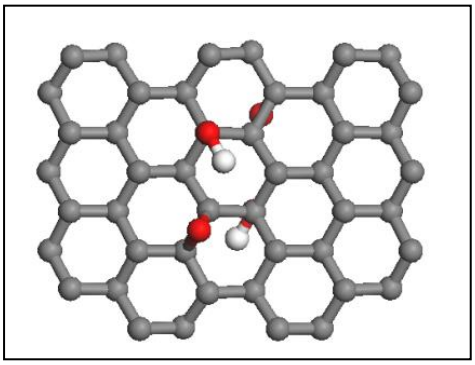

Figure 3. The optimized structure of rGO

Table 1. The comparison of Graphene and rGO

Molecular Structure	**HOMO – LUMO (eV)**	**Total Energy (Ha)**
Graphene	-1.094	-1613.348
rGO	-0.087	-2051.909

The optimized structure of rGO/PPy is calculated using the same method as the structure before. Figure 4 showed the structure of PPy, which consists of 10 monomers of pyrole. The calculation were done in three different postition of attachement of PPy on GO; at C-C bond, C-O bond (i.e. replacing the H atom from hydroxyl) and N-C bond. Based on DFT calculations, only rGO/PPy with C-C bond linking both structure converge. Table 2 below show the results obtained.

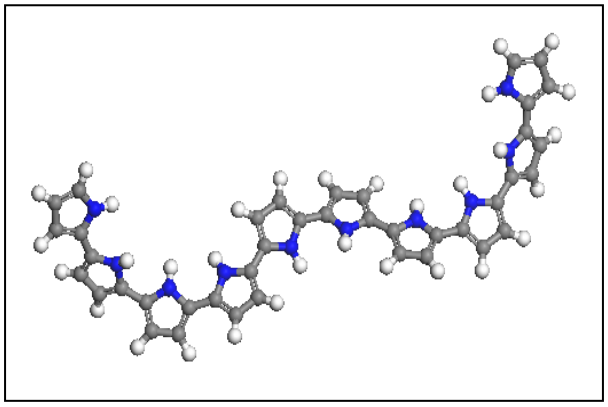

Figure 4. The optimized structure PPy with 10 monomers of pyrole

Table 2. Comparison between the optimized structure

Optimized Molecular Structure	HOMO – LUMO (eV)	Total Energy (Ha)
rGO	-0.087	-2051.909
PPy (10 monomers)	-2.094	-2091.038
rGO/PPy (C-C)	-0.145	-4106.005

From Table 2, the lowest energy structure is rGO/PPy composite at C-C bond which is -4106.005 Ha compared to the other structures. More negative the energy, more stable the structure. This proves that, the rGO/PPy composite possess stability which can be applied as electrode material. The HOMO-LUMO calculation was also done to the structure. The rGO/PPy possesses -0.145 eV which is slightly greater than rGO. Supposedly, the expected value for rGO/PPy is greater than rGO. Due to high eV for PPy, slightly greater energy needed to bind these two materials. Nevertheless, the data obtained is satifactory in giving early conclusion that rGO/PPy is stable to be applied as electrode materials in methanol sensor in DMFC. Further investigation on the binding on both materials is needed.

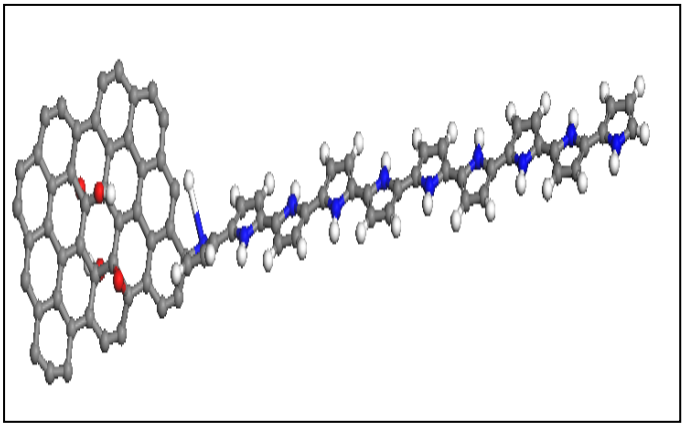

Figure 5. Optimize structure of rGO/PPy composite

Conclusion

In summary, DFT calculations were successfully applied to determine the lowest energy structure of rGO/PPy. In order to obtain the best result comparison of ideal graphene and rGO are made. It showed that rGO possess more stability than graphene in term of binding energy and also total energy. This is important to prepare rGO as the base in incoporation of polymer matrix, which in this case is PPy. Final optimized rGO/PPy structure is when the C atom of PPy matrix is attached at the C atom of rGO. The HOMO-LUMO calculated for GO/PPy optimized structure is -0.145 eV which is higher binding energy than the rGO but lower than graphene. The optimized rGO-PPy is good enough to be applied as electrode material of the methanol sensor but futher calculation should be made.

Abstract

Two alkaloid compounds: namely *3-(1-aminoethyl)tetrahydro-1H-pyrrolo[1,2-d][1,2,4]oxadiazine-1,4(3H)-dione* (**1**) and *tetrahydro-1H-pyrrolo[2,1-c][1,4]oxazine-1,3(4H)-dione* (**2**) was isolated from *Glyciozyma antarctica* (*PI12*), a psychrophilic yeast. The isolated compounds were isolated by Radial Chromatography and Thin Layer Chromatography techniques. The chemical structures were elucidated by Ultraviolet-visible, Infrared, Nuclear Magnetic Resonance and Mass Spectroscopy.

Keywords: *Glyciozyma antarctica* PI12, alkaloids, yeast, psychrophiles

Abstrak

Dua sebatian alkaloid: *3-(1-aminoetil)tetrahidro-1H-pirrolo[1,2-d][1,2,4]oksadiazin-1,4(3H)-dion* (**1**) and *tetrahidro-1H-pirrolo[2,1-c][1,4]oksazin-1,3(4H)-dion* (**2**) telah diasingkan daripada *Glyciozyma antarctica* PI12, sejenis yis psikrofilik. Sebatian-sebatian telah diasingkan menggunakan teknik Kromatografi Pepejal dan teknik Kromatografi Lapisan Nipis. Struktur-struktur kimia telah dicirikan dengan menggunakan Ultra-Lembayung, Infra-Merah, Resonans Magnet Nukleus dan Spektroskopi Jisim.

Kata kunci: *Glyciozyma antarctica* PI12, alkaloid, yis, psikrofil

Introduction

Since the 1960s, bioactive secondary metabolites have been isolated and structurally characterized from eubacteria, archaea, and fungi, microorganisms that have adopted strategies to grow in extreme terrestrial environments. The isolation and bioactivity of these molecules from the following extremophiles has been described such as thermophiles, psychrophiles, acidophiles, alkaliphiles, halophiles, xerophiles, epi- or endophytes, as well as metallotolerant, radioresistant, and unclassifiable microorganisms. Secondary metabolites often play an important role in defense systems of different organisms [1]. Humans use secondary metabolites as medicines, flavorings, and recreational drugs. Microbial secondary metabolites include antibiotics, pigments, toxins, effector of ecological competition and symbiosiss, pheromones, enzyme inhibitors, immunomodulating agents, receptor antagonists and

agonist, pesticides, antitumor agents and growth promoters of animals and plants. They have a major effect of the health, nutrition and economics of our society [2].

Scientist used the term "psychrophiles" to refer to microorganisms that grow optimally in extremely cold temperatures ranging from 15 °C or below (e.g. −20 °C in sea ice) to a maximum temperature of 20 °C [3]. Roughly 80 % of our planet's biosphere is at temperatures below 5 °C, which includes most of the world's oceans (70 % of the Earth's surface), sea ice, Antarctica, parts of North America and Europe, the deep-sea, mountain regions, as well as the mesosphere and stratosphere [4]. Thus, most microorganisms on Earth can be considered to be psychrophiles. *Glaciozyma antarctica* PI12 (previously known as *Leucosporidium antarcticum*) is a psychrophilic yeast strain which was isolated from a marine environment in Antarctica [5, 6]. Recently, Turchetti et al. [7] have proposed to reclassify this yeast from *Leucosporidium antarcticum* to *Glyciozyma antarctica*. Besides, *Glyciozyma antarctica* has also been isolated from various locations in Antarctica [8, 9]. Turkiewicz et al. [10] reported that *Glyciozyma antarctica* 171 has an optimum growth temperature at around 15 ^{0}C and is able to tolerate higher temperatures up to 20 ^{0}C. So far, the chemical constituents of this species have not been studied.

This paper describes the isolation and detailed characterization of new derivatives indolizidine alkaloid, 3-(1-aminoethyl)tetrahydro-1H-pyrrolo[1,2-d][1,2,4]oxadiazine-1,4(3H)-dione (**1**) and tetrahydro-1H-pyrrolo[2,1-c][1,4]oxazine-1,3(4H)-dione (**2**).

Materials and Methods

Material

Glyciozyma antarctica PI12 was isolated from sea ice collected in the vicinity of Case Station (66°21'25"S, 110°37'09"E), Antarctica. It was identified based on its LSU rRNA and ITS sequences which have been deposited in the GenBank database under accession number JX896855 and JX986956. *Glyciozyma antarctica* PI12 was routinely cultivated in yeast peptone dextrose (YPD) broth (Difco) medium.

Culturing material

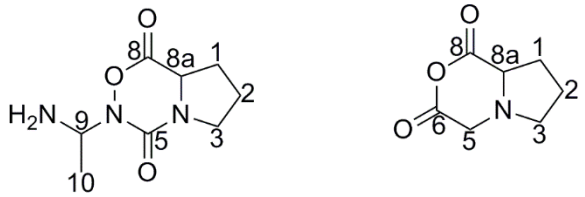
The culturing of *Glyciozyma antarctica* PI12 was conducted in collaboration with the Malaysia Genome Institute [11]. The psychrophilic yeast, *Glyciozyma antarctica* PI12 was originally isolated from Casey sea ice research station located in Antarctica. Initially, 10 µL of the *Glyciozyma antarctica's* glycerols stock was sub-cultured on the YPD agar with 50 µg/mL of Ampicillin and 50 µg/mL Kanamycin at 12 °C until a single colony is obtained. Next, a starter culture of *Glyciozyma antarctica* PI12 was prepared by inoculated a single colony of *Glyciozyma antarctica* PI12 from the agar plate into 10 mL of YPD medium (50 mL falcon tube) with 50 µg/ml of Ampicillin and 50 µg/ml Kanamycin. It is then cultured at 12 °C at 180 rpm until mid-log phase (OD600: 1.0 to 1.8) (5 days). Thirdly, a fix amount (10^{6} yeast cells/ml) of starter culture was inoculated into 50 mL of YPD medium (3 flasks of 250 mL of conical flask was used) with two antibiotics and then cultured at 12 °C at 180 rpm until mid-log phase (OD600: 1.0 to 1.8) (8 days). After the yeast culture has reached to the mid-log phase (OD600: 1.0 to 1.8), the flask with the yeast culture were exposed separately to -18 °C, 0 °C and 12 °C (without shaking) for 48 hours. Finally, the yeast culture was harvested by pouring them to a 50 mL falcon tube and centrifuged at 3000 rpm for 10 min at 4 °C. The supernatant and the pellet were collected.

Extraction and isolation

An amount of 200.7 mg n-butanol extract of *G. antarctica* PI12 was subjected to Radial Chromatography (RC) with 1 mm thickness silica gel on a round glass plate and eluted with the mixtures of dichloromethane and methanol with increasing polarity (Starting from DCM/Me-OH, 9.6:0.4). The eluents that showed the same profile on thin layer chromatography (TLC) chromatogram were combined to give three fractions (I-III). Purification of fraction I (1-4) (29.7 mg) was carried out using RC with silica gel plate of 0.5 mm thickness eluted with DCM and Me-OH (9.2:0.8) in 5 % polarity increment to yield compound **1** (4 mg). Purification of fraction II (5-7) (48.8 mg) was conducted utilizing another RC with silica gel plate of 0.5 mm thickness. Elution with DCM and Me-OH (8.4:1.6) produced compound **2** (12.5 mg).

Compound identification

Structures of pure compounds were determined based on the spectral data recorded on Shimadzu UV-260 spectrophotometer, Frontier Perkin-Elmer FTIR/NIR spectrophotometer and Bruker NMR 700 MHz Cryo-Probe instrument that included 1-D and 2-D NMR. HR-ESI-MS were recorded by using LCMS-Ultra Performance liquid Chromatography (UPLC), Brand Waters. The isolation was then carried out by radial chromatography using round glass plates of the Merck Kieselgel 60 PF254 (art. no. 7749) and profile was analyzed using smaller pieces from aluminium sheets 20 x 20 cm of the Merck TLC silica gel 60 F254 of 0.25 mm thickness (art. no. 5554) and then detected under UV light (254 nm) or by $CeSO_4$ spraying reagent followed by heating.



Results and Discussion

Characterization study

3-(1-aminoethyl)tetrahydro-1H-pyrrolo[1,2-d][1,2,4]oxadiazine-1,4(3H)-dione (**1**) is white amorphous solid. HR-ESI-MS $[M+H]^+$ at *m/z*: 200.2132 (calc. for $C_8H_{14}N_3O_3$ 200.2151). IR $\bar{\upsilon}_{max}$ (ATR) cm^{-1}: 3357, 2108, 1647, 1318-1238 and 1087. ^1H NMR (MeOD, 700 MHz) δ_H (ppm) and ^{13}C NMR (MeOD, 175 MHz) δ_C (ppm) are tabulated in Table 1.

Tetrahydro-1H-pyrrolo[2,1-c][1,4]oxazine-1,3(4H)-dione (**2**) is clear crystal. HR-ESI-MS $[M+H]^+$ at *m/z*: 156.1508 (calc. for $C_7H_{10}NO_3$ 156.1592). IR $\bar{\upsilon}_{max}$ (ATR) cm^{-1}: 3191, 1640, 1453, 1332, 1294-1217, 1110, 1004, 922-764. ^1H NMR (MeOD, 700 MHz) δ_H (ppm) and ^{13}C NMR (MeOD, 175 MHz) δ_C (ppm) are tabulated in Table 2.

The structure (Figure 1) elucidation of the compounds were conducted using several spectroscopic methods including mass spectrometer, UV, FT-IR, NMR 1D and 2D (HMQC, HMBC, COSY, and NOESY), and by comparison with reported data.

Figure 1. Chemical structures of isolated compounds **1** and **2**

3-(1-aminoethyl)tetrahydro-1H-pyrrolo[1,2-d][1,2,4]oxadiazine-1,4(3H)-dione **(1)**

Compound **1** was isolated as white amorphous. The molecular formula is $C_8H_{13}N_3O_3$, generated using HR-ESI-MS $[M + H]^+$ ion at *m/z*: 200.2132 (calc. for $C_8H_{14}N_3O_3$ 200.2151). The FTIR spectral data displays broad absorbance peak at 3357 representing primary amine ($-NH_2$), overtone (weak) at 2108 cm^{-1} and tertiary amine at 1318 cm^{-1}, 2985 and 2881 cm^{-1} representing the C-H (aliphatic cyclic). The presence of carbonyl group is characterized by absorbance bands, i.e. C=O stretch at 1647 cm^{-1} indicated that the carbonyl group linked with the tertiary amide. Furthermore, that tertiary amide is characterized by absorbance at 1318 and 1087 cm^{-1}.

The ^{13}C spectrum reveals that the compound contains 8 carbons consisting of one methyl, three methylenes, two methines and two quaternary carbons. The most highly deshielded signals at δ_C 170.1 (C-8) and 165.0 (C-5) were attributed to carbonyl group linked with tertiary amide and another one was from ester group. Two signal of methines at δ_C 58.8 (C-8a) provide information of the presence of an *1H-pyrrolo* carbon that linked with a quarternary carbon C-8 and a tertiary amine, while the other one (C-9) linked with an equivalent proton methyl and a primary amine. Three shielded carbons (C-1, C-2 and C-3) represent the existence of a pyrrolidine framework in the molecule. The Double Bond Equivalent (DBE) value of $C_8H_{13}N_3O_3$ is 4, indicating that the compound consists of two double bonds as carbonyls group and two ring of derivative indolizidine alkaloid as main structure. Meanwhile, 10 proton signals representing 13 protons appeared in the ^1H-NMR spectrum. Ten of the signals came

from the four signals, one each from a methyl group at H-10 (1.45, *d*, *J*= 7) bind with a methine proton at H-9 (δ_H 4.05) are *quartet*, while a primary amine bind this methine at C-9. Furthermore, the other methine at (δ_H 4.26) is triplet, indicating it is adjacent to a methylene at C-1. Meanwhile, the other two saturated methylenes form pyrrolidine skeleton in the molecule.

The structure is confirmed using 2D NMR (Table 1). The HMBC experiment shows H-8a has correlation with C-1, and H-1 with C-2 and C-3. Proton methine H-9 has correlations with C-10, while all methine protons have correlation with the carbonyl carbons, confirming the position of C-5 and C-8. In COSY spectrum, H-2 shows strong coupling with H-1 and H-3, while H-9 show strong coupling with methyl proton at H-10 (Fig. 2 (a)).

According to Silverstein et al. [12], the vicinal coupling constant between an axial H with another axial H ranges from 6 to 10 Hz, while the vicinal coupling constant between an equatorial H with an axial H is around 0 to5 Hz. The relative configuration of the sole chiral carbon (C-8a) was observed using Nuclear Overhauser Effect Spectroscopy (NOESY) experiment which describes the H–H correlation through space (Figure 2(b)). From the NOESY spectrum, it was observed that carbon methine at C-8a in pyrrolidine skeleton bind one proton in the axial position with coupling constant value *J* = 7 Hz. Since H-8a$_{(ax)}$ generates cross peak with H-2$_{ax}$, which means they are in the same orientation. According to Karplus curve, if a proton has correlation with another proton in the same orientation, indicating they are in the eclipse position (dihedral angel of 0^0). Then, methyl group at C-10 binds three *geminal* protons, has *doublet* splitting and *J* value is 7 Hz, indicating that H-10 is in axial position/eclipse position (dihedral angel of 0^0) toward H-9.

Figure 2. Compound **1**; 2D correlation NMR; (a) HMBC (⟶) & COSY (━), (b) NOESY

Tetrahydro-1H-pyrrolo[2,1-c][1,4]oxazine-1,3(4H)-dione **(2)**

Compound **2** was isolated as a clear crystal. The molecular formula $C_7H_9NO_3$ was generated using HR-ESI-MS [M + H]$^+$ ion at *m/z* 156.1532 (calc. for $C_7H_{10}NO_3$ 156.1592). The UV spectrum indicated that there was no conjugated double bond in the molecule; this was deducted by the presence of only one absorbance band at 203 nm. The FT-IR spectral data presence of carbonyl group was indicated by a strong stretching band of C=O at 1640 cm^{-1} and the vibration band at 1004 cm^{-1} indicated the C-O bending representing an ester group. The C-C(=O)-O asymmetrical stretching vibration was indicated by absorbance band at 1294 cm^{-1}. The Csp^3-H stretching band appeared at 2956-2889 cm^{-1}, while absorption bands at 1453 cm^{-1} indicated the asymmetrical bending vibrations of Csp^3-H of the methylene groups. A tertiary amine was detected in this compound at 1332 cm^{-1}.

The presence of functional groups is supported by NMR analysis of 1-D (^{1}H and APT experiment of ^{13}C-NMR) and 2-D (HSQC, HMBC, H-H COSY and H-H NOESY) data. The APT experiment data showed the presence of 7 carbon signals representing two quaternary, one methine and four methylenes carbons. The DBE value of four indicated that this compound was an indolizidine alkaloid containing two double bonds. The most deshielded carbons at δ_C 170.5 and 165.0 ppm was indicated as an asymmetrical carbonyl group. Three saturated non-equivalent methylenes signals at δ_C 27.9 (C-1), 21.9 (C-2) and 44.9 (C-3) are attributed to pyrrolidine ring in this molecule, while another methylene signal at δ_C 45.5 ppm (C-5) indicated the presence of a methylene existed between carbonyl and tertiary amine. Furthermore, methine carbon at δ_C 58.4 ppm (C-8a) is the specific of methine signal of indolizidine alkaloid for this molecule. Meanwhile, 9 proton signals representing 9 protons appeared in the ^{1}H-NMR spectrum as shown in Table 2. Eight of the signals came from the three methylenes proton, one each from isolated methylene at H-5 binds carbonyl and tertiary amine and another three non-equivalent methylenes at H-1, H-2 and H-3, forming a basic pyrrolidine ring. An aminated methine proton, H-8a$_{(ax)}$ (δ_H 4.25, *Ψt*, *J*= 7.0) are *pseudo doublet*, indicating that C-8a is adjacent to a methylene group (C-1).

The structure of **2** was confirmed using 2D NMR including HMBC, COSY and NOESY. The HMBC spectrum revealed a strong correlation between methine (C-8a) and the carbonyl carbon (C-8) as well as between C-8a and saturated non-equivalent methylene group (C-1). This indicated that the methine group as *chiral* position. The correlations between H-5 and C-8a as well as between H-5 and C-6 confirmed the position of the isolated methylene in the molecule as described in Figure 2(a). NOESY spectrum revealed correlation between H-8a$_{(ax)}$ and H-1ax as well as between H-8a$_{(ax)}$ and H-2ax confirming the position of the chiral group in the molecule (Figure 3(b)).

Conclusion

The phytochemical investigation of the psycrophilic yeast *Glyciozyma antarctica* PI12 resulted in the isolation of new derivatives indolizidine alkaloid named 3-(1-aminoethyl)tetrahydro-1H-pyrrolo[1,2-d][1,2,4]oxadiazine-1,4(3H)-dione (**1**) and tetrahydro-1H-pyrrolo[2,1-c][1,4]oxazine-1,3(4H)-dione (**2**). To the best of our knowledge, this is the first report for both of compounds from this species. In addition, these compounds contributed to the small yet expending database of secondary metabolites from psychrophiles.

Abstract

Nanocrystalline cellulose (NCC)/chitosan composite for immobilization of tyrosinase enzyme for the determination of phenol have been developed. The NCC/Chitosan composite film on screen printed carbon electrode (SPCE) was prepared by using drop casting technique. Characterization of the modified SPCE surface was investigated by using Transmission Electron Microscopy (TEM) and Fourier Transform Infrared (FTIR), respectively. Chronoamperometric (CA) technique is used to perform the electrochemical measurements. The detection of phenols by the developed system is derived on the direct electrochemical reduction of quinones produced by enzymatic reaction. The results demonstrated that the maximum response was observed at ratio of NCC/chitosan of 1 to 1 (v/v), tyrosinase concentration of 10 mg/mL and pH buffer of 7, respectively. It was found that the developed system gave linear response in the phenol concentration range of 0.39 – 7.74 µM (slope = 28.316, R^2 = 0.9808) with the detection limit of 0.38 µM. The reproducibility of the system was also estimated and the Relative Standard Deviation (RSD) was found to be at 4.27 %.

Keywords: nanocrystalline cellulose, nanocomposite, immobilization, electrochemical, phenol

Abstrak

Komposit selulosa nanokristalin/kitosan untuk pemegunan enzim tirosinase bagi penentuan fenol telah dibangunkan. Filem komposit NCC/Chitosan di atas elektod karbon skrin bercetak (SPCE) telah disediakan melalui kaedah penyalutan acuan. Pencirian permukaan SPCE dimodifikasi dikaji menggunakan Mikroskop Elektron Transmisi (TEM) dan Transformasi Fourier Inframerah (FTIR). Teknik kronoamperometri (CA) digunakan untuk menjalankan pengukuran elektrokimia. Pengesanan fenol oleh sistem yang dibangunkan ini adalah berasaskan penurunan langsung elektrokimia oleh kuinon yang dihasilkan daripada tindak balas enzim. Keputusan menunjukkan bahawa rangsangan maksimum diperhatikan pada nisbah NCC/kitosan adalah 1 kepada 1 (v/v), kepekatan tirosinase 10 mg/mL dan larutan penimbal pada pH 7. Didapati bahawa sistem yang dibangunkan memberi rangsangan linear dalam julat kepekatan fenol 0.39-7.74 µM (kecerunan = 28.316, R^2 = 0.9808) dengan had pengesanan 0.38 µM. Kebolehulangan sistem juga telah dianggarkan dan nilai sisihan piawai relatif (RSD) yang diperolehi ialah 4.27 %.

Kata kunci: selulosa nanokristalin, nanokomposit, pemegunan, elektrokimia, fenol

Introduction

Nanocrystalline cellulose (NCC) is a unique and sustainable nanomaterial obtained through acid hydrolysis of native cellulose, it has remarkable physical properties, such as biocompatibility, biodegradability and low toxicity as it originating from natural resources raw materials [1]. NCC has been studied to have a rigid rod-shape structure with 5 – 10 nm in diameter and 10 – 100 nm in length [2]. It can be extracted from native cellulose which is found in plants, animals and bacteria that composed of the nanoscaled structure material. Since nanocellulose is a natural nanoscaled material, it possesses varied characteristics different from traditional materials, as well as special morphology and geometrical dimensions like crystallinity, high specific surface area, rheological properties, liquid crystalline behaviour, alignment and orientation, mechanical reinforcement, barrier properties and surface chemical reactivity [1]. NCC is an attractive material for drug delivery excipients [3], support for immobilization of protein [4,5] and for applications of nanocomposite [4] because of its properties for instance high surface area, high aspect ratio, high and specific stiffness and strength, and low toxicity. Depending on the origin and method of extraction, the nano-dimensional cellulose might be in the form of rods, spheres, and have network morphology with an extremely high surface to volume ratio [6]. The presence of –OH groups on the NCC surface allow it to undergo further surface modification to alter its hydrophobicity, serve as a stable matrix that is compatible for widespread bioapplications, specifically in enzyme immobilization, antimicrobial and medical materials, green catalysis, biosensing and controlled drug delivery [5].

Chitosan is a natural biopolymer product found in the exoskeleton of crustaceans, in fungal cell wall and other biological materials. Chitosan is natural linear polysaccharide made primarily of glucosamine repeating units, partially deacetylated derivative of chitin and the second most abundant natural polysaccharide after cellulose [7]. Its properties of biodegradability, non-toxicity, biocompatibility, high mechanical strength and good adhesion make it a promising matrix for enzyme immobilization. In spite of its biodegradability, it has numerous reactive amino acid and hydroxyl groups that allows chemical modification possibilities, formation of a large variety of functional derivatives which are commercially available or can be made available through graft reactions and ionic interactions [8, 9]. The reaction of chitosan is considerably more versatile than cellulose as there is the presence of NH_2 groups.

Recently development of biosensor system with better sensitivity, selectivity and rapid detection is the key important step and gain much attention from many researchers. Among of that is the selection of new material for enzyme immobilization which offers good electronic properties, biocompatible, stable and easily accessible by the analyte and large surface area. However, it is difficult to find a single material that contains all these important characteristics. The use of composite materials made of two and more components has gotten increasing interest as a way to achieve adequate sensitivity and stability for biosensors development.

In this work, we explored the utilization of nanocrystalline cellulose (NCC) in combination with chitosan for biosensing application. The nanostructure of NCC could provide high surface to volume ratio and high surface activity, and thus possess unique advantages over other conventional materials in terms of enzyme immobilization and signal transduction. These biomaterials could preserve enzyme activity due to the desirable microenvironment and enhance the direct electron transfer between the enzyme active sites and the electrode.

Materials and Methods

Reagents

All chemicals used in this experiment were of analytical grade. Sodium phosphate dibasic, sodium phosphate monobasic, phenol and tyrosinase were obtained from Sigma Aldrich and Fluka (Switzerland). Sodium hydroxide was from Merck (Germany). Acetic acids and potassium chloride were obtained from R&M chemicals (United Kingdom). Chitosan powder was purchased from Chito-Chem (Malaysia) Sdn Bhd. Nanocrystalline cellulose (NCC) powder was acquired from Universiti Kebangsaan Malaysia. Deionized water was used throughout the experiment.

Preparation of NCC colloidal suspensions and chitosan solution

An amount 1 mg/mL or 0.1% (w/v) of NCC suspension was prepared by dissolving 0.025 g of NCC powder in 25 ml deionized water followed by sonication for 3 min. 1.0 % (w/v) of chitosan solution was prepared by dissolving

1.0 g of chitosan powder in 100 mL of acetic acid (1%, v/v). The viscous chitosan solution was stirred overnight at room temperature by using magnetic stirrer.

Immobilization of tyrosinase into NCC/Chitosan composite on SPCE

Preparation of NCC/Chitosan mixture was carried out by varying the ratio of NCC/Chitosan in the range of 1:3 to 3:1 (v/v). For immobilization of tyrosinase, 20 µL of NCC/Chitosan mixture with different ratio was mixed with 10 µL of tyrosinase (40 mg/mL) in eppendorf tube and stirred gently until homogeneous solution was obtained. Then 2 µL of the prepared mixture was deposited and spread onto SPCE. It was kept at 4 °C for drying process for overnight. All electrodes are stored at 4 °C prior to use.

Study the performance of NCC/Chitosan/tyrosinase composite electrode

An electrochemical measurement was performed by using Autolab potentiostat (Netherlands) controlled by GPES software connected to a PC and screen printed carbon electrode (Quasense, Thailand). Chronoamperometry method was used to record current-time activity. Two-electrode system was employed in this work with NCC/Chitosan/tyrosinase as a working electrode and an AgCl served as the reference/counter electrode.

Characterization of the SPCE modified with NCC/chitosan/tyrosinase composite was carried out using Transmission Electron Microscopy (TEM) and Fourier Transform Infrared (FTIR), respectively.

Results and Discussion

The morphology characterization of the composite film

Figure 1a depicts the TEM image of NCC showing agglomerated rod-like nanocrystals, ranging approximately 10 – 30 nm in diameter and corresponding length of about 100-300 nm. Similar observations were also reported by previous researchers which the NCC obtained was highly crystalline nanometer sized rod-like particle ranging from 50 – 60 nm that is obtained as a stable aqueous colloidal suspension [4,7]. Fig. 1b illustrates the image of NCC/chitosan with ratio of 1 to 1 (v/v). As can be seen the NCC/Chitosan appeared like a shiny dot which correspond to the transverse sections of the cellulose nanocrystals [10]. Fig. 1c exhibits the uniform distribution of tyrosinase on the NCC/Chitosan composite films.

FTIR analysis attempted to characterize the effect of NCC incorporation with chitosan and also to determine NCC-chitosan and NCC-chitosan-tyrosinase interactions from the infrared bands and related shifts. Fig. 2 shows the FTIR spectra recorded for NCC, chitosan, NCC-chitosan, and NCC-chitosan-tyrosinase. In the FTIR spectra of pure NCC film (Fig. 2a), the absorption band between 3600 and 3200 cm^{-1} which is related to the O-H stretching vibrations. The broad peak recorded at 3348 cm^{-1} may be attributed to the O-H vibrations because of the intramolecular hydrogen bonding [11]. The bands of absorption between 3000-2800 cm^{-1} and 1500-1250 cm^{-1} indicated the functional group of C-H and $C-H_2$ stretching and bending vibration, respectively [12]. The adsorption of C-H stretching was obtained at 2915 cm^{-1} and the strongest band across NCC spectra is at 1447 cm^{-1} which assigned to $C-H_2$ stretching. Other bands between 800-650 cm^{-1} originated from O-H out of plane bending vibrations. The position of the peaks of chitosan film spectrum is similar to those described by Cao et al. [13]. The absorption peaks of the chitosan film in Fig.2b are due to the stretching of intra- and intermolecular O-H and CH_2OH vibrations at 3500-3250 cm^{-1}, overlapped with stretching $-NH_2$ (3500-3400 cm^{-1}) and –NH secondary amides vibrations (3300-3280 cm^{-1}). The band between 2960-2870 cm^{-1} corresponds to symmetric and asymmetric C-H vibrations. Amide at 1557 cm^{-1} was also been observed.

There are some differences can be observed in FTIR spectra of chitosan films in Fig. 2c because of the incorporation of NCC to the chitosan matrix. A broad peak appeared at 3287 cm^{-1}, which was not present in the control chitosan film. The band intensity 3287 cm^{-1} increased suggesting hydrogen bonding which occurred between chitosan and NCC [14]. Band at 1569 cm^{-1} and 1397 cm^{-1}, their intensity was increased after NCC addition due to the bending of C-H and –OH group. Furthermore, a drastic increased was observed in the intensity of the absorption band at 1063 cm^{-1} due to incorporation of NCC which refer to C-H stretching vibration of C-O. An incorporation of tyrosinase enzyme in NCC-chitosan film (Fig. 2d) caused no changes in intensity of band spectra of NCC-chitosan which a broad peak appeared at 3286 cm^{-1}. Also, there was a decrease in intensity of bands at

1642 cm^{-1} might be attributed to the amide I vibrations indicating that tyrosinase had been successfully attached on the membranes consisting of NCC/chitosan film.

Principal of detection of phenol

In this work, the electrochemical measurements were performed using chronoamperometric technique. The electrochemical experiments were carried out with two-electrode system with NCC/Chitosan/tyrosinase on carbon electrode as a working electrode and an AgCl served as the reference/counter electrode. Tyrosinase is a copper containing enzyme, which catalyzes the oxidation of phenol group to o-quinone is commonly used in the detection of phenolic compounds. The oxidation of phenols by tyrosinase can be presented according to the following reactions:

The oxidation of phenol by tyrosinase has two steps: phenol is oxidized to catechol (o-benzenediol), which is consequently oxidized (by tyrosinase) to o-quinone [15]. The liberated quinone species catalytically oxidized by tyrosinase is electrochemically reduced and the reaction can be measured at low potential. Thus, this provides the additional advantages of the enzymatic/electrochemical recycling of the substrate, giving rise to signal amplification. In this work, effect of applied potential was investigated in the range of 0.0 V to -0.6 V and the optimum response of the immobilized tyrosinase in NCC/Chitosan composite film was observed at - 0.3 V vs AgCl. Thus, applied potential of - 0.3 V was chosen for further study.

Optimization parameter

Effect of ratio NCC/Chitosan on the sensing response was evaluated in this work by employing various ratios such as NCC, 1:3, 1:1, 3:1 and chitosan, respectively. As shown in Figure 3, the ratio of NCC/Chitosan of 1:1 (v/v) gave maximum current response. This shows that the NCC/Chitosan composite with composition of 1:1 gave relatively higher protein loading which might be attributable to the abundant active –OH groups and highly surface area of the NCC that contribute to the cross-linking of tyrosinase onto the composite film. However, pure NCC film gave the lowest current response due to the high solubility in water and hydrophilic character of NCC which caused the NCC to be easily detached from the surface of electrode and dissolved in buffer solution.

The zeta potentials of the NCC and chitosan were also evaluated to characterize the surface charge density of the material. The zeta potential was investigated at different pH value. It was observed that the zeta potential value at

pH 3, 7, 9 were -27.50, -14.37, -16.78 for NCC and +36.87, +12.78, -4.04 for chitosan, respectively. Remarkably, NCC and chitosan carried opposite surface charges at the pH range from 3 to 7, indicated in this range electrostatic attraction occurred. In a previous work, NCC and chitosan film was also prepared via electrostatic self-assembly due to electrostatic interaction between negatively charged NCC and positively charged chitosan [16].

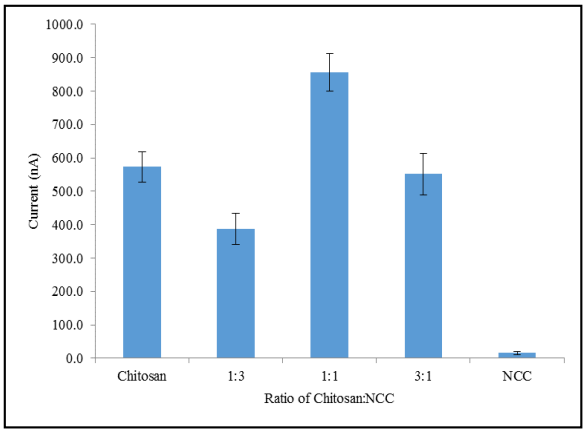

Figure 3. The effect of ratio of NCC/chitosan

The effect of a different amount of tyrosinase loading on the sensor response was also examined. As depicted in Figure 4, upon increasing the concentration, the biosensor response increased steeply to reach a maximum value when 10 mg/mL of enzyme concentration was utilized. Further increased in enzyme concentration, the sensor response decreased and thus concentration of 10 mg/mL was subsequently used for enzyme immobilization.

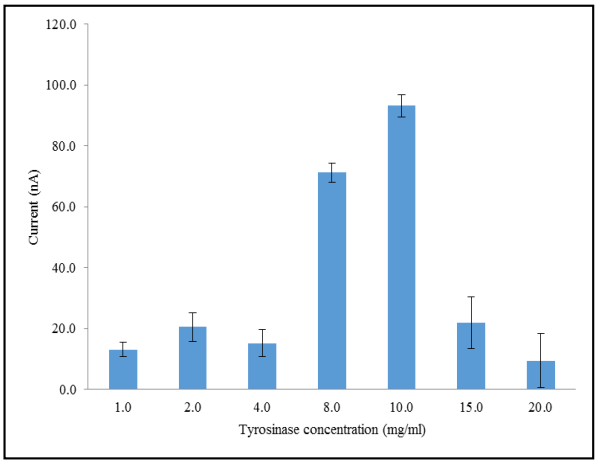

Figure 4. Effect of enzyme concentration used towards the response of the sensor

Influence of pH of the working buffer was also investigated by using 50 mM phosphate and acetate buffer. The buffering system covered over the range of pH 7.0 to 9.0. As shown in Figure 5, the sensor response increased drastically from pH 5.0 to 7.0. The optimum response was observed at pH 7.0. This indicates that the immobilization of enzyme does not alter its pH response characteristics [17]. Therefore, pH 7.0 was chosen for further studies.

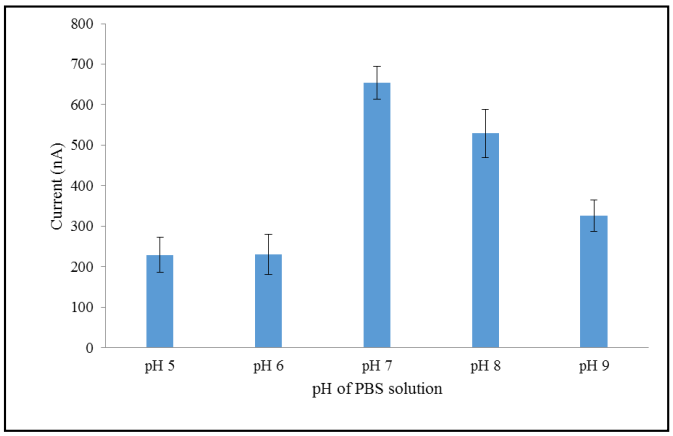

Figure 5. Influence of pH on the response of the immobilized tyrosinase in NCC/Chitosan composite film

Analytical performance

The dynamic range of the developed biosensor towards different phenol concentration was studied from the concentration range of 0.39 µM to 100 µM (Figure 6). The response was monitored by predicting the current of the composite films produced, which is proportional to the phenol concentration. As shown, a linear response of the biosensor was observed in the phenol concentration range of 0.39-7.74 µM (slope = 28.316, R^2 = 0.9808) with the detection limit of 0.379 µM. The reproducibility of the biosensor was estimated from the response of the electrode at 50 µM phenol. The relative standard deviation (R.S.D) obtained was 4.27 % (n = 10). This result shows a remarkable reproducibility of the proposed biosensor.

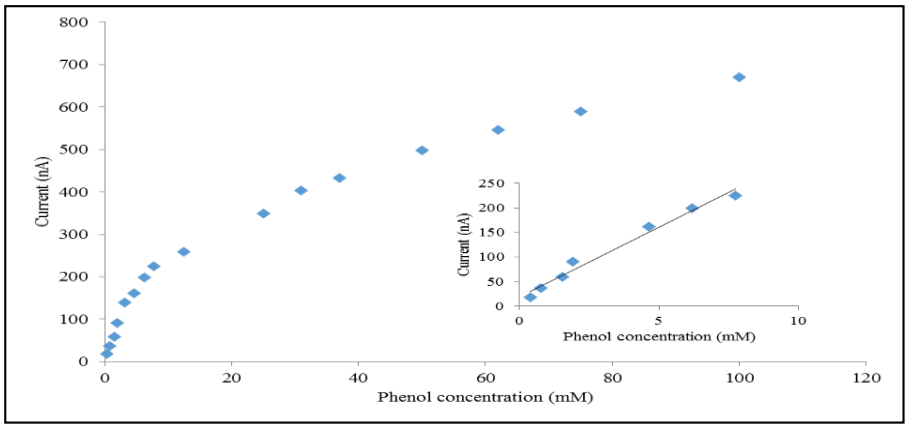

Figure 6. The dynamic calibration range of the sensor towards different concentration of phenol. Inset is the linearity range of the sensor

Conclusion

An amperometric biosensor based on the immobilized tyrosinase enzyme in a NCC/chitosan composite film has been successfully developed for the detection of phenol. The biosensor permits an attractive alternative to existing analysis methods in order to determine phenolic compounds as they offer advantages for instance minimal preparation of sample, good selectivity, better sensitivity, reproducibility, quick response time and easily for continuous analysis. The effect of immobilization of enzyme into nanocomposites material and its stabilization for

sensing application have been extensively determined. The nanocomposites showed significant improvement in performance of the biosensors which is promising for developing dependable enzyme-biosensors which has good potential use in quantitative determination of phenolic compunds in industrial applications.

Abstract

Bacillus subtilis UKMP-4M5 was isolated from a hydrocarbon contaminated site which was found to be the most potential biosurfactant producer. Isolates were grown in a mineral salt medium (MSM) supplemented with sunflower oil (1% v/v) as the main carbon source. Screening was based on both qualitative (oil spreading technique) and quantitative (emulsification index and surface tension measurement) methods. *B. subtilis* UKMP-4M5 produced the highest oil displacement activity with and emulsification index of 17%. It also reduced surface tension of culture medium from 58.95 to 41.75 mN/m. *B. subtilis* UKMP-4M5 produced biosurfactant with surface tension measurement of 32.7 ± 0.66 mN/m using 2% (v/v) palm oil and 0.5% (w/v) yeast extract as carbon and nitrogen sources respectively. The tested biosurfactant exhibited excellent thermal (up to 120 °C) and pH (6.0 – 8.0) stability as well as high tolerance for varying salt concentrations (1 – 5% w/v) in terms of surface tension reducing ability. This suggests potential applications in fields such as enhanced oil recovery, bioremediation, and the food industry.

Keywords: *Bacillus subtilis,* biosurfactant, palm oil, surface tension

Abstrak

Bacillus subtilis UKMP-4M5 yang dipencilkan dari kawasan yang tercemar dengan hidrokarbon didapati paling berpotensi sebagai penghasil biosurfaktan. Pencilan dihidupkan di dalam medium garam mineral (MSM) yang ditambahkan dengan 1% (i/i) minyak bunga matahari sebagai sumber karbon utama. Penyaringan adalah berdasarkan kepada kedua-dua kaedah kualitatif (teknik penyebaran minyak) dan kuantitatif (indeks emulsifikasi dan ukuran ketegangan permukaan). *B. subtilis* UKMP-4M5 merekodkan aktiviti sesaran minyak yang tertinggi dengan indeks emulsifikasi sebanyak 17%. Ia juga merendahkan ketegangan permukaan kultur medium dari 58.95 mN/m ke 41.75 mN/m *B. subtilis* UKMP-4M5 menghasilkan biosurfaktan dengan ukuran ketegangan permukaan 32.7 ± 0.66 mN/m menggunakan 2% (i/i) minyak kelapa sawit dan 0.5% (b/i) ekstrak yis masing-masing sebagai sumber karbon dan nitrogen. Biosurfaktan yang diuji menunjukkan kestabilan yang amat baik pada suhu (sehingga 120 °C) dan pH (6.0 – 8.0) serta toleransi yang tinggi pada kepekatan garam yang berbeza (1 – 5% b/i) dari segi keupayaannya merendahkan ketegangan permukaan. Ini mencadangkan potensi aplikasinya dalam industri seperti peningkatan perolehan minyak, bioremediasi dan industri makanan.

Kata kunci: *Bacillus subtilis,* biosurfaktan, minyak kelapa sawit, ketegangan permukaan

Introduction

Biosurfactants are amphiphilic molecules containing hydrophobic and hydrophilic moieties. They are produced by a variety of microorganisms such as yeasts, fungi, and bacteria. A majority of these molecules are produced by

bacteria which are able to interact between two immiscible interfaces, such as water-oil or water-air phases. *Bacillus subtilis,* for example, produces lipopeptide surfactin, a powerful biosurfactant that can reduce surface tension of water from 72 mN/m to 27 mN/m at a concentration of 0.05% [1]. Other lipopeptide biosurfactants synthesised by *Bacillus sp*. include iturin [2] and fengycin [3].

Many organisms produced biosurfactants which metabolise water-immiscible substrates such as hydrocarbons and vegetable oil, thus increasing bioavailability and allowing for their adsorption, emulsification, and dispersion. Furthermore, the ability to reduce surface tension is a major characteristic of a surfactant which has potential applications in many consumer and industrial products such as shampoos, detergents, and toothpaste. Other potential applications include enhanced oil recovery, bioremediation, pharmaceuticals, cosmetics, and food-related industries. In comparison with the current widely used chemical surfactants, biosurfactants offer several advantages such as lower toxicity, higher biodegradability, and effectiveness at extreme temperatures and pH values [1].

Although promising, biosurfactants in general cannot compete with their chemically synthesised counterparts in the surfactant market mainly due to their high production costs. Thus the attention is now geared to the need for cost-effective processes and the use of inexpensive substrates, as these can reduce overall production costs up to 30% [1]. Optimisation of culture conditions for maximum biosurfactant production would also be among the strategies employed by researchers for the purpose of cost reduction. Studies on the biosurfactant production by *Bacillus* sp. have been performed using water-soluble substrates such as glucose [4] and glycerol [5] as well as water immiscible substrates such as diesel oil [6]. Other substrates such as molasses were also used for the production of biosurfactants by *Bacillus subtilis* [7]. Others have reported the optimization of culture conditions such as pH and temperature on bacterial cell growth which in turn affecting biosurfactant production [8].

Identification of a newly-found bacterium strain capable of producing a biosurfactant combined with use of cheap substrates for growth medium could give a promising future to biosurfactant to become economically competitive in the surfactant industry. Therefore, the objectives of this study were to screen and identify potential biosurfactant-producing bacteria, determine the best culture conditions for increased production of biosurfactants, and carry out a stability study of the biosurfactant produced.

Materials and Methods

Bacterial culture

Twenty five bacterial isolates were obtained from culture collection in Microbiology laboratory, School of Biosciences and Biotechnology, Faculty of Science and Technology, Universiti Kebangsaan Malaysia.

Preparation of standard inoculum

The amount of bacteria was standardized as described by Hamzah et al. [9] in order to obtain the same number of bacteria for all the tests.

Screening methodology for biosurfactant production

Approximately 10% (v/v) of standard inoculum from each isolate were grown in a 250 mL Erlenmeyer flask containing 50 mL of mineral salt medium (MSM) [10] supplemented with 1% (v/v) sunflower oil as a carbon source. The pH value of the medium was adjusted to 7.0 and the cultures were incubated in shaking condition at 150 rpm, 37 °C for 5 days. Biosurfactant production was tested from the cell-free culture supernatant obtained via centrifugation at 15000 rpm for 20 mins at 4 °C (RC5C Sorvall Centrifuge Instrument, USA).

Screening of biosurfactant producer

Potential biosurfactant producing bacteria were screened via both qualitative (oil spreading technique) and quantitative (emulsification index and surface tension measurement) methods. In the oil spreading technique, the test method was carried out according to Yousseff et al. [11]. Tapis crude oil (15 μL) was added to a Petri dish containing 50 mL of distilled water. Then, 10 μL of cell-free culture supernatant was dropped onto the surface of oil. Formation of a clear zone indicates the presence of biosurfactant. The diameter of oil displaced was measured in cm.

The emulsification index was determined according to Cooper and Goldenberg [12]. Cell-free culture supernatant and Tapis crude oil (1:1, v/v) were mixed in a test tube and vortexed at high speed for 2 min. After 24 h of incubation at room temperature, the emulsification index (% E_{24}) was determined. Isolates that give high emulsification index indicates high emulsification activity of the biosurfactant produced.

The surface tension of cell-free culture supernatant was measured using a tensiometer (Surface Tensiomat, Fisher Scientific, USA) following the Du Nouy ring method [13]. An isolate that is able to reduce surface tension < 40 mN/m is regarded as the potential biosurfactant producer [14]. Sodium dodecyl sulphate (SDS) and MSM only were used as positive and negative controls, respectively. The selected potential biosurfactant producers will be used for identification.

Identification of biosurfactant-producing bacteria
Potential biosurfactant-producing bacteria were identified based on morphological (including Gram reaction) and biochemical characteristics. Isolates were further identified by 16S rDNA analysis. Bacterial DNA was extracted via a nucleic acid extraction kit (Macherey-Nagel, Germany) according to manufacturer's instruction and amplified by polymerase chain reaction (PCR) using universal primers (p16Sf: 5'–AGAGTTTGATCCTGGCTCAG-3'; p16Sr: 5'-GGTTACCTTGTTACGACTT-3'). The PCR products were purified with a PCR purification kit (Macherey-Nagel, Germany) and sent for sequencing analysis to First Base Laboratories Sdn. Bhd. The resulting sequences were compared with sequences in the GenBank database of NCBI using the BLAST network service.

Determination of the best carbon and nitrogen sources for biosurfactant production
The best carbon and nitrogen sources for increased biosurfactant production by the test bacteria was determined by the lowest surface tension value of the cell-free culture supernatant. Different types of carbon and nitrogen sources were evaluated for production of biosurfactants, followed by determining the optimum concentration of each source. For the following experiments, 10% (v/v) of standard inoculum was inoculated in a 250 mL Erlenmeyer flask containing 50 mL MSM. pH of the medium was adjusted to (7.0). The broth cultures were incubated with shaking condition at 150 rpm, 37 °C for 5 days. Production of biosurfactant was monitored by determining the surface tension value of the cell-free culture supernatant, via du Nouy ring method using a tensiometer. Measurements were performed in triplicate.

Five different carbon sources, namely crude oil, glycerol, molasses, palm oil, and palm oil mill effluent (POME) were used at 1% (v/v) added to MSM for for increased production of biosurfactant. The best carbon source will be selected based on the lowest surface tension value and used for determining optimum concentration, which may range from 0.5 to 3% (v/v).

Four nitrogen sources (ammonium chloride (NH_4Cl), ammonium nitrate (NH_4NO_3), peptone and yeast extract) were evaluated for increased production of biosurfactant, maintaining equal amount of total nitrogen in each media at 24.21%. For the evaluation of the most optimum nitrogen concentration, the selected nitrogen source was varied from 0.1 to 0.8% (w/v). The selected carbon and nitrogen sources at their optimum concentration will be used in the subsequent experiments.

Stability studies
Stability studies were carried out using extracted biosurfactant which was carried out via acid precipitation followed by solvent extraction method [7].

To study the effects of pH on biosurfactant activity, equal volumes of extracted biosurfactant (1% w/v in distilled water) and buffer solution were mixed and adjusted to pH 2 – 5 using citrate-phosphate buffer, pH 6 – 8 using phosphate buffer, and pH 9 – 12 using carbonate-bicarbonate buffer solutions and incubated for 30 min. at room temperature before measuring surface tension using a tensiometer.

For the thermal stability study, extracted biosurfactant was used to prepare biosurfactant solutions (1% w/v) in 0.1 M phosphate buffer solution (pH 7). Test tubes containing biosurfactant solutions were incubated at different

temperatures (10, 20, 30, 40, 50, 60, 70, 80, 90, 100 °C) for 1 hour, then autoclaved at 121 °C for 15 min. Test solutions were allowed to cool to room temperature before measuring surface tension.

A stability study at different salinity levels was performed by adding extracted biosurfactant (1% w/v) into sodium chloride (NaCl) solution at different concentrations (2 – 10% w/v). Surface tension was determined after incubation for 1 hour at room temperature.

Statistical analysis

The results are represented as the mean ± standard deviation from at least three replicates. One-way analysis of variance was performed on surface tension data to determine the significant differences in the values obtained. All statistical analyses were performed using SPSS (version 14.0).

Results and Discussion

Screening of biosurfactant production

Three analytical methods were selected for screening of biosurfactant production due to their advantages in terms of simplicity, low cost, and quick implementation. Of 25 isolates screened, five isolates (3M17, 6M1, 10M2, 1M13 & 4M5) showed occurrence of clearing zone by the oil spreading technique indicating potential biosurfactant production (Table 1). Isolate 4M5 scored the most positives results by producing the largest diameter of clearing zone of > 1.5 cm, emulsification index of 17% and the lowest surface tension value at 41.75 ± 0.54 mN/m.

The oil spreading technique is one of the common method used for detecting biosurfactant production [11]. This technique is more sensitive for biosurfactant detection in the cell-free culture supernatant than other screening methods such as drop collapse [15] and blood haemolysis [16]. The oil spreading technique depends on the decrease in water-oil interfacial tension due to the presence of biosurfactant regardless of its structures [17]. Of five isolates positive for oil spreading technique, it was found that isolate 4M5 produced the largest diameter of clearing zone of more than 1.5 cm, suggesting high biosurfactant concentration in the culture medium. Thavasi et al. [18] showed potential biosurfactant producers produced diameter of clearing zone of ≥0.5 cm. Karthik et al. [19], employing oil spreading technique as one of their screening methods, reported a potential biosurfactant-producing microorganism produced diameter of clearing zone in the range of 0.9 – 2.0 cm, whereas poor biosurfactant producers produced 0.1 – 0.2 cm.

Emulsification index (E_{24}) was employed to investigate the emulsifying properties of biosurfactant. Crude oil was used as the hydrophobic substrate, for isolates capable of releasing surfactant and emulsifying crude oil may have potential application in bioremediation processes of contaminated areas with crude oil. Table 1 showed no emulsification ($E_{24} = 0$) when distilled water (negative control) was mixed with crude oil, indicating no surfactant or surfactant-like molecules that may influence the results present in the system. The assumption is that if the cell-free culture supernatant contains biosurfactant, it will then emulsify hydrophobic substrates and maintain stable emulsions for at least 24 hours [20], consequently this method gives just an indication of the presence of biosurfactant. Of 25 isolates screened, only isolates 4M5 and Sf-S5-3 were able to form and maintain stable emulsions with E_{24} of 17% and 8% respectively, while all other isolates that showed negative in oil spreading technique had $E_{24} = 0$ (Table 1).

Emulsification index (17%) by isolate 4M5 was found to be lower by 30% compared to *Pseudomonas aeruginosa* [16] and 36% compared to *Serratia sp* [21] used for selection of biosurfactant producers. Karthik et al. [19] reported that an emulsification index ranging from 5.0 – 75% was indicative of biosurfactant producers by marine actinobacteria such as *Streptomyces, Nocardiopsis* and *Rhodococcus sp*. Isolate Sf-S5-3 on the other hand, may produce an extracellular compound, also known as a bioemulsifier that has emulsifying activity, but it could not effectively reduce the surface tension of culture media, as the diameter of the clearing zone was negative and surface tension value of isolate Sf-S5-3 was 55.5 mN/m.

Table 1. Comparison of three methods for biosurfactant producer

Bacterial isolates	Oil spreading technique	Surface tension (mN/m)	Emulsification index (% E_{24})

Oil spreading technique '-' clear zone diameter <0.5cm '+' clear zone diameter 0.5-0.9cm; '++' clear zone diameter 1.0-1.5 cm; '+++' clear zone diameter >1.5cm

Quantitative analysis using surface tension measurement additionally supported the biosurfactant production potential of isolate 4M5. It was able to reduce the surface tension of culture medium from 58.95 to 41.75 mN/m. This value is much closer to the surface tension value of 40 mN/m, which was recommended for selection of biosurfactant producer [14]. All other isolates showed surface tension measurements of > 45 mN/m.

A lot of studies related to screening of potential biosurfactant producers rely on surface tension measurement due to its reliability and accuracy in quantifying soluble biosurfactant in the culture medium [15]. Thavasi et al. [18] obtained surface tension values ranging between 30.8 - 38.75 mN/m for potential biosurfactant producers among *Bacillus* species. Surface tension value above 45 mN/m is regarded as negative for biosurfactant production [22].

Since the cell-free culture supernatant of isolate 4M5 was the only isolate that satisfied all three screening methods, it was then selected for identification, determination of the best carbon and nitrogen sources for biosurfactant production and stability studies. Production of extracellular biosurfactant is advantageous from an industrial point of view because product recovery process can be simplified, therefore becoming more economical [23].

Several studies have shown that the use of vegetable oils as the only source of carbon and energy stimulate biosurfactant production by microorganisms. *Pseudomonas* spp. were reported to produce higher amount of biosurfactant when using sunflower oil compared to other vegetable oil such as olive and corn oil [24], with some strains recorded surface tension value of < 40 mN/m [25]. Ferraz et al. [26] found that *Serratia marcescens* produced biosurfactant with surface tension value of 29.75 mN/m, while biosurfactant from *Enterococcus* strains recorded 68% reduction in surface tension of culture media [27] when using sunflower oil as the carbon substrate. Vegetable oil contains fatty acids that undergo modification for incorporation into surface active products [28]. Main fatty acid content in sunflower oil is linoleic acid (60%) [26], thus suggesting that this fatty acid was responsible for stimulating biosurfactant production by isolate 4M5.

Identification of biosurfactant-producing bacteria

Gram staining of isolate 4M5 showed that it is a Gram positive, rod-shaped bacterium. The colonies on nutrient agar were cream-coloured, flat, and circular with diameter between 5 – 6 mm. Biochemical tests revealed that isolate 4M5 is motile, hydrolysed starch and able to break down hydrogen peroxide suggesting the presence of the enzyme catalase. Isolate 4M5 fermented glucose but not sucrose or lactose and able to utilise citrate as its sole carbon source for growth. Biochemical test results for isolate 4M5 were negative for oxidase enzyme, indole, and H_2S production (Table 2). All of these features strongly indicate that isolate 4M5 is *Bacillus subtilis*. This was further confirmed by analysis of 16S rRNA gene sequences (1212 bp) by BLAST database. The BLAST analysis showed 99% similar identity with *B. subtilis*. Isolate 4M5 is now designated *Bacillus subtilis* UKMP-4M5.

Table 2. Characteristics of isolate 4M5

Test	Results	Test	Results
Gram reaction	+	Shape	rod
Motility	+	Catalase	+
Growth at		Starch hydrolysis	+
20 ºC	−	Methyl red	+
30 ºC	+	Vogues-Proskauer	+
50 ºC	+	H_2S production	−
60 ºC	−	Indole	−
Triple Sugar Iron	K/A	Simmon's citrate	+

+ = positive, − = negative, K/A = alkaline slant/acidic butt

The majority of Gram-positive bacteria capable of producing biosurfactant are from the *Bacillus* sp. often which was isolated from oil reservoir [29] or soil sample contaminated with petroleum [30]. The genus is reported to produce different types of lipopeptide biosurfactants, such as surfactin, lichenysin, gramicidins and polymyxins. *Bacillus subtilis*, for example, has been reported to produce three types of lipopeptides, namely surfactin, iturin and fengycin [1, 2].

Determination of the best carbon and nitrogen source for biosurfactant production

Production of biosurfactant by *B. subtilis* UKMP-4M5 has been found to be induced by carbon sources. All five types of carbon sources tested showed a reduction in surface tension of a culture medium (Figure 1). Surface tension values obtained were ranged from 39.7 – 51.7 mN/m indicating production of extracellular surface active

compounds by *B. subtilis* UKMP-4M5 using different carbon sources. There is no significant difference in surface tension value between palm oil and POME. Palm oil was chosen as the best carbon source for biosurfactant production based on the lowest surface tension value at 39.7 ± 1.23 mN/m, compared to POME which recorded a higher surface tension value at 43.0 ± 0.84 mN/m.

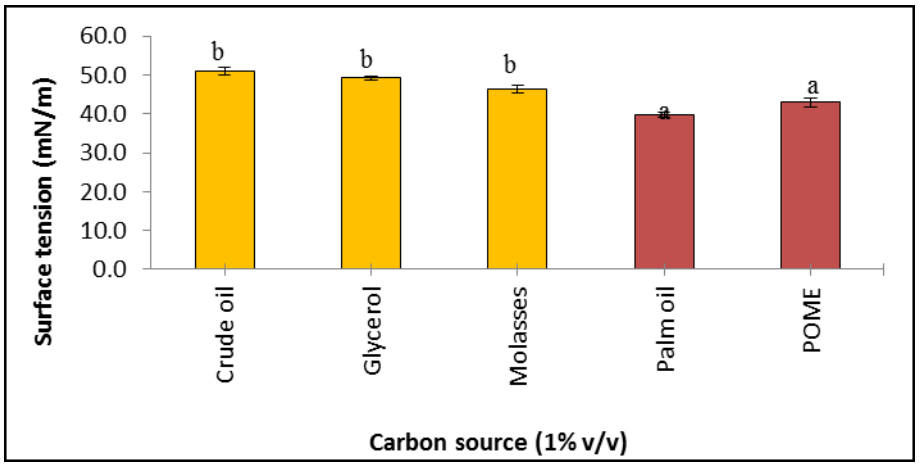

Figure 1. Effect of different carbon sources on the production of biosurfactant by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a and b indicate significant differences ($p < 0.05$) among different carbon sources.

Production of biosurfactant by *B. subtilis* had been reported utilizing mainly water-soluble substrates such as glucose [4], sucrose [31] and glycerol [5]. This is probably due to single-phase fermentation pathway using water-soluble substrate is simpler and thus preferred by microbes than biphasic fermentation [32]. The present study however, showed the ability of *B. subtilis* UKMP-4M5 to produce biosurfactant using various types of carbon sources. Although no experiments on cell growth towards different carbon substrates were conducted, *B. subtilis* strains were reported to be able to grow and subsequently produce biosurfactants on various carbon substrates tested such as POME [33], glycerol [5], palm oil [34], molasses [7] and crude oil [35]. In the present study, when palm oil was used as a carbon substrate, *B. subtilis* UKMP-4M5 produced biosurfactant with the lowest surface tension value (39.7 mN/m) compared to the other carbon substrates used. This suggests that *B. subtilis* UKMP-4M5 is a lipase positive. This enzyme might be responsible for hydrolysing vegetable oils to produce long chain fatty acids, the important precursors for biosurfactant synthesis [36]. Furthermore, at the same concentrations, vegetable oil can generate more energy than glucose. Other studies have also shown that the use of palm oil as carbon source induced biosurfactant production by *B. subtilis* PT2 [34] and *P. aeruginosa* FR [37]. A study by Li et al. [36] demonstrated that palm oil was the best carbon source for *P. aeruginosa* GIM32 produced the highest yield of rhamnolipid (30.4 g/L). The use of palm oil as carbon source is advantageous from industrial point of view since it is inexpensive substrates and abundantly available so it can drastically decrease the biosurfactant production cost. Alternative carbon sources from industrial byproducts such as POME can also be effectively used for biosurfactant production by *B. subtilis* UKMP-4M5 since it produces low surface tension values with no significant difference with palm oil. Nevertheless, palm oil produced the lowest surface tension value (39.7 mN/m) compared to POME (43.0 mN/m). Crude oil was found to be the least preferred carbon source for biosurfactant production. Crude oil in general contains various components such as saturated hydrocarbons, aromatic compounds, and heavy metals [38] that probably not suitable for enzyme synthesis necessary for biosurfactant production. Haddad et al. [32] reported that crude oil did not support the growth of *B. subtilis* HOB2, thus resulting in a high surface tension value for the culture medium, while Jazeh et al. [35] reported the use of crude oil as carbon substrate supported the growth of *B. subtilis* and subsequently production of biosurfactant.

Palm oil was then used to study the biosurfactant production by *B. subtilis* UKMP-4M5 at various concentrations (0.5 – 3% v/v). Figure 2 displayed that the highest biosurfactant activity was at 2% (v/v) palm oil concentration, with the lowest surface tension value of 35.89 ± 0.71 mN/m. Further increases in the concentration of palm oil resulted in a significant increase in surface tension measurements.

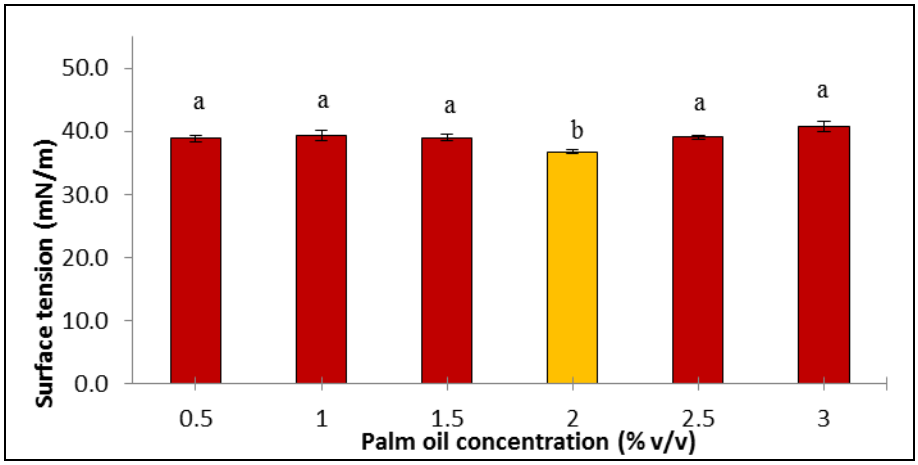

Figure 2. Effect of different concentrations of palm oil on the production of biosurfactant by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a and b indicate significant differences ($p < 0.05$) among different concentration of palm oil.

Pornsunthorntawee et al. [34] also reported in their study that optimum concentration of palm oil for biosurfactant production by *B. subtilis* PT2 was 2% (v/v) with maximum surface tension reduction of about 43%. This value is comparable to the percentage obtained in the present study, which was a 40% surface tension reduction from negative control (surface tension value of 58.89 mN/m). *P. aeruginosa* was also found to produce biosurfactant when using 2% (v/v) palm oil as carbon source with surface tension value of 30 mN/m [39]. Other researchers demonstrated the use of 5% (v/v) palm oil as an optimum concentration for maximum production of biosurfactant (30.4 g/L) by *P. aeruginosa* [37].

Medium constituents such as nitrogen source also affect the production of biosurfactants by *B. subtilis* UKMP-4M5. In this study, there was no significant difference between yeast extract and ammonium chloride in terms of surface tension reduction (Figure 3). Nevertheless, yeast extract was chosen to be the best nitrogen source as it produced the lowest surface tension value (35.02 ± 0.25 mN/m) compared to ammonium chloride (36.77 ± 0.71 mN/m).

A study by Pereira et al. [31] also showed yeast extract was found to be the best nitrogen source for optimum biosurfactant production by *B. subtilis* #309 with surface tension value of 28.73 ± 0.3 mN/m. A study by Fontes et al. [40] found that the use of yeast extract in combination with ammonium sulphate were the best nitrogen sources for optimum production of biosurfactant by *Yarrowia lipolytica* (surface tension value of 21.1 mN/m and E_{24}=60.4%). For inorganic nitrogen, ammonium chloride was shown to be a better source of nitrogen as opposed to ammonium nitrate for biosurfactant production by *B. subtilis* UKMP-4M5, though a study by Fonseca et al. [41] showed that ammonium nitrate was the best inorganic nitrogen source for biosurfactant production by *B. subtilis* YRE207. Besides growth, nitrogen plays an important role in biosurfactant production, especially in the lipopeptide biosurfactant as a peptide structure [42].

Effect of different yeast extract concentration (0.1 – 0.8% w/v) for biosurfactant production by *B. subtilis* UKMP-4M5 was investigated. An increase in the concentration of yeast extract increases the production of biosurfactant as

evidenced from reduction in surface tension of culture medium (Figure 4). Although there was no significant difference in the surface tension values for yeast extract concentration between 0.3 – 0.6% (w/v); the lowest surface tension value at 33.6 ± 0.33 mN/m was recorded when 0.5% (w/v) yeast extract was used. Therefore 0.5% (w/v) of yeast extract was chosen to be the best concentration for biosurfactant production rather than 0.3% (w/v) of yeast extract (higher surface tension value recorded at 35.9 ± 1.1 mN/m). An increase in the concentration of yeast extract beyond 0.6% (w/v) resulted in the increase of surface tension values significantly, indicating less biosurfactant production by the test bacterium.

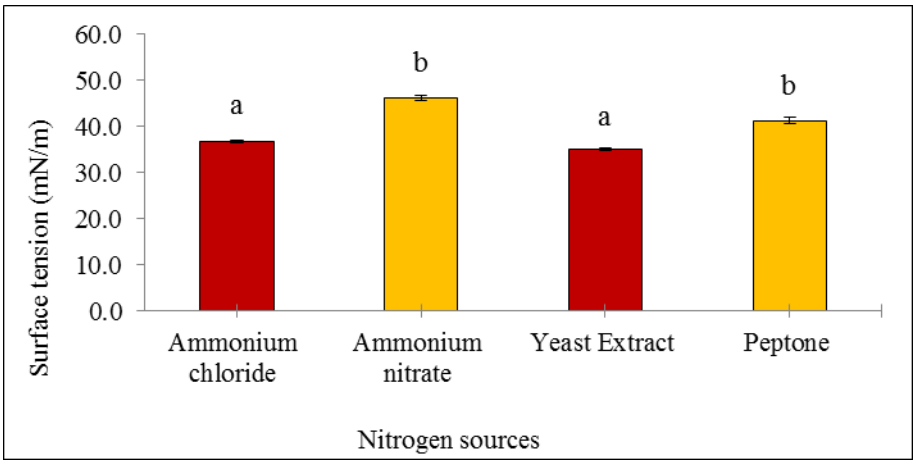

Figure 3. Effect of different nitrogen sources on the production of biosurfactant by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a and b indicate significant differences ($p < 0.05$) among different nitrogen sources.

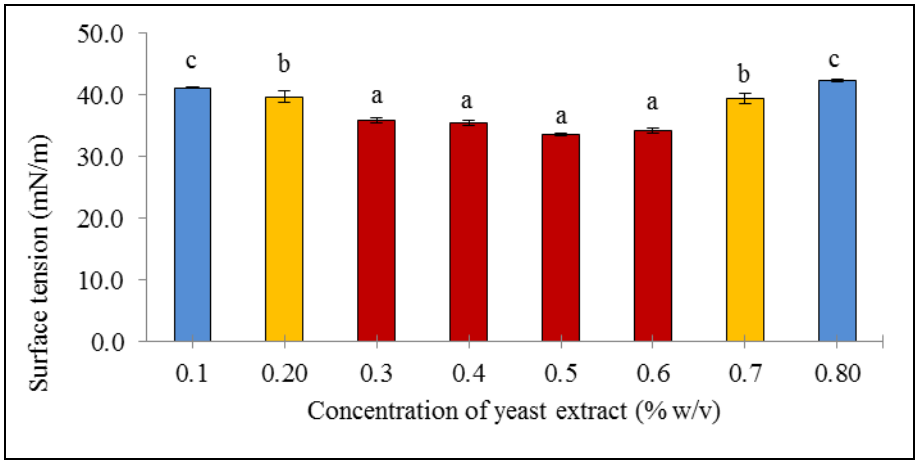

Figure 4. Effect of different concentrations of yeast extract on the production of biosurfactant by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a, b, and c indicate significant differences ($p < 0.05$) among concentrations of yeast extract.

Bacillus subtilis UKMP-4M5 was found to produce biosurfactant with the lowest surface tension value of 35.02 ± 0.25 mN/m when using 0.5% (w/v) yeast extract. Similar results were shown by Vedaraman & Venkatesh [43] whereby the use of 0.5% (w/v) yeast extract was optimum for surfactin production (983 mg/L) by *B. subtilis* MTC2423. Rashedi et al. [44] reported in their study that the use 0.5% (w/v) yeast extract in combination with 0.5% (w/v) soy flour were the best nitrogen sources for optimal production of rhamnolipid (3.7 g/L) by *P. aeruginosa*. A study by Nalini et al. [6] reported the use of 0.3% (w/v) yeast extract was optimal for biosurfactant production by *Bacillus sp* grown in a glucose-containing medium, while Pereira et al. [31] used 0.2% (w/v) yeast extract for biosurfactant production by *B. subtilis* #309 when grown in sucrose-containing medium. Fontes et al. [32] on the other hand, used a combination of 0.05% (w/v) yeast extract and 10 g/L ammonium sulphate to obtain optimum production of biosurfactant by *Y. lipolytica*, with surface tension value of 20.9 mN/m and emulsification index of 73.1%. The present study showed 0.3% (w/v) yeast extract was enough to produce biosurfactant with significant reduction in the surface tension value; however, 0.5% (w/v) produced the lowest surface tension value. The increase in surface tension value with further increase in yeast extract concentration (beyond 0.6% w/v) may be due to nitrogen-limiting conditions no longer being a factor in biosurfactant biosynthesis. Some studies reported that biosurfactant production is more efficient under nitrogen-limiting conditions [36].

The best conditions for biosurfactant production by *B. subtilis* UKMP-4M5 were using 2% (v/v) palm oil and 0.5% (w/v) yeast extract as carbon and nitrogen sources respectively as it produced the lowest surface tension value at 33.6 ± 0.33 mN/m.

Stability studies

Biosurfactant activity was tested over a range of pH values (2 – 12). Results showed the activity of biosurfactant was greatly affected by changes in pH. Low biosurfactant activity was detected at extreme pH; 2 to 4 and above 10 (Figure 5). Surface tension values remained relatively stable between pH 6 to 8 with no significant difference; however the lowest surface tension value was achieved at pH 6. The result also showed that highly acidic pH caused a greater reduction in surface activity than highly alkaline pH (surface tension value of 38.77 mN/m at pH 2 as opposed to 36.9 mN/m at pH 12).

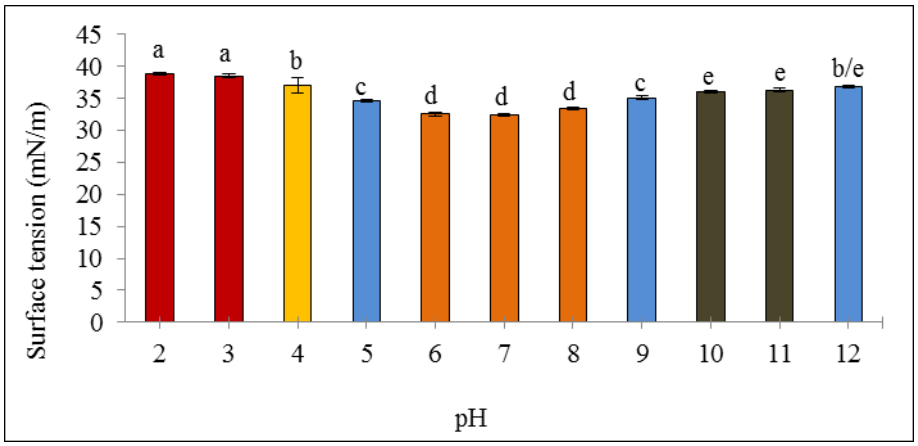

Figure 5. Effect of pH on biosurfactant activity produced by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a, b, c, d, and e indicate significant differences ($p < 0.05$) among different pH.

pH values between 2 to 4 showed a significant decrease in biosurfactant activity as shown by the increase in surface tension values. These results are in accordance with those reported by Vaz et al. [45], whereby biosurfactant stability from *B. subtilis* EG1 was found to be unstable by acidic pH. Abdel-Mawgoud et al. [7] also reported similar findings in their study in which surfactin activity started to decrease at pH < 5, samples become turbid due partial precipitation of biosurfactant in acidic conditions. The test biosurfactant showed better stability at alkaline

than acidic conditions, as shown by lower surface tension values when incubated in alkaline conditions as compared to acidic conditions. Similar results reported by El-Sersy [8] indicated that biosurfactant from *B. subtilis* N10 was found to have high surface activity predominantly in the alkaline condition, pH between 6.0-12. Abdel-Mawgoud et al. [7] reported that surfactin from *B. subtilis* was soluble in aqueous solutions at pH values higher than 5.0 with optimum solubility at pH 8.0-8.5. This could be due to the acidic nature of surfactin, as the presence of two carboxylic groups from glutamic and aspartic acid residues confers an anionic nature [7]. Similar results had been reported for biosurfactant production from other microorganisms such as *P. aeruginosa* [14], which was stable at a wide range of pH between 6.0-10.0, whereas stability of biosurfactant from *Nocardiopsis* sp. was found to be stable between pH 8 – 12 [46].

Thermal stability of biosurfactant was investigated over a wide temperature range (10 – 100 °C) for 1 hour and cooled to room temperature. Results showed that the biosurfactant from *B. subtilis* UKMP-4M5 exhibited excellent surface activity with no significant difference ($p > 0.05$) of the temperature tested (Figure 6). Surface activity remained relatively stable with surface tension values between 32.47 – 33.10 mN/m even after exposure to high temperature (100 °C). Interestingly, the test biosurfactant retained its surface activity even after autoclaving, with a negligible increase in surface tension value (0.67 mN/m) before and after autoclaving (Figure 7), suggesting that no degradation occurred.

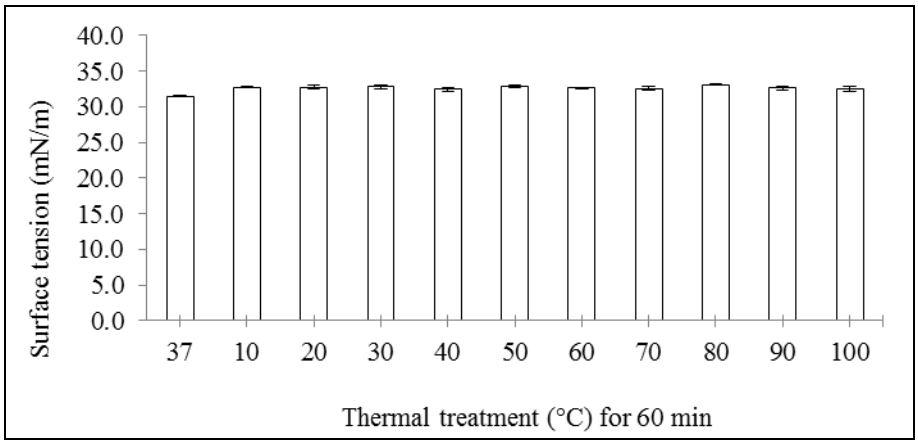

Figure 6. Effect of temperature on biosurfactant activity produced by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD.

Thermal stability studies of biosurfactant from *B. subtilis* UKMP-4M5 indicated that the surfactant was thermostable, as heating up to 100 °C caused no significant effect on the biosurfactant performances. The high thermal stability of the test biosurfactant is on par with other synthetic surfactants such as linear alkylbenzene sulfonate (LAS) and alkylpolyglucoside [45], but superior to sodium dodecyl sulphate, which exhibits a significant loss of activity at temperatures above 70 °C [46]. Interestingly, the test biosurfactant retained its surface activity even after autoclaving at 121 °C for 20 min, suggesting its potential application in food, pharmaceutical and cosmetic industries where heating to achieve sterility are important. Biosurfactants from *B. subtilis* have been reported to exhibit excellent thermal stability. Surfactin for example showed no change in surface tension value before and after heating treatment at 100 °C, though slight increase was observed at 121 °C for 10 min. This may be due to precipitation of heat-dependent substances such as proteins contaminating the surfactin solution which might have been co-extracted during the extraction steps [7]. Haddad et al. [32] investigated the stability of biosurfactant from a *B. subtilis* strain at 100 °C at different exposure time. The authors reported that no interference on the surface activity could be found, thus corroborating the results obtained in the current study. Results from the current study have thus illustrated the stability of biosurfactant produced by *B. subtilis* UKMP-4M5 at high temperatures which may be encountered in oil fields.

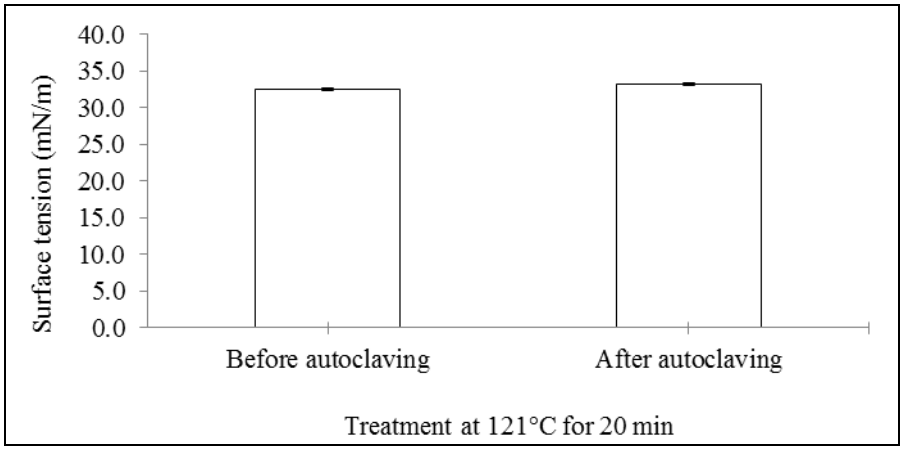

Figure 7. Effect of autoclaving on biosurfactant activity produced by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD.

The effect of different NaCl concentrations (1 – 15% w/v) on biosurfactant activity from *B. subtilis* UKMP-4M5 was studied to evaluate its potential application in bioremediation of contaminated marines. Figure 8 shows that the changed in surface tension value of the tested biosurfactant was not significant between 1 – 5% (w/v) NaCl concentrations. Optimum stability of biosurfactant was observed at 3% (w/v) NaCl with the lowest surface tension value at 33.18 mN/m.

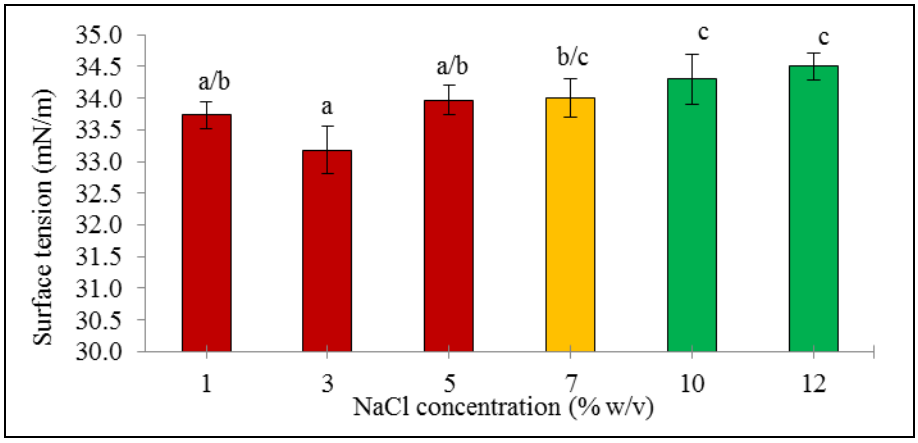

Figure 8. Effect of NaCl concentration on biosurfactant activity produced by *B. subtilis* UKMP-4M5. All values are mean of three replicates ± SD. The letters a, b, and c indicate significant differences ($p < 0.05$) among NaCl concentrations

The addition of NaCl in the range tested had a weak effect on the surface tension of biosurfactant produced by *B. subtilis* UKMP-4M5. Stability of biosurfactant from *B. subtilis* had been reported to be excellent in the presence of NaCl up to 20% (w/v) [8]. Ghojavand et al. [29], who reported that NaCl concentration, did not affect the surface activity of biosurfactant from *B. subtilis* PTCC 1696, the highest surface tension value recorded at 34 mN/m at 20% (w/v) NaCl. Similarly, Haddad et al. [32] reported that 25% (w/v) NaCl concentration showed only slight variation in the surface tension value (4 mN/m) of biosurfactant from *B. subtilis* HOB2. The stability of the biosurfactant

obtained from the present study is shown to be superior to other strain of *B. subtilis* which was reported to be losing its surface activity (surface tension value at 45 mN/m) when level of NaCl reached 11% (w/v) [5]. These findings have revealed that the tested biosurfactant had a high level of tolerance to ionic strength, and is thus an excellent candidate if compared with chemical surfactants for use in bioremediation of contaminated marine environments. Chemical surfactants, however, are deactivated by 2 – 3% salt concentrations [47].

Conclusion

In the present study, a bacterial isolate identified as *B. subtilis* UKMP-4M5 was found to be the most potential biosurfactant producer. This isolate can produce biosurfactant using 2% (v/v) palm oil with addition of yeast extract with low surface tension value. The semi purified biosurfactant is thermostable to extreme temperatures. Furthermore, the test biosurfactant has proved to be robust and stable over huge ranges of pH and salinity. Thus, the biosurfactant has great potential for commercial use in industries such as enhanced oil recovery, bioremediation, and food-related industries as an alternative to the synthetic surfactants. Further work is required to fully characterise the biosurfactant to better predict its potential applications.

Abstract

The effect of Al dopants and sintering temperature on thermoelectric properties of ZnO was studied using the response surface method. The design of experimental work was performed with the response surface method used to determine the significant level of factors which are sintering temperature in the range of 800 – 1000 °C and Al dopants in the range of 0 – 4 wt.%. The thermoelectric properties of Al-doped ZnO were enhanced with increasing Al dopants and slightly decreased when increasing sintering temperature. Additional phase $ZnAl_2O_4$ was detected for 3 wt.% and 4 wt.% Al-doped ZnO pellets as the sintering temperature increased to 1000 °C. The presence of $ZnAl_2O_4$ phase slightly decreased the electrical conductivity compared to single ZnO phase samples. The optimum parameter values for this study was Al dopant (4 wt.%) and sintering temperature (800 °C). The effect of Al doping to the band structure of ZnO was studied using first-principles based on density functional theory (DFT). The calculated band structure of ZnO and Al doped ZnO shows that ZnO is a direct band gap semiconductor. The calculated band gap of ZnO (0.749 eV) become smaller with the concentration of Al doping increased to 4 wt.% (0.551 eV). The trend of the calculated band gap of Al-doped ZnO was in agreement with the electrical conductivity test results which increased with increasing Al content. However, it must be noted that the software predictions do not take into account the presence of additional $ZnAl_2O_4$ phases. The presence of these extra phases may lead to even lower electrical conductivity.

Keywords: Al-doped ZnO, response surface method, sintering temperature, thermoelectric, electronic band structure

Abstrak

Kesan Al dop dan suhu pembakaran ke atas termoelektrik ZnO dikaji dengan menggunakan kaedah gerak balas permukaan. Reka bentuk kerja eksperimen telah dilakukan dengan kaedah gerak balas permukaan untuk menentukan aras signifikan suhu pembakaran pada julat 800 – 1000 °C dan Al dop dalam lingkungan 0 – 4% berat. Sifat – sifat termoelektrik Al-dop ZnO telah dipertingkatkan dengan peningkatan Al dop dan pensinteran suhu. Fasa tambahan $ZnAl_2O_4$ dikesan bagi 3% berat dan 4% berat Al-dop ZnO bila suhu pembakaran meningkat daripada 800 °C hingga 1000 °C. Kekonduksian elektrik menurun dengan kehadiran fasa $ZnAl_2O_4$ berbanding sampel fasa ZnO tunggal. Nilai – nilai parameter optimum untuk kajian ini adalah Al pendopan (4% berat) dan suhu pensinteran (800 °C). Kesan Al doping kepada struktur jalur ZnO dikaji menggunakan prinsip pertama berdasarkan teori fungsi ketumpatan. Struktur jalur yang dikira pada ZnO dan Al dop ZnO menunjukkan bahawa ZnO adalah semikonduktor jurang jalur terus. Dengan Al dop, jurang jalur ZnO (0.749 eV) menjadi lebih kecil dengan peningkatan kepekatan Al dop pada 4 wt.% (0.551 eV). Trend jurang jalur yang dikira pada ZnO Al-didopkan adalah selari dengan keputusan ujian kekonduksian elektrik yang meningkat dengan peningkatan kandungan Al. Walau bagaimanapun, ia perlu diambil perhatian bahawa ramalan perisian tidak mengambil kira kehadiran fasa $ZnAl_2O_4$ tambahan. Kehadiran kedua – fasa tambahan boleh membawa kepada kekonduksian elektrik yang lebih rendah.

Kata kunci: Al dop ZnO, kaedah gerak balas permukaan, suhu pembakaran, termoelektrik, struktur jalur elektronik

Introduction

Thermoelectric materials could potentially convert heat into electricity through thermoelectric power [1]. The efficiency of energy conversion depends on the thermoelectric figure of merit of the material. Based on the figure of merit, these materials must have the unique combination of high electrical conductivity, high Seebeck coefficient and low thermal conductivity [2]. Seebeck coefficient (S) of a material is the voltage generated between two points in the material per unit temperature difference between these points [3].

Zinc oxide (ZnO) is an II-VI compound semiconductor with a wide direct band gap at room temperature [4]. It is a widely used material in various application such as gas sensors, varistors, UV resistive coatings, piezoelectric devices, surface acoustic wave devices and transparent conductive oxide electrodes [5,6]. The main drawback of ZnO as thermoelectric materials is due to the low electrical conductivity at room temperature. The electrical conductivity can be increased by special heat treatment and doping of specific impurities into the crystal lattice. In the hexagonal close packed lattice of the ZnO wurtzite structure, half of the tetrahedral holes and all of the octahedral holes are empty, providing further possible dopant sites [7]. A dopant ion introduced to modify the electronic properties of a material needs to be incorporated into the crystal structure of the host material (either in lattice sites or interstitially). ZnO can even be made to exhibit metallic conductivity as for transparent electrode similar to Indium tin oxide glass. In general, 0.5 – 1% addition of trivalent cations such as aluminium (Al) and chromium (Cr) decrease the resistivity of ZnO approximately 10 orders of magnitude [8]. Jimenez-Gonzalez et al. [9] explains the increase in the conductivity of ZnO when Al is introduced as a dopant, in terms of donor behaviour from Al. Al has one valence electron more than Zn, substitution of Al for the Zn atom or Al occupation of the interstitial sites increases the concentration of charge carriers present in the material.

The properties of ZnO are related to the composition and phase formation. The conductivity properties of ZnO can be tailored by controlling the deviation from stoichiometry and doping [10]. Therefore, it is necessarily to understand the effect of the individual dopant element to the electrical properties and phase formation of ZnO. In this work, the effect of Al dopant (0 – 4 wt.%) and sintering temperature (800 – 1000 ^{o}C) on the thermoelectric properties were studied using the response surface methodology. The band structure of ZnO with different Al contents are calculated by first principles method based on Density Functional Theory (DFT) as a comparison for the electrical conductivity.

Materials and Methods

Chemical and reagent

Analytical grade ZnO powder and Al_2O_3 powder were used as the starting materials for the preparation of pellet samples. The properties of ZnO and Al_2O_3 were shown in Table 1.

Table 1. Properties of ZnO, Al_2O_3, Fe_2O_3 and CuO (HmbG Chemicals)

Properties	Zinc oxide	Alumina
Molecular formula	ZnO	Al_2O_3
Molar mass, g/mol	81.408	375.134
Appearance	white solid	white solid
Density, g/cm^3	5.606	3.95 – 4.1

Experimental procedure

Appropriate amounts of ZnO and Al_2O_3 powder were mixed using the solid state method to prepare 0, 1, 2, 3 and 4 wt.% Al-doped ZnO. The samples were shaped into pellets of 5 mm of thickness and 15 mm in diameter. All

samples were compacted using a cold hydraulic press machine at 75MPa for 10min. The green compact was sintered in furnace (Model HT4-1600-SIC) at different sintering temperature 800 °C, 900 °C and 1000 °C for 4 hours with heating rate of 10 °C/min. The synthesized samples were characterized by X-ray diffraction analysis (Shimadzu XRD 2000). The electrical conductivity of the samples was determined by the two-probe method. The current voltage measurements were carried out using a Keithley's source measure unit (Model SMU 236). The thermal conductivity of the samples was determined based on Fourier's law. The Seebeck coefficient was measured by using differential method [11] at room temperature.

Response surface methodology

Response surface methodology is a statistical method used to improve and optimize process. The response surface methodology has the advantages to evaluate multiple processing parameters and reduced the number of experimental trials. The experimental results were evaluated by the dependent variables of thermoelectric efficiency using Design Expert 8 [12] with surface response model. The results are obtained with the experimental design that was aimed at identifying the best levels of the Al doping (0 – 4 wt.%) and sintering temperature (800 – 1000 °C). The analysis of variance (ANOVA) is a statistical technique for the purpose of testing hypotheses on the parameters of the model. A 3-factor, 3-level factorial Box–Behnken design (BBD) was employed to investigate the effects of selected variables. BBD which is a widely used form of response surface methodology, specially made to require only 3 levels, coded as –1, 0, and +1. BBD is an independent, rotatable or nearly rotatable quadratic design (contains no embedded factorial or fractional factorial design) in which the treatment combinations are at the midpoints of the edges of the process space and at the centre.

Computational method

The ABINIT program was used to perform the band structure calculations. ABINIT is an open source program that used to compute band structure and ground state properties. The band structures of Al doped ZnO was calculated based on the DFT Kohn-Sham equations with GW computations. The GW method is a Green function technique that obtained the electron self-energy and provides an accurate determination of the quasiparticle excitation energies [13]. The k-point parameter was 3 x 3 x 1 Monkhorst-Pack. The cut off energy was set to be 816 eV (30 hartree). The ideal ZnO has a wurtzite structure at normal temperatures and pressures. The primitive cell parameters for ideal ZnO were determined as α = 3.2005 Å, c/α = 1.6131 and u = 0.3792. The parameters used in ABINIT were optimized with a convergence criterion 0.01 eV to calculate self-energy for the band gap.

Results and Discussion

XRD analysis

Based on Figure 1(a), all the samples peaks for 0, 1, 2, 3 and 4 wt.% Al-doped ZnO were identified as the plane reflection for wurtzite phase of ZnO according to the JCPDS data file (No. 36-1451). The XRD pattern of Al-doped ZnO sintered at 900 °C was indicated in Figure 1(b). Based on the test results, all the peaks for 0, 1, 2, 3 and 4 wt.% Al-doped ZnO matched the JCPDS data file (No.36-1451) as the plane reflection for wurtzite phase of ZnO. There was additional phase $ZnAl_2O_4$ that matched the JCPDS data file (No.05-0669) detected for 4 wt.% Al-doped ZnO sintered at 900 °C. From the test results show in Figure 1(c), additional phase $ZnAl_2O_4$ was detected for 3 wt.% and 4 wt.% Al-doped ZnO with the sintering temperature increased to 1000 °C. The existence of secondary phase $ZnAl_2O_4$ may reduce the electrical conductivity of the sample [14].

Electrical conductivity

Based on the analysis of variance (ANOVA) for electrical conductivity as shown in Table 2, the Model F-value of 404.80 implies the model was significant. The Prob > F values of less than 0.05 may indicate that Al dopants and sintering temperature have significant effects on the electrical conductivity of the samples.

Figure 2 show the 3D plot for electrical conductivity profile in accordance to the response surface model. The highest peak electrical conductivity for ZnO was achieved with 4wt.% Al dopants sintered at temperature 800 °C. Based on results shown in Figure 2, increasing the concentration of Al dopant caused a significant increase in the electrical conductivity. This might due to the Al dissolved in the ZnO crystal lattice acts as donor [15]. For example, the electrical conductivity of bulk pellets was increased significantly from 9.95 S/cm (pure ZnO) to 37.39 S/cm, 59.38 S/cm, 69.26 S/cm and 71.49 S/cm as the dopant increased to 1, 2, 3 and 4 wt.% respectively. The electrical conductivity for 4 wt.% Al-doped ZnO sintered in air at 1000 °C (70.98 S/cm) and 900 °C (71.49 S/cm) were slightly lower compared to 800 °C (71.87 S/cm). This might due to the existence of $ZnAl_2O_4$ phase as shown in Figure 1. The $ZnAl_2O_4$ phase believed to induce oxygen vacancies that lead to low conductivity. The formation of this phase may cause the resistivity increase in the samples [16].

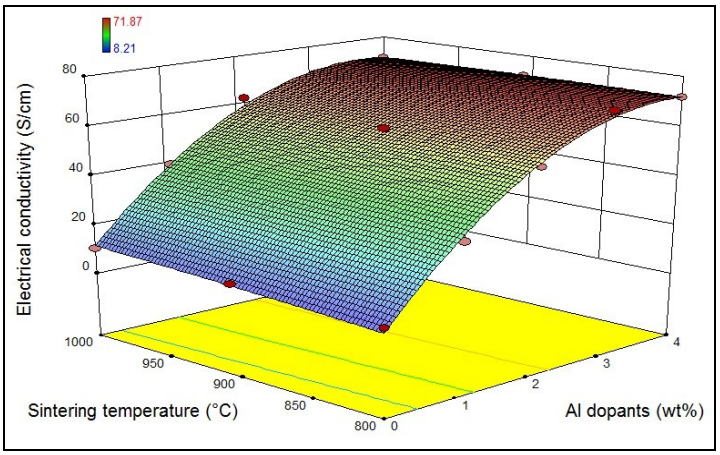

Figure 2. 3D response surface plot for electrical conductivity of Al-doped ZnO

Band structure

The electronic band structure for ZnO calculated using DFT was shown in Figure 3. The band structure shows that ZnO is direct band gap material with the valence band maximum (VBM) and the conduction band minimum (CBM) at G. The calculated band gap at point G is 0.749 eV for ZnO. Low band gap might be due to the lower exchange correlation between electrons made by the DFT-GW function.

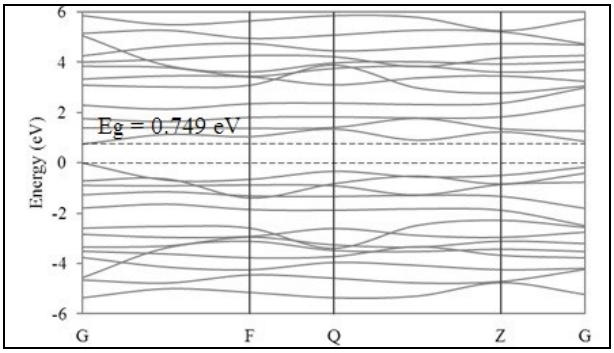

Figure 3. Electronic band structure of pure ZnO

Figure 4(a)-(d) shows the calculated band structure of 1 wt.% Al-ZnO, 2 wt.% Al-ZnO, 3 wt.% Al-ZnO and 4 wt.% Al-ZnO respectively, the corresponding band gap are 0.684 eV, 0.619 eV, 0.557 eV and 0.551eV. The band gap values of Al doped ZnO are smaller than pure ZnO shown in Figure 3. The band gap of Al doped ZnO becomes smaller with increasing Al doping content. This may due to increase of carrier concentration and enhancement of conduction [19]. As shown from Figure 4(a)-(d), The CBM and VBM are all located in the G point, it indicated that Al doped ZnO is a direct band gap semiconductor. The electrical conductivity test results were similar to the calculated band gap. The band gap becomes smaller with the amounts of Al doping increased that resulting an increase in electrical conductivity. This emphasized that a reduction of the band gap would increase the intrinsic (without defects) conductivity of ZnO. It shifts the intrinsic defect states to energies inside the conduction band.

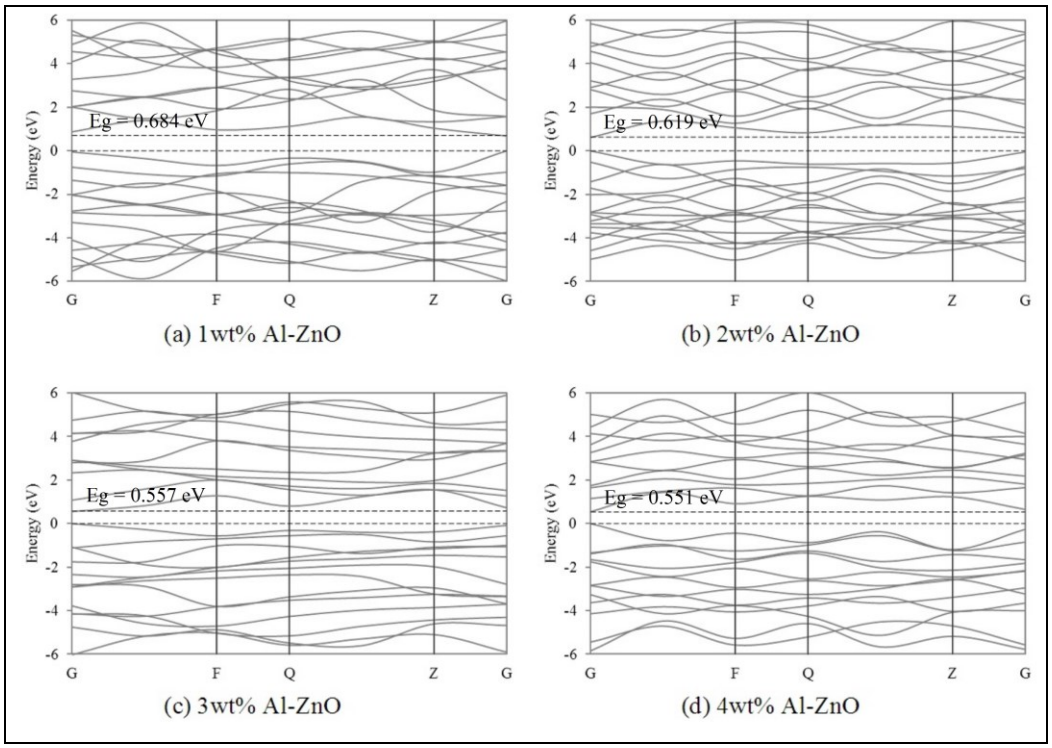

Figure 4. Electronic band structure of Al doped ZnO

Thermal conductivity

Table 3 show the analysis of variance (ANOVA) output used to estimate the variation due to each factor. The Model F-value of 51477.35 implies the model was significant. Values of "Prob > F" less than 0.05 indicate the model terms are significant. The ANOVA indicates that changing the sintering temperature and Al dopants may have a significant effect on the thermal conductivity of the samples.

The highest peak thermal conductivity for ZnO was achieved for pure ZnO sintered at 800°C. Based on results shown in Figure 5, increasing the amount of Al dopants caused a decrease in the thermal conductivity of the samples. The thermal conductivity of ZnO was 34.59 W/mK reduced to 33.21 W/mK, 31.82 W/mK, 30.44 W/mK and 29.05 W/mK with the Al doping increased to 1, 2, 3 and 4 wt% respectively. The reduction of thermal conductivity might due to the Al dopant suppress the lattice thermal conductivity of ZnO materials [20]. The thermal conductivity of the ZnO pellets decreased slightly when increasing the amount of Al dopants. The wurtzite ZnO has a high intrinsic thermal conductivity due to its strong covalent bonding and light atoms. The decrease in the thermal conductivity might be due to a phonon scattering caused by increased ZnO crystal lattice disorder when

Al dopants were added.

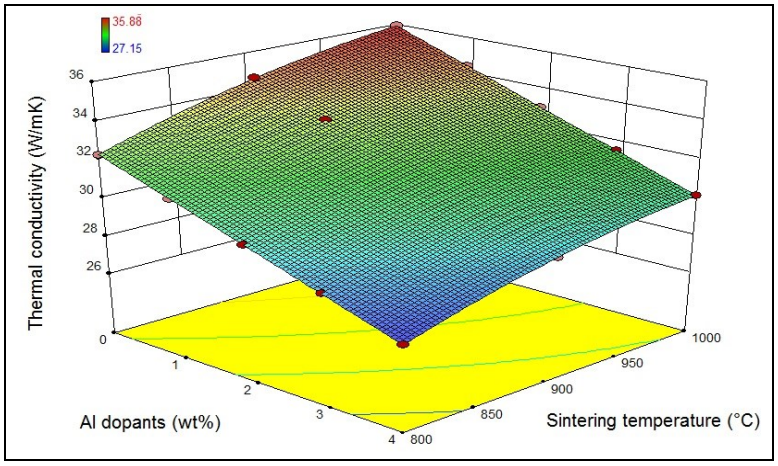

Figure 5. 3D response surface plot for thermal conductivity of Al-doped ZnO

Seebeck coefficient

Based on the analysis of variance for Seebeck coefficient as shown in Table 4, the Model F-value of 370.54 implies the model was significant. The Prob > F values below 0.05 may indicate that the sintering temperature and Al dopants have a significant effect on the Seebeck coefficient.

Figure 6 show a 3D plot curvilinear profile in accordance to the response surface model for the Seebeck coefficient. The highest peak Seebeck coefficient for ZnO was achieved for pure ZnO sintered at 1000 °C. Based on results shown in Figure 6, an increase in the Al doping concentration caused a decrease in the Seebeck coefficient of the bulk pellets. This might due to the Al dissolved in the ZnO crystal lattice acts as donor that improved the electrical conductivity and carrier concentration [21]. The negative sign of the Seebeck values was used to indicate the samples were n-type semiconductors. The magnitude of Seebeck coefficient for ZnO was 50.22 μV/K decreased to 49.22 μV/K, 48.71 μV/K, 48.21 μV/K and 47.95 μV/K with the Al dopant increased to 1, 2, 3 and 4 wt.% respectively.

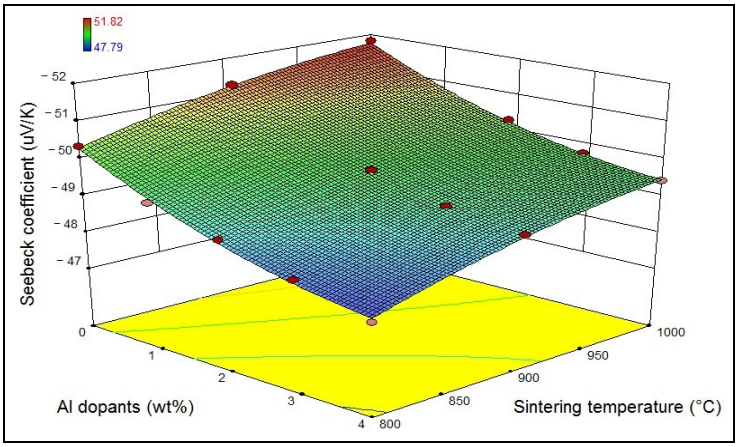

Figure 6. 3D response surface plot for Seebeck coefficient of Al-doped ZnO

Thermoelectric figure of merit

The thermoelectric figure of merit calculated from the measured values of electrical conductivity, Seebeck coefficient and thermal conductivity was shown in Figure 7. Higher figure of merit values (0.61) was observed for 4 wt.% Al-doped ZnO pellet sintered at 800 °C. The figure of merit for Al-doped ZnO was improved by doping Al. The figure of merit for 4 wt.% Al-doped ZnO sintered at 800 $^{\circ}$C was higher (Z ~ 0.58 x10^{-6}) due to high electrical conductivity and low thermal conductivity was obtained when increasing Al. The figure of merit for Al-doped ZnO (Al > 3 wt.%) was decreased when increasing sintering temperature. This was due to the formation of $ZnAl_2O_4$ phase at higher sintering temperature that lead to the reduction of electrical conductivity [22]. The presence of $ZnAl_2O_4$ phase was observed to reduce the figure of merit compared to single ZnO phase samples. This indicated the additional $ZnAl_2O_4$ phases had a deleterious effect on the thermoelectric properties.

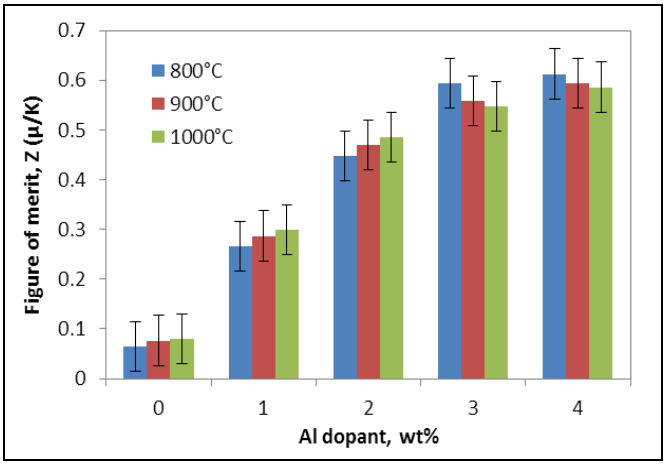

Figure 7. Figure of merit of Al-doped ZnO

Conclusion

Thermoelectric properties of ZnO were improved with increasing the amount of Al dopants. The thermoelectric figure of merit for 4 wt.% Al-doped ZnO (0.61) yielding a 10 times enhancement compared to the pure ZnO (0.06). The electrical conductivity of Al-doped ZnO was increased with increasing the amount of Al dopants. The Seebeck coefficient and thermal conductivity were decreased for Al-doped ZnO with increasing the amount of Al dopants. Thermoelectric properties of Al-doped ZnO were decreased with increasing the sintering temperature due to the additional phase $ZnAl_2O_4$. The thermoelectric figure of merit for 4 wt.% Al-doped ZnO (0.61) with lower sintering temperature (800 °C) was higher compared to the 4 wt.% Al-doped ZnO (0.58) sintered at higher temperature (1000 °C). Based on the analysis of variance, the sintering temperature and Al dopants have a significant effect to the thermoelectric properties of Al doped ZnO. Based on the response surface, the optimum values for this study were Al dopant (4 wt.%) and sintering temperature (800 °C). By using the first principles method based on DFT, the band structure of ZnO and Al doped ZnO were calculated. The band structure calculation of Al doped ZnO was investigated to provide a reference values for the electrical conductivity. Based on the DFT calculation, ZnO is a direct band gap. The band gap getting narrow as the concentration of Al doping increased from 1wt.% (0.684 eV) to 4 wt.% (0.551 eV) compare to pure ZnO (0.749 eV).

Abstrak

Hidrogel berasaskan kanji daripada ubi gadong dengan menggunakan teknik radiasi gamma telah disintesis dan pencirian terhadapnya telah dilakukan bagi mendapatkan hidrogel yang terbaik. Hidrogel berasaskan kanji ini dihasilkan dengan menggunakan asid akrilik (AA) sebagai monomer dan kanji ubi gadong sebagai ko-monomer. Teknik radiasi gamma telah digunakan sebagai agen penaut silang. Isipadu ubi gadong yang berlainan digunakan untuk menghasilkan hidrogel dengan nisbah asid akrilik (AA) kepada ubi gadong. Hidrogel dengan nisbah 4:1 dan 5:2 telah disintesis. Tindak balas yang terlibat ialah pempolimeran radikal bebas dengan menggunakan radiasi gamma. Ujian pengembangan telah dilakukan untuk menguji sensitiviti hidrogel terhadap perubahan pH. Analisis morfologi hidrogel dilakukan dengan menjalani analisis Mikroskopi Pengimbasan Elektron (SEM). Analisis struktur kimia hidrogel ditentukan oleh Spektroskopi Inframerah (IR). Pembelauan Sinar X (XRD) dijalankan bagi menunjukkan hidrogel mengandungi komponen amorfus. Kalorimetri Pengimbasan Perbezaan (DSC) dan Analisis Gravimetri Terma (TGA) dijalankan bagi menunjukkan kestabilan terma hidrogel yang disintesis. Ujian pembengkakan telah dijalankan di dalam larutan penimbal pH 3, 5, 7, 9 dan 12 pada suhu bilik. Dalam larutan penimbal 7, 9 dan 12, didapati bahawa hidrogel bernisbah 5:2 mempunyai nilai yang lebih tinggi berbanding dengan hidrogel bernisbah 4:1. Manakala di dalam larutan penimbal pH 3 dan 5 pula, hidrogel bernisbah 4:1 mempunyai nilai pengembangan yang lebih tinggi berbanding hidrogel bernisbah 5:2. Puncak pada Spektrum Inframerah membuktikan kehadiran kumpulan berfungsi –OH daripada kanji berkurangan kerana telah digunakan dalam proses pempolimeran. Daripada termogram DSC dan TGA dapat diperhatikan bahawa nilai peralihan kaca, Tg untuk hidrogel bernisbah 5:2 lebih tinggi berbanding dengan hidrogel bernisbah 4:1.

Kata kunci: hidrogel, kanji, ubi gadong, teknik radiasi gamma

Abstract

Starch-based hydrogel is synthesized using gamma radiation. The hydrogel is then characterized to obtain the best ratio of hydrogel. Starch-grafted-acrylic acid hydrogels is produced using acrylic acid as monomer and starch from gadong tuber as co-monomer. Gamma radiation is used as cross-linking agent. Different volume of starch is used to produce hydrogels with different ratios of acrylic acid (AA) to starch. Hydrogels with ratio of 4:1 and 5:2 are synthesized. The reaction involved in the synthesis of hydrogel was a free radical polymerization. Swelling test for the starch-based hydrogel is carried out to observe the ability of hydrogel respond to the environmental change. Scanning Electron Microscope (SEM) is used to determine the morphology of hydrogel. The analysis of chemical structure is determined using the Infrared Spectrometer (IR). X-Ray Diffraction (XRD) is used to determine the present of amorphous component in the hydrogel. Differential Scanning Calorimetry (DSC) and Thermogravimetric Analysis (TGA) are used to determine the thermal stability of the hydrogel. Swelling test for this hydrogel is carried out in 5 different pH buffer solution with pH 3, 5, 7, 9 and 12 at a room temperature. In the buffer solution of pH 7, 9 and

12, the hydrogel with ratio 5:2 shows high value of swelling percentage compare to the hydrogel with ratio 4:1. However, in the buffer solution of pH 3 and 5, the hydrogel with ratio 4:1 swells more compare to the hydrogel with ratio 5:2. The peak showed in the IR proved that the present of the carboxyl group in the hydrogel after the polymerization process. From the thermogram of DSC and TGA, the hydrogel with ratio 5:2 showed higher value of glass transition compared to the hydrogel with ratio 4:1.

Keywords: hydrogel, starch, ubi gadong, gamma radiation technique

Pengenalan

Hidrogel adalah rangkaian polimer tiga dimensi yang bersifat hidrofilik di mana ia boleh memerangkap dan mengekalkan sekurang-kurangnya 20 % kandungan air di dalam jaringannya [1]. Hidrogel yang mengandungi lebih daripada 90 % air dikenali sebagai bahan penyerap berkeupayaan tinggi dan mempunyai sifat biokeserasian yang baik. Ia juga mempunyai ciri-ciri keserupaan fisiokimia dengan matrik ekstrasel dari segi komposisinya serta sifat mekanikalnya [2]. Dewasa ini, aplikasi hidrogel adalah amat luas, terutamanya dalam industri seperti pemakanan, biobahan, pertanian, dan rawatan air [3].Oleh itu, pelbagai kaedah telah dikaji bagi penghasilan hidrogel. Namun demikian, penggunaan polimer sintetik seperti polivinil alkohol (PVA), polivinil pirolidon (PVP), poli(nisopropilakrilamida) dan poliakrililik asid dalam penghasilan hidrogel adalah mahal memandangkan ia melibatkan proses sintesis kimia yang rumit. Selain itu, polimer sintetik dan terbitan polisakarida ini merupakan bahan yang tidak boleh diperbaharui dan tidak mudah terbiodegradasi [1,4].

Penghasilan hidrogel menggunakan kanji pada masa kini mendapat perhatian yang serius daripada para pengkaji yang disebabkan oleh kos penghasilan yang rendah dan mesra alam. Kanji merupakan sumber yang boleh diperbaharui dan boleh didapati dengan mudah. Menurut Eichhom et al. [5] kanji dijangkakan akan menjadi bahan utama sumber kimia pada masa hadapan. Permintaan terhadap produk yang mesra alam dan juga produk bioserasi kini kian meningkat. Ini kerana penggunaan bahan berasaskan sumber asli boleh mengurangkan pencemaran terhadap alam sekitar. Selain daripada bahan penyerap bioserasi boleh diuraikan dan digunakan oleh mikroorganisma serta tumbuhan.

Dalam kajian yang dijalankan ini, teknik sinaran gamma telah digunakan dalam proses mensintesis hidrogel. Penghasilan biobahan menggunakan teknik radiasi telah mendapat tempat dalam penyelidikan di negara ini. Pushpamalar [6] melaporkan bahawa hidrogel yang dihasilkan melalui taut silang secara radiasi telah digunakan sebagai pembalut luka untuk pesakit di Hospital Navi 411. Justeru, penggunaan sinaran gamma telah dibuktikan selamat digunakan dalam industri perubatan. Penggunaan teknik gamma ini bukan sahaja dapat menggantikan penggunaan bahan kimia sebagai petaut silang yang secara umumnya bertoksik malahan teknik sinaran gamma ini juga turut dapat menjimatkan masa [7].

Bahan dan Kaedah

Sintesis hidrogel

Ubi gadong yang baru digali dibersihkan dengan air, dikupas dan dipotong kecil. Kemudian, ubi tersebut dikisar dengan menggunakan pengisar elektronik dan dikeringkan menjadi serbuk. Serbuk ubi gadong dilarutkan dengan menggunakan air suling dan natrium hidroksida yang berkepekatan 1.0 M. Kemudian, asid akrilik dicampurkan ke dalam larutan ubi dan campuran dipindah ke dalam piring petri. Sampel kemudian didedahkan pada radiasi gamma iaitu 40 kGy dengan menggunakan penyinar sel gamma model Gammacell 220. Hidrogel yang telah dihasilkan kemudiannya dikeringkan di dalam ketuhar pada suhu 45 °C selama 24 jam. Proses penyingkiran bahan kimia berlebihan dilakukan dengan merendam sampel hidrogel di dalam air suling dan dikeringkan di dalam ketuhar. Kaedah ini diulang dengan menggunakan nisbah asid akrilik kepada kanji yang berbeza iaitu 4:1 dan 5:2.

Ujian pembengkakan

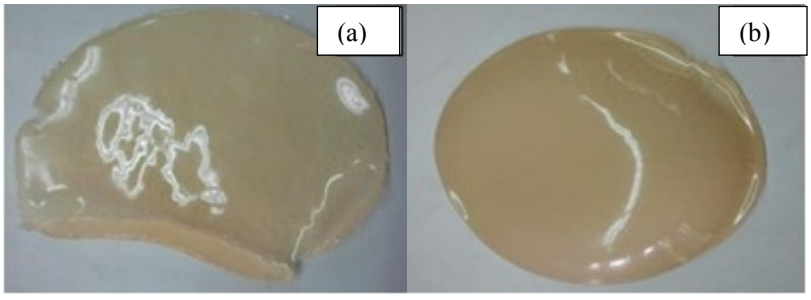
Kuasa pembengkakan, hidrogel diuji dengan merendamkan sampel hidrogel di dalam larutan pH yang berbeza iaitu pH 3, 5, 7, 9, dan 12 pada suhu bilik. Berat sampel hidrogel ditimbang dan dicatatkan pada setiap lima minit selama satu jam. Peratus pembengkakan hidrogel dikira dengan menggunakan persamaan 1 berikut.

$$\%S = \frac{M_0 - M}{M_0 \times 100\%} \quad (1)$$

S ialah peratus pembengkakan, M_o dalah jisim asal hidrogel (g) dan M adalah jisim hidrogel yang mengalami pembengkakan pada masa t (min).

Spektroskopi inframerah (IM)
Spektroskopi inframerah (IM) digunakan untuk menentukan kumpulan berfungsi yang hadir dalam struktur molekul. Prinsip spektroskopi inframerah adalah berdasarkan kepada perubahan tenaga yang disebabkan oleh peralihan molekul daripada aras tenaga getaran atau putaran ke aras tenaga yang lain. Dalam penentuan kumpulan berfungsi dalam hidrogel, spektroskopi inframerah untuk jumlah pantulan teratenuat (ATR-FTIR) dengan model Perkin Elmer telah digunakan. Imej dicerap pada panjang nombor gelombang di antara 4000 – 650 cm^{-1}.

Kalorimetri pengimbasan perbezaan (DSC)
Kalorimetri pengimbasan perbezaan digunakan untuk menentukan titik kritikal terma seperti takat lebur, haba spesifik entalpi dan suhu peralihan kaca dan merupakan kaedah yang cepat dalam penentuan sifat terma bahan polimer [8].

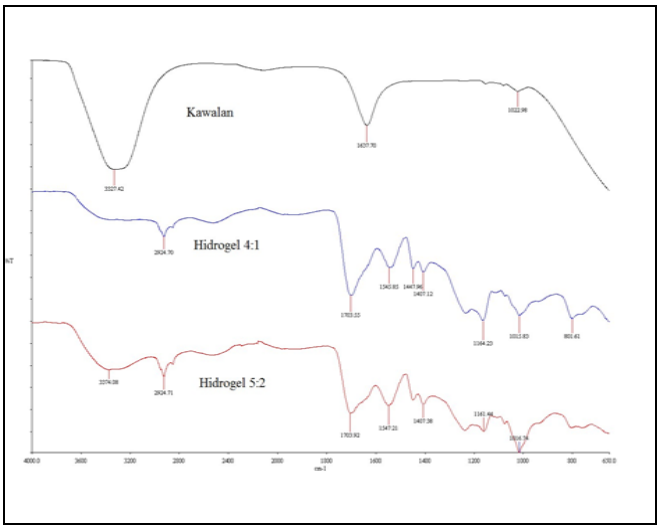


Analisis gravimetri terma (TGA)
Analisis gravimetri terma digunakan bagi mengukur jumlah dan kadar perubahan jisim sampel dalam keadaan suhu yang terkawal. Sampel dipanaskan dengan kehadiran nitrogen dan udara sintetik pada kadar haba yang tetap manakala perbezaan jisim diukur. Jisim yang kurang menunjukkan bahawa berlakunya degradasi sampel. Justeru teknik ini sesuai untuk analisis kerencaman daripada bahan-bahan multi-komponen atau campuran, kestabilan terma, kestabilan oksidatif, anggaran hayat produk, kinetik penguraian, kesan atmosfera reaktif terhadap bahan-bahan, kandungan pengisi bahan dan kelembapan serta kandungan meruap.

Pembelauan sinar-X
Pembelauan sinar-X sesuai digunakan untuk menganalisis ciri-ciri polimer dan kompositnya dalam keadaan struktur pepejalnya dan digunakan dalam aplikasi pengenalan sampel, penghabluran polimer, tekanan berbaki dan juga analisis tekstur.

Mikroskopi Pengimbasan Elektron (SEM)
Mikroskopi pengimbasan electron digunakan untuk menganalisis topografi permukaan sampel, komposisi, serta kekonduksian elektrik. Magnifikasi SEM boleh mencapai julat antara 10 hingga 500,000 kali. SEM merupakan satu teknik yang sesuai untuk melihat morfologi hidrogel [9].

Keputusan dan Perbincangan



Sintesis hidrogel
Dalam kajian ini, hidrogel berasaskan ubi gadong telah berjaya disintesis dengan menggunakan nisbah ubi gadong kepada asid akrilik yang berbeza iaitu 4:1 dan 5:2. Rajah 1 menunjukkan hidrogel yang telah berjaya disintesis. Hidrogel yang dihasilkan mempunyai tekstur yang lembut dan elastik seperti getah. Warna hidrogel adalah sedikit kekuningan dan tidak mempunyai sifat lut cahaya.

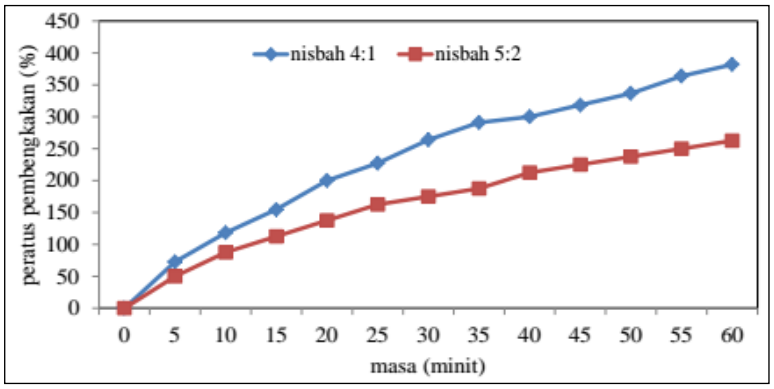
Rajah 1. Hidrogel dengan nisbah 4:1 (a) manakala hidrogel dengan nisbah 5:2 (b)

Analisis spektroskopi inframerah

Dalam Rajah 2, dapat diperhatikan bahawa kedua – dua hidrogel mempunyai puncak yang sama tetapi berlainan keamatan. Perbezaan antara keamatan spektrum menunjukkan penggunaan nisbah asid akrilik dengan ubi gadong yang berbeza. Manakala bagi sampel pemalar pula hanya menunjukkan beberapa puncak sahaja. Hal ini kerana, asid akrilik tidak dimasukkan ke dalam sampel pemalar dan memberikan perbezaan yang ketara antara spektrum hidrogel bernisbah 4:1 dan 5:2.

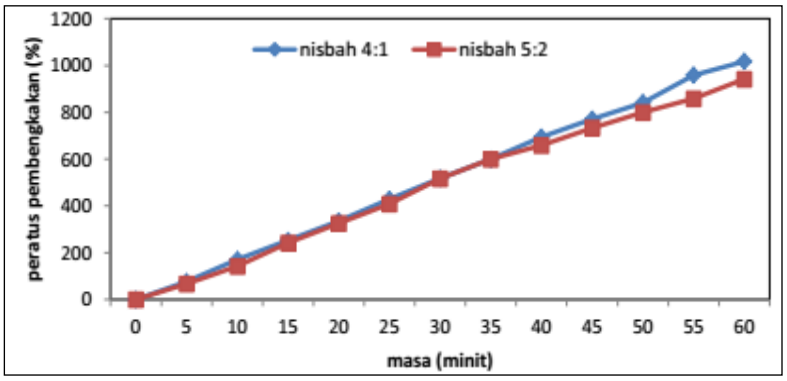
Rajah 2. Perbandingan spektrum inframerah untuk hydrogel bernisbah 4:1, 5:2 dan sampel pemalar

Spektrum inframerah untuk kedua-dua hidrogel 4:1 dan 5:2 menunjukkan puncak penyerapan masing-masing pada sekitar 3370 dan 3374 cm^{-1} yang mewakili kumpulan hidroksi (–OH) pada kanji. Puncak sekitar 2500cm^{-1} pada kedua-dua spektrum hidrogel adalah disebabkan oleh getaran regangan daripada puncak lebar –OH. Selain itu, puncak sekitar 2924 cm^{-1}dapat dilihat dan ia merupakan kesan daripada regangan $–CH_2$ tidak simetri dari kumpulan $–CH_2OH$ di dalam kanji ubi gadong [10]. Seterusnya, puncak 1703 cm^{-1} yang terdapat pada kedua-dua hidrogel menunjukkan getaran peregangan C=O kumpulan –COOH daripada asid akrilik. Puncak pada julat 1750 – 1400 cm^{-1} membuktikan bahawa wujudnya kumpulan karboksil di dalam hidrogel selepas pempolimeran. Kedua-dua hidrogel turut memberikan puncak pada 1164 cm^{-1} bagi hidrogel bernisbah 4:1 dan 1161 cm^{-1} pada hidrogel bernisbah 5:2 menunjukkan wujudnya peregangan C-O-C ikatan eter kanji [11]. Dapat diperhatikan dengan memperbandingkan ketiga-tiga puncak spektrum ini, puncak spektrum bagi kedua-dua hidrogel dengan sampel pemalar menunjukkan perbezaan yang ketara terutamanya pada puncak sekitar 3300 cm^{-1} iaitu puncak bagi –OH. Ini membuktikan berlakunya pembentukan hidrogel kerana keamatan puncak spektrum tersebut mengurang dengan ketara.



Pembengkakan hidrogel dalam larutan penimbal pH 3

Rajah 3 menunjukan peratus pembengkakan hidrogel di dalam larutan penimbal pH 3 selama satu jam. Nilai peratus pembengkakan bagi hidrogel dengan nisbah 4:1 menunjukkan pembengkakan yang lebih tinggi iaitu sebanyak 382 % berbanding hidrogel dengan nisbah 5:2 iaitu hanya 263 % sahaja.



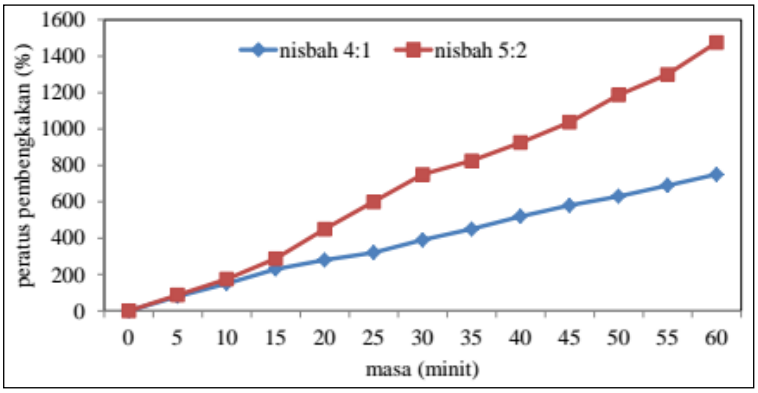
Pembengkakan hidrogel dalam larutan penimbal pH 5

Pada pH 5, dapat diperhatikan bahawa peratus pembengkakan bagi kedua-dua jenis hidrogel tidak mempunyai perbezaan yang ketara seperti yang ditunjukkan pada Rajah 4. Peratus pembengkakan bagi hidrogel dengan nisbah

4:1 mencapai nilai pembengkakan 1018 % manakala bagi hidrogel dengan nisbah 5:2 pula mencapai 942 %. Dapat diperhatikan, hidrogel 4:1 masih mempunyai keupayaan menyerap air yang lebih baik berbanding dengan hidrogel 5:2 di dalam larutan penimbal pH 5.

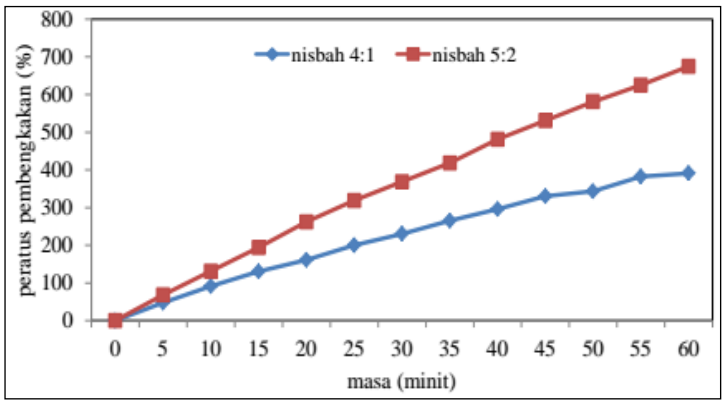
Rajah 3. Graf peratus pembengkakan hidrogel di dalam larutan penimbal pH 3

Rajah 4. Graf peratus pembengkakan hidrogel di dalam larutan penimbal pH 5



Pembengkakan hidrogel dalam larutan penimbal pH 7

Hidrogel dengan nisbah 5:2 mula menunjukkan keupayaan penyerapan yang baik iaitu dengan nilai peratus pembengkakan sebanyak 1475 % manakala hidrogel bernisbah 4:1 dengan nilai peratus pembengkakan sebanyak 750 % dalam larutan penimbal pH 7. Pada awal ujian, dapat diperhatikan peratus pembengkakan bagi kedua – dua hidrogel tidak mempunyai perbezaan yang ketara, namun selepas 15 minit hidrogel dengan nisbah 5:2 menyerap air dengan kadar yang jauh lebih cepat berbanding dengan hidrogel bernisbah 4:1. Ini bermakna, pada larutan penimbal pH 7, hidrogel bernisbah 5:2 lebih efisien dalam keupayaan penyerapan air berbanding dengan hidrogel bernisbah 4:1. Rajah 5 menunjukkan perbezaan peratus pembengkakan antara hidrogel bernisbah 4:1 dan 5:2 di dalam larutan penimbal pH 7.

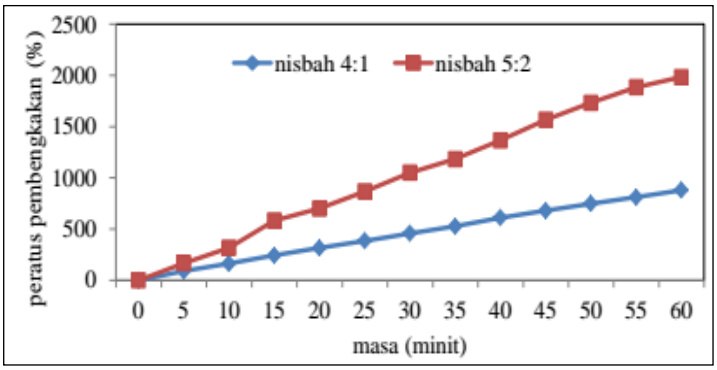


Pembengkakan hidrogel dalam larutan penimbal pH 9

Bagi larutan penimbal pH 9 pula, hidrogel dengan nisbah 5:2 masih lagi mendominasi iaitu dengan nilai peratus pembengkakan sebanyak 675 % dan hidrogel bernisbah 4:1 hanya mencapai nilai peratus pembengkakan sebanyak 391 % sahaja. Rajah 6 menunjukkan kadar pembengkakan bagi hidrogel dengan nisbah 5:2 adalah lebih tinggi

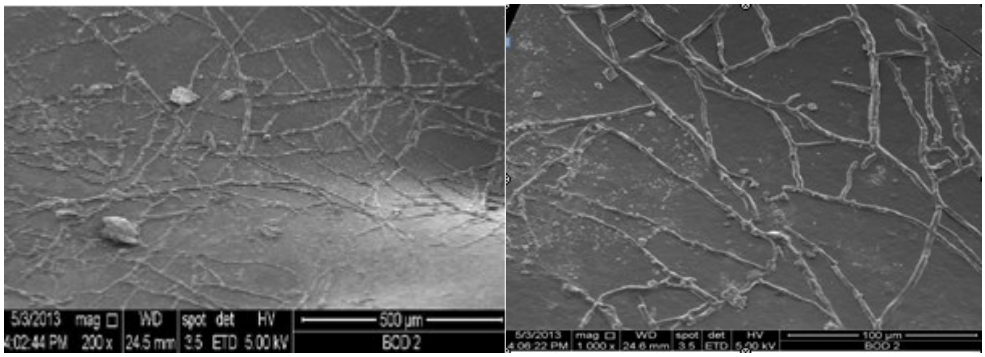
berbanding dengan hidrogel dengan nisbah 4:1. Perbezaan kadar pembengkakan dapat diperhatikan dari awal ujian sehingga ke akhir ujian.

Rajah 5. Graf peratus pembengkakan (%) hidrogel di dalam larutan penimbal pH 7



Rajah 6. Graf peratus pembengkakan (%) hidrogel di dalam larutan penimbal pH 9

Pembengkakan hidrogel dalam larutan penimbal pH 12

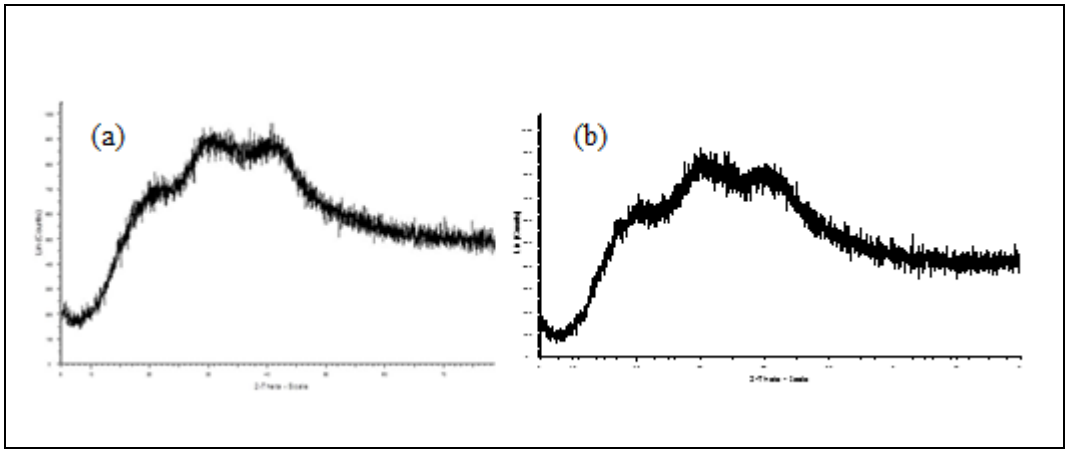


Dalam larutan penimbal pH 12, dapat diperhatikan pada Rajah 7, hidrogel dengan nisbah 5:2 mempunyai nilai peratus pembengkakan sebanyak 1983 % berbanding dengan hidrogel bernisbah 4:1 yang hanya mencapai nilai peratus pembengkakan sebanyak 879 % sahaja. Ini menunjukkan bahawa pada larutan penimbal pH 12, hidrogel 5:2 jauh lebih baik berbanding dengan hidrogel 4:1 dalam keupayaannya menyerap air.

Analisis mikroskopi pengimbasan elektron

Rajah 8 menunjukkan morfologi bagi permukaan hidrogel dengan nisbah 5:2 yang telah dihasilkan berdasarkan kepada imej mikrograf, hidrogel dengan nisbah 5:2 mempunyai kerapuhan yang baik di mana tiada berlakunya peretakan di atas permukaan hidrogel [12].

Rajah 7. Graf peratus pembengkakan (%) hidrogel di dalam larutan penimbal pH 12



Rajah 8. Mikrograf bagi hidrogel dengan nisbah 5:2 (a) dan hidrogel dengan nisbah 5:2 pada pembesaran 100 µm

Analisis pembelauan sinar-X

Rajah 9 menunjukkan difraktogram pembelauan sinar X yang telah dijalankan bagi menentukan peratusan penghabluran hidrogel. Kedua-dua hidrogel memberikan puncak spektrum yang sama kerana berlakunya taut silang. Ketiga-tiga puncak ini membuktikan terdapatnya pembentukan kristal yang membuktikan berlakunya taut silang antara hidrogel. Perbandingan antara kedua-dua difraktogram tersebut, hidrogel dengan nisbah 4:1 memberikan spektrum dengan puncak keamatan yang lebih tinggi berbanding dengan hidrogel yang bernisbah 5:2. Spektrum yang menunjukkan puncak yang luas dan lebar disebabkan hidrogel mengandungi komponen amorfus. Manakala puncak spektrum yang tajam menunjukkan peratus penghabluran yang lebih tinggi. Peratus penghabluran yang terlalu tinggi boleh mendorong kepada peningkatan kadar kerapuhan hidrogel.

Analisis kalorimetri pengimbasan pembezaan-analisis gravimetri terma (DSC-TGA)

Jadual 1 menunjukkan perbezaan nilai peralihan gelas bagi hidrogel dengan nisbah 4:1 dan 5:2. Dalam analisis kalorimetri pengimbasan pembezaan (DSC), nilai peralihan gelas bagi hidrogel dengan nisbah 4:1 adalah dalam julat 125 – 175 °C manakala bagi hidrogel 5:2 pula, nilai peralihan gelas berjulat antara 175 – 200 °C. Bagi analisis gravimetri terma (TGA) pula, kadar kehilangan berat maksimum berlaku pada julat 125 – 175 °C bagi hidrogel 4:1 manakala 175 – 200 °C bagi hidrogel 5:2. Hidrogel 5:2 mempunyai kestabilan terma yang lebih baik berbanding hidrogel 4:1. Hal ini disebabkan oleh perbezaan kandungan serbuk ubi gadong dalam hidrogel. Menurut Halib et al. [13], struktur kanji mempunyai banyak kumpulan hidroksil di mana kumpulan ini akan membentuk ikatan hidrogen dengan air dan menyebabkan nilai peralihan kaca tinggi. Justeru, hidrogel 5:2 lebih stabil berbanding hidrogel dengan nisbah 4:1. Puncak yang terhasil pada keluk DSC bagi kedua – dua hidrogel berkemungkinan disebabkan oleh peralihan fasa yang berkaitan dengan pembentukan dan pemutusan jaringan struktur kompleks kanji [14].

Rajah 9. Difraktogram bagi hidrogel dengan nisbah 4:1 (a) manakala hidrogel dengan nisbah 5:2 (b)

Jadual 1. Perbandingan termogram bagi kedua – dua hidrogel

Nisbah hidrogel	Nilai Peralihan Gelas	
	DSC (℃)	TGA (℃)
4:1	125 – 175	125 – 175
5:2	175 – 200	175 – 200

Kesimpulan

Hidrogel berasaskan serbuk ubi gadong telah berjaya disintesis dengan menggunakan teknik radiasi gamma. Hidrogel dengan nisbah 5:2 di dapati mempamerkan ciri – ciri yang baik berbanding hidrogel 4:1. Hidrogel dengan nisbah 5:2 mempamerkan peratus pembengkakan yang tinggi pada pH 7, 9 dan 12. Analisa DSC dan SEM menunjukkan ciri – ciri hidrogel yang baik manakala keputusan TGA menunjukkan hidrogel dengan nisbah 5:2 lebih stabil secara termodinamiknya berbanding dengan hidrogel bernisbah 4:1.

Penghargaan

Penulis ingin mengucapkan terima kasih kepada UKM kerana memberi peluang penyelidikan dijalankan menggunakan geran KOMUNITI-2014-010 dan GUP-2014-079

Abstrak

Biosensor DNA elektrokimia bagi pengesanan jujukan DNA porsin berasaskan kompleks rutenium (II) sebagai label aktif redoks telah dibangunkan. Sistem biosensor difabrikasi berdasarkan elektrod bercetak skrin (SPE) terubahsuai dengan zarah nano emas (AuNPs) sebagai transduser yang dipegunkan bersama mikrosfera poli (n-butilakrilat-N-akriloksisuksnimida) dan jujukan DNA prob terikat melalui ikatan kovalen. Kompleks interkalator rutenium (II), $[Ru(bpy)_2PIP]^{2+}$ dan (bpy = bipiridina, PIP = 2-fenillimidazo[4,5-f[1,10-fenantrolina] digunakan dalam pengesanan DNA porsin. Pengukuran dan pengoptimuman biosensor telah dilakukan dengan menggunakan voltammetrik siklik (CV) dan voltammetrik denyutan pembezaan (DPV). Interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan beberapa jenis jujukan DNA telah dikaji iaitu, i) bebenang tunggal DNA prob, ii) selepas penghibridan DNA sasaran dan iii) selepas penghibridan dengan DNA bukan sasaran. Keputusan menunjukkan bahawa interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan DNA sasaran yang telah terhibrid memberikan rangsangan yang paling tinggi. Prestasi biosensor adalah dipengaruhi oleh beberapa faktor antaranya ialah kepekatan $[Ru(bpy)_2PIP]^{2+}$ dan DNA prob, masa pemegunan dan penghibridan DNA prob, pH, kekuatan ion, kepekatan larutan penimbal dan suhu juga dikaji untuk menilai prestasi biosensor. Hasil kajian menunjukkan kepekatan kompleks $[Ru(bpy)_2PIP]^{2+}$ dan DNA prob, masing-masing adalah 50 µM dan 2 µM. Masa yang optimum bagi pemegunan DNA prob dan penghibridan DNA sasaran adalah 7 jam dan 60 minit. Keadaan optimum bagi pH, kekuatan ion, kepekatan larutan penimbal dan suhu, masing-masing adalah pH 7.0, 1.0 M NaCl, 0.05 M potassium fosfat pada suhu 25°C. Julat linear bagi kepekatan DNA sasaran yang berbeza adalah antara 1.0×10^{-13} M to 1.0×10^{-8} M. Kajian ini adalah yang pertama melaporkan tentang penggunaan $[Ru(bpy)_2PIP]^{2+}$ bagi pengesanan DNA porsin

Kata kunci: biosensor, DNA porsin, kompleks rutenium bipiridina

Abstract

Electrochemical DNA biosensor for detection of porcine oligonucleotides based on ruthenium (II) as label redox complex has been developed. The system of biosensor is based on the modified screen printed carbon electrode (SPE) with goldnanoparticles (AuNPs) as transducer immobilized with poly(n-butylacrylate-N-acryloxysuccinimide) microsphere and porcine DNA probe sequences was attached onto it via the covalent bond. The ruthenium(II) complex, $[Ru(bpy)_2PIP]^{2+}$ PIP = 2-phenylimidazo[4,5-f[1,10-phenanthroline] intercalator has been been used to determine prcine DNA. The biosensor was measured and optimized by cyclic voltammetry (CV) and differential pulse voltammetry (DPV). The interaction of $[Ru(bpy)_2PIP]^{2+}$ with various DNA with different sequences, i) single stranded probe DNA, ii) after hybridization with its complementary DNA and iii) after hybridization with mismatch complementary DNA were studied. The results indicated that the interaction of $[Ru(bpy)_2PIP]^{2+}$ with hybridized complementary DNA gave the highest response. Thus, development of porcine DNA biosensor and influences of many factors such as $[Ru(bpy)_2PIP]^{2+}$ complex and DNA probe concentration, DNA probe immobilization and hybridization

time, pH, ionic strength, buffer concentration and temperatures were also studied to evaluate the performance of biosensor. The concentration of $[Ru(bpy)_2PIP]^{2+}$ complex and DNA probe were found to be optimal at 50 μM and 2 μM, respectively. The optimal time for DNA probe immobilization and hybridization were 7 hours and 60 minutes, accordingly. The optimal condition of pH, ionic strength, buffer concentration and temperatures were at pH 7.0, 1.0 M NaCl, 0.05 M of Na-phosphate buffer and 25 °C, respectively. The linear range of different concentration complementary DNA was within the range between 1.0×10^{-13} M to 1.0×10^{-8} M. This study was first reported the used of $[Ru(bpy)_2PIP]^{2+}$ for detection of porcine oligonucleotides

Keywords: biosensor, porcine DNA, ruthenium bypyridine complex

Pengenalan

Asid deoksiribonukleik (DNA) merupakan suatu bahan biomolekul yang penting dalam organisma sebagai asas kepada ekspresi gen [1]. DNA membawa maklumat genetik organisma dan maklumat yang wujud dalam DNA adalah lebih banyak daripada protein disebabkan oleh kemerosotan kod genetik yang berlaku apabila DNA mengalami perubahan bentuk daripada DNA kepada protein [2]. Pada masa kini, pengesanan DNA adalah satu bidang yang menarik minat penyelidik kerana aplikasinya yang meluas dalam bidang klinikal, forensik, farmaseutikal dan pemprosesan makanan [3]. Selain daripada itu, penggunaan DNA dalam bidang biosensor mempunyai pelbagai manfaat seperti kebolehannya dalam pengesanan molekul secara semulajadi [4]. Pengesanan urutan-urutan spesifik dalam asid nukleik dengan menggunakan kaedah biosensor ini dapat mengatasi masalah penyediaan sampel yang rumit, kaedah analisis yang memakan masa yang lama, penggunaan bahan kimia yang berbahaya dan instrumentasi yang mahal [5].

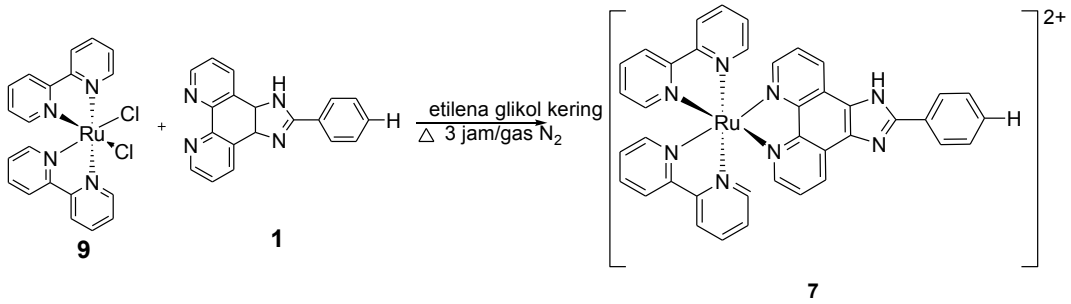
Biosensor DNA secara elektrokimia memberikan hasil yang menarik kerana teknik elektrokimia mempunyai kelebihan mengatasi alat yang sedia ada. Kebiasaannya, teknik elektrokimia yang digunakan oleh penyelidik ialah transduksi voltammetri siklik (CV) dan voltammetri pembezaan denyutan (DPV) sebagai alat menganalisis interaksi larutan penunjuk redoks dengan DNA. Teknik elektrokimia ini juga ringkas dan mempunyai kos yang rendah [6]. Kaedah pengesanan penghibridan DNA berdasarkan kepada penggunaan penunjuk redoks menawarkan cara yang lebih menarik dan digemari para penyelidik berbanding pengesanan secara label bebas. Maka, pembangunan penunjuk elektrokimia yang lebih peka adalah penting untuk digunakan dalam biosensor DNA [3]. Kompleks logam polipiridil seperti ruthenium(II), rhodium(II), kuprum(II) dan sebagainya sering digunakan di dalam interaksi DNA bagi menghasilkan prob DNA elektrokimia, pemecahan kimia dan reagen biomedikal. Kini, kompleks ruthenium(II) pula telah digunakan secara meluas dalam kajian pengikatan DNA disebabkan oleh kestabilannya dari segi kimia, elektrokimia, geometri dan enantiomer serta kepekaan sifat – sifat fotofizikalnya kepada interaksi pengikatan dengan DNA [7]. Hal ini dilapor dengan kajian literatur yang dilakukan oleh Arockiasamy et al. [8] bahawa keupayaan kompleks logam polipiridil seperti ruthenium(II) mempunyai sifat pengikatan yang baik sebagai interkalator pada DNA.

Penggunaan kaedah – kaedah konvensional bagi pengesanan DNA seperti tindak balas rantai pempolimeran (PCR) dan southern blot mempunyai kekurangan seperti penyediaan sampel yang rumit, prosedur analisis yang banyak dan memakan masa yang lama serta instrumentasi mahal. Oleh kerana itu, kaedah biosensor DNA yang lebih praktikal ini mampu mengatasi masalah yang dihadapi pada kaedah-kaedah konvensional. Pembangunan biosensor DNA menghasilkan alat yang kecil, mudah alih, berkos rendah dan mudah dikendalikan [9].

Bahan dan Kaedah

Bahan kimia

Bahan kimia yang digunakan di dalam eksperimen ini seperti 1, 10 –fenontralina, ruthenium (III) klorida, 2, 2-bipiridina, benzaldehid, DNA sintetik porsin, DNA sasaran, DNA sintetik bos Taurus, DNA sintetik gallus didapati daripada Sigma Aldrich. kepekatan asid sulfurik 30% dan kepekatan asid nitric 10% dibeli daripada Sigma Aldrich dan garam natrium klorida dan garam natrium hidroksida daripada Fluka. Air nyahion yang digunakan diperoleh daripada daripada alat penyahion (Milipore).



Pengukuran fizikal

Spektrum NMR (^1H and ^{13}C NMR) bagi kompleks ruthenium direkod menggunakan Bruker /AVANCE III 600 MHz Fourier 600 MHz. Spektrum Inframerah direkodkan menggunakan dis KBr (FTIR Perkin-Elmer GX Model).

Alat potentiostat Autolab dilengkapi dengan peranti *General Purpose Electrochemical System (GPES)* digunakan untuk pengukuran keupayaan biosensor.

Sintesis dan pencirian kompleks $[Ru(bpy)_2PIP]^{2+}$

Kompleks logam polipiridil $[Ru(bpy)_2PIP]^{2+}$ adalah tindak balas antara rutenium bipiridina diklorida dengan ligan pembantu, PIP, 2-fenilimidazo[4,5-f[1,10-fenantrolina] seperti yang dilaporkan oleh Li et al [10]. Gambarajah umum penyediaan kompleks ini ditunjukkan pada Rajah 1.1 di bawah.

Rajah 1. Sintesis penghasilan komples $[Ru(bpy)_2PIP]^{2+}$

Penyediaan elektrod bercetak skrin (SPE) terubah suai

Pemegunan zarah nano emas (AuNPs) dan mikrosfera poli(n-butilakrilat-N-akriloksisuksimida)

Elektrod karbon bercetak skrin (SPE) diubahsuai dengan pemendapan 0.1 mg zarah nano emas (AuNPs) dan 0.1 mg mikrosfera poli(n-butilakrilat-N-akriloksisuksimida) ke atas SPE. 0.1 mg zarah nano emas (AuNPs) yang telah dilarutkan methanol itu dikeringkan selama 20 minit. Mikrosfera akrilik yang digunakan di dalam kajian ini adalah seperti yang dilakukan oleh Ulianas et al [11].

Pencirian larutan $[Ru(bpy)_2PIP]^{2+}$

Kajian voltammetri siklik (CV) terhadap larutan $[Ru(bpy)_2PIP]^{2+}$

Elektrolit yang digunakan ialah 0.05 M larutan penimbal K-fosfat pH 7.0. Kajian voltammetri siklik bagi larutan penunjuk redoks $[Ru(bpy)_2PIP]^{2+}$ pada kepekatan 30 µM dijalankan dengan menggunakan kadar imbasan 100 mV/s. Kitaran voltammetrik siklik diimbas pada julat keupayaan 0.85 V hingga 1.2 V. Kajian voltammetri siklik dijalankan dalam keadaan statik.

Pencirian interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan DNA porsin terpegun

Kesan kepekatan DNA prob

Kesan kepekatan DNA prob dikaji dengan memegunkan pelbagai kepekatan DNA prob (1.0, 2.0, 3.0, 4.0, 5.0 µM) ke atas SPE yang telah terubah suai dengan AuNPs dan mikrosfera akrilik. SPE terubah suai direndamkan di dalam larutan yang mengandungi prob DNA dan 0.05 M larutan penimbal K-fosfat pH 7.0.

Kesan masa pemegunan dan penghibridan DNA

Kajian kesan masa pemegunan DNA prob dilakukan pada sela masa 1 jam sehingga 24 jam manakala kajian terhadap masa penghibridan DNA sasaran dilakukan dengan pelbagai masa penghibridan antara 0.5 hingga 3.0 jam. Pemegunan 5.0 µM DNA prob dilakukan dalam larutan penimbal K-fosfat 0.05M (pH 7.0) manakala penghibridan dengan 2.0 µM DNA sasaran di dalam 0.05 M penimbal Na-fosfat (pH 7.0) yang juga mengandungi 30 µM larutan penunjuk redoks $[Ru(bpy)_2PIP]^{2+}$ dan kekuatan ion Na^+ 1.5 M.

Kesan pH dan kepekatan penimbal terhadap penghibridan DNA

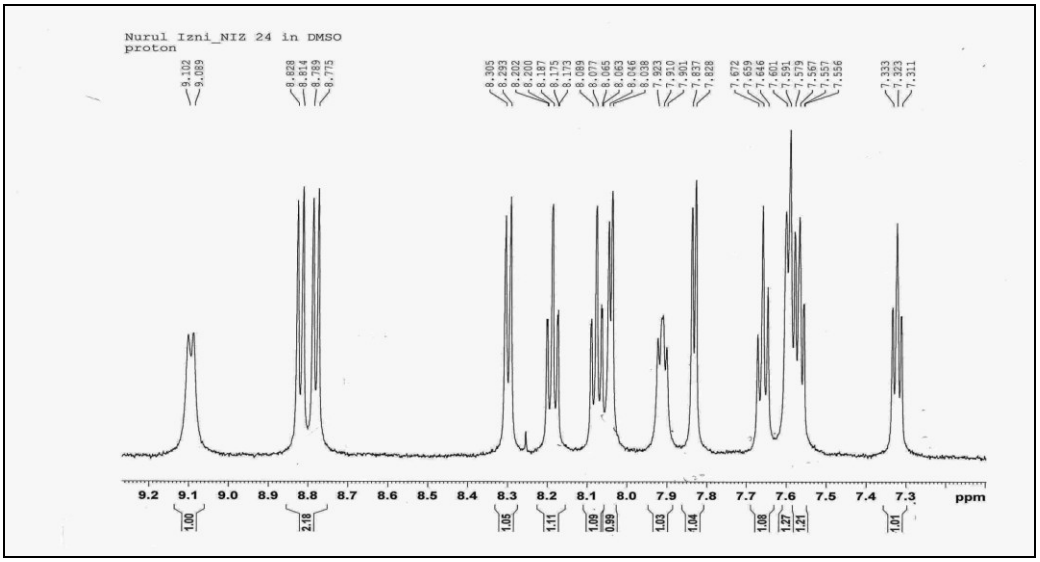
Kajian kesan pH dilakukan dengan menyediakan larutan DNA sasaran 2.0 µM dalam larutan penimbal Na-fosfat 0.05 M pada pH yang berbeza (6.0 hingga 8.0). Kesan kepekatan penimbal pula dilakukan dengan menyediakan 2.0

μM larutan DNA sasaran dalam penimbal Na-fosfat pada pH 7.0 dengan kepekatan penimbal yang berlainan (0.02 M hingga 0.25 M). Proses penghibridan DNA sasaran dilakukan dengan kehadiran 30 μM $[Ru(bpy)_2PIP]^{2+}$ dan 1.5 M Na^+ ion.

Kesan kekuatan ion terhadap penghibridan DNA
Kesan kekuatan ion dikaji dengan menyediakan larutan 2.0 μM DNA sasaran dalam penimbal Na-fosfat 0.05 M (pH 7.0) yang mengandungi 30 μM $[Ru(bpy)_2PIP]^{2+}$ dan kekuatan ion yang berbeza iaitu 0.05 M hingga 2.0 M.

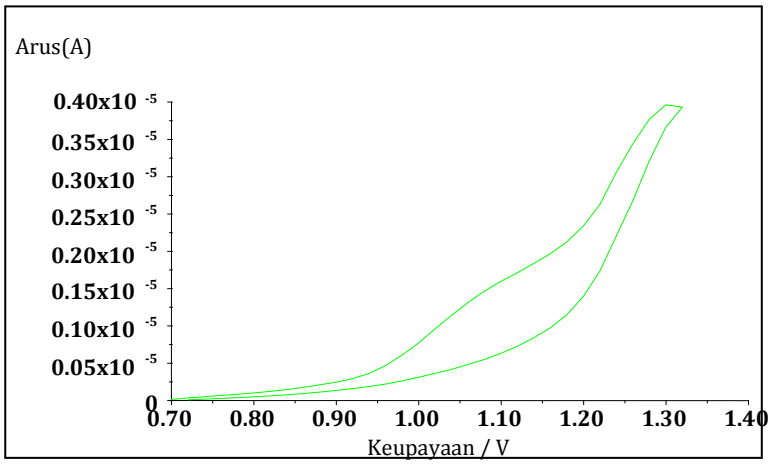
Kebolehasilan biosensor DNA
Kajian kebolehasilan terhadap interaksi 30 μM $[Ru(bpy)_2PIP]^{2+}$ dengan DNA sasaran ditentukan dengan melakukan pengukuran arus puncak secara berturutan dengan menggunakan lima SPE yang sama keadaan. SPE yang telah terubah suai itu mengandungi kuantiti AuNPs, mikrosfera akrilik, kepekatan prob dan DNA sasaran, masa pemegunan dan penghibridan DNA serta kepekatan larutan penimbal fosfat dan kekuatan ion Na^+

Keselektifan biosensor DNA pada DNA sasaran
Kajian keselektifan biosensor DNA sasaran porsin diuji dengan menggunakan jenis – jenis DNA sasaran yang berbeza iaitu DNA gallus (ayam), DNA bos taurus (daging lembu) dan DNA bukan sasaran porsin manakala DNA prob porsin dijadikan sebagai pengosong.



Julat rangsangan linear
Pelbagai kepekatan DNA sasaran daripada 1.0×10^{-13} μM sehingga 1.0×10^{-5} μM telah digunakan bagi menentukan julat rangsangan linear.

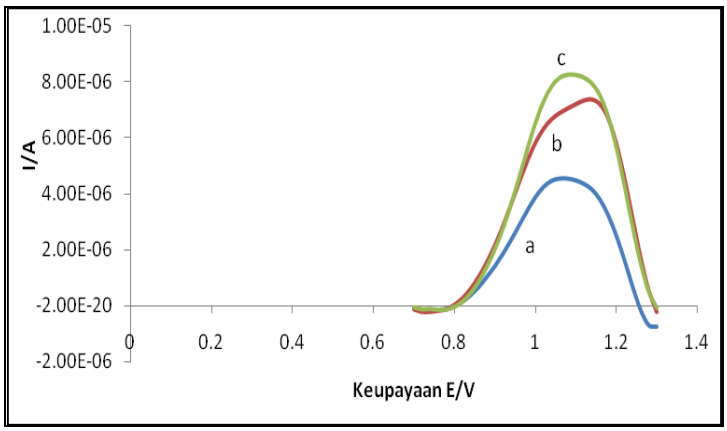
Keputusan dan Perbincangan



Sintesis dan pencirian kompleks ruthenium (II), $[Ru(bpy)_2PIP]^{2+}$
Analisis spektroskopi inframerah bagi kompleks $[Ru(bpy)_2PIP]^{2+}$ dilakukan bagi mengenal pasti kumpulan berfungsi yang terdapat pada kompleks ruthenium (II) ini. Data NMR (^1H dan ^{13}C) adalah bersamaan dengan data yang didapati pada kajian literatur. Spektroskopi infra merah menunjukkan kewujudan ligan 2-fenilimidazo[4,5-f[1,10-fenantrolina] dalam kompleks $[Ru(bpy)_2PIP]^{2+}$. Di dalam spektrum ini, terdapat jalur penyerapan pada 3369.77 cm^{-1} yang berpunca daripada regangan N-H pada kumpulan imidazol dalam ligan. Ciri – ciri gelang 2,2-bipiridina dalam kompleks logam $[Ru(bpy)_2PIP]^{2+}$, iaitu regangan –N=C aromatik, regangan C=C aromatik, getaran C-N aromatik dan bengkokkan =C-H (luar satah) juga dapat dikesan masing-masing pada 2373.61 cm^{-1}, 1604 cm^{-1}, 1314.5 cm^{-1} dan 763.1 cm^{-1}.

Pencirian kompleks $[Ru(bpy)_2PIP]^{2+}$ dengan menggunakan kaedah spektroskopi resonans magnet nukleus (RMN) ^1H dan ^{13}C (Rajah 2) dilakukan dengan melarutkan sampel dalam pelarut dimetilsulfoksida terdeuterat. Anjakan kimia bagi pelarut dimetilsulfoksida terdeuterat dapat dilihat pada spektrum RMN ^1H masing-masing pada 2.50 dan 3.50 ppm. Spektrum RMN ^1H menunjukkan terdapat lapan isyarat proton yang dapat dikesan pada julat 7.32 – 8.00 ppm. Isyarat dalam julat 7.32 hingga 8.00 ppm adalah dikenalpasti daripada proton-proton yang terdapat pada gelang benzena, 1,10-fenantrolina dan 2,2-bipiridina dalam kompleks $[Ru(bpy)_2PIP]^{2+}$.

Sifat voltammetri siklik larutan penunjuk redoks, $[Ru(bpy)_2PIP]^{2+}$
Rajah 3 menunjukkan voltammetrik siklik bagi 1 mM $[Ru(bpy)_2PIP]^{2+}$ dalam larutan penimbal K-fosfat pada pH 7.0 menggunakan SPE yang tidak diubahsuai. Keupayaan puncak anodik (E_{pa}) dan keupayaan puncak katodik (E_{pc}) dapat dilihat pada voltammogram siklik masing-masing pada 1.0 V dan 1.1 V dan nilai ini adalah menyamai keupayaan yang dilaporkan dalam kajian – kajian lepas oleh Erdem et al. [12] dan Johnston et al. [13].



Rajah 2. Data spektroskopi RMN ^{1}H bagi kompleks ruthenium $[Ru(bpy)_2PIP]^{2+}$

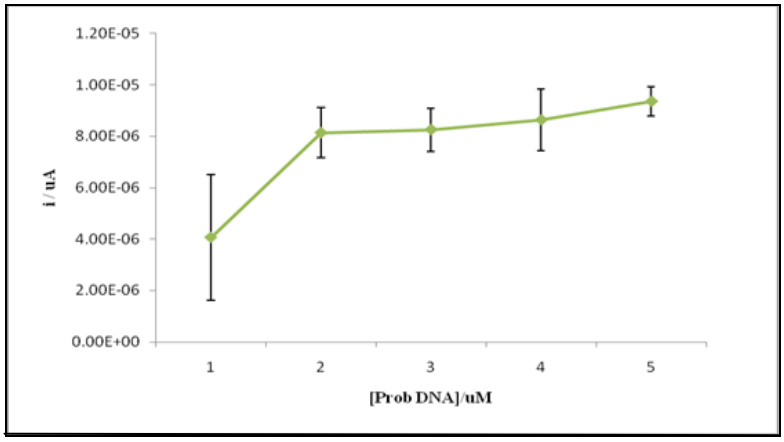
Rajah 3. Voltammogram siklik bagi 1.0 mM $[Ru(bpy)_2PIP]^{2+}$ pada kadar imbasan 50 mV/s dalam larutan penimbal 0.05 M K-fosfat, elektrod rujukan Ag/AgCl, 3M KCl

Kajian voltammetri pembezaan denyutan (DPV) bagi $[Ru(bpy)_2PIP]^{2+}$ dengan DNA

Disebabkan oleh isyarat yang kurang jelas ditunjukkan daripada voltammogram siklik di atas, kajian interaksi antara kompleks ruthenium(II) ini dengan pelbagai DNA dikaji dengan menggunakan voltammetri pembezaan denyutan (DPV) kerana DPV lebih sensitif dan peka berbanding CV. Rajah 4 menunjukkan interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan a) prob DNA porsin sahaja, b) DNA bukan sasaran selepas penghibridan dan c) DNA sasaran porsin selepas penghibridan. Daripada hasil kajian interaksi di atas, terdapat peningkatan arus DPV apabila kompleks $[Ru(bpy)_2PIP]^{2+}$ berinteraksi dengan baik secara interkalasi dengan DNA prob yang mengalami penghibridan dengan DNA sasarannya. Ini menyokong dapatan kajian yang telah dilakukan pada kajian sebelum ini oleh Xiong and Ji [14] di mana melaporkan bahawa kebanyakan kompleks logam polipiridil ruthenium(II) berinteraksi dengan DNA secara interkalasi.

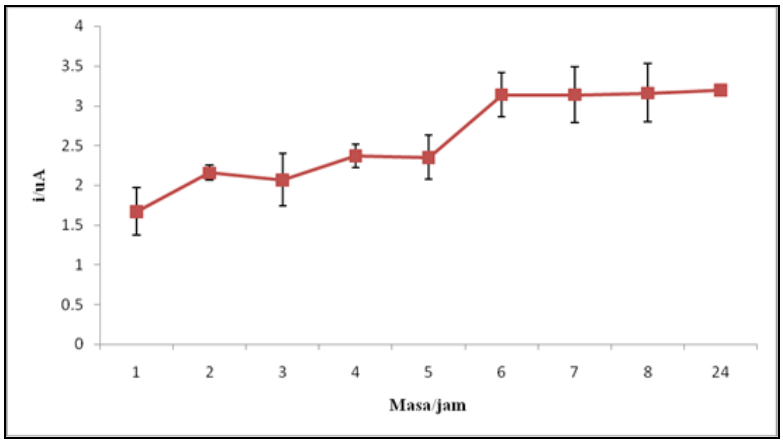
Rajah 4. Voltammogram pembezaan denyutan (DPV) bagi interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan a) prob DNA sahaja (bebenang tunggal), b) DNA bukan sasaran selepas penghibridan dan c) DNA sasaran selepas penghibridan

Pembangunan biosensor DNA porsin berdasarkan elektrod bercetak skrin (SPE) terubahsuai zarah nano emas (AuNPs), mikrosfera akrilik dan interkalator, $[Ru(bpy)_2PIP]^{2+}$



Kaedah bagi penyediaan SPE terubahsuai AuNPs-mikrosfera akrilik ini adalah seperti yang telah dijelaskan pada bahagian bahan dan kaedah. Kehadiran kumpulan berfungsi NH pada DNA adalah bagi membentuk ikatan kovalen kepada mikrosfera akrilik suknimida yang digunakan. Ini membuatkan mikrosfera akrilik itu seolah –olah memegang DNA prob dalam keadaan tegak, memudahkan proses penghibridan DNA sasaran dan interkalator menyelit ke dalam pasangan-pasangan bes DNA. Rangsangan biosensor DNA porsin diuji dengan voltammetrik siklik (CV) dan voltammetrik pembezaan denyutan (DPV) pada keupayaan 0.85 V sehingga 1.10 V di dalam larutan penimbal K-fosfat pada pH dan kepekatan tertentu.

Kesan kepekatan prob DNA porsin

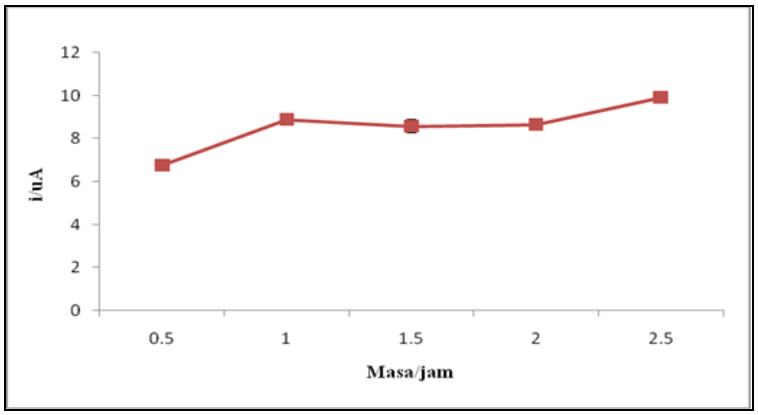


Rajah 5 menunjukkan kesan kepekatan prob DNA yang terpegun pada SPE yang terubahsuai dengan 0.025 mg zarah nanoemas (AuNPs) dan 0.1 mg mikrosfera akrilik terhadap rangsangan biosensor DNA porsin. Rangsangan DPV bagi interkalator $[Ru(bpy)_2PIP]^{2+}$ meningkat pada kepekatan prob DNA 1.0 µM sehingga 2.0 µM, kemudian selepas itu tiada perubahan ketara pada rangsangan yang dihasilkan sehingga kepekatan prob DNA 5 µM. Peningkatan rangsangan ini adalah disebabkan oleh peningkatan kepekatan prob DNA yang terpegun di atas SPE kerana semakin tinggi kepekatan prob DNA yang digunakan, semakin tinggi peluang prob DNA terpegun di atas SPE. Peningkatan kuantiti prob DNA yang terpegun pada bahan penyokong jika kepekatan prob DNA ditingkatkan adalah sama seperti yang dilaporkan oleh kajian – kajian lepas [15] yang menggunakan elektrod karbon berkaca (GCE) dan [16] elektrod emas terubahsuai sebagai tapak pemegunan prob DNA. Hasil kajian ini mendapati bahawa kepekatan prob DNA porsin yang optimum ialah 2.0 µM.

Kesan masa pemegunan prob DNA porsin

Dalam tindak balas kimia, masa tindak balas memberi kesan terhadap kuantiti hasil tindak balas. Oleh itu, kajian kesan masa pemegunan dan penghibridan perlu dijalankan seperti yang pernah dilaporkan oleh Ping et al [17]. Ini bertujuan untuk menentukan masa optimum pemegunan prob DNA dan penghibridan DNA sasaran. Rajah 6 menunjukkan kesan masa pemegunan 2.0 µM prob DNA porsin terhadap SPE terubahsuai.

Rajah 5. Kesan kepekatan prob DNA terhadap rangsangan biosensor DNA. Penghibridan dilakukan dalam larutan penimbal Na-fosfat 0.05 M pada pH 7.0 yang mengandungi 1 M NaCl dan $[Ru(bpy)_2PIP]^{2+}$

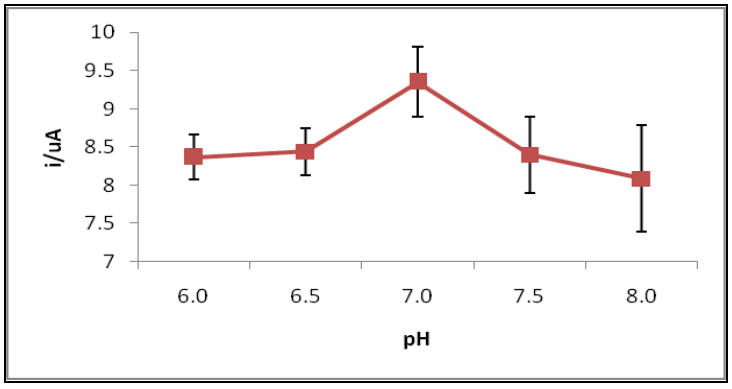


Rajah 6. Kesan masa pemegunan 2 µM prob DNA porsin ke atas SPE-AuNPs-mikrosfera terhadap rangsangan biosensor. Pemegunan dilakukan dalam 0.05 M penimbal K-fosfat pH 7.0 manakala penghibridan pula dilakukan dalam penimbal Na-fosfat 0.05 M pH 7.0 yang mengandungi 1.0 M NaCl dan 30 µM $[Ru(bpy)_2PIP]^{2+}$

Peningkatan rangsangan DPV interkalator $[Ru(bpy)_2PIP]^{2+}$ direkodkan berlaku pada 1 jam sehingga 6 jam prob DNA dipegunkan ke atas mikrosfera akrilik. Ini kerana berlakunya peningkatan kuantiti prob DNA yang terpegun ke atas SPE terubahsuai (SPE-AuNPs-mikrosfera). Selepas 6 jam, didapati tiada perubahan yang ketara pada arus DPV dan ia menjadi malar sehingga mencapai 24 jam. Ini menunjukkan bahawa semua tapak pemegunan mikrosfera akrilik (0.1 mg) telah terpegun dengan prob DNA (2 µM) pada masa pemegunan 6 jam. Oleh itu, tiada penambahan kuantiti prob DNA yang terpegun direkodkan selepas 6 jam sehingga jam ke 24. Hasil kajian mendapati masa yang optimum bagi pemegunan prob DNA pada permukaan mikrosfera akrilik adalah 6 jam.

Kesan masa penghibridan DNA sasaran porsin

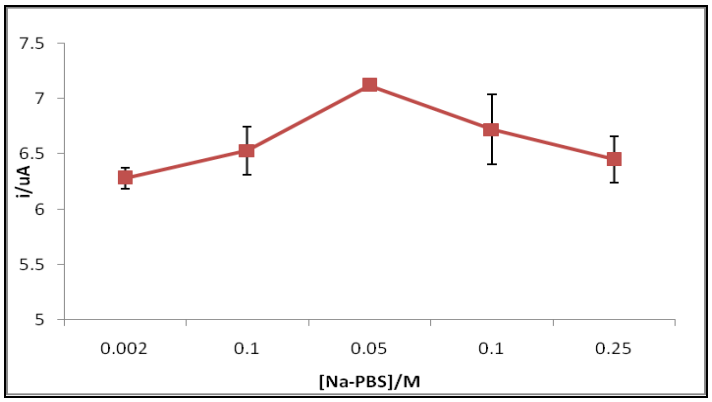
Rajah 7 pula menunjukkan kesan masa penghibridan DNA terhadap rangsangan biosensor. Masa penghibridan DNA daripada 0.5 sehingga 1 jam telah meningkatkan penghibridan DNA, namun setelah masa penghibridan dipanjangkan sehingga 2.5 jam, rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ tidak menunjukkan peningkatan yang ketara. Ini



kerana pada 1 jam penghibridan semua prob DNA yang terpegun ke atas SPE-AuNPs-mikrosfera oleh DNA sasaran. Hasil kajian ini mendapati bahawa masa optimum bagi penghibridan DNA sasaran adalah optimum setelah 1 jam.

Rajah 7. Kesan masa penghibridan DNA sasaran porsin terhadap rangsangan biosensor. Penghibridan dilakukan dalam 0.05 M penimbal Na-fosfat pH 7.0 yang mengandungi 1.5 M NaCl dan 30 µM $[Ru(bpy)_2PIP]^{2+}$

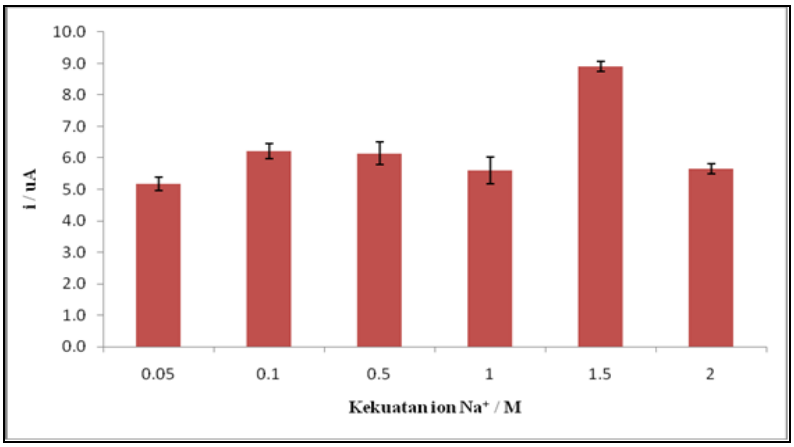
Kesan pH dan kepekatan larutan penimbal terhadap penghibridan DNA



Rajah 8 menunjukkan kesan pH terhadap rangsangan biosensor DNA. Arus DPV $[Ru(bpy)_2PIP]^{2+}$ meningkat daripada pH 6.0 sehingga 7.0 dan kemudian menurun sehingga pH 8.0. Peningkatan rangsangan biosensor DNA ini menunjukkan bahawa penghibridan DNA sasaran semakin meningkat dengan peningkatan pH di dalam larutan. Sebaliknya penurunan rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ menunjukkan kuantiti penghibridan DNA semakin kurang pada julat 7.5 hingga 8.0. Ini menjelaskan bahawa kadar tindak balas penghibridan DNA boleh dipengaruhi oleh pH larutan seperti yang dilaporkan oleh kajian literatur [18]. Pada keadaan berasid berlaku tindak balas pemprotonan rantai fosfodiester DNA. Pemprotonan rantai fosfodiester akan menurunkan kelarutan molekul DNA [19]. Kelarutan yang menurun boleh mengganggu dan menurunkan kadar tindak balas penghibridan DNA.

Rajah 8. Kesan pH terhadap penghibridan DNA porsin. Penghibridan dilakukan dalam penimbal 0.05 M Na-fosfat yang mengandungi 1.5 M NaCl dan 30 µM $[Ru(bpy)_2PIP]^{2+}$

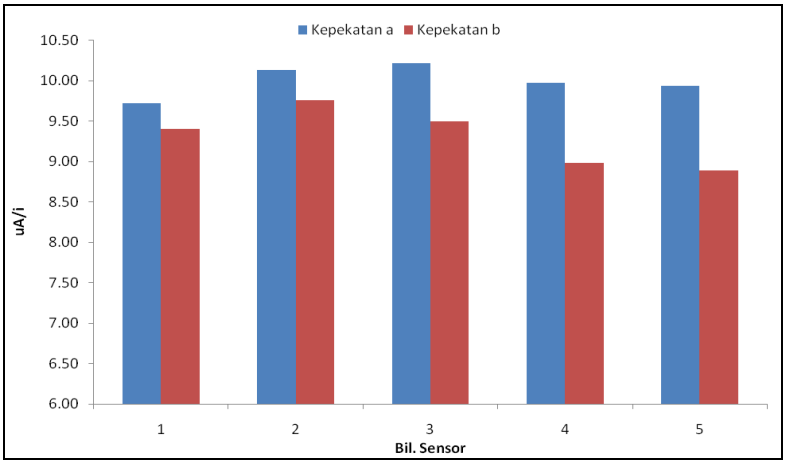
Rajah 9 pula adalah rangsangan biosensor DNA porsin dengan pelbagai kepekatan penimbal. Rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ meningkat daripada 0.002 M sehingga 0.05 M dan kemudian mulai merosot. peningkatan



rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ menunjukkan berlakunya peningkatan kuantiti penghibridan DNA. Ini disebabkan oleh meningkatnya kuantiti ion Na^+ (kekuatan ion) jika kepekatan penimbal meningkat. Hasil kajian ini mendapati bahawa kepekatan penimbal Na-fosfat 0.05 M adalah optimum untuk penghibridan DNA porsin.

Rajah 9. Kesan kepekatan penimbal terhadap penghibridan DNA. Penghibridan dilakukan dalam pelbagai kepekatan penimbal Na-fosfat pH 7.0 yang mengandungi 1.5 M NaCl dan 30 µM $[Ru(bpy)_2PIP]^{2+}$

Kesan kekuatan ion terhadap penghibridan DNA sasaran porsin

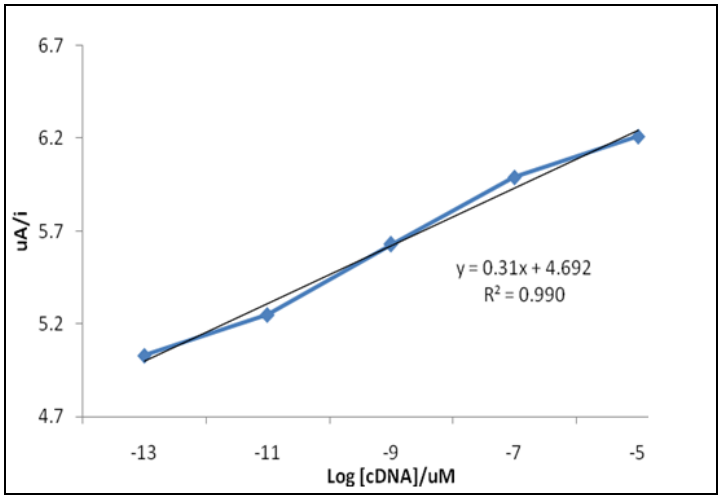


Kajian kesan kekuatan ion terhadap penghibridan DNA sasaran telah dilakukan dengan pelbagai kepekatan ion Na^+ daripada 0.05 M sehingga 2.0 M di dalam larutan penimbal Na-fosfat 0.05 M pada pH 7.0. Rajah 10 menunjukkan kesan kekuatan ion terhadap rangsangan biosensor. Rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ meningkat jika kekuatan ion meningkat dari 0.05 M hingga 1.5 M. Kekuatan ion berkesan menurunkan penolakan elektrostatik molekul DNA dan memberi kesan terhadap penghibridan DNA. Kadar tindak balas penghibridan meningkat dengan bertambahnya kepekatan garam. Kepekatan garam yang tinggi boleh menstabilkan bebenang dubel DNA (dsDNA) [20]. Kekuatan ion yang didapati daripada hasil kajian ini mencapai keadaan optimum pada 1.5 M ion Na^+ dalam larutan penimbal Na-fosfat 0.05 M dengan nilai pH 7.0.

Rajah 10. Kesan kekuatan ion Na+ terhadap penghibridan DNA. Penghibridan dilakukan dalam penimbal 0.05 M Na-fosfat pada pH 7.0 yang mengandungi 30 µM $[Ru(bpy)_2PIP]^{2+}$

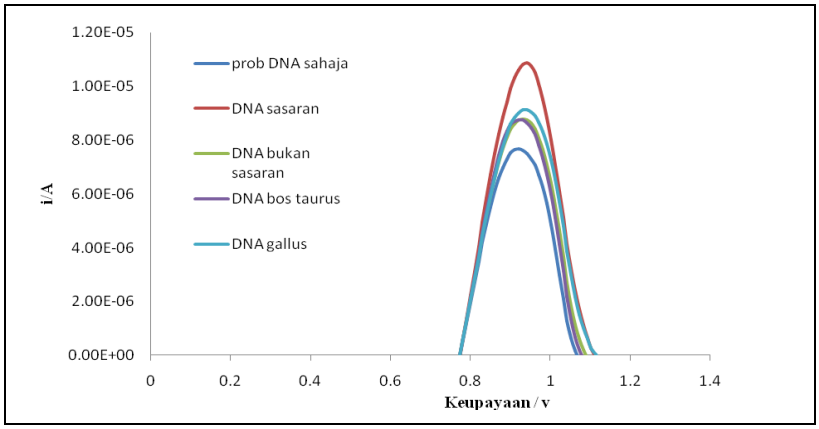
Kebolehasilan biosensor DNA porsin

Rajah 11 menunjukkan rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ untuk setiap kepekatan DNA sasaran. Ia menjelaskan tiada perbezaan yang ketara prestasi setiap biosensor dengan nilai RSD, masing-masing ialah 1.93 % dan 3.97 % (n = 5) bagi kepekatan 1 x 10^{-5} (a) dan 1 x 10^{-9} (b) µM. Nilai RSD yang diperolehi di dalam kajian ini adalah lebih rendah berbanding dengan kajian yang dilaporkan oleh kajian literatur seperti Erdem et al. [12] dan Wang et al. [21] iaitu masing-masing mencapai 10.13 % dan 10.12 %. Hal ini membuktikan bahawa interaksi antara kompleks logam $[Ru(bpy)_2PIP]^{2+}$ dengan DNA adalah lebih baik daripada kajian literatur yang menggunakan penunjuk redoks, $[Ru(bpy)_3]^{2+}$ dan $[Co(phen)_3]^{3+}$.



Rajah 11. Kebolehasilan biosensor DNA porsin dengan pelbagai kepekatan DNA sasaran dengan masa penghibridan selama 1 jam pada suhu bilik

Julat rangsangan linear bagi biosensor DNA porsin

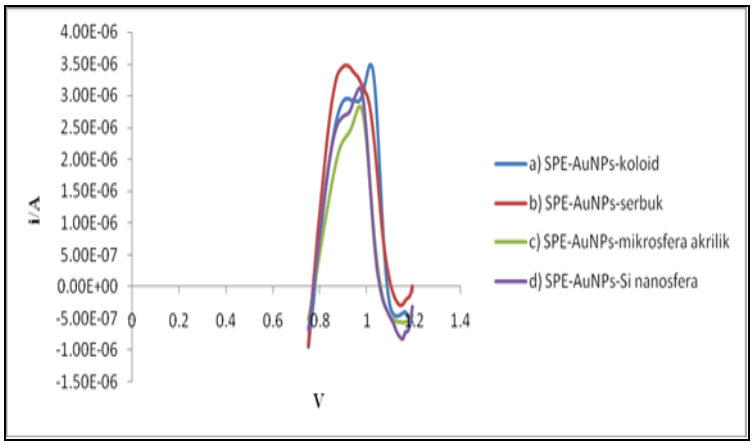


Hasil kajian mendapati rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ berkadar terus dengan kepekatan DNA sasaran pada julat kepekatan 1 x 10^{-13} sehingga 1 x 10^{-5} µM (Rajah 12). Menurut Kerman et al. [6] rangsangan biosensor DNA ini dengan menggunakan kompleks logam ini mempunyai had pengesanan yang baik. Hasil yang lebih baik ini adalah disebabkan oleh sifat hidrofobik dan peningkatan luas satah permukaan struktur 2,2-bipiridina dan 1,10-fenantrolina yang terdapat pada kompleks ruthenium ini. Ia meningkatkan sifat keafinan kompleks logam $[Ru(bpy)_2PIP]^{2+}$ berinteraksi dengan DNA.

Keselektifan biosensor DNA pada DNA sasaran

Rajah 13 menunjukkan rangsangan DPV bagi interaksi antara $[Ru(bpy)_2PIP]^{2+}$ dengan prob DNA porsin tanpa penghibridan, DNA bukan sasaran, DNA bos taurus (daging), DNA gallus (ayam) dan DNA sasaran porsin. Setiap satu DNA sasaran yang diuji mempunyai jujukan DNA yang berbeza. Hasil kajian menunjukkan bahawa rangsangan DPV yang paling tinggi terhasil daripada interaksi antara $[Ru(bpy)_2PIP]^{2+}$ tersebut dengan penghibridan DNA sasaran yang berpadanan dengan prob porsin itu. Manakala, didapati rangsangan DPV bagi penghibridan DNA prob dengan DNA bukan sasaran, DNA gallus (ayam) dan DNA bos taurus (daging) adalah lebih rendah daripada penghibridan dengan DNA sasaran (cDNA) dan interaksi kompleks $[Ru(bpy)_2PIP]^{2+}$ dengan prob DNA sahaja tanpa dihibrid menunjukkan rangsangan DPV yang paling rendah. Namun begitu, perbezaan rangsangan DPV antara penghibridan dengan DNA sasaran (cDNA) dengan DNA bukan sasaran yang lain tidak begitu ketara iaitu masing – masing, 10.9 uA (100%) dengan 8.74 uA hingga 9.12 uA (80 – 83.67 %). Hal ini menunjukkan biosensor DNA ini tidak dapat menghasilkan hasil keselektifan yang baik.

Rajah 12. Kesan pelbagai kepekatan DNA sasaran terhadap rangsangan biosensor DNA porsin. Penghibridan dilakukan dalam larutan penimbal K-fosfat 0.05 M pada pH 7.0 yang mengandungi 30 µM larutan $[Ru(bpy)_2PIP]^{2+}$ dan 1.5 M NaCl.



Rajah 13. Keselektifan biosensor DNA terhadap DNA sasaran porsin dan pelbagai jenis DNA tidak berpadanan. Penghibridan dilakukan dalam larutan penimbal K-fosfat 0.05 M pH 7.0 yang mengandungi 30 µM $[Ru(bpy)_2PIP]^{2+}$ dan 1.5 M NaCl

Hal ini berlaku dijangkakan kerana berlaku deposit kompleks $[Ru(bpy)_2PIP]^{2+}$ ke dalam permukaan karbon elektrod skrin bercetak (SPE) semasa proses penghibridan prob DNA dengan DNA sasaran (cDNA). Apabila kompleks logam ruthenium tersebut telah diserap terlebih dahulu ke dalam permukaan elektrod, maka apabila penghibridan DNA berlaku atau tidak, ia tetap memberikan rangsangan pada arus DPV kerana redoks berlaku dengan kehadiran kompleks logam $[Ru(bpy)_2PIP]^{2+}$ iaitu dioksidakan kepada $[Ru(bpy)_2PIP]^{3+}$ dan diturunkan kembali kepada $[Ru(bpy)_2PIP]^{2+}$.

Justeru itu, kajian diteruskan dengan mengubahsuai permukaan elektrod iaitu daripada menggunakan mikrosfera akrilik suksinimida ditukar kepada menggunakan silika nanosfera (SiO_2). Signifikan pengubahsuaian ini adalah kerana SiO_2 yang mempunyai cas positif, di mana ia akan menolak tarikan dengan kompleks interkalator $[Ru(bpy)_2PIP]^{2+}$.

Rajah 14 menunjukkan rangsangan DPV bagi $[Ru(bpy)_2PIP]^{2+}$ pada elektrod yang terubahsuai yang berbeza-beza iaitu, a) SPE yang dipegunkan dengan 50 µL zarah nanoemas (AuNPs) koloid, b) SPE yang dipegunkan dengan 20 µL (1 mg/350 µL EtOH), c) SPE yang dipegunkan dengan mikrosfera akrilik 10 µL (1 mg/1000 µL EtOH) dan d) SPE yang dipegunkan dengan 2 µL (6 mg/500 µL EtOH). Ini bagi mengkaji punca sebenar deposit kompleks ruthenium (II) ke atas elektrod. Walau bagaimanapun, hasil kajian mendapati tiada perbezaan signifikan terhadap rangsangan DPV $[Ru(bpy)_2PIP]^{2+}$ pada SPE yang terubahsuai. Justeru itu, ia dapat disimpulkan bahawa penggunaan SiO_2 juga tidak dapat menyelesaikan masalah ini. Maka, kajian lanjutan perlu dilakukan bagi memastikan pembangunan biosensor DNA porsin ini mampu menghasilkan keselektifan yang tinggi. Kajian masa hadapan yang boleh dilakukan adalah dengan memberi tumpuan kepada fabrikasi biosensor sendiri. Kajian lanjutan menggunakan beberapa elektrod juga adalah wajar. Walaubagaimanapun, hasil kajian ini telah membuktikan bahawa penggunaan ruthenium kompleks memberikan rangsangan yang tinggi dalam pengesanan DNA porsin.

Rajah 14. Rangsangan DPV bagi $[Ru(bpy)_2PIP]^{2+}$ pada SPE terubahsuai berlainan

Kesimpulan

Secara keseluruhannya, hasil kajian menunjukkan bahawa elektrod skrin bercetak (SPE) yang telah terubahsuai dengan menggunakan zarah nanoemas dan mikrosfera akrilik yang dihubungkan dengan voltammetri pembezaan denyutan (DPV) adalah sesuai untuk mengesan DNA porsin pada kepekatan rendah. Kaedah ini adalah mudah, kebolehpercayaannya tinggi dan memerlukan penggunaan sampel yang kecil. Kelebihan utama biosensor DNA ini adalah ia tidak memerlukan penggunaan bahan kimia beracun dan modifikasi asid nukleik. Selain itu, pengesanan DNA terpegun pada permukaan elektrod juga dapat dilakukan dengan cepat.

Penghargaan

Pengarang ingin mengucapkan ribuan terima kasih kepada Universiti Kebangsaan Malaysia kerana menyediakan fasiliti penyelidikan. Penyelidikan ini mendapat sokongan dan dana daripada Kerajaan Malaysia melalui Kementerian Pengajian Tinggi melalui geran e-science fund 02-01-02-SF1212 dan FRGS/1/2015/ST01/UKM02/2.

Abstract

In this research, a simple method was used to synthesize poly(aniline-*co*-*m*-aminobenzoic acid) also known as P(ANI-*co*-*m*-ABA) composite polystyrene (PS) nanofibers by using *in situ* chemical polymerization technique. The copolymer was polymerized on electrospun PS nanofibers mats with varied monomers solution concentration and the polymerization time. P(ANI-*co*-*m*-ABA) was also polymerized on PS films were prepared for comparison. The conductivity of the composites was studied and the result showed addition of graphene (GP) into the composites improved the conductivity of the composites. The composites of P(ANI-*co*-*m*-ABA)/PS nanofibers and films were characterized by Fourier transform infra-red (FTIR), thermogravimetric analysis (TGA) and ultraviolet visible (UV-vis) spectroscopy. Surface morphology of the composite was studied by scanning electron microscopy (SEM).

Keywords: poly(aniline-*co*-*m*-aminobenzoic acid), nanofibers, electrospinning

Abstrak

Dalam kajian ini, satu cara mudah telah digunakan untuk sintesis poli(anilina-*ko*-*m*-asid aminobenzoik) atau diringkas sebagai P(ANI-*co*-*m*-ABA) komposit polistirena (PS) fiber nano dengan menggunakan teknik pempolimeran kimia *in situ*. Pempolimeran kopolimer telah dijalankan ke atas PS fiber nano pada kepekatan monomer dan masa pempolimeran yang berbeza. P(ANI-*co*-*m*-ABA) juga menjalani proses pempolimeran ke atas filem PS sebagai perbandingan. Konduktiviti komposit telah dikaji dan keputusan menunjukkan dengan penambahan grafin (GP) ke dalam filem PS, bacaan konduktiviti elektrik telah meningkatkan. Komposit P(ANI-*co*-*m*-ABA) dan fiber nano PS telah dicirikan dengan menggunakan spektroskopi inframerah transformasi Fourier (FTIR), analisis termogravimetri (TGA) dan spektroskopi ultraungu nampak (UV-vis). Morfologi komposit juga telah dikaji dengan menggunakan mikroskopi elektron imbasan (SEM).

Kata kunci: poli(anilina-*ko*-*m*-asid aminobenzoik), fiber nano, putaran elektro

Introduction

PANI is one of the most studied conducting polymers due to its high electronic conductivity, redox and ion-exchange properties, excellent environmental stability and ease of preparation from common chemicals. The utilization of homopolymer PANI in industrial and technological application is hampered by its poor processability and miscibility due to low solubility [1]. The synthesizing copolymer of aniline and substituted aniline with

carboxylic acid is one of the attempts that have been made in order to increase its processability. Acid functionalize PANI such as P(ANI-*co*-*m*-ABA) was prepared chemically by adding the aniline with co-monomer, in this case is *m*-aminobezoic acid (*m*-ABA). The incorporation of functional group (COOH) into polymer backbone gives different properties from those of PANI in terms of lower conductivity with increasing solubility [2].

Meanwhile, PS nanofiber have received attention due to their unique properties such as low density, large surface area to mass, and high pore volume with controllable pore size [3]. In recent years, PS nanofibers have been fabricated by electrospinning technique. The electrospun PS nanofibers have a good macromolecular orientation along the fibers direction, which is produced by stretching of the polymer jet during electrospinning. The high molecular orientation of polymer molecules in the electrospun nanofibers enhances their mechanical properties (e.g. higher elastic modulus and strength) as compared to bulk material [4]. Therefore, the composite of P(ANI-*co*-*m*-ABA) and PS nanofiber can enhace the properties of both polymers.

GP is known for its very low weight and great efficiency in conduction of both and electricity [5]. Due to graphene's exceptional thermal, mechanical and electrical properties, it stands out as the most promising candidate to be a major filling agent for composite applications. GP nanocomposites at very low loading show substantial enhancements in their multifunctional aspects, compared to conventional composites and their materials. This not only makes the material lighter with simple processing, but also makes it stronger for various multifunctional applications. The remarkable properties of GP are able to improve the physicochemical qualities of the host matrix upon distribution [6].

The aim of this study is to prepare the poly(aniline-co-m-aminobenzoic acid) composite polystyrene (PS) nanofibers by using in situ chemical polymerization technique and characterize their physical and chemical properties.

Materials and Methods

Materials

Aniline was purchased from Fischer Chemical. The aniline was purified by distillation and hermetically sealed in the absence of light. The co-monomers, *m*-ABA, and oxidizing agent, APS ($(NH_4)_2S_2O_2$) with purity 97 % was supplied by Merck Schuchardt OHG. Solvents used namely dimethyl-formamide (DMF) and tetrahydrofuran (THF) were purchased from the Fischer Chemical.

Preparation of PS nanofibers

Electrospinnable solutions was obtained by dissolving 0.2 g of PS in THF/DMF (1:1) Then, the PS solution was filled in a 5 mL syringe attached with a blunt steel needle of 0.8 mm inner diameter. A square box covered with aluminium foil was placed 10 cm away from the needle tip as counter electrode. Electrospinning was carried out at room temperature in a horizontal spinning configuration, using the applied voltages 8 kV, driven by a high voltage power with a flow rate of 1 mL/h. The aluminum foil was placed over the counter electrode as collecting substrate.

Preparation of PS and PS/GP films

The preparation of PS/graphene film was similar to the preparation of PS nanofibers. An amount 10 wt. % of PS thin film was prepared by stirring 0.2 g of PS in 2 mL of THF/DMF (1:1) using a magnetic bar until PS completely dissolved. The polymer solution was poured into the petri dish and left for air dried overnight. Then, the thin PS film was cut into 5 cm x 1cm. PS/graphene film was prepared using 10 wt. % PS solution added with 15 mg of graphene powder and stirred until the whole mixture homogenously mixed together. The solution was poured into the petri dish and left for air dried overnight. The thickness of PS and PS/graphene films were measured using vernier caliper.

Preparation of PS/P(ANI-*co*-*m*-ABA) composite via *in-situ* polymerization

The PS nanofibers and film were cut into 5cm x 1cm and put in the aniline and/or *m*-ABA solution for *in situ* polymerzation. The P(ANI-*co*-*m*-ABA) was synthesized at fixed ratio of aniline to *m*-ABA 1:1. APS (3.65 g) in 50 mL of 1M HCl was added dropwise into 100 ml of 1M HCl containing aniline (1.46 mL) and *m*-ABA (1.100 g) at room temperature. The solution was stirred and left for 24 hours. The concentration of monomers (aniline and *m*-ABA) in HCl was varied from 0.5 M to 1.5 M to obtain thin P(ANI-*co*-*m*-ABA) coated on PS film or nanofibers.

The time of polymerization was also altered, 24 hours, 48 hours and 72 hours. After that, polymer composite was rinsed using deionized water and dried in oven at 40 ºC for a day.

Characterization of composite polymer

The morphologies of the products were investigated with a JEOL XL30S field emission scanning electron microscope (SEM). The samples for SEM were mounted on aluminium studs using adhesive graphite tape and sputter-coated with gold before analysis. Infrared spectra were measured in the range 200 – 2000 cm^{-1} on PANI pellets made with KBr at a Perkin Elmer 1600 FTIR spectrophotometer, taking 10 scans at a resolution of 4 cm^{-1}. Two-probe resistivity and hall voltage measurements with the model Kethley 2611-SMU is used to determine the resistivity of the sample. Two-point probe technique is used to measure the conductivity of the polymer. The sample is put on the holder and two probes was stick on the sample. A graph of current against voltage was plotted throughout this technique. Thermal gravimetric analysis (TGA) Mettler Toledo Star SW 7.01 was used. The sample was purged with nitrogen gas with a flow rate of 50 ml/min and the sample was heated from ambient temperature to 700 °C with heating rate 10° C/min.

Results and Discussion

Spectroscopic study of PS/P(ANI-*co*-*m*-ABA) composite film

Figure 1 and 2 show the UV-Vis spectra of the P(ANI-*co*-*m*-ABA) with different monomers concentrations and polymerization times. The UV-Vis spectra as shown in figure 1 and 2 display two main absorption peaks at 225 – 325 nm and 465 – 565 nm. The first peak contributed to π→ π* transition and significant to extended conjugation in polymer chain [7]. The copolymer undergoes blue shifted as the concentration of monomers used in the polymerization lower due to the less conjugated property and belongs high energy. The second peak in between 465 – 565 nm attributed to the transition of exciton of quinine due to the inter- and intrachain charge transfer [8]. The hypsochromic shift in copolymer is due to the carboxylic interruption in polymer chain as mentioned before, in which give implication to its conductivity property. The behavior of copolymer that proved in this UV-Vis is in agreement with the conductivity measurement results in which suggest that higher concentrations of monomers will decrease the conductivity property in copolymer.

In P(ANI-*co*-*m*-ABA) there is hypsochromic shift and hypochromic shift display due to the incorporation of *m*-ABA into backbone of parent structure. This phenomenon can be explained by the increasing of steric repulsion between adjacent groups as consequences of carboxylic acid group from *m*-ABA substituent addition that lead to the twisting of the polymer chain. Indirectly, this situation will lower the degree of co-planarity and interrupt the conjugation of the polymer rings, as well as increase the transition energy.

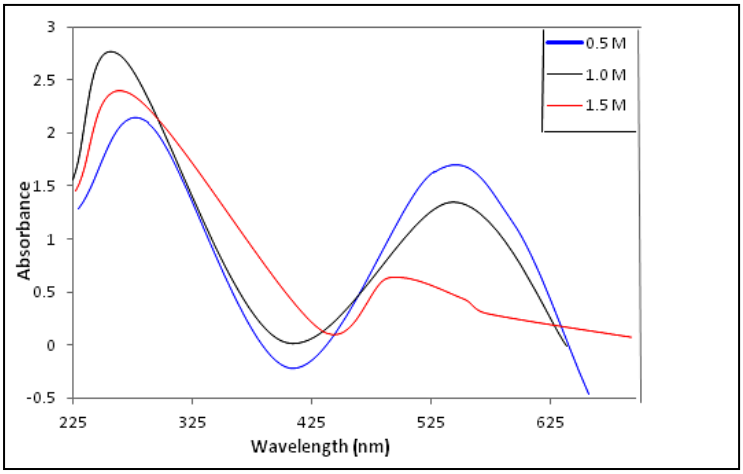

Figure 1. UV-Vis spectra of P(ANI-*co*-*m*-ABA) synthesized with monomers concentrations of 0.5 M, 1.0 M and 1.5 M, respectively

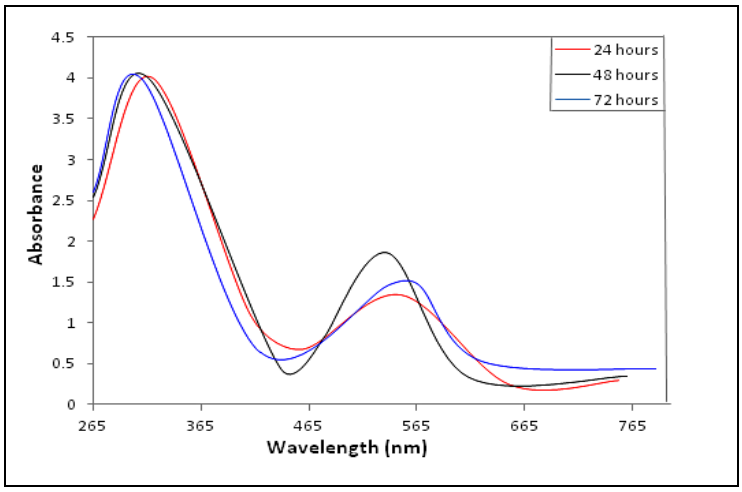

Figure 2. UV-Vis spectra of P(ANI-*co*-*m*-ABA) at 24, 48 and 72 hours

Figure 3 and Figure 4 show FT-IR spectra of composite film of the copolymer at different concentrations of monomers and polymerization time. As shown in the spectra of all samples the peaks are approximately presented at 700, 1000, 1250, 1490, 1570 cm^{-1}. The main peaks at 1490 cm^{-1} can be associated with C=N and C=C stretching vibrations of quinone and benzene rings in PANI chains. The peaks at 1250 cm^{-1} are attributed to the C-N stretching mode and the vibration of C-H in benzene ring. The peak at 1000 cm^{-1} is due to quinonoid unit of doped PANI. These related peaks confirm the successfully formation of PANI at different monomers ratios. The carbonyl group, C=O can be observed in the region in between 1500 cm^{-1} to 1600 cm^{-1}. The FT-IR results confirming the incorporation of *m*-ABA into polymer backbone due to copolymerization of aniline and *m*-ABA, thus proving that there is carboxylic group presence in the polymer structure. Both of the spectra in Figure 3 and Figure 4 assign the bands in between 650 – 750 cm^{-1} and 500 cm^{-1} in which indicates the presence of N-H bending, C-H bending in-plane and out-plane respectively [9]. The FTIR spectra of PS/P(ANI-*co*-*m*-ABA) composite nanofibers is not shown here because it is very similar to PS/P(ANI-*co*-*m*-ABA) composite film.

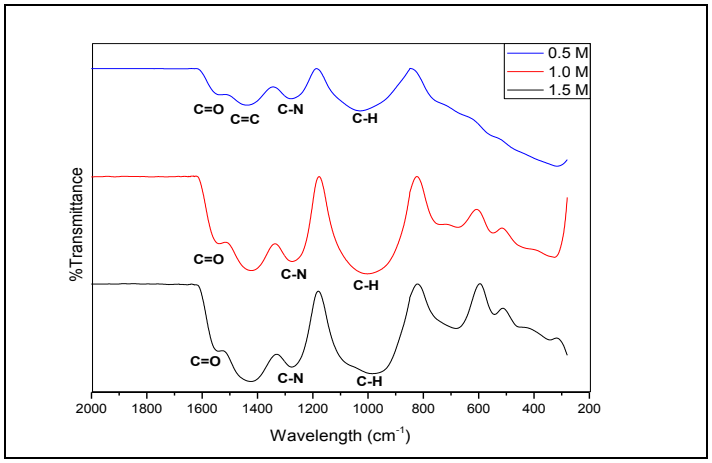

Figure 3. FTIR spectra of PS/P(ANI-*co*-*m*-ABA) film at different concentrations of monomer

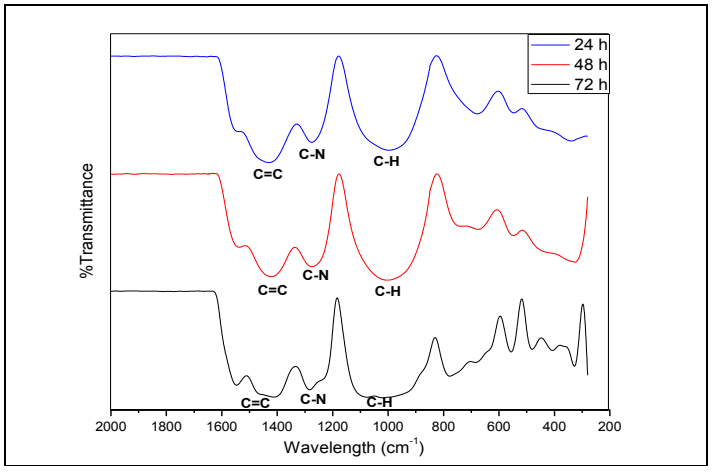

Figure 4. FTIR spectra of PS/P(ANI-*co*-*m*-ABA) composite film at different polymerization times

Thermal study of the P(ANI-*co*-*m*-ABA)/PS composite nanofiber

Figure 5 and Figure 6 represent the TGA thermograms for P(ANI-*co*-*m*-ABA)/PS at different polymerization times and different concentrations of monomers, respectively. Figure 5 and Figure 6 shows three degradation steps of PS/P(ANI-*co*-*m*-ABA) composite nanofibers**.** The composite shows a weight loss of 7 – 8 % up to 100 ℃, a weight loss of 22 % from 100 – 450 ℃ and a weight loss of 40 % from 450 – 800 ℃. Our data are found in good agreement with the data reported in literature [10, 11] which confirms the reliability of our results. When P(ANI-*co*-*m*-ABA) was polymerized onto PS nanofiber at different monomer concentration and polymerization time, a different thermal behaviour with respect to the parent polymer, i.e. PANI are shown in figures below. Thermogram suggests that weight loss mainly occurs in two steps. First step corresponds to the loss of water molecules, slow removal of oligomers and loss of impurities up to 120 ℃ with a total weight loss of 6 % at ratio concentration of monomer to monomer 0.5 M, up to 150 ℃ with a weight loss of 9 % in 1.0 M and up to 100 ℃ with a weight loss of 12 % in 1.5 M. Second weight loss is due to the expulsion of oxidizing agent, ammonium persulphate (APS).

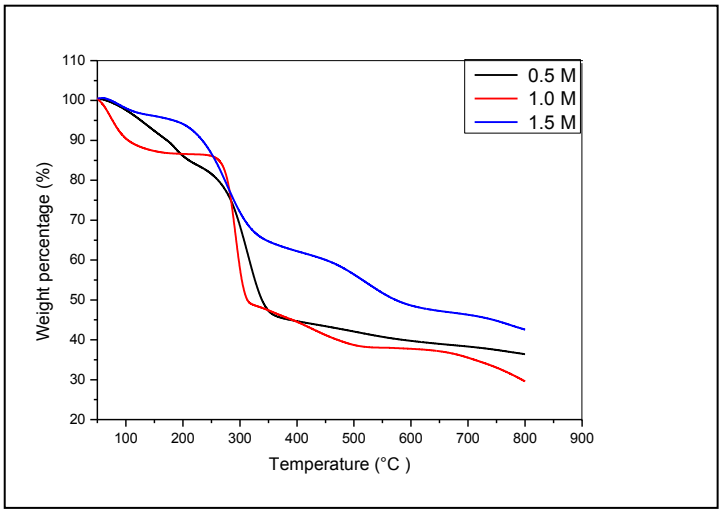

Figure 5. TGA thermograms of P(ANI-*co*-*m*-ABA)/PS composite nanofibers at different concentrations of monomers

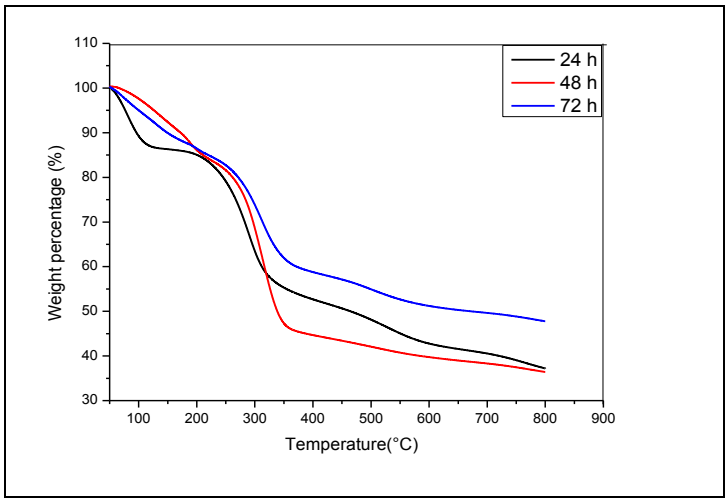

Figure 6. TGA thermograms of P(ANI-*co*-*m*-ABA)/PS composite nanofibers at different polymerization times

For P(ANI-*co*-*m*-ABA)/PS at 0.5 M and 1.5 M, the weight losses of polymer had occurred at 200 °C to 350 °C whereas for P(ANI-*co*-*m*-ABA)/PS at 1.0 M, it occurred at 270 °C to 330 °C. Third step corresponds to the degradation of polymeric backbone and polystyrene ions in the range of 300 – 400 ℃ (weight loss of ca. 13 %) in 0.5 M, in the range of 300 – 500 ℃ (weight loss ca. 25 %) in 1.0 M, and in the range of 140 – 360 ℃ (weight loss of ca. 38 %) in 1.5 M. Thus, the thermal stabilities of all the composites are considerably less than that of polyaniline. This may be attributed to the decreased chain length and presence of bulky groups in the composites. PS shows a negligible weight loss up to 350 ℃ and a continuous weight loss (ca. 15 %) is observed up to 650 ℃, which is possibly due to the degradation of PS in its thermogram. The explanation for thermograms of P(ANI-*co*-*m*-ABA)/PS at different polymerization time is almost similar to the explanation for P(ANI-*co*-*m*-ABA)/PS with different concentration. From figure 6, initial weight loss occurred because the water loss whereas the second weight loss happened because of expulsion of APS and then degradation of P(ANI-*co*-*m*-ABA).

Surface morphology of the composite film and nanofibers

Figure 7(a) and (b) show the surface morphology of the PS/GP films before and after coated with copolymer respectively. Based on the results from thermal analysis, PS/P(ANI-co-m-ABA) composite films and nanofibers were prepared using 0.5 M concentration of monomers and 24 hours' polymerization time. Figure 7(a) shows the PS film before undergoes *in situ* polymerization. There are pores presences on the surface of PS films due to the presence of air bubble inside the films. The other reasons of formation of holes on the surface of PS films may be due to the solvent DMF evaporate slowly to the surrounding during drying process. While Figure 7(b) shows the image of PS films after being coated with copolymer. The presence of copolymer can be seen as the surface of the PS film become rough and the absence of the pores is because the pores are fully covered by the copolymers. The Figure 7(b) also shown that P(ANI-*co*-*m*-ABA) has been completely and uniformly coated the surface of PS films.

Figure 8(a) and (b) show SEM images of 10 % and 15 % PS nanofibers before coated with copolymer. PS nanofibers appear to be long, thin and small in diameter. PS nanofiber has larger surface area compare to PS films due to its built up from small diameter of fibers. These special properties of nanofibers will enhance and wider its application in industry such as filter, membrane, drug delivery and many more. Figure 8(c) and (d) show the image of PS nanofiber after been coated with copolymer. The surface of the nanofiber becomes rough and thicker indicates the presence of the P(ANI-*co*-*m*-ABA). 10 % PS nanofiber has higher thickness of coating compare to 15 % PS nanofiber due to its small diameter which is 0.15 µm compare to 15 % with diameter 0.21 µm. The smallest

diameter has higher surface to volume ratio thus increasing the amount of copolymer can be deposited onto the nanofiber. The last Figure 9(a) and (b) shows the surface morphology of the PS/GP films before and after coated with copolymer. The image of PS/GP films is quite similar to the image of PS films where the surface of the film is smooth with the presence of some air bubble trapped inside the film. After copolymer is coated on top of PS/GP film, the surface of the film becomes rough and become thicker too.

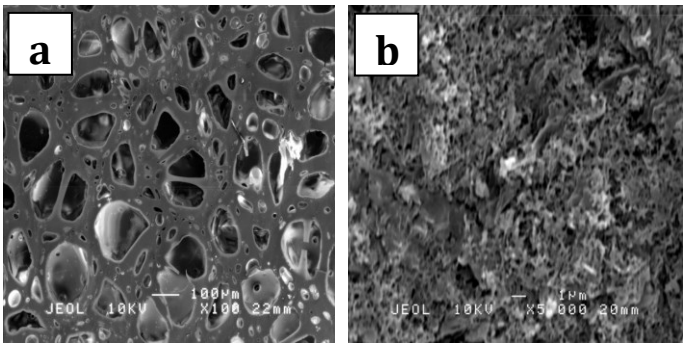

Figure 7. SEM image of (a) PS film and (b) P(ANI-*co*-*m*-ABA)/ PS film

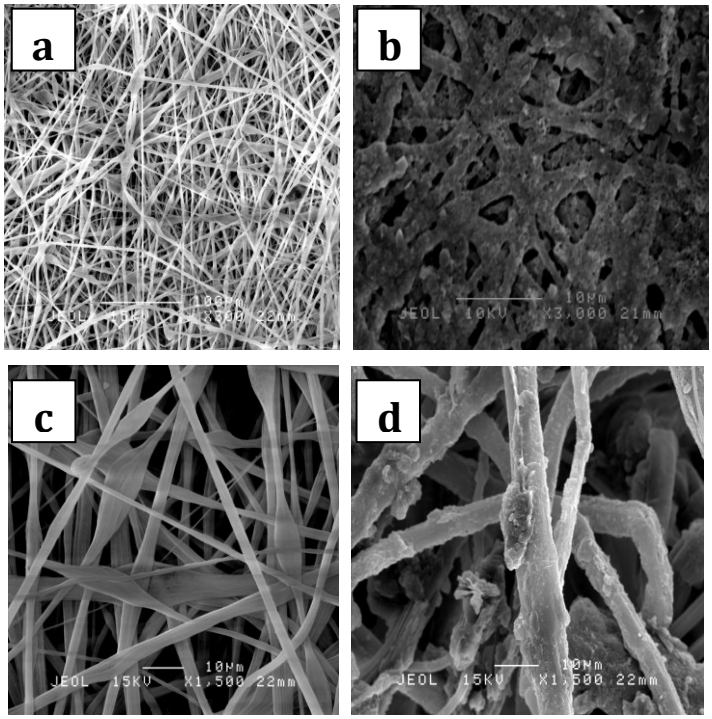

Figure 8. SEM image of (a) 10 % PS nanofiber, (b) P(ANI-*co*-*m*-ABA)/ 10 % PS nanofiber, (c) 15 % PS nanofiber and (d) P(ANI-*co*-*m*-ABA)/ 15 % PS nanofiber

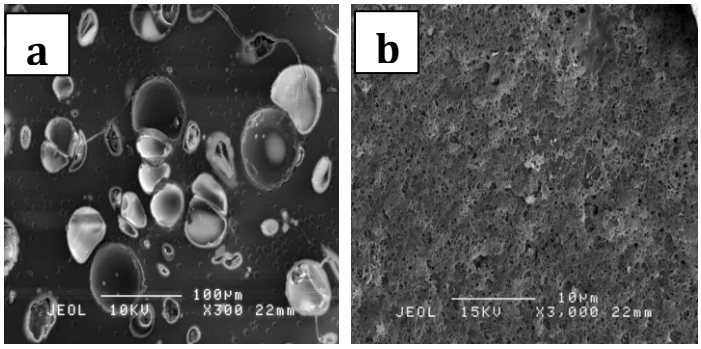

Figure 9. SEM image of (a) PS/graphene film and (b) P(ANI-*co*-*m*-ABA)/ PS/graphene film.

Electrical conductivity of the composite fibers

Electrical conductivity was measured by four-probe method (Stejskal and Gilbert 2002). Table 1 shows the conductivity values for PS nanofiber before and after coated with copolymer. Both of PS nanofiber at 10 % and 15 % before undergoes *in situ* polymerization show no conductivity value which indicates that PS nanofibers have no electrical conductivity. The copolymer coated of P(ANI-*co*-*m*-ABA)/PS nanofibers showed the conductivity of PS/P(ANI-co-m-ABA) nanofibers up to 0.26 S cm^{-1} for 10 % PS and 0.17 S cm^{-1} for 15 % PS. The composite of copolymer with PS nanofiber increase the conductivity values thus indirectly will increase the electrical conducting properties of PS as well.

Table 1. Conductivity measurement of P(ANI-*co*-*m*-ABA)/PS fiber composite

Sample	**Conductivity (S cm^{-1})**
10 % PS fiber	0.00
P(ANI-*co*-*m*-ABA)/10 % PS fiber	0.26
15 % PS fiber	0.00
P(ANI-*co*-*m*-ABA)/15 % PS fiber	0.17

Table 2 demonstrates the value of conductivity of PS film when graphene is added into the polymer film. Graphene is well known material that can conduct electrical with great efficiency. Incorporation of graphene into PS film increases the conductivity value. The conductivity value for PS film after adding graphene increased to 0.74 Scm^{-1}.

Table 2. Conductivity measurement of P(ANI-*co*-*m*-ABA)/PS/GP composite films

Sample	**Conductivity (S cm^{-1})**
PS film	-0.25
P(ANI-*co*-*m*-ABA)/PS/GP films	0.74

Conclusion

In this work, P(ANI-*co*-*m*-ABA) was deposited on PS film and nanofiber using *in situ* polymerization method. The composites were synthesized varying the amount of aniline and *m*-ABA in the composites and also varying the polymerization time. The copolymer was incorporated on PS nanofiber to become composite, hence increasing the

mechanical strength and electrical properties of the whole polymer. The structures were confirmed by FT–IR spectroscopy. The copolymer formation was confirmed by UV–Vis spectroscopy and electrical measurements. The surface morphology showed a nanofibrous structure. The conductivity of the composite increased with the addition of graphene.

Abstract

Molecular distillation is industrially useful in the purification of highly oxidative oils and fats, and their derivatives. Free Fatty Acids (FFAs) were isolated from high free fatty acid crude palm oil (HFFA-CPO) using molecular distillation. The isolation conditions were set-up with feeder flow rate of 2.3 g/min, wipers speed of 350 rpm, evaporator temperature ranging from 150 °C to 265 °C and pressure at 10 torr respectively. The results showed that the yield of crude palm oil after separation (CPO_{AS}) was 88 % (wt/wt). The physicochemical properties of CPO_{AS} showed a distinct difference in acid value, FFA content, iodine value and hydroxyl value compared to that of HFFA-CPO and it is more favourable for food product usage. The results showed that CPO_{AS} has lower acid value (reduced from 21.3 ± 0.1 to 2.1 ± 0.01 mg NaOH/g), increased iodine value from 50.6 ± 0.2 to 53.5 ± 0.2 mg KOH/g, reduced hydroxyl value from 43.4 ± 0.2 to 25.5 ± 0.1 mg KOH/g and lower FFA content from 9.4 ± 0.1 % to 0.9 ± 0.1 % in CPO_{AS} respectively. The work has proven that molecular distillation is an effective method for the separation of FFA from high free fatty acid crude palm oil.

Abstrak

Penyulingan molekul adalah bermanfaat untuk industri bagi penulenan minyak dan lemak yang telah teroksida, serta bahan-bahan terbitannya. Asid lemak bebas (FFA) telah dipisahkan daripada minyak sawit mentah berasid lemak bebas tinggi (HFFA-CPO) menggunakan penyulingan molekul. Keadaan pemisahan telah ditetapkan masing-masing dengan kadar alir suapan pada 2.3 g/min, laju pengelap 350 rpm, suhu penyejat daripada 150 °C hingga 265 °C dan tekanan pada 10 torr. Hasil kajian menunjukkan peratusan hasil minyak sawit mentah selepas proses pemisahan (CPO_{AS}) adalah 88 % (wt/wt). Sifat fiziko-kimia CPO_{AS} menunjukan beberapa perbezaan dalam nilai asid, kandungan FFA, nilai iodin dan nilai hidroksil berbanding dengan HFFA-CPO. Hasil kajian membuktikan CPO_{AS} mempunyai nilai asid yang lebih rendah (menurun daripada 21.3 ± 0.1 kepada 2.1 ± 0.01 mg NaOH/g), nilai iodin meningkat daripada 50.6 ± 0.2 kepada 53.5 ± 0.2 mg KOH/g, nilai hidroksil menurun daripada 43.4 ± 0.2 kepada 25.5 ± 0.1 mg KOH/g dan kandungan FFA menurun daripada 9.4 ± 0.1 % bagi HFFA-CPO kepada 0.9 ± 0.1 % bagi CPO_{AS}. dan menjadikannya lebih sesuai untuk digunakan dalam kegunaan makanan. Kajian ini telah membuktikan bahawa penyulingan molekul adalah suatu kaedah efektif bagi pemisahan FFA daripada minyak sawit mentah berasid lemak tinggi.

Kata kunci: asid lemak bebas, minyak sawit mentah, penyulingan molekul

Introduction

South East Asia and Equatorial Africa are considered the best locations where palm oil is widely grown and produced. In fact, there are mainly two types of oil which can be obtained from palm oil. The first part is known as crude palm oil from the flesh of the fruit (mesocarp), and the second part is palm kernel oil from the seed or kernel. Unripe fruit contains very little oil, but the mesocarp of ripe fruits has an oil content of (70 – 75 %) of its total weight. In Malaysia, production of palm oil is considered as one of the highest among other producing countries, due to the suitable climate and proper management [1, 2]. Crude palm oil (CPO) mainly consists of glycerides and small quantities of non-glyceride components. The non-glyceride components include free fatty acids (FFAs), trace metals, moisture, impurities and minor components [3]. The fatty acid composition of crude palm oil is mainly palmitic (44 %), stearic (4 %), oleic (40.6 %) and linoleic (9.8 %) [4].

According to literatures, Prasanth et al. [5] and Azlan et al. [6] reported, the Malaysian crude palm oil comprises more than (80 %) triacylglyceride, (3 – 8 %) diacylglyceride, less than (3 %) monoacylglyceride and (3 – 4 %) free fatty acids and approximately (1 %) of minor components which include carotenoids, vitamin E (tocopherols and tocotrienols), sterols, phospholipids, glycolipids, and terpenic and aliphatic hydrocarbons. Based on the standards by Malaysian Palm Oil Board (MPOB), the basic quality specifications of CPO are maximum 5 % FFA and 0.25 % of moisture content and impurity respectively [7]. Meanwhile, the Palm Oil Refiners Association of Malaysia (PORAM) specifies lower than 0.1 % FFA content in palm oil [8].

The high level of FFAs in CPO indicates its lower ability due to the enzymeic and microbial lipase reactions of palm fruit, as well as the storage of CPO under bad conditions such as high temperature and high moisture which can affect the quality of oil [9, 10]. The most commonly used methods for FFA separation are molecular distillation, chemical esterification, supercritical extraction, and organic solvent nanofiltration [11, 12]. Chemical esterification with or without catalyst involves separation of FFA from the crude palm oil at high temperature and inert medium with free hydroxyl groups remain in the oil. Supardan and Satriana [12] effectively reduced FFA content from 33.3 % to 1% through esterification with methanol using sulphuric acid as catalyst at 1% (wt/wt). Although high rate of FFA can be removed using chemical esterification, high temperature during distillation would increase the production cost. In another study, Shah and Venkatesan [13] achieved selectively free fatty acids separation from vegetable oil at ambient temperature using 75% aqueous and 80 % isopropyl alcohol as the extraction solvent. The key factor which has contributed to such effective separation is the presence of water in the aqueous isopropyl. As the free fatty acids were transferred into the aqueous isopropyl layer, a progressive decoupling effect was exerted on the alcohol and oil layers and consequently formed immiscible phases.

The molecular distillation process is a useful mechanism to separate and purify high molecular weight materials, as well as compounds that are thermally sensitive such as free fatty acids and vitamins. Furthermore, this technique offers a major advantage that it avoids problems with toxicity among others that use solvents as the separating agent. Molecular distillation processes, enable maximum removal of free fatty acids by manipulating the feed flow rate and temperature of distillation for the extraction of minor components from palm fatty acid distillates. The removal capacity is associated to the yield, purity, and rate of evaporation in terms of concentrations, distribution coefficients, and relative volatilities [14, 15]. In previous study, molecular distillation has been employed to reduce FFAs from soybean oil by varying the operating conditions. High separation was achieved in the distillate with 81.37 % FFA, performed under 140 °C evaporator temperature and 1.87 g/min feed flow rate [15].

The FFA content is an important specification that influences the palm oil quality within the production, storage and marketing stages. The objective of this research work was to extract the FFAs from the HFFA-CPO and to determine the physicochemical properties.

Materials and Methods

Sample collection

Malaysian high free fatty acid crude palm oil (HFFA-CPO) was obtained from a local refinery, Sime Darby, Selangor Malaysia.

Chemicals and reagent
Sodium hydroxide, potassium iodide, Wijs solution, n-hexane, sodium thiosulphate, potassium hydroxide, hydrochloric Acid, acetic anhydride, pyridine and ethyl alcohol were purchased from Sigma-Aldrich.

Free fatty acid separation
Free fatty acid separation from high free fatty acid crude palm oil was carried out using molecular distillation apparatus (Incon ILC-04 SPD, USA). HFFA-CPO of 100 g was added into a feed tank. The conditions of distillation were as follows: 10 torr (pressure), 60 °C (condenser temperature), 150 °C − 270 °C (evaporator temperature), 2.3 g/min feed flow rate and 350 wiper basket speed. After distillation, the distillate and retentate products were collected, weighed and analysed.

Chemical characteristic analysis: *Acid value (AV) & FFA %*
Acid value of oil was determined according to AOCS (1989) standard methods Cd 3a-63[16]. FFA % and acid value in CPO as palmitic acid was calculated using the following equations 1 and 2 below:

$$\%\ \text{FFA as Palmitic acid} = \frac{25.6 \times \text{N} \times V}{W} \quad (1)$$

where the value of 25.6 is the formula for FFA determination is equivalence factors for palmitic acid; the predominant fatty acid in palm oil. N is normality of NaOH, V is volume of NaOH solution used in mL and W is weight of sample.

$$\text{Acid value} = \%\ \text{FFA as palmitic acid} \times 2.19 \quad (2)$$

where the value of 2.19 is the conversion factor for palmitic acid.

Iodine value (IV)
The iodine value was calculated as recommended by the (AOCS 1989) standard methods Cd 1-25 [16] as given in equation 3 below:

$$\text{I.V} = \frac{12.69 \times \text{N}(\text{Vb} - \text{Vs})}{W} \quad (3)$$

where N is the normality of the $Na_2S_2O_3$ solution, Vb is the volume (mL) of $Na_2S_2O_3$ solution used for the blank test, Vs is the volume (mL) of $Na_2S_2O_3$ solution used for the determination of the sample, W is the weight in grams of the sample test portion. The value of 12.69 are used to transfer equivalent thiosulphate to g (iodine). The molecular mass unit or relative molecular unit of iodine is 126.9.

Saponification value and unsaponifiable matter
Saponification value and unsaponifiable matter of oil were determined by adopting the methods by Salimon et al. [17].

Hydroxyl value
Hydroxyl value was determined according to AOCS standard methods Cd 13-60 [16].

Physical characteristic analysis
Colour
The oil colour was determined using a Lovibond tintometer Model F/10508, according to the PORIM test method [18]. The frozen oil samples were melted by placing them in an oven at a temperature of 60 °C. The liquefied samples were placed into an inch cell up to three quarters full, and the colour was determined at 28 °C by achieving the best possible match with the standard colour slides of red and yellow indices.

Viscosity
The viscosity of the HFFA-CPO and CPO_{AS} was determined using a Brook field model RV DV-I+ (U.S.A) Spindle of SO5. The viscosity was read in Pascal second (Pa.s) directly from the viscometer, which was maintained at 1 min and 100 rpm at room temperature.

Moisture Content
The moisture content of HFFA-CPO and CPO_{AS} was determined by using a Moisture Analyzer model AND MX-50. Approximately 5g of CPO was weighed into a moisture dish, and dried in the moisture analyser for 30 minutes at 101 °C.

Refractive Index
The refractive index of HFFA-CPO and CPO_{AS} was determined according to AOCS standard methods Cc 7-25, [16] using a refractometer at 26.5 °C.

Specific gravity
The density of HFFA-CPO and CPO_{AS} was obtained using a delicate balance. An amount 1 mL of oil was placed on a balance, and its weight was recorded at room temperature. Later, the specific gravity was determined according to The Lund relationship [19].

Free fatty acid and fatty acid composition
The fatty acid composition (FAC) of HFFA-CPO and CPO_{AS} were determined using a Gas Chromatography (Shimadzu GC-17A) equipped with a capillary column BPX 70 (30m x 0.25mm x 0.25 µm) and an FID detector. The column temperature was programmed at 120 °C, with an increment of 3 °C per minute up to 245 ^{o}C, whereas the injector and detector temperature were set at 260 °C and 280 °C respectively. High purity helium gas (99.99 %) was used as the carrier gas with a flow rate of 0.3 mL/min. Fatty acid methyl ester (FAME) was prepared with base-catalysed trans esterification according to Salimon et al [17], and using acid-catalysed transesterification proposed by Ichihara et al. [20]. Peaks were identified by comparing with the retention times of the authentic standards.

Analysis of TAG in crude palm oil
Chromatography separation was performed using High performance liquid chromatography (HPLC), model 1525 equipped with refractive index detector and Spherisorb C18 (5 µm; 250 × 4.6 mm) column. HPLC was employed to analyse the triacylglyceride, diacylglyceride, monoacylglyceride and free fatty acid. The parameters of HPLC were carried out according to Cunha et al. [21]. The eluent used was a gradient of acetone (A) and acetonitrile (B). Elution was performed with a solvent flow rate of 0.4 mL/min with a linear gradient as follows: 0 min 30 % B, 20 min 25 % B, 35 min 20 % B and maintained for 20 min before returning to the initial conditions within 3 min. The effluent was monitored with an ELSD detector with the following settings: evaporator temperature of 40 °C, air pressure of 3.5 bar and photomultiplier sensitivity of 6. The samples were prepared by dissolving 0.15 g in 5 mL mixture of acetone: acetonitrile (63.5:36.5) prior to injection into the HPLC.

Fourier transform infrared spectroscopy analysis of crude palm oil
Fourier Transform Infrared Spectroscopy (FTIR) analysis was carried out according to Salimon et al. method [22]. FTIR spectrum was recorded with Perkin Elmer Spectrum GX spectrophotometer in the range of 700−4000 cm^{-1}. FTIR was used to measure functional groups of HFFA-CPO and CPO_{AS}. A very thin film of HFFA-CPO and CPO_{AS} were individually covered on NaCl cells (25 mm i.d × 4 mm thickness) and were used for analysis.

Results and Discussion

Free fatty acid separation
Molecular distillation separates free fatty acids from HFFA-CPO at varying evaporator temperature depending to the boiling points of the fatty acids. It usually operates with a low feeder flow rate of 2.3 g/min and wiper speed of 350 rpm. As the evaporator temperature reached the boiling points of the free fatty acid, the distillate flow rate will increase with the feed flow rate and the highest processing capacity of the unit should be achieved. However, heat transfer limitation between the oils and evaporator will maintain a steady distillate flow rate. At that time when the feed flow rate has been increased, the material volume inside the evaporator is already high. Therefore, the heat

transfer efficiency between the material and the evaporator is reduced due to poor contact with the evaporator walls, thereby, declines the separation ratio [15].

When the HFFA-CPO was subjected to the molecular distillation, it was split in two fractions, the residue and distillate. The residue comprises low PFAD of crude palm oil (CPO_{AS}) and the recovered FFA in the distillate (PFAD). The percentage yield of DFA and CPO_{AS} is shown in Table 1. It shows in the distillate, the DFA yield is 12 % with 97.3 ± 0.1 % acid value which suggest that the distillate contains relatively high percentage of FFA. According to MPOB standards [7], the specified FFA value of a CPO should be lower than 5 % to avoid any defects on the quality of the oil. In this study, the residue has a lower percentage of FFA in CPO_{AS} (0.9 ± 0.1%). Based on these results, the CPO_{AS} in the residue exhibits the property of edible oil, and the FFA recovered in the distillate can be utilized in future industrial applications.

Table1. Yield of DFA and CPO_{AS} after molecular distillation of 100 g HFFA-CPO

	Distillate (PFAD)	**Residue (CPO_{AS})**
Yield (%)	12	88
FFA (%)	97.3±0.1	0.9±0.1

FTIR analysis of HFFA-CPO and CPO_{AS}

Verification of the isolated FFA from HFFA-CPO was carried out using FTIR spectroscopy. The characteristic of main functional groups in HFFA-CPO and CPO_{AS} is given in Table 2.

Table 2. The functional groups of HFFA-CPO and CPO_{AS} in terms of main wavenumber in the FTIR

Functional group	**Wavenumber (cm^{-1})**	
	HFFA-CPO	**CPO_{AS}**
OH stretching (FA)	3473	-
C = C bending vibration (aliphatic)	3006	3005

-CH3 sym deformation	1377	1377
-C-O-Stretching vibration(ester)	1238−1165	1237 - 1164
C-H group vibration (aliphatic)	722	722

Notes: HFFA-CPO high free fatty acid crude palm oil, CPO_{AS} crude palm oil after separation

Figure 1 shows the FTIR spectrum of HFFA-CPO where the peaks of C=O for carboxylic acid and ester were clearly seen at 1714 cm^{-1} and 1744 cm^{-1}, respectively. However, the peak of C=O of carboxylic acid disappeared after separation (Figure 1) which proven the effectiveness of the FFA separation process. The C=O (ester) peak in CPO_{AS} appeared at 1746 $cm^{-1}$and the OH stretching also disappeared after molecular distillation as shown in Figure 1.

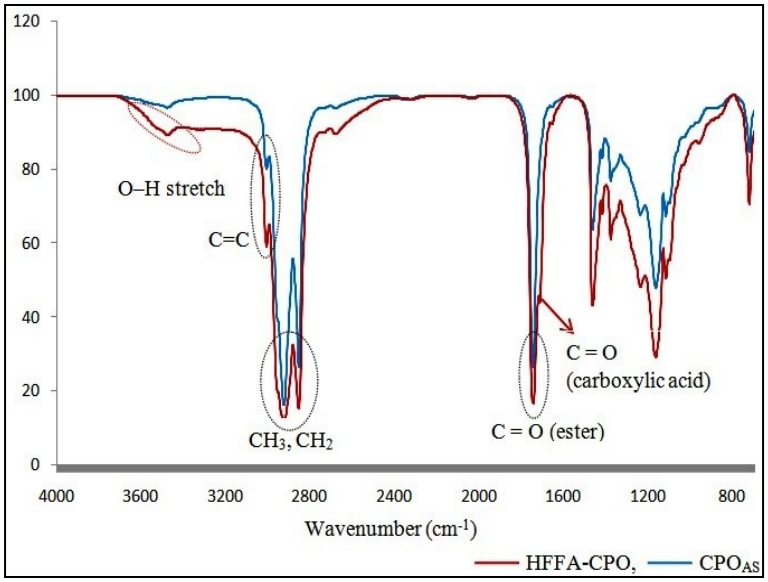

Figure 1. FTIR spectrum of HFFA-CPO and CPO_{AS}

Physicochemical properties of HFFA-CPO and CPO_{AS}

Table 3 presents the physicochemical properties of HFFA-CPO and CPO_{AS}. These properties are different in terms of the acid value, iodine value and hydroxyl value. They have similar physical properties despite the slight differences in their specific parameter values. The result shows that the average value of FFA for HFFA-CPO is high (9.4 ± 0.1%). FFA is one of the most important quality parameters in the palm oil industry as it indicates the level of deterioration of the oil. The FFA limit in Malaysian palm oil mills is 5 % [23], which clearly remarks that the FFA of CPO_{AS} (0.9 ± 0.01 %) is within standard requirement and therefore, is edible. The iodine values of the HFFA-CPO and CPO_{AS} were 50.6 ± 0.2 mg/g and 53.5 ± 0.2 mg/g respectively. This was due to the high content of unsaturated fatty acids in CPO_{AS}. This value is compatible with a typical palm oil [24]. The colour of HFFA-CPO and CPO_{AS} was 50 red and 40 yellow at room-temperature. In addition to that, their refractive value at 28 °C is equal to 1.4669. The CPO_{AS} shows high viscosity at room temperature (0.060 Pa.s) compared to HFFA-CPO (0.052 Pa.s). The results of CPO_{AS}, shown in Table 3, are similar to the physicochemical properties Malaysian crude palm oil standard (CPO_{MS}). Thus, the separation process was optimally conducted and this makes it possible for the product to be used for food industry.

Fatty acid composition

The fatty acid composition and FFA of HFFA-CPO and CPO_{AS} are summarized in Table 4. By comparison, it was proven from this work that the FFA compositions are within the standard permitted by Malaysian palm oil standard (CPO_{MS}) [26]. The results exhibit only a slight difference between the fatty acids composition of HFFA-CPO and CPO_{AS} from the base-catalysed reaction, and the values are within the standard requirements by Malaysian palm oil. Table 2 have shown palmitic acid and stearic acid as the major saturated fatty acids in HFFA-CPO. The values before and after separation are (45.7 %) and (43.9 %) for palmitic acid; (4.3 %) and (4.2 %) for stearic acid respectively. The main unsaturated fatty acids in HFFA-CPO were oleic acid and linoleic acid, with values of (39.5 %) and (9.4 %) respectively, meanwhile in CPO_{AS} the values obtained are (39.8 %) and (10.7 %) respectively.

Table 4 shows that the compositions of fatty acids for CPO_{AS} are within the Malaysian palm oil standard. Furthermore, the composition of FFA in HFFA-CPO and CPO_{AS} from the transesterification with acid catalyst is close to each other, with only minor difference with base-catalysed. FFA of HFFA-CPO and CPO_{AS} Palmitic acid (44 %) and stearic acid (4 %) were the major components of HFFA-CPO and CPO_{AS} obtained from the acid-catalysed transesterification comprises of (44.2 %) palmitic acid and (4 %) stearic acid. Oleic acid and linoleic acid

as the main components of unsaturated fatty acids in HFFA-CPO were recorded as (39.8 %) and (10.7 %) respectively. These values were increased slightly to (39.1 %) and (11.1 %) for CPO_{AS}. In addition, the composition of fatty acids for Distillate of free fatty acid (PFAD) obtained from the acid-catalysed transesterification comprises of lauric acid (0.2 %), myristic acid (0.7 %), palmitic acid (57.4 %), stearic acid (4.8 %), oleic acid (34.6 %) and linoleic acid (2.3 %).

Triacylglycerol composition (TAG) profile

The TAG composition in HFFA-CPO and CPO_{AS} with lower free fatty acids was identified according to the equivalent carbon number (ECN). Table 5 shows the TAGs detected for HFFA-CPO and CPO_{AS} from the chromatograph and compared with the Malaysian crude palm oil standard. The HFFA-CPO and CPO_{AS} are composed of at least fourteen important TAGs (Figure 2), whereas (74.2 %) in HFFA-CPO and (84.3 %) in CPO_{AS} depending on the percentage of the MAG and DAG [27]. The dioleoyl-palmitoyl-glycerol (POO) percentage is 25 %, and the percentage of dipalmitoyl-oleoyl-glycerol (POP) is 31% which are higher in CPO_{AS}. The TAGs exist in solid or liquid form depending on the nature of the fatty acids constituent. Most of the triacylglycerols are semi-solid at room temperature due to an equal proportion of saturated and unsaturated fatty acids contain [19]. Table 5 shows that the results of percentage of TAGs for CPO_{AS} are similar to the percentage of TAGs for Malaysian crude palm oil standard (CPO_{MS}). Therefore, this separation was conducted successfully.

Conclusion

The high free fatty acids content in crude palm oil is unfavourable condition and need to be reduced for edible oils usage. The separation was accomplished successfully as high percentage of free fatty acids has been isolated from the crude palm oil. The optimum free fatty acid separation process conditions were at 2.3 g/min flow rate, 350 rpm wipers speed, 150 °C to 265°Cevaporator temperature range, and 10 torr pressure. The yield of crude palm oil which is edible favour after the separation (CPO_{AS}) is 88 % (wt/wt). The FFA recovered in the distillate can be utilized in future for industrial applications such as in biolubricant and bioplastic production.

Abstract

The performance of electrogenerated metals supported on HY zeolite ($EGZrO_2$-$EGFe_2O_3$/HY) was studied under sunlight irradiation for the decolorization of methylene blue (MB) and Congo red (CR) in aqueous solutions. The prepared photocatalysts were examined using X-ray diffraction (XRD), transmission electron microscopy (TEM), and Brunnauer-Emmett-Teller surface area analysis (BET). An amount of 0.375 g L^{-1} $EGZrO_2$-$EGFe_2O_3$/HY was found to be the optimum dosage for 10 mg L^{-1} dyes, which gave almost complete photodecolorization of both MB and CR dye after 2 hours of contact time at pH 9 and pH 7, respectively. In addition, a control experiment was also conducted under similar conditions to confirm the efficacy of the prepared photocatalyst. The simple preparation of the photocatalyst and low amount of metal loading required, with simultaneously existence of synergistic effect from both metal oxides exhibits the great potential of the system that could be applied in textile or other industries wastewater treatment.

Keywords: photocatalyst, dyes, decolorization, sunlight

Abstrak

Keupayaan logam elektrogenerasi disokong pada zeolit HY ($EGZrO_2$-$EGFe_2O_3$/HY) telah dijalankan di bawah sinar matahari untuk penyahwarnaan metilena biru (MB) dan Congo merah (CR) dalam larutan akues. Fotomangkin telah dikaji menggunakan pembelauan sinar X-ray (XRD), mikroskopi elektron transmisi (TEM), dan analisis luas permukaan Brunnauer-Emmett-Teller (BET). Sejumlah 0.375 g L^{-1} $EGZrO_2$-$EGFe_2O_3$/HY telah didapati sebagai dos optimum untuk 10 mg L^{-1} larutan pewarna, yang memberikan penyahwarnaan hampir lengkap bagi kedua-dua pewarna MB dan CR selepas 2 jam tindak balas pada pH 9 dan pH 7. Di samping itu, satu eksperimen kawalan juga telah dijalankan pada keadaan yang sama untuk mengesahkan keberkesanan fotomangkin yang disediakan. Penyediaan yang mudah untuk fotomangkin dan jumlah muatan logam sedikit yang diperlukan, pada masa yang sama dengan kewujudan kesan sinergi dari kedua-dua oksida logam mempamerkan potensi besar untuk sistem ini digunakan dalam industri tekstil atau industri rawatan air sisa yang lain.

Kata kunci: fotomangkin, pewarna, peyahwarnaan, sinar matahari

Introduction

Over the decades, an environmental problems distress on soil and water pollution has become an important issue. In accordance, the major pollutants in wastewater such as organic dyes were produced, wherein about 15% of total

world production of dyes is lost during dyeing processes and is released in textile effluents [1-3]. In Malaysia, about 97% of the dye effluents are mainly come from three industrial classes, which are food, chemical and textiles industry [3]. Among this, about 22% of the total volume of these industrial wastewater is from the textile industry, commonly use basic dyes, such as crystal violet, rhodamine B, methyl violet, methylene blue and etc., to add colour for their final products of wool, silk, cotton, linen and modified acrylic fibres [3-4]. Though, most of the unspent dyes generate undesirable effluents and usually discharged to the environment with or without further treatment [1,5-7]. These effluents run into water bodies and can cause severe problems if not being treated properly as they are toxic, mutagenic and carcinogenic to human life as well as prohibit the photosynthesis of aquatic life even as small quantities as 1 ppm [3, 4]. To overcome this problems, several methods have been reported for the removal of such dyes including chemical and biological oxidation, adsorption, electrochemical oxidation, coagulation and flocculation, ion exchange, and membrane separation [5, 6, 8-10]. However, those methods have their own limitations for example time-consuming, generation of secondary wastes, expensive, and commercially unattractive.

Advanced oxidation processes (AOPs) particularly using semiconductors such as TiO_2, ZnO, WO_3, Fe_2O_3, CuO, ZrO_2, CdS, In_2O_3, SnO_2, etc. as photocatalysts has became attractive and accorded great importance due to its potential to destroy and transform a wide range of harmful dyes at ambient temperature to the simplest form of non-toxic products, CO_2 and water [2-4]. Zeolite is considered to be an important support owing to their high surface area, high thermal stability, eco-friendly nature, and also have reported to provide specific photophysical properties such as control charge transfer and electron transfer processes [3,4]. A review of recent research revealed that some of the succesful examples of metal oxides supported zeolite are TiO_2-HZSM-5, Co-ZSM-5, CuO-X zeolite and Fe-exchange zeolite [3,4,11-13]. Most of the popular one are TiO_2 and ZnO but the report on the ZrO_2 supported zeolite photocatalyst is quite rare. ZrO_2, which have specific optical and electrical properties, possesing both acid-base and redox function, thermal stability, and strong mechanical strength is believed to exhibit a great performance when support on zeolite [3].

Recently, we have reported a new preparation method for an α–Fe_2O_3 and EGZrO_2 supported HY catalyst by a simple and rapid electrochemical process, which possesses high photoactivity in the decolorization of methylene blue [3,14]. The nanosized metal oxides as well as the synergistic interaction between the metal and the support were found to play important roles in the enhancement of the reaction [4]. Further study on the property of that zinc metal oxide showed that it was nanoparticle in size, which showed promising photoactivity in the removal of methyl orange from aqueous solution [15]. Thus, by the corresponding method, we have succeeded to generate a very fine particles metal with higher reactivity.

Herein, as an extension of our study, we attempted to prepared nanoparticles electrogenerated ZrO_2–Fe_2O_3 supported HY zeolite (EGZrO_2–EGFe_2O_3/HY) by using the corresponding novel preparation method which is fast, simple and efficient than other methods with the aim to reduce amount of metal oxide used and tested its photoactivity on the decolorization of methylene blue (MB) and Congo red (CR) towards a green environment. The prepared catalyst was characterized by X-ray diffraction (XRD), transmission electron microscopy (TEM), and Brunnauer-Emmett-Teller of surface area analysis (BET). The performance of photoactivity decolorization was investigated to obtain the optimum conditions.

Materials and Methods

Materials

The HY zeolite had a Si/Al ratio of 80 and was purchased from Zeolyst International. The *N,N*-dimethylformamide (DMF) was purchased from Merck and the naphthalene was obtained from Fluka. The sodium hydroxide (NaOH), hydrochloric acid (HCl), and methylene blue (C.I. 52015 for microscopy) were obtained from QReC™. The platinum (Pt), zirconia (Zr), and iron (Fe) plate cells were obtained from Nilaco Metal, Japan. All of the reagents were analytical grade and were used as received. Deionized water was used for the preparation of the pH solution and adjustments to the pH were performed using a 0.1 M HCl and NaOH solution.

Catalyst preparation

The 1 wt.% EGZrO_2–1 wt.% EGFe_2O_3/HY was prepared following a previously reported protocol [3,4]. A DMF solution (10 mL) containing 0.1 M tetraethylammonium perchlorate was electrolyzed in the presence of a

naphthalene mediator (6 mmol) and HY zeolite (1.5 g) in a normal one-compartment cell fitted with a Pt plate cathode (2 x 2 cm^2) and Zr plate anode (2 x 2 cm^2), then switched to Fe plate anode, at a constant current density of 120 mA/cm^2 under a nitrogen atmosphere at 273 K. Naphthalene was used as a mediator in the system to produce radical anions, which then reduced the metal cations from the anode to give metal nanoparticles. After electrolysis, the mixture was impregnated, oven dried overnight at 378 K and calcined at 823 K for 3 h to yield a white powder ($EGZrO_2$–$EGFe_2O_3$/HY), and finally ready for characterization and photocatalytic testing. Furthermore, the $EGZrO_2$ and $EGFe_2O_3$ photocatalyst was prepared by the same procedure except for the addition of the HY zeolite (1.5 g) prior to electrolysis, and a white powder was obtained as the final product. The required weight percent of the $EGZrO_2$ and $EGFe_2O_3$ supported on HY was calculated based on Faraday's law of electrolysis as expressed in equation 1

$$t = \left(\frac{F}{I}\right)(z \times n) \tag{1}$$

where t = total time for the constant current applied (s); F = 96486 C mol^{-1}, which is the Faraday constant; I = the electric current applied (mA); z = the valency number of ions of substance (electrons transferred per ion); and n = the number of moles of substance (number of moles, liberated n = m/M) [3,4].

Characterization

The crystalline structures of the photocatalyst were studied by X-ray diffraction (XRD) recorded on a D8 Advanced Bruker X-ray diffractometer using Cu K_α radiation at a 2θ angle ranging from 3 to 90°. The phases were identified with the aid of the Joint Committee on Powder Diffraction Standards (JCPDS) files. The morphological properties of the $EGZrO_2$–$EGFe_2O_3$/HY photocatalyst were examined by transmission electron microscopy (TEM) (JEOL JEM-2100F). The textural properties (i.e. specific surface area, pore volume and pore diameter) were determined from nitrogen adsorption-desorption isotherms at liquid nitrogen temperature using a Micromeritics ASAP 2010 instrument. The surface area was calculated with the Brunnauer-Emmett-Teller (BET) method, and the pore distributions were determined by the Barrett-Joyner-Halender (BJH) method. Prior to measurement, all of the samples were degassed at 110 °C to 0.1 Pa.

Reaction testing

The photocatalytic activity of the prepared $EGZrO_2$–$EGFe_2O_3$/HY photocatalyst was tested for the decolorization of MB and CR. A 0.075 mg sample of the photocatalyst was dispersed in 200 mL of 10 mg L^{-1} MB aqueous solution. The adsorption-desorption equilibrium was achieved under dark conditions after 30 min, and the mixture was irradiated for 120 min with constant stirring under sunlight (January to March 2015, between 12 NN until 3 PM with an average intensity 1.315×10^5 Lux unit). However, during the illumination time, no volatility of the solvent was observed. At specific time intervals, 2.5 mL of the sample solution was withdrawn and centrifuged prior measurements of the MB and CR concentration by a UV-vis spectrophotometer (Agilent Technologies Cary 60 UV-vis) using the characteristic adsorption band at 664 nm and 496 nm. The decolorization percentage was calculated as follows (equation 2):

$$Decolorization\ (\%) = \frac{(C_0 - C_t)}{C_0} \times 100 \tag{2}$$

where C_o represents the initial concentration, and C_t denotes a variable concentration.

Results and Discussion

The XRD pattern of 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY photocatalysts were compared with bare HY, and the results are shown in Fig. 1a. The peak intensity of HY was decreased as the addition of $EGZrO_2$ and $EGFe_2O_3$ due to the presence of foreign substances that could affected the morphology of the HY fingerprint. A series of characteristic peaks were observed for $EGZrO_2$ at 30.2° (101), 35.2° (110), 50.3° (112), and 60.2° (211), which are consistent with the tetragonal (*t*) phase of ZrO_2, and in agreement with JCPDS file PDF No 01-072-2743 (Fig. 1b) [3,14]. Characteristic peaks were observed at 2θ equal to 28.2°, 31.5°, and 34.5° and corresponded to the diffraction patterns of (−111), (111), and (002) of the monoclinic (*m*) phase of ZrO_2 (Fig. 1b) [3,14]. Next, the XRD peaks of $EGFe_2O_3$ (Fig. 1b) were observed at 2θ = 24.1° (012), 33.1° (104), 35.6° (110), 40.7° (113), 49.4° (024), 54.1°

(116), 62.5° (214) and 64.2° (300). These peaks can be indexed to pure rhombohedral symmetry of Fe_2O_3 indicating the crystalline hematite phase (JCPDS file PDF No 00-024-0072) [3,14]. Hence, there is no other diffraction peaks were detected which indicated the purity of the prepared $EGZrO_2$ and $EGFe_2O_3$.

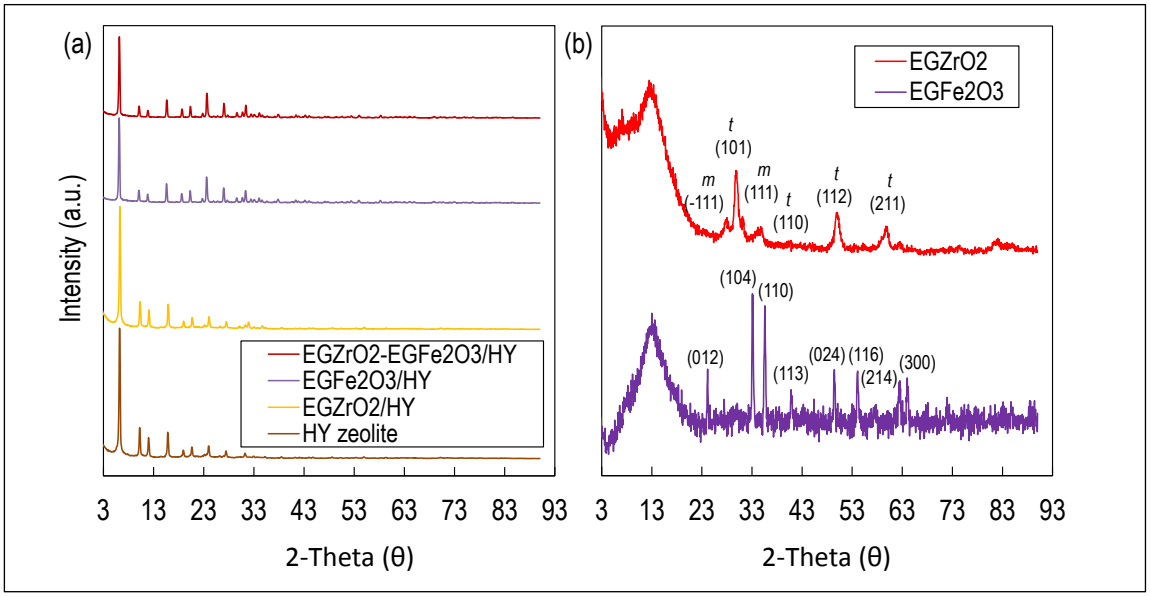

Figure 1. XRD patterns of the photocatalyst

The morphological properties of the 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY photocatalyst were observed by the transmission electron microscopy (TEM), and the images are presented in Fig. 2, respectively. The value of the interplanar distance (*d*-spacing) of the lattice fringes was estimated from this image was consistent with the value of lattice spacing of $EGZrO_2$ and $EGFe_2O_3$ obtained from the XRD analysis. This agreement confirms that the $EGZrO_2$ and $EGFe_2O_3$ nanoparticles were well dispersed on the HY support.

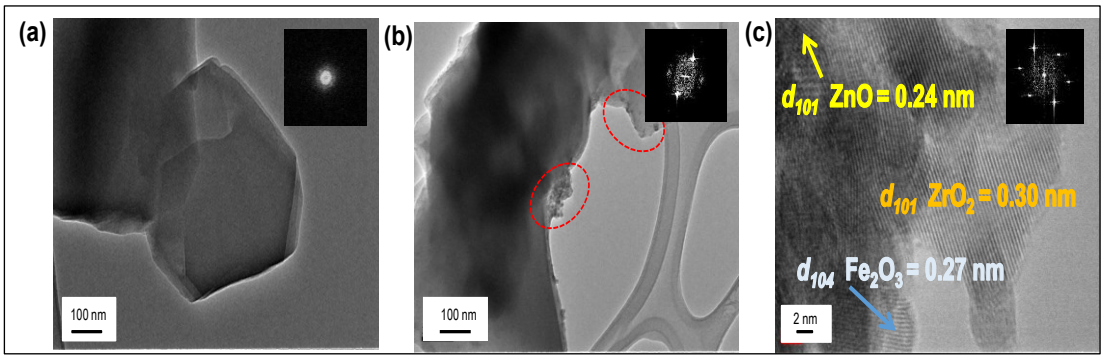

Figure 2. TEM micrographs of 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY photocatalyst

The surface area analysis data obtained from the BET method as well as the pore volume and pore diameter determined by the Barret-Joyner-Halenda (BJH) desorption isotherms method was tabulated in Table 1. The

addition of $EGZrO_2$ and $EGFe_2O_3$ onto HY decreases the surface area and pore volume, but increases the pore diameter. The decrease in the pore volume may be a reflection of the uneven particle sizes of the catalyst [16-18].

Table 1. The textural properties of the photocatalyst

Catalysts	**Surface area (m^2g^{-1})**	**Pore diameter (nm)**	**Pore volume (cm^3g^{-1})**
HY zeolite	557	2.70	0.376
$EGZrO_2$/HY	505	1.83	0.323
$EGFe_2O_3$/HY	496	1.79	0.222
$EGZrO_2$–$EGFe_2O_3$/HY	536	1.87	0.250

The performance of the prepared 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY photocatalyst for the decolorization of MB and CR was examined, and the results are shown in Fig. 3. A controlled experiment was conducted for both MB and CR, under six different conditions including photolysis and reaction in the presence of the bare HY, $EGZrO_2$, $EGFe_2O_3$, $EGZrO_2$–$EGFe_2O_3$, and 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY catalysts. Each experiment was performed under both dark and sunlight conditions. The experiments under dark conditions removed less than 22% of the MB after 2 hours of contact time, which indicated the importance of sunlight in this study. Under photolysis conditions, 2% MB was decolorized because of the degradation of the substance after long exposure to sunlight. No significant effect was observed using bare HY under dark and UV–light conditions where 22% and 27% MB was removed, respectively. The use of $EGZrO_2$, $EGFe_2O_3$, $EGZrO_2$–$EGFe_2O_3$ under sunlight resulted in 32%, 40%, and 67% decolorization of MB, in respectively, which is higher than the same reaction under dark conditions. Indeed, the removal percentage was increased up to 99.8% by using 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY.

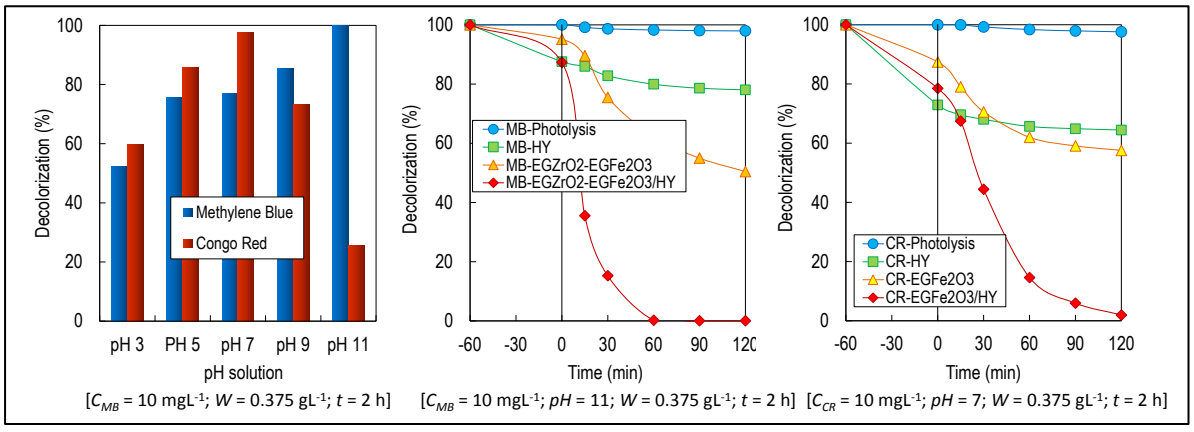

Figure 3. The performance and photoactivity of photocatalyst

Furthermore, for CR dye, less than 17% of the CR was adsorbed under dark conditions after 2 hours of contact time, and no photolysis was occurring after long exposure to sunlight. About 15% and 20% of CR was removed using bare HY under dark and sunlight conditions, in respectively. The $EGZrO_2$, $EGFe_2O_3$, $EGZrO_2$–$EGFe_2O_3$ was resulted in 27%, 34%, and 63% decolorization of CR under sunlight, respectively, indicates the significance the use of sunlight in this study. The 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY shows the highest removal percentage which accounted 98% decolorization. Based on all above, we can conclude that the porosity of the catalyst surface may play an important role in adsorption, as previously reported in liquid–gas adsorption systems for wastewater

treatment. Good distribution of the $EGZrO_2$ and $EGFe_2O_3$ nanoparticles on the surface of the HY might facilitate their surface contact with sunlight and lead to higher efficiency of the reaction. The synergistic effect from both $EGZrO_2$–$EGFe_2O_3$ and HY were also found to play an important role in enhancing the photodecolorization reaction. This result reveals that $EGZrO_2$–$EGFe_2O_3$/HY is a potential photocatalyst semiconductor.

Conclusion

In this study, the 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY photocatalyst with enhanced photoactivity was prepared by a simple electrochemical method. The physicochemical properties of the prepared photocatalyst were studied by XRD, TEM, BET surface area analysis. The photocatalyst were evaluated for the decolorization of 10 mg L^{-1} of MB and CR under different pH, at pH 9 and pH 7, using an amount of 0.375 g L^{-1} 1 wt.% $EGZrO_2$–1 wt.% $EGFe_2O_3$/HY after 2 hours of contact time, hence gave removal percentage of 99.8% and 98.0%, in respectively. This system exhibits great potential for improving the quality of the wastewater discharged from textile industry and other industries because of the simple preparation of the photocatalyst and the low amount of metal loading required. It was believed to be extendable to the synthesis of other catalysts with different characteristics and be used in various applications. Furthermore, more technologies and instrument were needed in order to examine and investigate the mechanism pathways of the synthesis of catalyst using this electrolysis system. In addition, it also provides new findings to explore the new structural model of the catalyst.

Abstract

Methanol and isopropanol were used as extraction solvent to determine the percentage yield of chlorogenic acid (CGA) in green Robusta (*Coffea canephora)* coffee bean. CGA was extracted by using isolation method with activated carbon to trap the CGA content from the complex compounds in green coffee beans. Results indicated that percentage yield of CGA extracted by using isopropanol was significantly higher (5.21%) compared to methanol (4.55%). Besides, antioxidant activity and total phenolic content were also analyzed. From this study, isopropanol extracted more antioxidant activity and total phenolic content as compared to methanol. For antioxidant activity, isopropanol and methanol extracted 0.48 mg and 0.15 mg of Fe (II) per gram of dry sample, respectively. For total phenolic content, isopropanol and methanol extracted 30.65 mg and 16.26 mg of gallic acid per gram of dry sample, respectively. Isopropanol extraction with ratio 60:40 (isopropanol: water) conserved more CGA content than methanol which was analyzed using high performance liquid chromatography. Chromatogram showed that the retention time of CGA is at 4.68 minutes which is similar to the retention time of standard CGA.

Keywords: green coffee bean, antioxidant, phenolic, methanol, isopropanol

Abstrak

Metanol dan isopropanol telah digunakan sebagai pelarut ekstrak untuk menentukan peratusan hasil asid klorogenik (CGA) di dalam biji kopi hijau Robusta (*Coffea canephora)*. CGA diekstrak dengan menggunakan kaedah pengasingan dengan karbon teraktif berfungsi sebagai perangkap kandungan CGA daripada sebatian kompleks di dalam biji kopi hijau. Keputusan hasil peratusan CGA yang diekstrak oleh isopropanol adalah secara signifikan lebih tinggi (5.21%) berbanding metanol (4.55%). Selain itu, aktiviti antioksidan dan jumlah kandungan fenolik juga telah dianalisis. Daripada kajian ini, pelarut isopropanol mengekstrak lebih banyak aktiviti antioksidan dan jumlah kandungan fenolik berbanding pelarut metanol. Bagi penentuan aktiviti antioksidan isopropanol dan metanol berupaya mengekstrak masing – masing 0.48 mg dan 0.15 mg Fe (II) bagi setiap gram sampel kering. Bagi penentuan jumlah kandungan fenolik, isopropanol dan metanol mengekstrak 30.65 mg dan 16.26 mg asid gallic bagi setiap gram sampel kering. Pengekstrakan isopropanol dengan nisbah 60:40 (isopropanol: air) memelihara lebih kandungan CGA daripada metanol yang dianalisa menggunakan kromatografi cecair prestasi tinggi. Kromatogram menunjukkan bahawa masa tahanan CGA adalah pada 4.68 minit selari dengan masa tahanan larutan piawai CGA.

Kata kunci: biji kopi hijau, antioksidan, fenolik, metanol, isopropanol

Introduction

Overweight or obesity becomes common contributing factors of many unnecessary diseases, such as diabetes mellitus, high blood pressure and cancer. Common causes of the disease are usually due to wrong diet and lack of physical activity [1]. A latest survey in Japan reveals that occurrence of diabetes mellitus is increasing. Furthermore, International Obesity Taskforce (IOTF) reported that up to 1.7 billion people all over the world could eventually be exposed to weight-related health risks [2]. Since these health problems create a big economic impact on health care system in the world, health food supplements are now quite popular among weight observant. Recently, chitosan and citrus (*Citrus aurantium*) fruits are some of the food supplements for weight loss which helps in reduce fat absorption and breaking down fat respectively. Additionally, it has been identified that coffee bean extract releases chlorogenic acid as an inhibitor for the production of glucose in liver and promote insulin secretion [3]. Therefore, further study on chlorogenic acid as weight loss agent can be explored.

Chlorogenic acid (CGA) as shown in Figure 1 belongs to a family of ester consist of caffeic acid and quinic acid [4]. The melting and boiling point of CGA is 205 – 209 ℃ and 665 °C at 760 mmHg, respectively. It is known that CGA solubilizes in ethanol, dimethylsulfoxide and dimethylformamide. Chlorogenic acid is well known as a natural antioxidant that has properties of retarding the oxidation of food products which help keeps the fresh flavor and nutritional value for longer time. This antioxidant also reduces the release of glucose into the bloodstream after a meal [5]. The current commercial source of chlorogenic acid is green coffee beans. It was found that coffee pulp contains natural antioxidants like hydroxycinnamic acids [6].

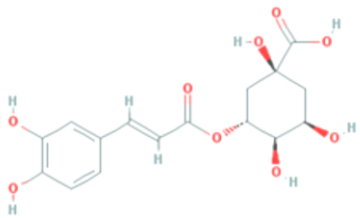

Figure 1. Chemical structure of chlorogenic acid (CGA)

Green coffee beans are basically the seeds from the fruit of coffee trees. The two main green coffee beans that are commonly produced and sold are Arabica coffee (*Coffea arabica*) and Robusta coffee (*Coffea canephora*) [7]. Moreover, coffee is well known as a good source of antioxidant [8]. Coffee also rich with antioxidants and contain of flavonoids. The presence of antioxidant will slow or prevent the oxidation of other chemical. Oxidation can be simplified as gain of oxygen and loss of electron. On the other hand, antioxidants may be either present in two forms which are natural antioxidants and synthetic antioxidants. Natural antioxidants include flavonoids, phenolic, tocopherols (Vitamin E) and also ascorbic acid. About the caffeine and chlorogenic acid content, Arabica generally has less amount of caffeine which is approximately 1.2% and 5.5 to 8.0% of chlorogenic acid while Robusta has 2.2% of caffeine and 7.0 – 10.0% of chlorogenic acid [9]. The post-harvest processing gives effect on the chemical composition of coffee seeds especially in water-soluble components like sugar, caffeine, trigonellie and chlorogenic acid [9].

Nowadays, the worldwide consumption of coffee is increasing in popularity due to their health benefits. These benefits appear to be effected by their antioxidant activity. Antioxidant is a substance that protects living tissues against damage caused by free radicals. Free radicals are species produced during aerobic respiration due to the incomplete reduction of oxygen molecule and directly related to various diseases such as cancer, cardiovascular, inflammatory and neurogenerative pathologies are associated with oxidative stress [10]. Besides fruits and vegetables, plant beverages such as coffee brew have been proposed as an important source of antioxidant in human diet [11, 12]. Additionally, phenolic compounds have an important role in nutritional, organoleptic and commercial

properties of agricultural foodstuffs as they contributed to the sensory properties such as colour, astringency, bitterness and flavour of coffee, because of the interaction between phenolics, mainly procyanidin and glycoprotein in saliva [13].

Solvent extraction technique was used to extract chlorogenic acid from green coffee bean. For this solvent extraction, methanol and isopropanol was used to extract the chlorogenic acid and determine the yield extract. Activated carbon was used to extract the cholorogenic acid content in the filtered extraction [14]. Thus the aim of this study was to compare which solvent (isopropanol or methanol) gives better chlorogenic acid yield antioxidant activity and total phenolic content. Efficient solvent extraction information for antioxidant activity and total phenolic content in green coffee beans was also investigated.

Materials and Methods

Chemicals

Coffee canephora (Robusta coffee) was supplied from Teluk Gong, Klang, Malaysia. All the chemicals were of analytical grade. Folin-Ciocalteu, 3,4,5-trihydroxybenzoic acid (gallic acid), methanol (HPLC grade), acetic acid (HPLC grade) and isopropanol (HPLC grade) were purchased from Merck, Malaysia. The remaining chemicals were purchased from Systerm, Malaysia, listed as follows: Chlorogenic acid, 1,3,5-triazine,2,4,6-tri-2-pyridinyl (TPTZ), 2,2-diphenyl-1-picrylhydrazyl (DPPH), ascorbic acid and $FeCl_3.6H_20$ (ferric chloride hexahydrate).

Equipment's

The water bath (Varian) for extraction of green coffee beans, UV-Vis spectrophotometer (Cary 50 model) and rotary evaporator to dry green coffee bean extract which is located in Universiti Teknologi MARA (UiTM) Shah Alam.

Pre-treatment of samples

Green coffee beans were washed thoroughly with tap water for several times to remove the remaining soil, dirt and contaminants such as tiny stones and other unnecessary particles. The green coffee beans were collected and grinded to form spent ground coffee. The samples were placed in sealed plastic bags and kept at 4 ºC until needed for analysis.

Solvent extraction of chlorogenic acid

Solvent extraction was carried out according to previous method [15]. Approximately 10 g of spent ground coffee was weighed and loaded into glass column. The samples were extracted with selected solvent at samples to solvent ratio 1:10. Solvents mixture of either isopropanol or methanol with water in ratio 60:40 was used for extraction. An amount 100 mL of solvent was added into glass column and allowed it to stand over a period of 5 hours whereas for the methanol water mixture, it was allowed to stand over 24 hours. The activated carbon was used to extract chlorogenic acid content in the filtered extract. The extract was drained and distilled on rotary evaporator at 50 ºC under reduced pressure (40 millibar) and the product was freeze dried and stored at room temperature prior to analysis.

Determination of chlorogenic Acid

The High Performance Liquid Chromatography (HPLC) analysis was performed by using Agilent Technologies 1200 Series (Santa Clara, California, United States) with diode-array detector (DAD) equipped with LiChroCART 250 mm x 4.6 mm i.d. Eclipse Puresper STAR RP-C18 column (5 µm) (Merck, United States), using a binary solvent system: Solvent A, water-acetic acid, 97:3 (v/v); solvent B, methanol and reverse phase. A program of gradient to 100 – 90% A from 0 – 10 minutes, 90 – 30% A for 10 – 32 minutes, 30 – 0% A from 32 – 45 minutes at a flow rate of 1.0 ml/min was used at a wavelength of 320 nm. The sample volume is 20 µL injected into HPLC. An amount 50 ppm of CGA standard was prepared in order to calculate the response factor, R_f for the standard using the following formula adapted from Aishah et al. [16] (equation 1):

$$Response\ Factor, R_f = \frac{amount}{area} \quad (1)$$

The amount of CGA present in the sample was then compared to the standard CGA using the calculated R_f.

Ferric reducing antioxidant power (FRAP)

The FRAP assay was conducted according to method described previously [17]. The FRAP reagent were prepared by mixing acetate buffer (0.3 mol/L), TPTZ (10 mmol/L) and $FeCl_3.6H_20$ (20 mmol/L) in the ratio 10:1:1. FRAP reagent were prepared as required by mixing 25 mL acetate buffer, 2.5 mL TPTZ solution, and 2.5 mL $FeCl_3.6H_2O$ solution. For a volume of 100 µL of the coffee extract, 3.0 mL of the FRAP reagent was added to test tubes with stoppers and the mixture was then left at rest in dark for 30 min at 37 °C. The absorbance of blue colouration was measured against a blank sample at a wavelength of 593 nm, using a UV-Vis spectrophotometer. The calibration curve was prepared using standard solutions of ferrous sulphate at concentration of 0.5 – 2.5 mmol/L. All of the measurements were conducted in triplicate and the results were expressed in mmol Fe^{2+} per litre sample.

Determination of total phenolic content using Folin-Ciocalteu reagent

Total phenolic content in spent ground coffee was determined by using the Folin-Ciocalteu reagent according to the colorimetric method described previously [18]. Approximately 2 mL of filtered extract will be mixed with 30 mL of sodium carbonate solution at 7.5% (w/v) and 7.5 mL of Folin-Ciocalteu reagent. Subsequently, 200 µL of distilled water was added and the solution was mixed. After that, the mixture was heated at 60 ºC for 5 minutes and allowed to cool at room temperature. The absorbance was measured by using spectrophotometer at 700 nm. A calibration curve was made from gallic acid standard solution (100, 150, 200, 250 and 300 mg/L) and the blank was prepared with distilled water. The total phenolic content was expressed as milligram gallic acid equivalent (GAEs) per dry weight material.

Statistical analysis

The results for extraction yield, antioxidant assays and total phenolic determination were expressed as mean ± standard deviation (n= 3). All data were analyzed by one-way analysis of variance (ANOVA) followed by Tukey's multiple comparison test. The level of significance was limited at $p < 0.05$.

Results and Discussion

Assessment of percentage yield and retention times of chlorogenic acid

Solvent extraction method was used to extract chlorogenic acid in green coffee bean which involved two different types of solvent, methanol and isopropanol. Each solvent was mixed with water with ratio of 60:40, respectively. Activated carbon was used to isolate the chlorogenic acid content.

Table 1 shows the percentage yield, concentration and appearance of chlorogenic acid. From the results, the extraction of chlorogenic acid by using methanol was 4.55% (2.28 ppm) while isopropanol was 5.21% (2.61 ppm). The results indicated that the isopropanol solvent extracted significantly higher yield as compared to methanol solvent. This finding is also consistent with previous reports. Chlorogenic acid yield preserved by using isopropanol was about 27% in a ratio of 60:40 as reported previously [15]. The chlorogenic acid yield from green coffee beans using methanol and isopropanol solvent were 4.67% and 5.28% respectively [14]. The mixture of isopropanol and water (60:40) used in this study increased the strength for extracting bioactive compounds such as chlorogenic acid. Attributable to polar nature of isopropanol, the yield of chlorogenic acid generally increases in those solvent, which are isolated using activated carbon [19]. It is widely accepted that higher concentration of phenolic compounds increases antioxidant activity, thus correlating to higher CGA yield [15, 20].

Table 1. Percentage yield, concentration and appearance of chlorogenic acid

Type of Solvent	% Yield of Chlorogenic Acid	Concentration (ppm)	Appearance
Methanol	$4.55^{b} \pm 0.18$	$2.28^{b} \pm 0.18$	Light green
Isopropanol	$5.21^{a} \pm 0.68$	$2.61^{a} \pm 0.68$	Light green

Means with different letters were significantly different at $p < 0.05$

The characterization of chlorogenic acid was conducted to determine retention time of chlorogenic acid standard and sample. Based on the Figure 2a, chromatogram of the standard chlorogenic acid (50 ppm) indicates the retention time at 4.68 minutes. Meanwhile, Figure 2b shows the peak of chlorogenic acid content in green coffee beans. Based on the results, the chromatogram shows the retention time of chlorogenic acid at 4.68 minutes which was similar to the standard of chlorogenic acid. From the results, it is worthy to point that the isolation using activated carbon is suitable to trap the chlorogenic acid from a complex medium such as green coffee beans.

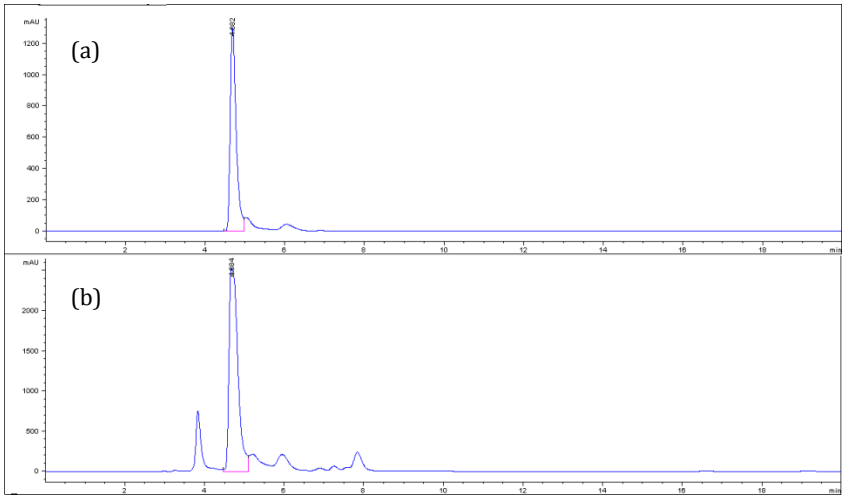

Figure 2. Chromatogram of (a) standard chlorogenic acid (50 ppm) and (b) green coffee beans

Assessment of antioxidant properties and total phenolic content

Table 2 shows the antioxidant activity found in green coffee beans expressed as mg Fe (II) per g dry sample. From the results, the antioxidant activity extracted by methanol solvent was 0.15 ± 0.07. Besides that, the extraction using isopropanol solvent was 0.48 ± 0.19. The antioxidant activity extracted by methanol solvent in spent coffee grounds was 0.109 mg Fe (II)/g dry sample [21].

Table 2. Antioxidant activity of green coffee beans

Type of solvent	**in mg Fe (II)/ g dry sample**
Methanol	0.15^{b} ± 0.07
Isopropanol	0.48^{a} ± 0.19

Means with different letters were significantly different at $p < 0.05$

Meanwhile, Table 3 shows the results on total phenolic content found in green coffee beans. Total phenolic content extracted by isopropanol was significantly higher (30.65 mg GAE/g dry sample) as compared to extraction carried out using methanol (16.26 mg GAE/g dry sample). The total polyphenol conserved by methanol extraction was 16.00 mg GAE/g dry sample [21]. Other than that, the total phenolic content conserved by isopropanol solvent is 31.71 mg GAE/g dry sample [15]. Here again, the isopropanol ratio with water (60:40) extract of green coffee bean showed higher activity as compared to methanol extracts [15].

Table 3. Total phenolic content in green coffee beans

Type of solvent	in mg of GAE/g dry sample
Methanol	$16.26^{b} \pm 0.59$
Isopropanol	$30.65^{a} \pm 0.44$

Means with different letters were significantly different at $p < 0.05$

Extraction solvent plays an important factor that affects the antioxidant capacity and total phenolic content in food materials. Vitamin E and oryzanol that has distinctive antioxidant activities extracted using isopropanol has more yield compared with using hexane as extraction solvent [22]. Isopropanol extract has comparatively higher amount of antioxidant due to the possibility of more polar phenolic compounds and lipids contained in the extract [20]. Antioxidants are extremely crucial in coffee beans to minimize the release of reactive oxygen species (ROS). If production of ROS exceeds the capacity of antioxidant systems, damage to sub-cellular compartments occurs, leading to cell destruction [23]. Hence it is important to maintain the antioxidant and total phenolic pool so that the integrity of green coffee beans is not jeopardized. This would enable the usage of these extracts to be used as ingredients in pharmaceutical industry or as food supplement as CGA implies positive impact on slimming and weight loss.

Conclusion

Higher in percentage yield of chlorogenic acid was found when isopropanol (5.21%) was used as extraction solvent compared to methanol (4.55%) solvent with ratio with water at 60:40. Furthermore, the amount of chlorogenic acid present in green coffee beans has been analyzed by using High Performance Liquid Chromatography (HPLC) with the retention time at 4.68 minutes. Besides that, isopropanol solvent also conserved more antioxidant activity and total phenolic compound. The amount of antioxidant extracted from green coffee bean by using isopropanol was significantly higher 0.48 mg Fe (II)/dry sample compared to methanol 0.15 mg Fe (II)/dry sample. Total phenolic content extracted by isopropanol was also significantly higher (30.65 mg GAE/dry sample) compared to methanol was 16.26 mg GAE/dry sample. The obtained data would be useful for further application of green coffee bean extracts as weight reducing agent in nutraceutical and food supplement industry.

Abstract

Leaching of lead (Pb) from the shooting range soil may contaminate water resource if rain pH decreases and soil has a low cation exchange capacity (CEC). Over exposure of Pb may cause brain injury and death. In this study, leaching of Pb from shooting range soil was simulated with column leaching test using artificial rain at pH 4 and 7. Soil physico-chemical parameters (i.e. pH, organic matter (OM), and CEC) were determined, and its' correlation with Pb concentrations in soil (Soil Pb) and leachate (Leachate Pb) were studied using Pearson's correlation. Compare to control soil, shooting range soil has higher contents of Pb (12,163 – 17,278 mg/kg, dry weight basis) and sand (64 – 68 %). The CEC value of shooting range soil (193 cmol/kg at pH 7) is lower than those in control soil (85 – 140 cmol/kg at pH 7), possibly due to low contents of clay and OM. There is positive correlation between Soil Pb and Leachate Pb variable pair (r = 0.94; p = 0.06); while Soil OM and Leachate Pb variable pair has a negative correlation (r = -0.94; p = 0.06). In conclusion, the combination of high soil Pb content, low CEC, and low rain pH increases leaching of Pb from shooting range soil.

Abstrak

Larut lesap Pb daripada tanah lapang sasar boleh mencemarkan sumber air jika nilai pH hujan menurun dan tanah mempunyai keupayaan pertukaran kation (CEC) yang rendah. Pendedahan Pb yang keterlaluan boleh menyebabkan kecederaan otak dan kematian. Dalam kajian ini, larut lesap Pb dari tanah lapang sasar telah disimulasikan dengan ujian larut lesap turus menggunakan air hujan tiruan pada pH 4 dan 7. Parameter tanah (iaitu, pH, jirim organik (OM), dan CEC) telah ditentukan, dan dikaji korelasinya dengan kepekatan Pb di dalam tanah dan larut resap dengan menggunakan korelasi Pearson. Berbanding dengan tanah kawalan, kandungan Pb (12163 – 17278 mg/kg, secara berat kering) dan pasir (64 – 68 %) pada tanah lapang sasar adalah lebih tinggi. Nilai CEC tanah lapang sasar (193 cmol/kg pada pH 7) adalah lebih rendah daripada tanah kawalan (85 – 140 cmol/kg pada pH 7), mungkin disebabkan oleh kandungan rendah tanah liat dan jirim organik. Terdapat hubungan yang positif antara pasangan pemboleh ubah Pb tanah dan Pb larut lesap (r = 0.94; p = 0.06); manakala pasangan pemboleh ubah jirim organik tanah dan Pb larut lesap mempunyai korelasi negatif (r = -0,94; p = 0.06). Kesimpulannya, gabungan faktor-faktor seperti kandungan Pb yang tinggi di dalam tanah, nilai CEC tanah yang rendah dan nilai pH hujan yang rendah boleh meningkatkan risiko larut lesap Pb dari tanah lapang sasar.

Introduction

Soils are reservoirs for many harmful heavy metal pollutants, such as copper, lead, cadmium, aluminium, and etc. These metals are released by anthropogenic activities such as mining, smelting, traffic emission and firearm shooting. Bullet contains lead (90 – 99 %), antimony (1 – 10.5 %), and copper (0.1 %) may be a point source for lead contamination in the shooting range [1]. Total lead concentration in shooting range soils may be as high as 54,000 mg/kg [2]. Lead in bullet is subjected to weathering and may lead to accumulation in soil [3]. Metallic lead will be converted to hydrocerussite ($Pb_3(CO_3)_2(OH)_2$), cerussite ($PbCO_3$), and massicot (PbO) within one week [2].

Lead is toxic to human health especially for children, as it attacks the brain and central nervous system. High level exposure of lead may cause coma, convulsions and even death. Ecological risks of lead at shooting range may also be significant. High level of lead may affect local and migratory, aquatic and terrestrial biota. The risk of lead contamination in groundwater system is higher with high content of lead in shooting range soil [4], and close proximity of groundwater table to the surface of shooting range soil. As groundwater is used as daily drinking water, these contaminations may affect human health.

To the best of our knowledge, there is no study on the risk of lead contamination in groundwater from shooting range soil in Malaysia. Lead contamination in groundwater may depends on the several soil physico-chemical parameters (i.e. soil pH, CEC and OM), and the pH of rain water. The objectives of this study to determine the soil physico-chemical parameters and the soil lead content at the Kem Sungai Besi shooting range, and to simulate the leaching process using artificial rain at various pH values. A correlation study was conducted to determine the risk factors for lead contamination in the groundwater.

Materials and Methods

Soil collection and preparation

Soil samples were collected using the coring technique at a sampling site (3° 3' 0" North, 101° 42' 0" East) located at Kem Sungai Besi, Kuala Lumpur, Malaysia. Baseline soil was taken at the boundary of the shooting range, and is free of the bullets and lead shots. Target 4, 6 and 8 located at the center of the berm were chosen as sampling points. Little vegetation was observed on the target soils (Figure 1a). Three soils replicates were collected at the top, middle and bottom of each targets, and were homogenized to form composite sample (Figure 2).

The soil samples were air dried for 6 days before being sieved to 2 mm. After sieving, the fragment of bullets was hand-picked from the soil sample. The fragments were visibly corroded and have reduced in size, indicating the weathering process of lead shots in the soil (Figure 1b). The soil samples were kept in air-tight plastic container to avoid contact with moisture.

(a) (b)

Figure 1. Shooting range (a) and bullet fragments (b) at Kem Sungai Besi, Kuala Lumpur

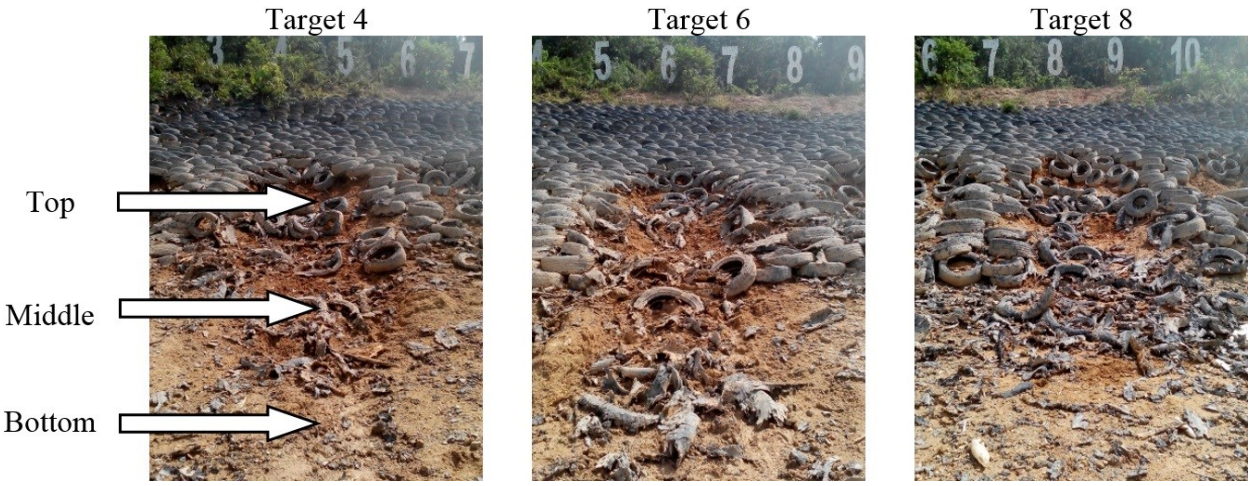

Figure 2. The location of soil sampling points at target 4, 6, and 8

Soil pH

Soil pH was measured on a soil-deionized water suspension (1:1 w/v ratio) using a calibrated pH meter. Twenty grams of soil samples from shooting target were suspended in 20 mL deionized water in a 100 mL beaker. The suspension was mixed using a glass rod and allowed to stand for 30 min with interval stirring at 10 min and again after 1 h to ensure complete homogeneity. The pH reading was taken after immersing the pH meter into the suspension (at about 3 cm depth) for 30 sec at 25 °C.

Soil particle distribution

Soil particles distribution was determined through the hydrometer method. A dispersing solution was prepared by dissolving 40 g sodium hexametaphosphate [$(NaPO_3)_6$] and 10 g of sodium carbonate (Na_2CO_3) in 1 L of volume with deionized water. Sixty millilitres of dispersing solution was poured into a 600 mL beaker containing 40 g of soil sample. The beaker was covered with watch glass and left overnight. The content was stirred for 3 min and then transferred quantitatively into a 1 L calibrated cylinder and was brought to volume with deionized water. To determine the distribution of a mixture of silt and clay, the suspension was mixed in the hydrometer jar. After the paddle is withdrawn, the hydrometer was inserted into the jar and the reading (R_{sc}) was taken after 40 sec. For clay particle distribution determination, the solution was left undisturbed for 4 h before the reading (R_c) was recorded. For the determination of silt in the soil, the suspension was sieved into 50 μm sieve. The sieved soil was washed with water until the sieve is clear. The sand was quantitatively transferred to crucible of known weight. The crucible then was dried in the oven at 105 °C overnight. The crucible was cooled in desiccator and weighed.

Soil organic matter

The organic matter (OM) in the soil was estimated as soil organic carbon (SOC), using the loss-on-ignition method (LOI). Crucibles were dried at 105 °C for at least 1 h and cooled in dessicator for 30 min. About 5.0 g of soil was transferred into the crucible; oven dried overnight at 105 °C, cooled in dessicator and reweighed using an analytical balance. The crucible was placed into a furnace at 450 °C for 4 h, and reweigh after proper cooling. The percentage of LOI and SOC were determined using Eq. 1 and Eq. 2, respectively.

$$\text{LOI} = \frac{(W_3 - W_1) - (W_2 - W_1)}{(W_2 - W_1)} \times 100 \quad (1)$$

$$\text{SOC} = \frac{LOI}{1.72} \quad (2)$$

where W_1 is the weight of empty crucible; W_2 is the weight of crucible and soil samples before ignition; and W_3 is the weight of crucible and soil samples after ignition.

Cation exchange capacity

The CEC values were determined with the sodium acetate method. Four grams of soil sample was mixed with 30 mL of 1.0 N sodium acetate (NaOAc) solution in a 50 mL centrifuge tube for 5 min using a mechanical shaker. Then the content was centrifuged and the supernatant was decanted. The step was repeated thrice using NaOAc solution. Thirty three millilitres of 99 % isopropyl alcohol was added to the centrifuge tube. Then, the tube was shaken in mechanical shaker for 5 min and centrifuged to decant the liquid. This step was repeated for twice. Next, 33 mL of ammonium acetate (NH_4OAc) solution was added into the tube. Then, the tube is shaken for 5 min. The liquid was centrifuged and the supernatant was decanted into a 100 mL volumetric flask. The procedure was repeated twice. The combined washing was diluted to 100 mL with NH_4OAc solution and the solution was analysed using Inductively Couple Plasma- Optical Emission Spectrometry (ICP-OES) for sodium concentration.

Acid digestion of soil sample

About 0.5 g of soil sample was digested in 100 mL beaker using aqua regia solution. The content of the beaker was heated at 100 °C until the volume of acid is decreased to about 5 mL without precipitation. Digested solution was cooled, filtered and diluted to 50 mL in a volumetric flask. The metal composition of the digested solution was analysed using ICP-OES.

Soil column leaching test

A glass column with 13 cm height and 4 cm diameter was used in the column leaching test. This column was packed to about 10 cm height, using composite of soil samples from three targets at the shooting range. The soil composite was transferred to the glass column in small portions to obtain uniform packing. The soil column was pre-wetted with artificial rain (0.01 M $CaCl_2$, pH 7) from the top to bottom in order to displace the air in the soil pores. The soil then was allowed to equilibrate and the excess water was drained off by gravity. Then, 200 mL artificial rainwater was applied to the soil column. To obtain homogenous distribution the solution, the artificial rainwater was applied evenly over the surface of the soil column. The surface of the soil column was covered with a gauze cloth to ensure even distribution of the artificial rain, and to avoid the disturbance of the soil surface by the rain drops. With the aid of peristaltic pump, a total of 600 mL artificial rain was added drop-wise on to the top of the soil column. Soil leaching test was repeated using 0.01 M $CaCl_2$ at pH 4. Leachates were collected in three successive fractions, and were analysed with ICP-OES.

Correlation studies

Correlation of Pb concentrations in leachate fractions (i.e. Leachate Pb) and soil physico-chemical parameters (i.e., Soil Pb, Soil pH, Soil OM, CEC) were analysed with Pearson correlation using SPSS version 13.

Results and Discussion

Physico-chemical properties of shooting range soil

The physico-chemical properties (i.e., pH, OM, CEC), soil composition and lead concentration in shooting range soil are shown in Table 1. The pH of the soil is slightly acidic (i.e. 5.55 to 6.34). The acidity may be due to acid deposition from the atmosphere in Kuala Lumpur [5]. Baseline soil has a similar pH value (5.54) with those at the targets. The percentage of the silt, sand, and clay in the soil are 9%, 66% and 27%, respectively. The soil texture is of sandy clay loam according to United States Department of Agriculture (USDA) soil textural diagram. The OM content for baseline soil is 5.40 %, which is higher than those at the targets (i.e. 1.32 to 1.55 %). Vegetation on top of the baseline soil may have contributed to higher plant biomass and OM contents. Moreover, baseline soil has higher CEC value compared to those at three targets, possibly due to the higher OM contents in baseline soil [6]. However, the CEC value of all soil samples decreased with decreasing pH value. A large CEC value of the soil samples is crucial for holding large amounts of lead cations. However, a combination of low rain pH, low clay

content and OM content in soil may increase the risk for dissolution and mobilization of lead from shooting range soils into groundwater [7].

Table 1. Physico-chemical properties, particle size distribution and concentrations of Pb, Al, Fe, Ca, and K in shooting range soil at target 4, 6 and 8.

Variable	Field soil			
	Baseline	**Target 4**	**Target 6**	**Target 8**
pH	5.54	5.85	6.34	5.55
OM (%LOI)	5.40	1.55	1.37	1.32
% Clay	32	23	26	25
% Silt	13	9	10	8
% Sand	55	68	64	67
CEC- pH 7, (cmol/kg)	193.85	140.21	85.51	85.25
CEC- pH 4, (cmol/kg)	112.15	62.70	54.76	57.00
Pb, (mg/kg, dw)	4.4	17278	14126	12163
Al, (mg/kg, dw)	380	372	347	333
Fe, (mg/kg, dw)	178	152	172	154
Ca, (mg/kg, dw)	132	106	112	16
K, (mg/kg, dw)	27	13	11	13

The concentration of the lead and other metal in shooting range soil is shown in Table 1. The average total lead contents at the targets are 14522 ± 2580 mg/kg, significantly higher than those at the baseline (4.4 mg/kg). The concentration of lead in soil is also the highest compare to other metals, indicating the excessive enrichment of lead in the shooting range soil. The average lead concentration in target soils is 36 times higher than the limits set by United States Environment Protection Agency (USEPA) [8].

Soil column leaching test

Figure 3 shows the average lead concentration in leachate from baseline and target soils, eluted with artificial rain water at pH 7 and 4. Overall, the lead concentration in leachate is higher than the safe limit (0.10 mg/L) set by the Ministry of Natural Resources and Environment [9]. The lead concentration in leachate decreased with successive fractions for all soil samples. The highest lead concentration was recorded in the leachate of target soil at pH 4. Lead concentrations of leachates from target soil are higher than those of baselines soil at pH 4 and 7. High lead content of target soils increases the amount of soluble lead ions in leachate. The concentration of lead is further increased by acidic rain water, possible due to: (1) decrease of CEC of soil, and (2) increased solubility of lead in the soil [10]. This leaching behaviour shows that the risk of leaching of lead is significantly increased in the event of acid rain.

In Table 2, the Pearson's correlation coefficient (r) value for lead concentration in soil (Soil Pb) and leachate (Leachate Pb) variables pair is 0.938, which means the concentration of lead in leachate increases with increasing of lead concentration in soil. The CEC and Soil OM variables pair has positive correlation (r = 0.891). The surface of OM may contain negatively-charged polar functional groups (i.e. carboxylate or phenolic groups) that can attract cations and help increase the CEC value of the soil [11]. The negative r values for Leachate Pb variable with both CEC and Soil OM variables show negative correlations. Decreasing OM and CEC values may depletes the capacity of the soil for retaining Pb ion, thereby, increasing the Pb concentration in leachate. Leachate Pb variable is positively-correlated with Soil Pb variable (r = 0.94; p = 0.06); but is negatively-correlated with the Soil OM variable (r = -0.94; p = 0.06). This indicate that Pb in shooting range soil is the source for Pb ions in the leachate,

and increasing Pb in soil causes higher concentration of Pb in the leachate. High soil OM content may reduce leaching of Pb through sorption with polar functional groups in the OM [12, 13].

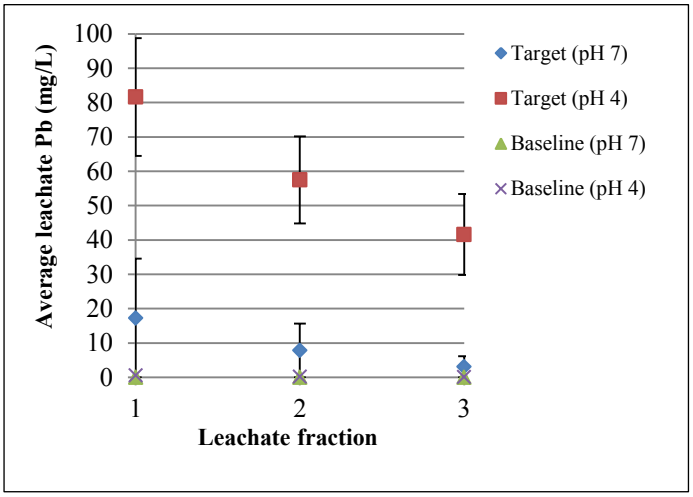

Figure 3. Concentration of lead in leachate (mg/L) from baseline and target soil at pH 4 and 7 as a function of leachate fraction

Table 2. Pearson's correlation coeffeicient (r) and significance level (p) for variables pairs

Variable		Soil Pb	Soil pH	Soil OM	CEC	Leachate Pb
Soil Pb	r	1	0.550	-0.946	-0.705	0.938
	p (2-tailed)		0.450	0.054	0.295	0.062
Soil pH	r	0.550	1	-0.500	-0.485	0.250
	p (2-tailed)	0.450		0.500	0.515	0.750
Soil OM	r	-0.946	-0.500	1	0.891	-0.939
	p (2-tailed)	0.054	0.500		0.109	0.061
CEC	r	-0.705	-0.485	0.891	1	-0.721
	p (2-tailed)	0.295	0.515	0.109		0.279
Leachate Pb	r	0.938	0.250	-0.939	-0.721	1
	p (2-tailed)	0.062	0.750	0.061	0.279	

Conclusion

The risk of leaching of the lead from the shooting range soil at Kem Sungai Besi is a concern due to (1) high concentration of lead in shooting range soil, (2) high percentage of sand in the shooting range soil, (3) lower rain pH value at Kuala Lumpur and Selangor [14], and (4) low CEC value from low soil OM content. On normal radiation practice, soil liming is employed to increase soil pH, and converts lead ions to insoluble hydroxide complexes. However, increasing soil pH may also increase the soluble fraction of the soil OM (i.e. DOM). Lead concentration in leachate may be increased due to an increased formation of soluble lead-DOM complex. In situ remediation method can be used to reduce the possibility of leaching of lead to groundwater. An immediate and economic

solution to this problem is by artificially increasing recalcitrant soil OM (i.e., activated carbon, biochar) to increase immobilization of soil Pb. Further study on the bore waters and air borne particles at the shooting range is warranted to understand the actual migration and impact of soil Pb to water resources.

Abstract

A range of MoVTeNbOx catalysts were synthesised by slurry method assisted with a microwave irradiation. The pH of the synthesis solution was varied at pH = 1, 3, 5, and 7 and the obtained solid were calcined in air at 553 K for 1 hour and followed in N_2 at 873 K for 2 hours. The calcined samples were characterised and their reduction properties were evaluated. The pH of the synthesis solution was shown to affect the physicochemical properties where the formation of orthorhombic M1 phase was obtained for catalysts prepared at pH 1 and 3. The reducibility of the catalyst is improved for catalyst prepared at pH 3 as compared to those prepared at pH 1. Although higher synthesised pH (5 and 7) gave much higher reducibility of the metal oxides, however the removable oxygen could be of the unselective ones.

Keywords: MoVTeNbOx catalysts, pH, reducibility, propane, acrylic acid

Abstrak

Satu siri mangkin MoVTeNbOx telah disintesis menggunakan kaedah buburan dibantu oleh radiasi gelombang mikro. Nilai pH bagi larutan sintesis telah dikaji pada pH = 1, 3, 5, dan 7 dan pepejal yang diperolehi telah dikalsin dalam udara pada 553 K selama 1 jam dan diikuti dalam nitrogen pada 873 K selama 2 jam. Sampel terkalsin telah dicirikan dan sifat kebolehturunan telah dikaji. Di dapati, pH bagi larutan sintesis memberi kesan kepada ciri fizikokimia di mana pembentukan fasa ortorombik M1 telah terjadi bagi mangkin yang disediakan pada pH 1 dan 3. Kebolehturunan mangkin ini dipertingkatkan bagi mangkin yang disediakan pada pH 3 berbanding yang disediakan pada pH 1. Walaupun mangkin yang disediakan pada pH yang lebih tinggi (5 dan 7) memberikan kebolehturunan logam oksida lebih tinggi, namun penyingkiran oksigen mungkin menjadi tidak selektif.

Kata kunci: mangkin MoVTeNbOx, pH, kebolehturunan, propana, asid akrilik

Introduction

MoVTeNbOx is a quaternary mixed metal oxide catalyst consists of four different elements which are molybdenum, vanadium, tellurium and niobium. The catalyst is reportedly the most effective catalyst system for the vapour phase catalytic oxidation of propane to form acrylic acid [1-6]. It is because the catalyst contains necessary active sites which is fundamental in propane oxidation [7]. The active MoVTeNbOx system possesses two crystalline phases which are orthorhombic M1 phase, $Te_2M_{20}O_{57}$ (M = Mo, V, Nb), and hexagonal M2 phase, $Te_{0.33}MO_{3.33}$ (M = Mo, V, Nb) [8]. The significant difference exists among these two phases is that the M1 phase contains V^{5+} centres, as an agent for propane activation [4, 7]. Meanwhile, M2 is incapable of activating propane, but it does convert

propylene. Figure 1 suggested the reaction pathway in oxidation of propane to acrylic acid. For the reaction to occur successfully, the catalyst need at least three important active sites. The first site is a V-Mo-O phase for the activation of propane. After hydrogen is successfully abstracted from propane to form propene, a second site which is a Te-Mo-O phase is needed to oxidise propene into aldehyde. Finally, a third site, a V-Mo-O phase is needed for another oxygen insertion to convert aldehyde into acrylic acid. It is recognized that the V^{5+} ion activates alkane by first H abstraction and followed by second H abstraction to produce the allylic radical before the insertion of oxygen [9].

It has been reported that the synthesis parameters affect the properties of the final catalyst. In this context the pH of synthesis solution is of high importance because the chemical composition and phase formation depend closely on it [10-12]. The catalyst precursors suggest the presence of Anderson-type heteropolyanion, $(NH_4)_6TeM_6O_{24}.nH_2O$ in the samples prepared at pH > 3 and favouring the formation of amorphous materials at pH < 3 [12]. The acidity of the catalyst's surface was suggested to affect the binding and reactivity of propene molecules which possess a basic character [13]. Higher synthesis pH promotes the formation of MoO_3 after heat treatment, which is known to be inactive in propane oxidation [10]. The heat-treated (873K in a N_2 stream) samples from precursors prepared at lower pH suggests the presence of $Te_2M_{20}O_{57}$, $Te_{0.33}MO_{3.33}$ (M = Mo, V, Nb) and $Mo_{5-x}(V/Nb)_xO_{14}$ crystalline phases which possibly involved in the active and selective alkane activation to acrylic acid [12].

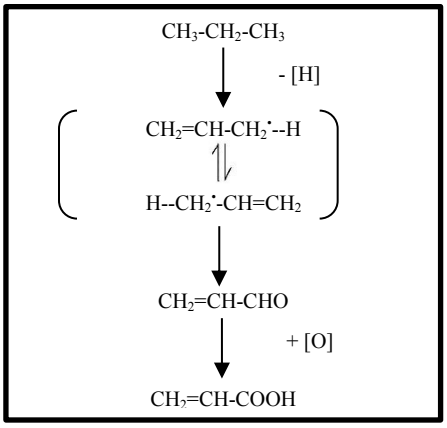

Figure 1. Reaction pathway in oxidation of propane to acrylic acid

In the present work, the MoVTeNbOx catalysts were prepared by using a slurry method assisted with microwave irradiation. During the synthesis, the pH of the solution was varied and its effect on the physicochemical properties and reducibility were studied.

Materials and Methods

Catalyst preparation

$Mo_{1.0}V_{0.3}Te_{0.23}Nb_{0.12}O_x$ catalysts were prepared by a slurry method followed by microwave irradiation according to the patented procedure [14].

Commercial chemicals which were ammonium heptamolybdate tetrahydrate, $(NH_4)_6Mo_7O_{24}.4H_2O$ (Merck), ammonium metavanadate, NH_4VO_3 (Merck), telluric acid, $Te(OH)_6$ (Sigma-Aldrich) and ammonium niobium oxalate, $(NH_4)_2Nb_2(C_2O_4)_5$ (Sigma-Aldrich), were used as the sources for Mo, V, Te and Nb respectively. The microwave used in this study was the conventional Panasonic microwave model no. NN-S554WF (750 W).

The synthesis process begun by dissolving ammonium heptamolybdate tetrahydrate in a 15 ml of irradiated deionised H_2O. The solution was irradiated before ammonium metavanadate was added. The solution was then irradiated, followed by the addition of telluric acid. The irradiated ammonium niobium oxalate solution was added

to the MoVTe suspension that were separately prepared using ammonium niobium oxalate dissolved in 5 ml of deionised H_2O. Finally, the resulting orange slurry formed were irradiated for 3 min. The pH of resultant slurry precursor was recorded with the value of 4.5 (±0. 01) using Thermo-line PHS-3BW digital pH meter.

The pH of the final slurry was adjusted by using 1 M aqueous sulphuric acid for pH range 1 to 3 and 1 M of an aqueous ammonium hydroxide for pH 5 to 7. Then, the solution was left overnight and later dried using a rotary evaporator at 353 K. These samples were denoted as $MVTN_{1p}$, $MVTN_{3p}$, $MVTN_{5p}$, and $MVTN_{7p}$ respectively.

The precursor samples were later calcined for 1 h in air at 553 K to remove the organic substances and followed by 2 h in the N_2 stream at 873 K to control the phase formation of the catalyst. These samples were denoted as $MVTN_{1c}$, $MVTN_{3c}$, $MVTN_{5c}$, and $MVTN_{7c}$ respectively.

Catalyst characterisation

All the catalysts were characterised by the following analytical techniques. Powder X-ray diffraction patterns were collected by using a Shimadzu Model XRD 6000 Diffractometer equipped with CuK_α radiation with wavelength, λ= 1.542 Å which were continuously scanned in the range of $2\theta = 2° - 60°$ at a scanning rate of 2° min^{-1}. Induced coupled plasma-atomic electron spectroscopy (ICP-AES) measurements of bulk MoVTeNbOx compositions were carried out using a model Perkin Elmer Emission Spectrometer Plasma 1000. Fourier Transform Infrared Spectroscopy (FTIR) were analysed using a Perkin Elmer 1725X spectrometer by employing the standard KBr method and the spectra were recorded in the 400 cm^{-1} to 4000 cm^{-1} regions. Field emission-scanning electron microscopy (FESEM) images were collected using Nova 200 NanoLab at an accelerating voltage of 5.0 kV. The aluminium stud was used with the carbon paint was tapped on the sample and coated with gold.

Reducibility study

Temperature programmed reduction in hydrogen (H_2-TPR) analysis was carried out by using ThermoFinnigan TPDRO 1110 Instrument. Before subjecting the catalyst to a reducing environment, it was pre-treated under a N_2 flow by heating sample to 423 K at a heating rate of 10 K min^{-1}. After which, the nitrogen gas was switched to hydrogen (5 % H_2 in Argon) and temperature programming up from 323 K to 1223 K at a heating rate of 10 Kmin^{-1}. The amounts of water, H_2O which was produced was flowed through the thermal conductivity detector.

Results and Discussion

Physicochemical properties of MoVTeNbOx catalysts

The XRD patterns of four precursors prepared at different pH are shown in Figure 2. At pH 1, there are no visible peaks due to metal oxide crystal phase can be observed. The $MVTN_{1p}$ displays two humps at $2\theta = 6°$- 15° and 21° - 35° which reckons that the sample is amorphous due to randomly distributed of atoms in the solid particles [15]. As the pH of synthesis solution increases, the metal oxide peaks become apparent. All of the other three samples ($MVTN_{3p}$, $MVTN_{5p}$, and $MVTN_{7p}$) exhibited sharp peaks at $2\theta = 10.3°$, 12.5°, 13.1°, 16.0°, 18.1°, 23.2°, 25.0° and 27.8° suggesting the orderly arranged of the atoms. The peaks suggested the presence of Anderson-type heteropolyanion $(NH_4)_6TeMo_6O_{24}.7H_2O$ and/or $(NH_4)_7TeMo_5VO_{24}.8H_2O$ [15, 16]. A similar case has been reported, whereby an Anderson-type heteropolyanion, $(NH_4)_6TeMo_6O_{24}.nH_2O$ was formed in samples prepared at pH 3.0– 4.5 whereby at pH < 3 the heteropolyanion partially decomposed with the formation of mostly amorphous materials and at a very low pH 1.0–1.5 indicates the present of polyoxovanadates in the precursors [12]. Therefore, as observed in this work at low pH the crystallinity of heteropolyanion compounds decreases and amorphous materials are observed due to the partial incorporation of heteroatoms or the heteroatoms are highly dispersed on the compounds. The results show that pH influences the incorporation of heteroatoms (V and Nb) on heteropolyanion which determines the formation of active crystalline phases.

The XRD patterns of calcined samples are shown in Figure 3. The peaks evolved for samples synthesised at pH 1 and 3 i.e. $MVTN_{1c}$ and $MVTN_{3c}$, respectively suggests the presence of orthorhombic M1 and hexagonal M2 phases. The presence of both phases can be clearly indicated by $2\theta = 6.6°$, 7.9°, 9.0°, 22.1° and 45° which correspond to orthorhombic M1 (JCPDS: 58-790) meanwhile $2\theta = 22.1°$, 28.3°, 36.2° and 50° correlate to hexagonal M2 phase (JCPDS: 57-1099). On the other hand, the two other samples which are $MVTN_{5c}$ and $MVTN_{7c}$ synthesised at pH 5

and 7 respectively, show the occurrence of hexagonal M2 phase and the additional peaks at 2θ = 7.7°, 8.9°, 22.1°, 24.2° and 31.3° which can be correlated to the existence of tetragonal phase, $(V_{0.07}Mo_{0.93})_5O_{14}$ (JCPDS: 31-1437).

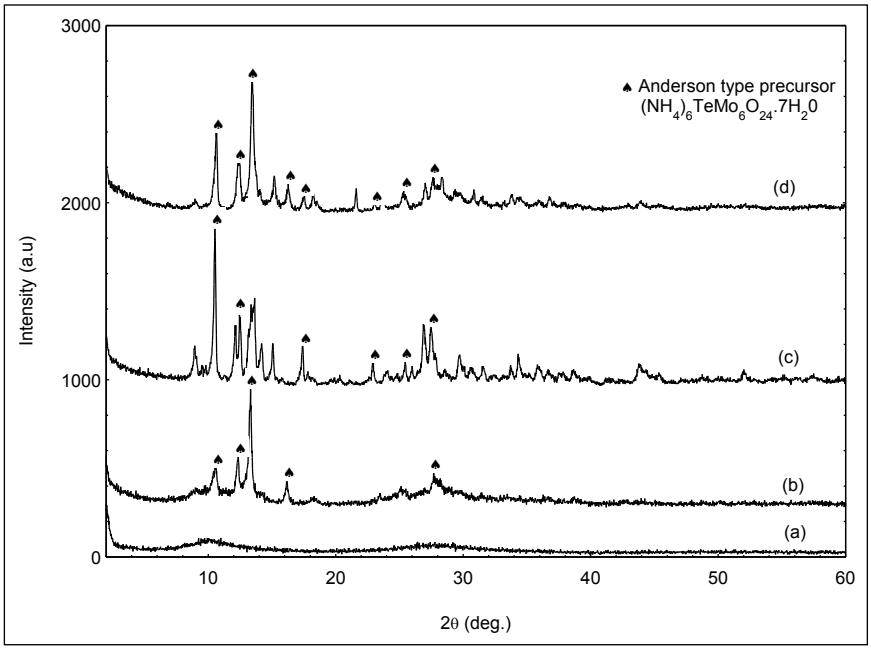

Figure 2. XRD patterns of precursor MoVTeNbOx catalysts (a) $MVTN_{1p}$ (b) $MVTN_{3p}$ (c) $MVTN_{5p}$ (d) $MVTN_{7p}$

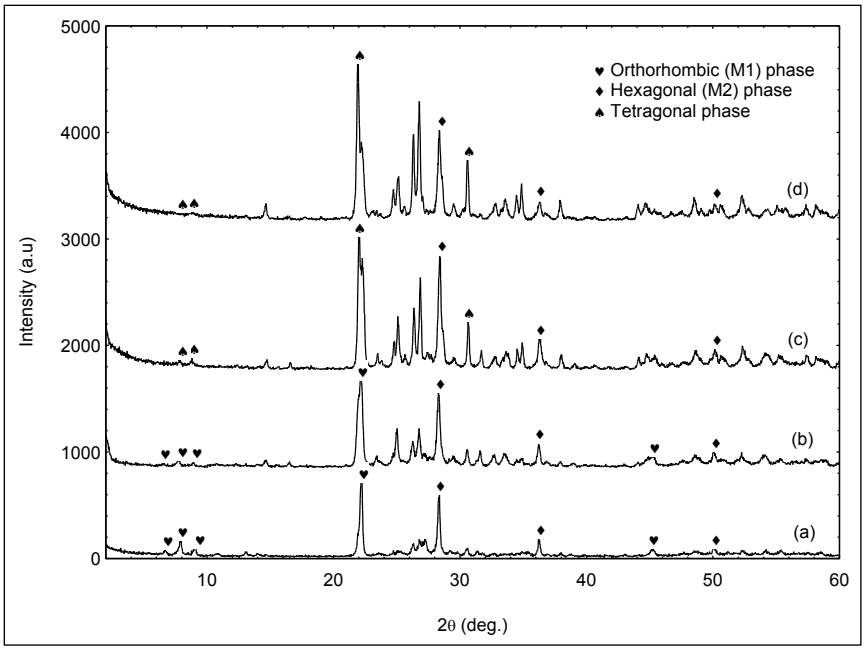

Figure 3. XRD patterns of calcined MoVTeNbOx catalysts (a) $MVTN_{1c}$ (b) $MVTN_{3c}$ (c) $MVTN_{5c}$ (d) $MVTN_{7c}$ [23].

It can be noted that orthorhombic M1, hexagonal M2 and tetragonal phases have the same diffraction peak of 22.1° which suggests that the mixture of phases in the samples [15]. The formation of these phases may be due to the formation of pseudo-amorphous or semi crystalline Anderson-type compound (ammonium containing phase) which has been observed during precursor stage [17].

The crystallite size of the calcined MoVTeNbOx catalysts can be determined by using the full width half maximum (FWHM) for three characteristic peaks of orthorhombic M1 phase at 2θ = 6.6°, 7.9°and 9.0°. The crystallite size was estimated by the using the Debye Scherrer equation as in (1).

$$t = \frac{0.9\lambda}{\beta_{hkl} \cos \theta_{hkl}} \quad (1)$$

where, t = crystallite size, λ = 1.5438 Å, θ = Bragg angle, β_{hkl} = the full width at half maximum (FWHM) of the peak in radian.

The value of crystallite size in Table 1 suggested that the crystallite size of the $MVTN_{1c}$ and $MVTN_{3c}$ samples are 35.12 nm to 36.42 nm respectively. The values are in the nanometer range, which gives a good indication of the pH influence on the catalyst particle size. However, there is no orthorhombic phase were present in $MVTN_{5c}$ and $MVTN_{7c}$, therefore particle size for these samples were not calculated.

Table 1. Crystallite size and bulk composition of $MVTN_{1c}$, $MVTN_{3c}$, $MVTN_{5c}$ and $MVTN_{7c}$

Sample	**2θ (°)**	**FWHM (°)**	**t (nm)**	**Bulk composition[1] (Mo: V: Te: Nb)**

			Average: 35.12	
$MVTN_{3c}$	6.6	0.2445	32.6	1.0: 0.29: 0.17: 0.09
	7.7	0.2550	31.3	
	8.9	0.1760	45.4	
			Average: 36.42	
$MVTN_{5c}$	NA[2]			1.0: 0.29: 0.17: 0.09
$MVTN_{7c}$	NA[2]			1.0: 0.29: 0.17: 0.09

Preparative composition of Mo: V: Te: Nb = 1.0: 0.3: 0.23: 0.12, [1]Determined by ICP-AES, [2]NA: Not applicable

The bulk compositions of Mo-V-Te-Nb mixed oxide catalysts determined by ICP-AES are summarised in Table 1. The bulk compositions of all the oxides were not so different from the preparative compositions. The Mo element is justified in all samples as Mo is the main component in the mixture. For all samples, the V element obtained which is 0.29 are closely resemble to the theoretical value of 0.3. The molar ratio of the Mo and V element are important in the catalyst system because these elements are responsible for the structural formation of the MoVTeNbOx catalysts and M1 phase will be formed with Mo:V ratios higher than 0.14 [6,18].

The difference is found in the tellurium contents which were slightly lower in the bulk. A possible explanation for the loss of tellurium could be related to the presence of oxalate anions (reducing agent) from the starting material of

niobium oxalate, which could facilitate the reduction of tellurium cations to metallic Te [19] that were detached away from the structure during calcination. The Nb content is also found lower after calcination in all samples. It has been reported that Nb play the same structural role as vanadium in order to obtain the mono-phasic orthorhombic M1 structure [20]. In the case of the catalyst in this work, the condition of lower amount of Nb gave MoVTeNbOx catalysts containing several phases as has been observed in the XRD analysis. Still, the presence of Nb despite of its amount is important for the stability of the element in the solid structure.

The FTIR spectra of the precursors are shown in Figure 4. The bands around 3178 cm^{-1} and 1441 cm^{-1} are due to the symmetric and asymmetric stretching vibrations of the tetrahedral ammonium cation [16]. The H–O–H bending mode is observed in the range 1668 cm^{-1} and bands at 1301 cm^{-1} could be attributed to stretching and vibration modes of C=O, a stretching combination of C–O and C–C associated with the oxalate anion [15]. Meanwhile, the absorption band at 1101 cm^{-1} is discovered to only exist in sample $MVTN_{1p}$ that can be related to the S=O stretching [21]. This is caused by the presence of sulphate group while incorporating H_2SO_4 during pH adjustment of precursor solution. In this case, only two samples required H_2SO_4 during pH adjustment, which are $MVTN_{1p}$ and $MVTN_{3p}$. However, this peak only intense for $MVTN_{1p}$ and almost unnoticeable for $MVTN_{3p}$. This is due to the reason that the pH of the solution before adjustment was around pH 4.3, so only little amount of H_2SO_4 ions present in the $MVTN_{3p}$ solution, compared to $MVTN_{1p}$. In addition, the sharp peak detected around 884 cm^{-1} corresponds to no vibrations and bands around 623 cm^{-1} can be due to the Mo-O, Te–O and Mo–O–Te vibrations, since the different bands of these vibrations overlapped in this range [16]. The stretching of V=O group and V-O-Me (Me= Mo, Te, Nb) gave the absorption band around 449 cm^{-1}.

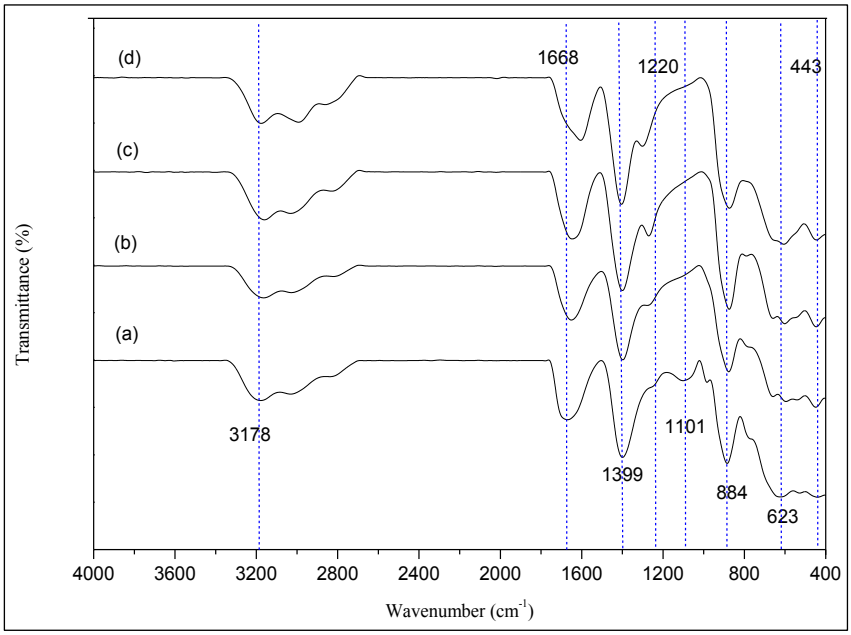

Figure 4. FTIR spectra of precursor MoVTeNbOx catalysts (a) $MVTN_{1p}$ (b) $MVTN_{3p}$ (c) $MVTN_{5p}$ (d) $MVTN_{7p}$

For the calcined samples, there are no bands observed in the region above 1000 cm^{-1} as can be seen in Figure 5, therefore it is sufficient to show spectra of low frequency region [15]. The disappearance of the high frequency region above 1000 cm^{-1} indicates that all of the organic species functional groups such as hydroxyl, sulphate, ammonium and water are completely removed from the samples during calcination. The band at 861 cm^{-1} and 699 cm^{-1} are assigned to asymmetric stretching vibrations of bridging Mo-O-*M* bonds (*M* = Mo, Nb, Te) [12] which lies in the range of 800 – 1000 cm^{-1}. The bands around 530 cm^{-1} and 431 cm^{-1} can be assigned to V = O group and V-O-Me bonds (*M* = Mo, Te, Nb) in the range of 400 – 600 cm^{-1} [16].

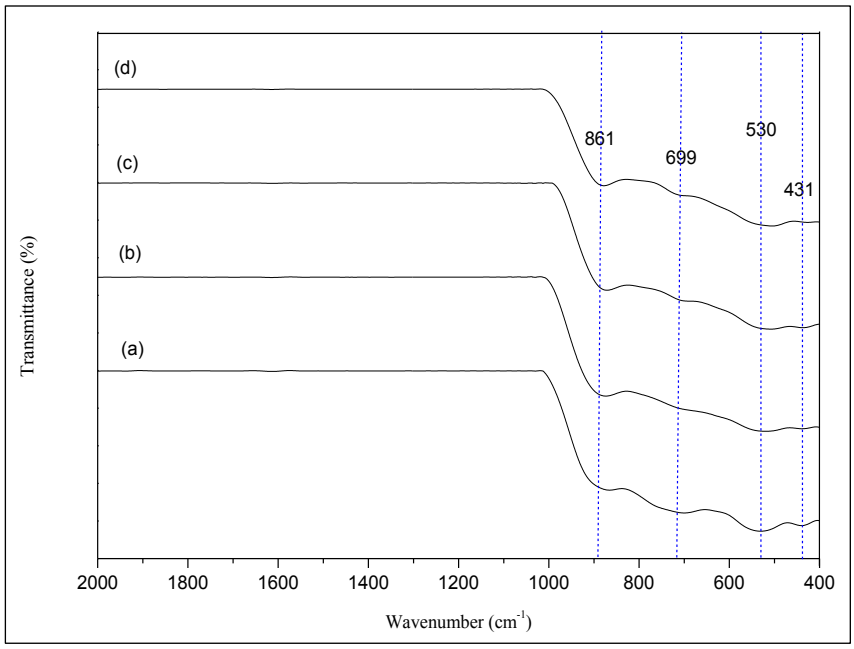

Figure 5. FTIR spectra of calcined MoVTeNbOx catalysts (a) $MVTN_{1c}$ (b) $MVTN_{3c}$ (c) $MVTN_{5c}$ (d) $MVTN_{7c}$

The morphology of calcined catalysts was investigated by FE-SEM analysis. The images are shown in Figure 6. The micrographs display the formation of rod-shaped morphology in all of the samples. This kind of morphology is similar to the reported works [20, 22]. The formation of a rod-shaped morphology could be due to V^{5+} derived from ammonium metavanadate in the synthesis step which contribute to the formation of long and large needles during the slurry synthesis [22]. For catalyst synthesised at pH 1, it gives a more homogeneous and rather disperse particles as compared to catalysts prepared at higher pH. Not to be denied is the presence of other shaped particles, thus stating the mixture of phases in accordance with the XRD patterns which showed mixed phase of the calcined catalyst [12].

Reducibility properties

The study on the catalyst reducibility is important in a mixed metal oxide catalyst used for the oxidation reaction. It will give an indication of the availability of the oxygen for insertion into reactants. During the reduction process, hydrogen gas is in contact with the oxygen species from the surface of the catalyst. The hydrogen is consumed and formed water vapour in the gaseous state as a product, leaving an oxygen vacancy on the catalysts. The interaction of the gas phase hydrogen with catalyst can be represented as in equation (2).

$$H_{2(g)} + O_{(surface)} \longrightarrow H_2O_{(g)} + \square \qquad (2)$$

where (g) = gaseous species, *(*s) = surface or lattice species and □ = oxygen vacancy.

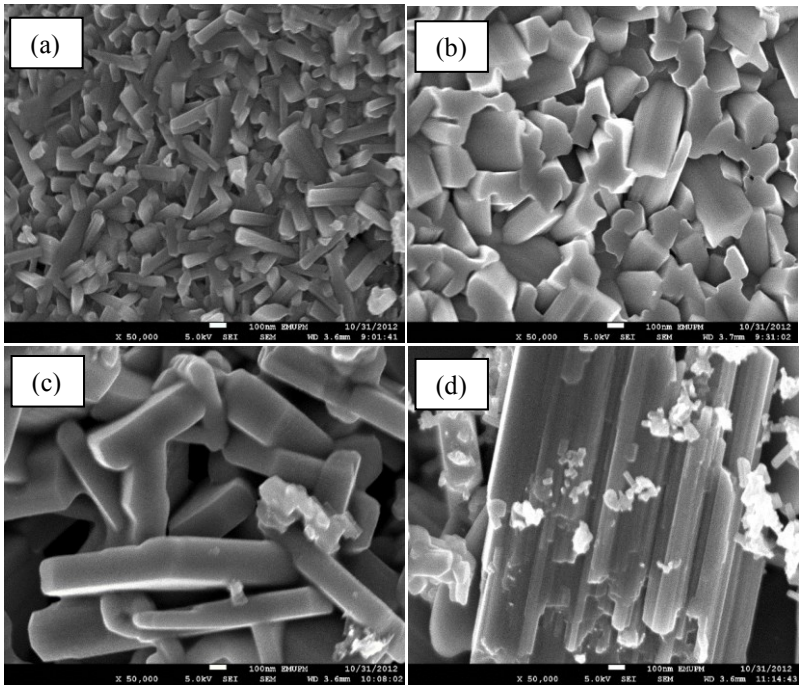

Figure 6. FESEM image of calcined MoVTeNbOx catalysts (a) $MVTN_{1c}$ (b) $MVTN_{3c}$ (c) $MVTN_{5c}$ (d) $MVTN_{7c}$

The reduction profiles of MoVTeNbOx catalysts are shown in Figure 7. There are at least two peak maximum which are overlapped with each other are observed in all of the samples. The occurrence of multiple reduction peaks indicates the presence of a number of reducible metal oxide species present in the catalyst.

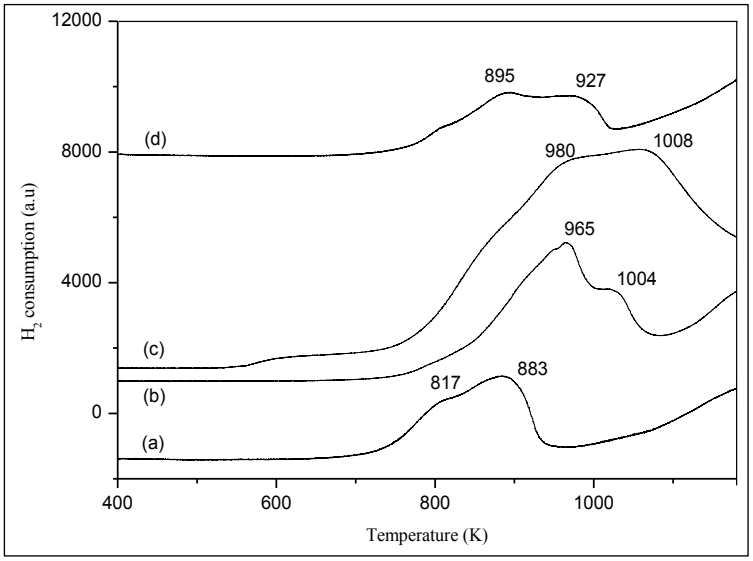

Figure 7. H_2-TPR profiles of calcined MoVTeNbOx catalysts (a) $MVTN_{1c}$ (b) $MVTN_{3c}$ (c) $MVTN_{5c}$ (d) $MVTN_{7c}$

The reduction peak suggests reductive decomposition of metal oxides where MoO_n reduced at 948 K and 995 K for a stepwise reduction of $Mo^{6+} \rightarrow Mo^{4+}$ and $Mo^{4+} \rightarrow Mo^0$ under H_2-TPR, meanwhile VO_n reduced at temperature of 913 K and 943 K from $V_2O_5 \rightarrow VO_2$ [24,25]. Additionally, reduction of Nb^{5+} to Nb^{4+} occur at around 1243 K [26].

The reduction activation energy of the catalysts can be calculated using the modified version of the Redhead equation as stated in equation (3). The results are summarised in Table 2.

$$\frac{E_r}{RT_m^2} = \left(\frac{A_r}{\beta}\right)[H_2]_m \exp\left(\frac{-E_r}{RT_m}\right) \quad (3)$$

where, E_r = reduction activation energy (kcal mol^{-1}), T_m = peak maximum temperature (K) in the rate of production of H_2, A_r = reduction pre-exponential term ($cm^3mol^{-1}s^{-1}$) which is given a standard collision number of 10^{13} cm^3 $mol^{-1}s^{-1}$, β = heating rate (Ks^{-1}) and $[H_2]_m$ is the gas phase concentration of hydrogen (mole cm^{-3}) at the peak maximum.

Table 2. The reduction activation energy, E_r and total O_2 removed determined from H_2-TPR for (a) $MVTN_{1c}$ (b) $MVTN_{3c}$ (c) $MVTN_{5c}$ (d) $MVTN_{7c}$

Sample	**T_{max}, (K)**	**Reduction activation energy, E_r (kJ mol^{-1})**	**O_2 removed (atom g^{-1}) × 10^{21}**
$MVTN_{1c}$	817	136.5	0.72
	883	147.5	1.67
			Total = 2.39
$MVTN_{3c}$	965	161.2	4.67
	1004	167.7	0.94
			Total = 5.61
$MVTN_{5c}$	980	163.7	8.39
	1008	168.4	7.26
			Total = 15.65
$MVTN_{7c}$	895	149.5	1.60
	927	154.9	1.05
			Total = 2.65

The values of reduction activation energy, E_r for all samples is more than 100 kJ mol^{-1} indicates that the oxygen species are strongly bonded. Thus, these strongly bonded oxygen species that has been removed in these samples may be originated from the surface and/ or lattice of the catalyst [27].

Interaction of hydrogen with MoVTeNbOx mixed oxides during H_2-TPR involves the adsorption of hydrogen on all active sites of the molybdenum oxide surface, taken up the oxygen species and caused the reduction of the MoO_n component. The higher amount of oxygen removed indicate the high activity of the catalysts. The amount of oxygen removed of each sample can be estimated by integrating the area under the peak. For catalyst prepared at pH 1, the total amount of removable oxygen is 2.39 x 10^{21} atom g^{-1} whereas the amount is doubled to 5.61 x 10^{21} atom g^{-1} when synthesised at pH 3. This is an indication of the high removable oxygen of the catalyst when prepared at pH 3 which was contributed by the formation of the much desired orthorhombic M1 phase. Although the catalyst prepared at pH 5 gives a much higher of removable oxygen species (15.65 x 10^{21} atom g^{-1}), nevertheless it could be the unselective oxygen species due to the catalyst does not contains the orthorhombic M1 but hexagonal M2 phase instead. The same goes with catalyst prepared at pH 7.

Conclusion

The results revealed that the pH of the slurry strongly influences the formation of crystalline Anderson-type heteropolyanions for catalysts prepared at pH 3, 5 and 7. While the as-synthesised sample at pH 1 showed the presence of pseudo-amorphous materials which allow for the formation of orthorhombic M1 phase upon calcination. The formation of orthorhombic M1 phase is also observed in pH 3 samples (after calcination), but none was found in the other samples. Therefore, high acidity condition is required for the formation of desired catalyst phase. Although, all of the catalysts give similar reduction profiles in the anaerobic hydrogen-TPR, the lattice oxygen that were removed in catalysts which contains orthorhombic M1 could be the selective ones. This is because, the catalysts with M1 phase can undergo charge transfer on the Mo and V sites with the lattice oxygen could be involved in the abstraction of H at the vanadium sites and oxygen insertion at the molybdenum sites. There is a clear relationship between synthesis pH and catalyst properties, suggesting that the reducibility of crystalline phases is a key factor in the propane selective oxidation into acrylic acid.

Abstract

Multi walled carbon nanotubes (MWCNT) hold the increasing interest in many different fields. To employ MWCNT as an effective reinforcement in order to enhance the thermal conductivity of polylactic acid (PLA) modified with liquid natural rubber (LNR), proper dispersion and appropriate interfacial adhesion between MWCNT and PLA/LNR have to be guaranteed. This paper used ultrasonic technique as the method to help to improve the dispersion of MWCNT in PLA/LNR matrix. The result shown that the sample with 3.5 wt.% of MWCNT provided higher thermal conductivity which is believe to be the optimum loading due to better dispersion of MWCNT in PLA/LNR matrix. The 4 wt.% of MWCNT shows decreasing of thermal conductivity due to the presence of agglomeration of MWCNT. The results confirmed by Scanning Electron Microscopy (SEM) micrograph. Fourier Transform Infrared (FTIR) spectra shown that there were no chemical changes happen.

Keywords: polylactic acid, multi-walled carbon nanotubes, thermal conductivity, nanocomposites, ultrasonic

Abstrak

Tiub karbon berbilang dinding (MWCNT) telah menarik minat dalam pelbagai bidang yang berbeza. Bagi memastikan MWCNT dapat digunakan secara berkesan sebagai agen pengukuh dalam peningkatan kekonduksian terma polilaktik asid (PLA)/ cecair getah asli (LNR) nanokomposit, serakan dan lekatan antara muka yang sempurna dan baik di antara MWCNT dan PLA/LNR adalah di antara aspek yang perlu diberi perhatian. Di dalam kertas ini, teknik ultrasonik telah digunakan bagi memastikan membantu penyerakan MWCNT di dalam PLA/LNR matrik. Keputusan menunjukkan sampel yang mengandungi 3.5 wt% MWCNT menghasilkan kekonduksian terma yang tertinggi dengan pencapaian nilai kandungan optima disebabkan oleh serakan yang baik di dalam PLA/LNR matrik. Pada kandungan MWCNT 4 wt%, kekonduksian terma menunjukkan penurunan disebabkan oleh gumpalan MWCNT. Keputusan disahkan oleh Imbasan Elektron Microskopi (SEM) mikrograf. Spektra Fourier Transform Inframerah Spektroskopi (FTIR) pula menunjukkan tiada perubahan kimia yang berlaku.

Kata kunci: polilaktik asid, tiub karbon berbilang dinding, kekonduksian terma, nanokomposit, ultrasonic

Introduction

Recently, carbon nanotube (CNT) has been widely explored and gains much attention to be used as filler in polymer due to their ability to transform an insulating polymer matrix to a conductive composite. CNT developed in 1990s and available as single wall (SWCNT), double wall (DWCNT) and multi wall (MWCNT) [1]. CNT has unique

structure which enables to be filled with polymer and have low percolation threshold concentration [2,3]. CNT not only helps in enhancing in terms of tensile modulus, tensile strength, toughness, glass transition temperature, electrical conductivity but also the thermal conductivity of the polymer composites due to outstanding aspect ratio. CNT incorporated in polymer show thermal conductivity enhancement even at very low loading by forming percolating network. However, it is controlled by many factors such as aspect ratio, dispersion and its interfacial interactions with the polymer matrix.

Even after a decade of research, the potential of employing CNT as reinforcements has become limited because of the difficulties to get good dispersion of CNT during processing and poor interfacial interaction between CNT and polymer matrix. CNT has small diameter in nanometer scale with high aspect ratio (>1000) and extremely large surface area which make the nature of dispersion of CNT differ from other conventional fillers like carbon fibers or spherical particles [1]. Therefore, the basis of CNT dispersion method is introduced here which is ultrasonication which is the most frequently used method for nanoparticle dispersion. This is the method where ultrasound energy is applying in order to agitate particles in the solution by using either an ultrasonic bath or an ultrasonic probe (also known as sonication) [1]. This method is an effective method to disperse CNT in liquids having low viscosity such as water, ethanol and toluene.

In this study, polymer nanocomposites were prepared from biodegradable polymer which is polylactic acid (PLA) with modification using liquid natural rubber (LNR) in order to reduce the brittleness of PLA and filled with MWCNT. The optimal LNR content in the blend was found to be 10 wt.% where it shows it has improve the brittleness and crystallization ability of the PLA [4]. MWCNT was mixed with LNR using ultrasonication method before melt blended with PLA. According to Adilah and Sahrim [5], the tensile strength and Young's modulus of the PLA/LNR/MWCNT nanocomposites which prepared using ultrasonic method shows an improvement compared to the manual method of mixing LNR with MWCNT. The optimum time of ultrasonication was found to be at 1 hour [6]. Thermal conductivity of the polymer nanocomposites produced is discussed in detail.

Materials and Methods

Materials

Polylactic acid of Natureworks IngeoTM Biopolymer 3251D grade supplied by Unic Technology Ltd, China was used as the base polymer matrix. It has a density of 1.24 g/cm^3 and melt flow index of 30-40g/10 minutes (190°C/2.16Kg) with melting temperature between 188 – 210 °C. MWCNT is manufactured by Nanocyl^{TM} having average diameter of 9.5 nm, carbon purity of 90% and surface area of 250 – 300m^2/g. Figure 1 show the MWCNT used in this paper. LNR was produced by using photochemical sensitized degradation technique. NR of SMR L grade which supplied by Malaysian Rubber Board were immersed in toluene and exposing it to ultraviolet radiation for 6 hours.

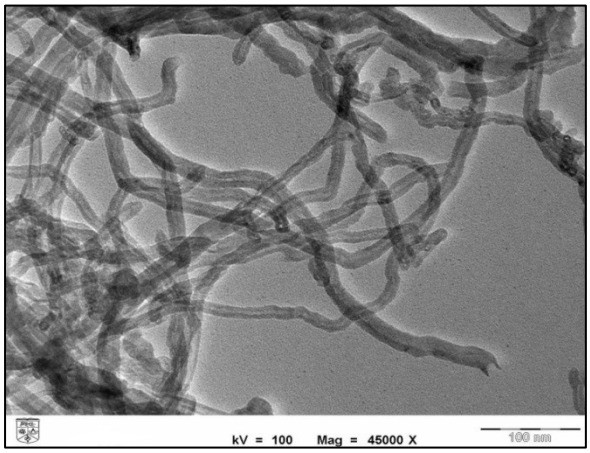

Figure 1. TEM image of pure MWCNT

Preparation of PLA/LNR/MWCNT nanocomposites

PLA/LNR/MWCNT nanocomposites were prepared using melt blending using Haake Rheomix internal mixer. The processing parameter is at 190 °C, rotor speed of 90 rpm with 14 mins of mixing time. The LNR concentration was fixed at 10 wt.%. The MWCNT loading was varied at 0.5, 1.5, 2.5, 3.5 and 4 wt.%. The MWCNT was initially dispersed in the LNR by ultrasonic for 1 hour before melt blended with PLA.

Characterizations of PLA/LNR/MWCNT nanocomposites

To study the effect of MWCNT filler on thermal conductivity of PLA/LNR nanocomposites, the temperature was varied from 30 °C to 180 °C using thermal conductivity analyzer brand NETZSCH and model number LFA 44712-41. The samples used are in disc type having diameter of 12.7 mm and 1 mm in thickness. The Fourier Transform Infrared (FTIR) spectroscopy analysis was carried out on Perkin Elmer spectrum V-2000 spectrometer. The samples were scanned between 700 to 4000 cm^{-1} wave number. The tensile fractured surfaces of the composite were examined by scanning electron microscope (Philips XL 30).

Results and Discussion

Thermal conductivity

The thermal conductivity of a material is dominated by atomic vibration or phonons and electrons. However, for insulating materials, conduction by electrons is generally negligible [1]. Generally, thermal conductivity of polymer/CNT nanocomposites depends on several factors such as the interfacial interactions of the CNT with the polymer matrix, the content and dispersion of the CNT.

From the Figure 2, the PLA/LNR and PLA/LNR with 1.5 wt.% and 3.5 wt.% of MWCNT shows the decreasing trend of thermal conductivity with increasing temperature for all samples. This is due to the presence of defects and large boundaries at the interface of MWCNT/matrix which increase the thermal resistivity as the temperature increase. Phonons mean free path also will be lowered because it was hindered by interfacial boundary of the PLA/LNR matrix. Thus it will reduce the thermal conductivity of the polymer nanocomposites. From this it shows that the interfacial interaction will affect the thermal conductivity of the PLA/LNR nanocomposites. However, at 4 wt% of MWCNT, the graph shows an increment of thermal conductivity with the increasing temperature. At high content of MWCNT in PLA/LNR, MWCNT will provide large surface area and extended shape of MWCNT which will reduce the crystallization of matrix as the temperature increase [7,8]. The large amount of junctions among MWCNT makes the increasing of the thermal conductivity by forming conducting path in the matrix. This shows that the content of MWCNT in matrix will affect the thermal conductivity behavior of the PLA/LNR nanocomposites.

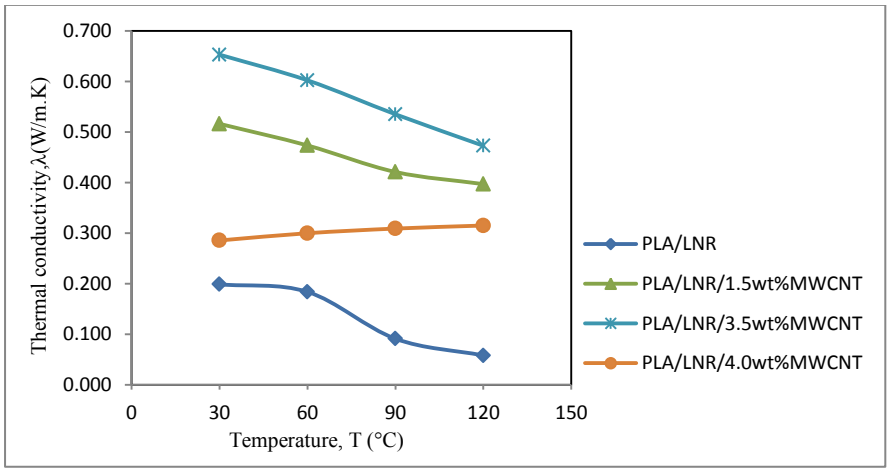

Figure 2. Thermal conductivity dependence of PLA/LNR at different loaded of MWCNT

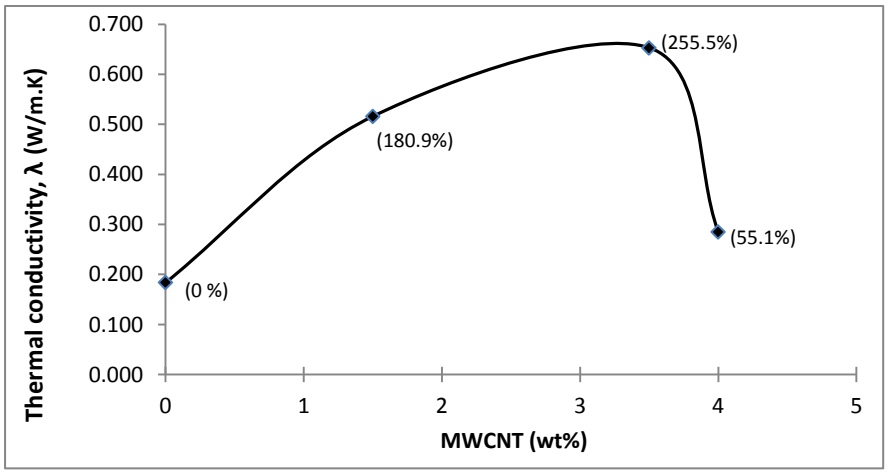
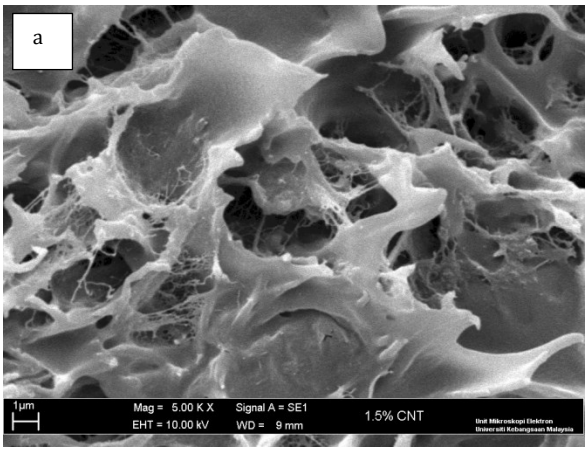
Figure 3 it shows of thermal conductivities of PLA/LNR nanocomposites containing 1.5 wt.%, 3.5 wt.% and 4 wt.% of MWCNT at 30 °C. It shows remarkable enhancement of thermal conductivity for 1.5 wt.% and 3.5 wt.% of MWCNT compared to 4 wt.% of MWCNT in PLA/LNR. This result obtains due to the presence of highly conductive MWCNT in the PLA/LNR matrix. It provides higher mean free path and higher number of phonons' vibrational modes due to the increasing of crystalline structure. The percolated network of MWCNT inside the PLA/LNR matrix also helps to enhance the thermal conductivity of PLA/LNR nanocomposites. The dispersion of 1.5 wt.% and 3.5 wt.% content of MWCNT in PLA/LNR matrix are better than 4 wt.% of MWCNT as shown in Figure 4. Higher content of MWCNT in the PLA/LNR matrix leads to the reduction of thermal conductivity. This is due to the presence of agglomeration of MWCNT as shown in Fig. 4. The agglomeration of MWCNT will block the phonon travels. This shows that dispersion of MWCNT in matrix plays an important role in enhancing thermal conductivity. From this, the optimum value of thermal conductivity at 30 °C was achieved by 3.5 wt.% of MWCNT content in PLA/LNR. If the MWCNT was added more than this limit, it will give adverse effect to the value of thermal conductivity.





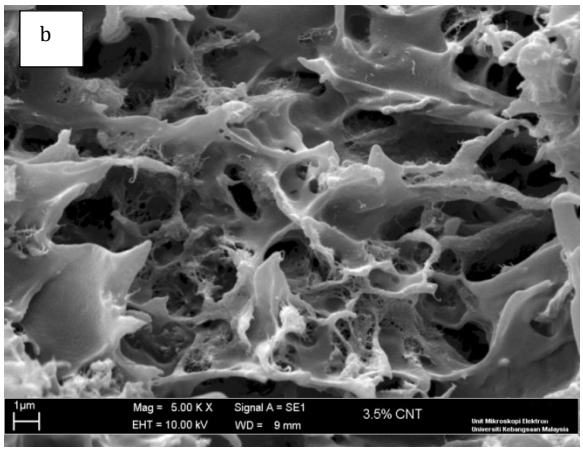


Figure 3. Comparison of thermal conductivities of nanocomposites containing MWCNT with different weight percent at 30 °C (Data in bracket indicate % increase in thermal conductivity against the polymer matrix)

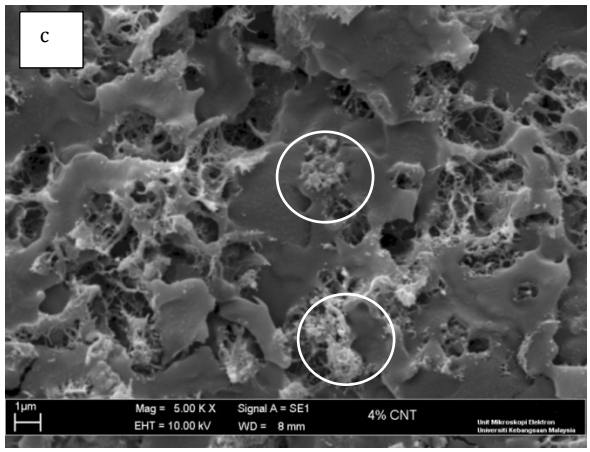

Figure 4. SEM micrograph of a) PLA/LNR at 1.5 wt.% MWCNT b) PLA/LNR at 3.5 wt.% MWCNT and c) PLA/LNR at 4 wt.% MWCNT

FTIR analysis

The FTIR spectra of PLA/LNR and PLA/LNR filled with 3.5 wt.% of MWCNT are given in Figure 5. The IR bands at 2995 and 2849 which is in the single bond stretch region are assigned to the C-H stretch. In the double bond region, the IR band at 1747 is assigned as carbonyl group of C=O bond. The peaks at 868 and 755 are related to the amorphous and crystalline region [4]. The peak at 1080 belongs to C-O-C stretching of the PLA. From that figure, it was found that there were no chemical changes happen.

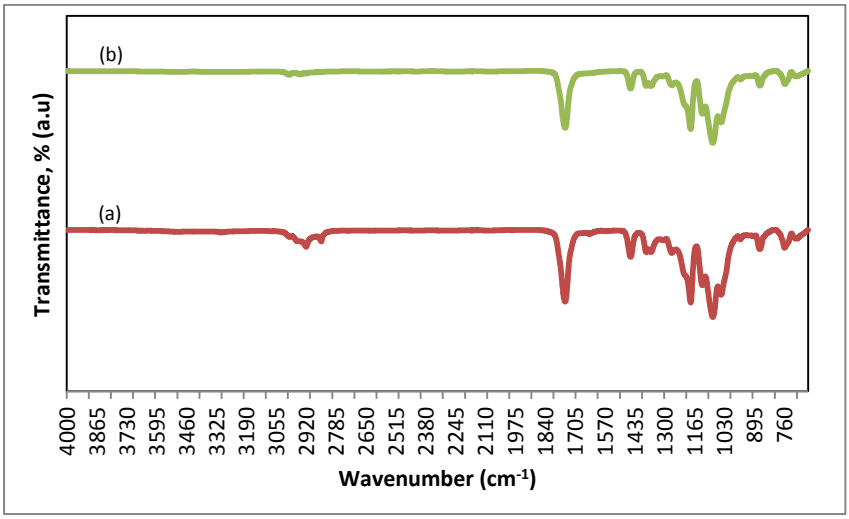

Figure 5. FTIR spectra of a) PLA/LNR and b) PLA/LNR at 3.5 wt.% of MWCNT

Conclusion

Conductive polymer nanocomposites was prepared by impregnating PLA/LNR with MWCNT nanoparticles using melt blending technique. SEM micrographs showed good dispersion for 1.5 wt.% and 3.5 wt.% of MWCNT in PLA/LNR which leads to high thermal conductivity. On the other hand, 3.5 wt.% of MWCNT sample attained the

optimum enhancememt in the thermal conductivity value. FTIR spectra showed that there is no chemical changes occur when PLA/LNR was being added with MWCNT.

Abstract

The focus of this research is to prepare epoxidised natural rubber (ENR)/poly(vinylidene fluoride) (PVDF) (ENR/PVDF) membrane using solution casting method and to characterize the ENR/PVDF membrane using universal tensile machine (UTM) and scanning electron microscope (SEM). Composite membrane of ENR/PVDF was prepared by solution casting technique. The tensile strain increases when ratio of ENR increases in the composite. SEM micrograph shows the compatibility of ENR and PVDF in 40/60 wt% sample but agglomeration of ENR in 60/40 wt% ENR/PVDF sample was observed. The micrograph also shows the existence of pores in the composite membrane which is essential when applying the membrane for separation of gas and waste water treatment.

Keywords: composite membrane, epoxidised natural rubber, poly(vinylidene fluoride)

Abstrak

Fokus kajian ini adalah untuk menyediakan membran getah asli terepoksida (ENR)/ poli (vinilidina fluorida) (PVDF) (ENR/PVDF) menggunakan kaedah penuangan larutan dan untuk mencirikan membran ENR/PVDF menggunakan mesin ujian tensil (UTM) dan mikroskop imbasan elektron (SEM). Membran komposit ENR/PVDF telah disediakan menggunakan teknik penuangan larutan. Rintangan tegangan bertambah apabila ratio ENR bertambah didalam komposit. Mikrograf SEM menunjukkan kesesuaian ENR dan PVDF pada sampel 40/60 wt% tetapi terdapat penggumpalan ENR pada sampel ENR/PVDF 60/40 wt%. Mikrograf juga menunjukkan kehadiran liang pada membran komposit tersebut dimana ianya penting untuk diaplikasikan sebagai membran pemisahan gas dan rawatan air buangan.

Kata kunci: membran komposit, getah asli terepoksida, poli (vinilidina fluorida)

Introduction

Polymer composite is formed when two or more polymers are combined together using various methods such as internal mixture and solution blending. This combination becomes more attentive in polymer industries because it can improve the properties of individual polymer at the end of the process. Combination between thermoplastic polymer and rubber, or known as thermoplastic rubber (TPR) exhibits the properties of elastomeric materials with the possibility of thermoplastic at ambient temperature [1]. Membrane is one of the examples of materials that can

be made from composite polymer. It can be prepared by using solution casting and solvent exchange method. Membrane is a layer that allowed permeation and selectivity of fluid to happen and it usually has a porous support layer to provide mechanical strength to the membrane [2]. Many industries use membrane for the separation of wastewater and gas. The advantages of using membrane are minimum energy of processing, no addition of chemical, environmental friendly and efficient treatment [3].

The combination of epoxidised natural rubber (ENR) with thermoplastic poly (vinylidene fluoride) (PVDF) using internal mixture at high temperature has been reported before [4]. It is found that the tensile strength of PVDF decreased with increasing ENR. PVDF has the properties of high initial modulus, which is brittle and need to be applied as composite. PVDF has many applications as membranes in industries including microfiltration (MF), ultrafiltration (UF), gas separation and pollutant removal from waste water because of the chemical resistivity, thermal stability, and easy to dissolve in variety of solvent. Besides, PVDF is a semi-crystalline polymer, which has different phases of crystallinity named α (form II), β (form I), and γ (form III) [5]. Phases of crystal can be controlled in various ways; such as suitable solvent [6], temperature [7, 8], and addition of additive [9, 10]. ENR is natural rubber which has undergone the addition of epoxide group in the chains by performic epoxidation [11]. ENR is elastic good in tensile strength, oil resistance, and permeable to gas.

Solubility parameter or miscibility between solvent and solute is very important to make composite solution for membrane. The compressibility of solution will be less than that of solvent, so the solute will gain mobility and have some probability of contracting the solvent molecule [12]. Mixing of solvent between tetrahydrofuran (THF) and N,N-Dimethylacetamide (DMAC) has been reported Bagheripour et. al. [13]. THF was used to increase the phase separation time in coagulation bath and preventing macro voids. In current research, PVDF is not soluble in THF. Thus, DMAC was used to make PVDF soluble before combining with ENR. The solubility parameter of each solvent is displayed in Table 1. When the solubility parameter increases, it will be easier for the solvent to dissolve the solute and the non-solvent will be more able to diffuse in membrane casting. So, the exchange of solvent and non-solvent in coagulation bath will be faster and lead to the formation of pores.

The objectives of this paper are to prepare ENR/PVDF membrane in different ratios using solution casting method and to characterize the ENR/PVDF membrane using universal tensile machine (UTM) and scanning electron microscope (SEM). The possibility of using the ENR/PVDF composite as membrane will be discussed.

Table 1. Solubility Parameters

Solvent	**Solubility Parameter (δ)**
THF	11.44
DMAC	11.13
Water	9.4
THF/DMAC (57/43 vol%)	11.30

Materials and Methods

Materials

Epoxidised natural rubber with 50% mol of epoxidation level, ENR-50 (Mw = 640 000 g/mol) was obtained from Rubber Research Institute of Malaysia (RRIM). PVDF (Mw = 543 000 g/mol) in powder form was purchased from Sigma-Aldrich (M) Sdn. Bhd. Tetrahydrofuran (THF) (Mw = 72.11 g/mol) with 99.8% purity was purchased from Systerm Sdn. Bhd. N,N-Dimethylacetamide (DMAC) with 99% purity was purchased from Merck. Distilled water was used in coagulation bath for exchanging between solvent and non-solvent.

Membrane preparation

ENR/PVDF membrane was prepared using different ratios (0/100 wt%, 20/80 wt%, 40/60 wt%, and 60/40 wt%) by solution casting technique. ENR was swelled in THF for 24 hours before vigorously stirred until homogeneous solution was produced. At the same time, PVDF was stirred in DMAC solution in separate container until homogenous. Then, the solution was mixed and continuously stirred for 3 hours. The membrane solution was then degassed for one night to eliminate bubbles. Solution casting was done on a glass plate using a casting knife to get a membrane. After 2 minutes, the membrane was immersed in distilled water for solvent exchange to occur until the white solid membrane formed. Lastly, the sample was dried at ambient temperature and kept in desiccators before testing. The average thickness of the membrane after drying was about 0.02 mm.

Membrane characterization

The membrane had been characterized as follows:

(a) Universal tensile machine (UTM)

The tensile strength of the membrane was measured using Zwick Roell universal tensile machine, Z1.0 model at jogging rate of 50 mm/min. Membranes were tested according to ASTM D412. Prior to that, the samples were cut into the standard dumbbell shape using hollow die punch at ambient temperature. For each membrane, five replications were used and their average values were reported.

(b) Scanning electron microscope (SEM)

The surface morphology of the membrane was obtained by using variable pressure scanning electron microscope (VPSEM) with energy dispersion X-ray (EDX). The model is ZEISS EVO MA 10 (UK) with EDAX Apollo X (USA). The sample was sputter coated with gold before analysis and the magnification used was 5000×.

Results and Discussion

Figure 1 (a) is the appearance of the ENR/PVDF membrane. The colour of the membrane solution becomes dark brown when the colourless solution of PVDF was added into the ENR solution. After the sample was dried at room temperature, it turned into a transparent film as can be seen in Figure 1 (b). The thickness during casting was 0.15 mm and 0.02 mm after it dried. The solvent evaporated from the membrane, resulting to reduce of the overall thickness.

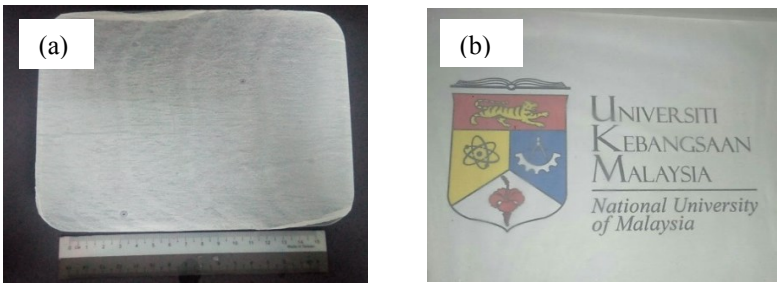

Figure 1. ENR/PVDF membrane for ratio 60/40 wt%

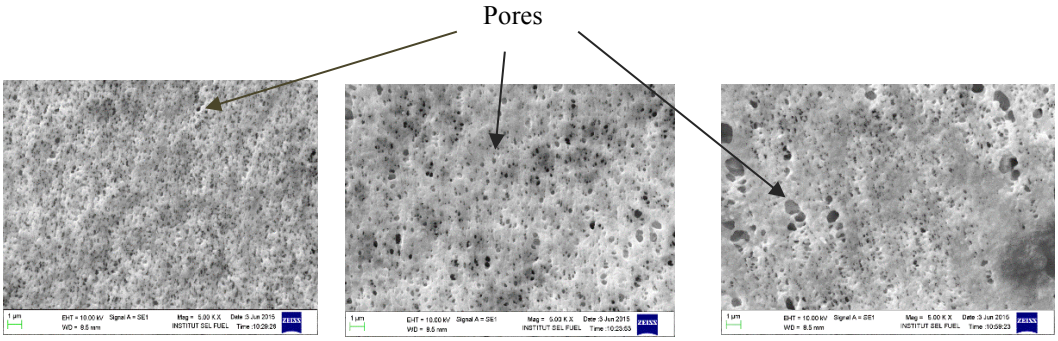
Mechanical properties



Tensile stress is the resistance of a material towards the force per unit area to the point to tear it apart. While tensile strain is deformation of a solid due to stress that applied. Table 2 shows that the tensile stress decreases with increasing ratio of ENR due to the sample cannot withstand with the force applied. The tensile strain, on the other hand increased. As mentioned before, PVDF is a brittle polymer which is easy to tear apart. Decreasing the ratio of PVDF caused the tensile strain to increase and the addition of ENR introduced a greater chain movement in the membrane. Molecular chain of the sample kept it in metastable state between the amorphous and crystalline states.

Table 2. Tensile stress and tensile strain for ENR/PVDF membrane with different composition

ENR/PVDF Membrane (wt%)	Tensile Stress (MPa)	Tensile Strain (%)
20/80	3.92	8.26
40/60	1.72	14.82
60/40	1.40	15.90

Surface morphology

Figure 3 shows the physical images of ENR/PVDF membrane with different compositions of ENR and PVDF. The micrographs show that pores are present on the surface of all membranes. Random pores were formed due to the property of PVDF and the exchange between solvent and non-solvent during solvent-exchange process. The average pore size for the membranes is shown in Table 3. The pore size increased with the increase ratio of ENR which proven that the addition of ENR caused more chain movement which caused bigger pores on the membrane. This is in a good agreement with previous reported study [14]. For the 60/40 wt% sample (Figure 3c), it can be seen that surface is not even which is due to the agglomeration of ENR in the composite. However, the same problem was not observed on 40/60 wt% (Figure 3b) which make it suitable to be applied as membrane as pores and high tensile strain were observed.

(a) 0/100 wt% (b) 40/60 wt% (c) 60/40 wt%

Figure 3. Scanning electron micrographs of surface for ENR/PVDF at magnification × 5000

Table 3. Average pore sizes of the ENR/PVDF membranes

ENR/PVDF Membrane (wt%)	Average pore size (nm)
0/100	89.32 – 268.9
40/60	157.9 – 625.7
60/40	271.7 – 861.9

Conclusion

As conclusion, ENR/PVDF membrane with different ratios can be prepared by using solution casting method. The thickness of the membrane during casting was 0.15 mm and the average thickness after dried was 0.02 mm. SEM micrographs showed the agglomeration of ENR in the ENR/PVDF solution with the ratio of 60/40 wt% because of

the immiscibility between ENR and PVDF but the 40/60 wt% membrane did not show any incompatability. The increasing ratio of ENR in PVDF had caused the tensile strain to increase and the tensile stress to decrease. Due to the porosity and the tensile property of 40/60 wt% ENR/PVDF composite, it has the potential to be applied to as membrane for gas separation and pollutant removal from wastewater.

Abstract

The effect of chemical treatment on the chemical composition, functional group, crystallinity and thermal stability of palm oil empty fruit bunch (EFB) fiber were investigated. Chemical treatment was conducted by treating EFB with 10% sodium hydroxide aqueous solution and 2% hydrogen peroxide aqueous solution separately. The results indicated that chemical treatment managed to affect chemical composition of the fiber. FTIR analysis proved the removing of hemicellulose and lignin during the treatment based on the peak disappearance around 1700 cm^{-1} and 1600 cm^{-1}. The XRD diffractogram showed an increase in crystallinity index of the fiber especially for NaOH treatment. Removal the amorphous component of the fiber influences the thermal degradation of the fiber.

Keywords: empty fruit bunch, chemical treatment, thermal properties

Abstrak

Kajian ke atas serabut tandan kosong sawit (EFB) telah dijalankan untuk melihat kesan rawatan kimia terhadap komposisi serabut, kumpulan berfungsi, kehabluran dan kestabilan terma serabut. EFB telah menjalani rawatan kimia menggunakan 10% larutan akues natrium hidroksida dan 2% larutan akues hidrogen peroksida secara berasingan. Hasil kajian menunjukkan rawatan kimia memberi kesan terhadap komposisi kimia serabut. Melalui analisis spektroskopi FTIR, penyingkiran hemiselulosa dan lignin telah berlaku semasa rawatan dijalankan. Keadaan ini dibuktikan melalui kehilangan puncak serapan sekitar 1700 cm^{-1} dan 1600 cm^{-1}. Difraktogram XRD pula menunjukkan peningkatan dalam indek kehabluran bagi serabut yang menjalani rawatan NaOH. Penyingkiran komponen amorfus didapati mempengaruhi degradasi terma serabut EFB.

Introduction

Common pretreatment for lignocellulose is to distort the lignocellulosic complex structures of the fiber. The aims of fiber pretreatment are to get rid of lignin and hemicellulose for cellulose extraction and to increase enzyme accessibility; to reduce the crystallinity of cellulose; to increase the porosity of the lignocellulosic materials and for surface modification. Fiber pretreatment can be classified into several categories; that are physical, chemical, biological or a combination of all these methods [1, 2].

Caustic treatment using base aqueous solutions such as sodium hydroxide (NaOH) is one of the most used treatments studied by researchers [1]. NaOH helps the removal of waxes, hemicellulose, pectin and some lignin

monomers [3, 4]. This treatment disturbs the hydrogen bonding in cellulose and hemicellulose, breaking the ester linkages that crosslink lignin and xylan, and deprotonation of phenolic groups [5]. Treatment with high concentration of alkali may rearrange or change the crystalline structure from cellulose type I to cellulose type II [3]. Hydrogen peroxide (H_2O_2) is an oxidizing agent in which it has the ability to decolorize the fiber by removing lignin, hemicellulose and surface impurities. H_2O_2 is always considered as a base even though it is a weak acid (pH ~ 6.2) and often used as bleaching agent in pulp and paper industry. It is often being used on lignocellulose such as oil palm empty fruit bunch fiber (EFB), kenaf, rice husk, bagasse and many others. Different treatments cause various effects to the fiber in term of degree of impurities removed and chemical composition. These also affect the thermal stability of the fiber as reported by previous researchers [6, 7, 8].

EFB as the main feedstock in this research has been intensively studied for decades especially when Malaysia is one of the main producers of palm oil. EFB is the by-product generated after oil refining process. Approximately 400 g of EFB is produced from each bunch of oil palm fresh fruit and it leads to abundancy of EFB biomass [9]. At present, shredded EFB has already been used commercially since it offers several advantages in terms of availability, biodegradability and cost [10]. EFB becomes one of the important lignocelullosic materials and has extensively been used in wood and furniture industry as reinforcement of polymer-based composites. Generally EFB contain 45.0% cellulose, 32.8% hemicellulose and 20.5% lignin [11]. Cellulose is the main component of the cell wall that gives strength to plant. It consists of long carbon chains of polysaccharide. Hemicellulose is a branched polysaccharide containing sugar monomers with shorter chains and various conformations. It exists together with cellulose and lignin in the plant cell wall [12]. On the other hand, lignin is a complex polymer consists of three phenylpropane units which are cross-linked together by alkyl-aryl, alkyl-alkyl, aryl-aryl ether bonds and carbon-carbon bonds [5, 13, 14].

The thermal behavior of the polymer can be explored using thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). TGA consist of TG curves and DTG curves. TG curve states the decomposition of polymer based on weight loss as a function of temperature while DTG curve reveals the corresponding rate of weight loss. DSC is a thermo analytical technique to determine the thermal transitions of polymer [15, 16]. Our research goal is to investigate the influence of treatment on the thermal characteristic of EFB. Information regarding thermal degradation of natural fiber is considered important for processing temperature in applications related to development of flame retarded products, fiber-reinforced composite and many others [17, 18].

Materials and Methods

Materials

EFB fiber was obtained from Sri Ulu Langat Palm Oil Mill Sdn Bhd, Selangor, Malaysia. It was ground and sieved to obtain a size range of 250 – 315 µm. It was then dried in the oven at 105 °C for 24 hours and was kept in an air-tight container. Sodium hydroxide pellet (NaOH, ~99% purity) and glacial acetic acid (CH_3COOH, 99.8 wt.%) were supplied by Merck (M) Sdn Bhd, Selangor, Malaysia. Hydrogen peroxide (H_2O_2, 30 – 32% purity) was manufactured by Friendemann Schmidt Chemical, Germany.

Fiber treatment

EFB fiber was immersed in 10% NaOH aqueous solution at a ratio of 1:20 at room condition. After 48 hours, the mixture was then filtered through Büchner funnel and rinsed with diluted CH_3COOH until it reached pH 7. The fiber was then dried in an oven at 105 ^{o}C for 24 h following ASTM D2016-65 (Methods of test for moisture content of wood). However, for the H_2O_2 treatment, the EFB fiber was refluxed with 2% H_2O_2 aqueous solution at a ratio of 1:25. The treatment was conducted at 60 – 70 °C with continuous stirring for 3 hours. The mixture was then filtered; rinsed several times until it reached pH 7 and dried in the oven. The treated fibers were labelled as NTF and HTF respectively and were stored in a drying chamber for further analysis.

Characterization

The physicochemical analyses carried out on the samples were determination of moisture content (TAPPI T208 om-84), water solubility (TAPPI T207 om-81), and determination of ethanol-benzene extractives (TAPPI T204 cm-97), holocellulose [19], α-cellulose (TAPPI T203 om-83) and Klason lignin content (TAPPI T222 om-83). Fourier transform infrared spectroscopy (FTIR) analysis was conducted on a spectrophotometer model Perkin Elmer

Spectrum 400. Each spectrum was recorded in a frequency range of 4000 to 650 cm^{-1} using ATR-FTIR technique. The crystallinity of the sample was examined using Bruker X-ray diffractometer model D8-Advance with Cu Kα radiation (λ= 0.15406 nm) and the data were recorded every 0.025° (2θ) within the range of scattering angles from 5° to 60°. Thermogravimetric analysis (TGA) was performed using Perkin Elmer thermal analyzer. The analysis was operated under nitrogen gas atmosphere at a constant heating rate of 10 °C/min heating rate. The glass transition temperatures (T_g) of the samples was carried out using Mettler Toledo differential scanning calorimeter (DSC) in nitrogen gas atmosphere. The samples were first heated to 100 °C to eliminate moisture. Then, the samples were cooled and reheated to 250 °C at a constant heating rate of 10 °C/min.

Results and Discussion

Chemical composition

Lignocellulose is composed of three main components which are cellulose, hemicellulose and lignin. The composition of these three components may differ from one fiber to another. Data of the compositional analysis conducted onto the untreated EFB (UTF), NaOH-treated EFB (NTF) and H_2O_2-treated EFB (HTF) is presented in Table 1.

UTF contained 45.3% cellulose, 35.6% hemicellulose and 17.7% lignin. Generally, treatment with base solution was meant to remove cementing materials exist in the fiber such as lignin, hemicellulose, wax and oil [20]. Upon treatment, NaOH has removed a significant percentage of hemicellulose thus increasing the cellulose content for NTF compared to HTF. The percentages of cellulose, hemicellulose and lignin of HTF were 47.9%, 38.4% and 10.5% respectively. This indicates that hydrogen peroxide was not an efficient delignification agent for the removal of lignin and hemicellulose. On the other hand, NaOH worked effectively as a delignification agent where the lignin content decreased from 17.7 % in the UTF to 9.0% in the NTF.

Table 1. Compositional analysis of the untreated EFB (UTF), NaOH-treated EFB (NTF) and H_2O_2-treated EFB (HTF)

Samples	Composition percentage (%)			
	Cellulose	Hemicellulose	Lignin	Others
UTF	45.3	35.6	17.7	1.4
NTF	62.4	19.9	9.0	8.7
HTF	47.9	38.4	10.5	3.2

Fourier transforms infrared spectroscopy

The structural changes taking place after treatment was determined from the analysis of the FTIR spectra of UTF, NTF and HTF as shown in Figure 1. A peak observed at the region 3600-3200 cm^{-1} indicating hydroxyl (O–H) group in phenolic and aliphatic structures [21]. Peaks at 2850 $cm^{-1}$and 2930 cm^{-1} are attributed to C-H stretching vibration of methyl and methylene group [22]. After the treatment, peak at 2850cm^{-1} diminished due to effect from the reduction of methyl and methylene of cellulose [23]. Differences between these spectra can be observed from the loss of absorption peak at the region 1705-1750 cm^{-1}. These peaks corresponds to the C=O stretching of carbonyl groups in uronic acids or acetyl in hemicellulose [24]. According to Alemdar and Sain (2008), these peaks may also indicate the ester linkage of the carboxylic group in the ferulic and *p*-coumeric acid of lignin and hemicellulose. For NTF spectra, this peak was completely disappeared while the intensity of this peak decreased for HTF spectrum. Both of these related to the removal of lignin and hemicellulose during the treatment [25]. A decrease in the intensity was observed at 1509–1609 cm^{-1} associated to C=C aromatic skeletal vibrations and it was also related to delignification [26]. Differences between NTF and HTF spectra were identified based on peak intensity at specific peaks. At peak around 3300 cm^{-1}, HTF spectrum exhibited low peak adsorption indicating that H_2O_2 treatment may cause more cellulose degradation [23]. FTIR spectra for all samples showed a peak around 898 cm^{-1} which is attributed to the presence of *β*-glycosidic linkage between glucose units in cellulose.

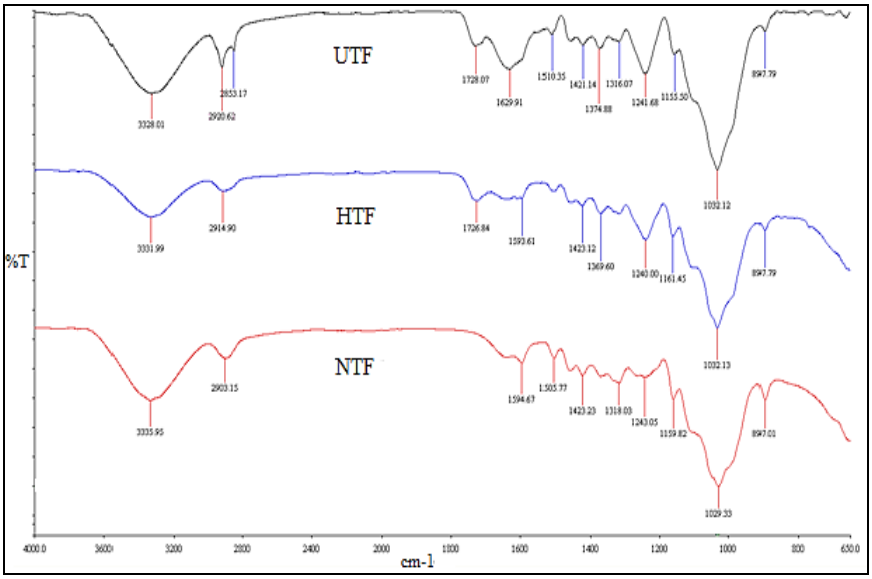

Figure 1. FTIR spectra of UTF, NTF and HTF

X-ray diffraction

X-ray diffraction (XRD) analysis was conducted onto all samples. The diffractogram are as shown in Figure 2 whereas Table 2 tabulated the crystallinity index (CrI) of the samples. Lignocellulose fiber consists of amorphous and crystalline regions that were contributed by the constituents in the fiber [27]. The crystallinity index (CrI) of the sample was calculated using the following equation 1 [28].

$$\text{CrI}, \% = \frac{(I_{002} - I_{AM})}{I_{002}} \quad (1)$$

where I_{002} is the maximum intensity of the lattice diffraction at about $2\theta \cong 22.4°$ and I_{AM} is the intensity attributed to the amorphous portion of sample at $2\theta \cong 18.6°$. From Figure 2, all samples showed similar XRD patterns with two significant peaks at 2θ position around 16.0° and 22.6° contributed by the crystalline regions of cellulose type I [29].

The peak around 22.6° for NTF tends to be more narrow compared to UTF. This is attributed to the increase in crystallinity index of the fiber (46.2 compared to 43.0). It might be due to the removal of amorphous structure of hemicellulose and lignin during the treatment [27]. This situation is parallel to the reduction in the percentages of hemicellulose and lignin (Table 1). Upon treatment, the extracted cellulose is in the form of Cellulose Type I (main peak occurred to be unchanged).There is greater tendency for the transformation of crystalline state from cellulose I to cellulose II to happen when treated with high concentration alkaline solution [20]. However, XRD diffactrograms of HTF and UTF showed similar diffraction pattern with slight reduction in peak intensity of HTF indicating that this treatment has not made any significant changes in the crystal structure of the cellulose [29].

Thermogravimetric analysis

The TG and DTG curves obtained for UTF, NTF and HTF are presented in Figure 3. The total weight loss was 70.6% for UTF, 81.8% for NTF and 89.3% HTF. The weight loss of the samples is related to the thermal degradation of hemicellulose, cellulose and lignin [7]. The DTG thermogram shows the derivative weight loss as a function of time. The peak observed around 100°C for all sample was connected to moisture loss.

A shoulder observed around 270 °C in the DTG peak of UTF (Figure 3(a)) was mainly related to the decomposition of extractives and hemicelluloses [30]. At this temperature range, the cleavage of glycosidic linkages of cellulose may occur as reported by Deepa et al. (2011) [7]. Major weight loss for UTF occurred around 330°C, contributed by the degradation of cellulose. The weight loss of lignin occurs above 350 °C [7].

The disappearance of a shoulder peak around 270 °C indicated the removal of hemicellulose and extractives upon NaOH treatment. This was confirmed by the FTIR results with the absence of carbonyl group representing the hemicellulose [4]. The decomposition of cellulose for NTF (Figure 3 (b)) was slightly shifted to 345 °C compared to UTF. This may be influenced by the arrangement of the molecular structure of the cellulose. Higher crystallinity means more heat is required to experience thermal degradation [4]. HTF showed two significant peaks in the DTG thermogram. The lower peak (Figure 3 (c)) at 300 °C could be associated to the trace of hemicellulose present after the treatment. A clear sharp peak around 370 °C indicated the degradation of crystalline cellulose. In the study of Brebu and Vasile, lignin thermally decomposed over a broader temperature range of 200 – 500 °C due to different thermal stabilities of various oxygen functional groups from its structure. Thus its scissoring occurred at different temperatures [32].

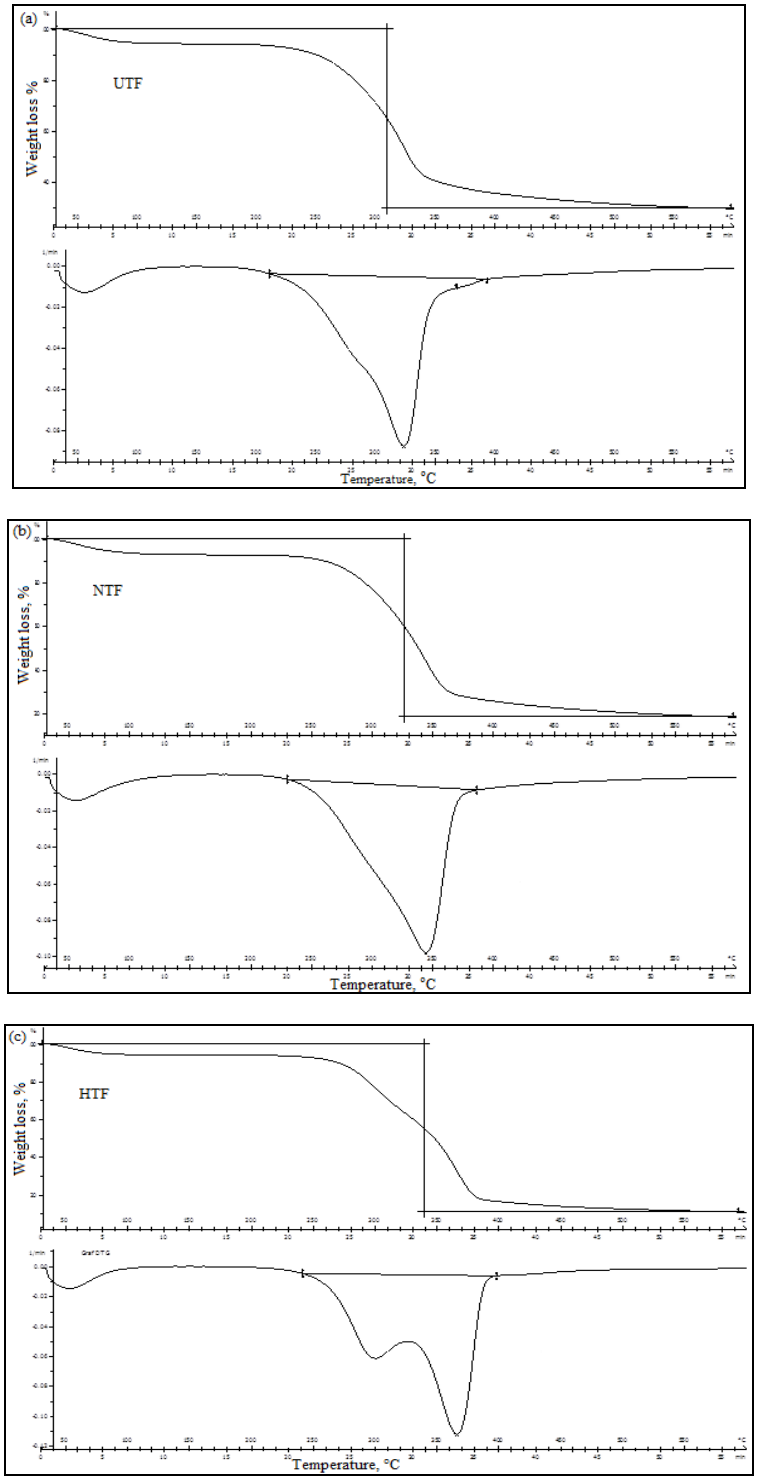

Figure 3. TG and DTG curvesof UT, NTF and HTF

Differential scanning calorimetry

Glass transition temperature or T_g is temperature at which the polymer undergoes a phase change that is from a glassy state a rubbery state. Figure 4 shows DSC thermograms of the samples. T_g of the sample shifted to higher temperature to 186.7°C (NTF) and 185.6°C (HTF) after treatments. These treatments have greater tendency to stabilize the cellulose structure where there was an increase in cellulose crystallinity and hydrogen bonding between the closely packed cellulose chains. More energy is needed to break down the crystalline structure and to cleave the macromolecules for phase transition [31].

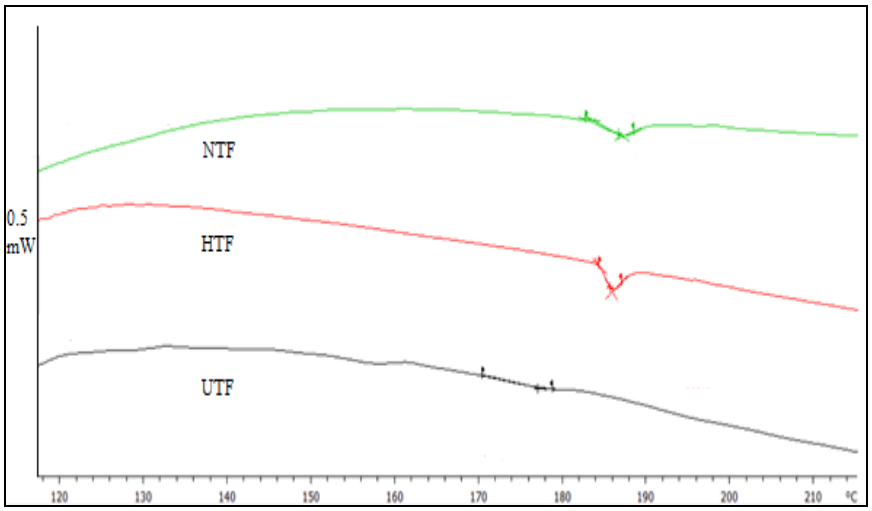

Figure 4. DSC thermograms of UTF, NTF and HTF

Conclusion

The influence of fiber treatments by acid-base approach on the chemical composition, structural and thermal stability has been investigated. Treatments caused the removal of surface impurities, lignin and hemicellulose. Alkaline treatment gave more effect in removing lignin and hemicellulose and exposing more cellulose. Thermal study reveals that thermal stability of fiber increased upon treatment. The thermal stability of the fiber was much related to the composition of the fiber.

Abstract

This paper describes the effect of protein denaturants namely, urea and sodium dodecyl sulphate (SDS) in the deproteinisation of high ammonia natural rubber latex (HA-NRL). It had been shown that latex proteins were reduced more in the presence of urea alone (48%) than in the presence of SDS (18%). The synergistic effect when both urea and SDS were used in the latex deproteinisation attributed to the higher protein removal efficacy (55%). Higher zeta potential value was observed when only SDS was used, suggesting higher colloidal stability. Environmental Scanning Electron Microscopy (ESEM) revealed that without SDS, the use of urea single-handedly in the deproteinisation process promoted aggregation of latex particles, possibly due to the dismissal of latex proteins which helped to stabilise latex colloidal. Thus, it is most likely that urea serves as a protein unfolding agent during latex deproteinisation process, while SDS functions as a latex stabiliser with no significant effects on latex proteins discharge.

Keywords: urea, sodium dodecyl sulphate, deproteinisation, zeta potential, environmental scanning electron microscopy

Abstrak

Kertas kerja ini menghuraikan kesan bahan-bahan pengubah sifat protein iaitu urea dan natrium dodekil sulfat (NDS) dalam penyahprotein lateks getah asli tinggi ammonia (HA-NRL). Ia telah menunjukkan bahawa protein lateks lebih banyak dikurangkan dengan kehadiran urea sahaja (48%) berbanding dengan kehadiran NDS sahaja (18%). Keberkesanan penyingkiran protein yang lebih tinggi (55%) mungkin telah disebabkan oleh kesan sinergi apabila kedua-dua urea dan NDS digunakan di dalam penyahprotein lateks. Nilai keupayaan zeta yang tinggi diperhatikan apabila hanya NDS digunakan, menunjukkan kestabilan koloid yang lebih tinggi. Pengimbas Persekitaran Mikroskopi Elektron (ESEM) menunjukkan bahawa tanpa NDS, penggunaan hanya urea dalam proses penyahprotein menyumbang kepada kesan pengagregatan zarah lateks, kemungkinan disebabkan oleh penyingkiran protein lateks yang membantu dalam kestabilan koloid lateks. Oleh yang demikian, besar kemungkinan fungsi utama urea semasa proses penyahprotein lateks adalah sebagai ejen pembuka protein manakala NDS berfungsi sebagai penstabil lateks tanpa kesan ketara pada penyingkiran protein lateks.

Kata kunci: urea, natrium dodekil sulfat, penyahprotein, keupayaan zeta, pengimbas persekitaran mikroskopi elektron

Introduction

Natural rubber (NR) latex in general can be defined as a material that consists stable dispersion of polyisoprene rubber (hydrocarbon) and a large number of non-rubber constituents mainly carbohydrates, lipids, and proteins in an

aqueous serum phase. These non-rubber constituents are dissolved, freely suspended in the aqueous phase or absorbed on the surface of rubber particles [1-3]. During latex concentrate processing through centrifugation for instance, most of the smaller latex particles are removed together with the non-rubbers present in the serum. It is known that not all non-rubbers can be removed completely during the centrifugation process hence commercially supplied NR latex still contains considerable amounts of non-rubbers.

In its native state, NR latex contains about 6% of non-rubbers and the content is reduced to more than half during processing. However, the presence of non-rubbers is regarded imperative not only in conferring stability of rubber latex but also in governing the properties of end products. Any modification in the rubber composition may result in deterioration of properties especially in vulcanisation and cure characteristics [4]. The presence of proteins and other non-rubber linkages are also presumed to provide outstanding mechanical properties of rubber due to strain-induced crystallisation characteristic [5].

On the other hand, the presence of proteins is responsible for certain undesirable properties in NR for instance poor creep, storage hardening, high moisture absorption and poor stress relaxation behaviour [6-7]. Detrimental effects of proteins present in NR were reported in several studies [8-10]. The high moisture uptake in NR is presumably due to interaction of proteins and phospholipids at the terminal chains of rubber with water (moisture). It is generally established that the hardening phenomenon of rubber is attributed to the inter-chain crosslink formation. Proteins and phospholipids at the chain-ends of rubber molecules may interact with water under ambient condition, leads to disruption for branching points due to hydrogen bonding. Thus, when water is removed from the rubber, both functional groups at the terminal chains of rubber will undergo chain-branching and crosslinking which contribute to the gel formation during storage hardening behaviour [10].

The development and production of low protein latexes and products are an important research area ever since the emergence of allergy issues attributed to the latex proteins. Allergic responses are triggered by extractable proteins present in NR latex products especially rubber gloves. Malaysia as one of the largest exporters of latex products is affected by the negative perception of NR latex. Therefore, research in NR latex deproteinisation has continued to balance out the desirable properties which associated with rubber proteins and at the same time to eliminate the adverse proteins.

Generally, proteins can be easily destabilised and its destabilisation is determined by a balance of many competing factors. By nature, a functional native protein is in a folded (F) structure conformation [11-12] and when it loses the conformation (F), it ceases to function. The unfolding (U) process of proteins is called protein denaturation. The stability of protein can be easily affected by slight changes in temperature, pressure or solvent conditions. For instance, the presence of even a small organic molecule in aqueous solution can have profound effect on protein stability, structure, and function. In nature, this occurrence enables the proteins to either retain its stability or promote destabilisation indirectly by controlling the conformational equilibrium between folded (F) to the unfolded (U) structures.

Deproteinisation of NR latex can be achieved using protein denaturants. Urea has a long good reputation as protein denaturant owing to its ability to denature proteins by causing it to unfold. This denaturant has been described elsewhere [13] to produce low protein NR latex. Another common chemical used in latex deproteinsation is sodium dodecyl sulphate (SDS) which is an anionic surfactant [$CH_3(CH_2)_{11}OSO_3Na$]. Owing to the synergistic effect between both chemicals, effective proteins removal was described [14]. It is proposed in urea-SDS protein denaturation mechanism (Figure 1), urea may unfolded the proteins while SDS binds onto the surface of unfolded proteins and imparts negative charges, resulting in the protein to have higher net negative charge compared to its previous state. This phenomenon then creates electrostatic forces which cause the proteins to unfold into rod like shape. The unfolded proteins are then removed during the centrifugation process.

To the best of our knowledge, further elucidation on individual functions of urea and SDS or the combination of both during NRL deproteinisation is obscured hence creating a gap in knowledge. Thus, the aim of this paper is to explicate and address aforesaid gap in scientific knowledge.

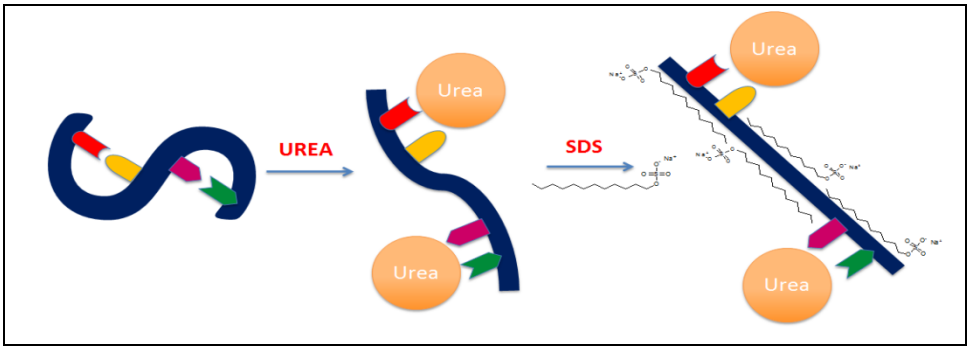

Figure 1. Proposed mechanism on simple protein denaturation via urea – SDS combination treatment

Materials and Methods

Preparation of deproteinised latex

Commercial high ammonia NR latex (HA-NRL) was used for deproteinisation. HA-NRL was incubated with 0.1% urea (w/w) in a mixing vessel under continuous stirring for 1 hour prior to centrifugation. Centrifugation was carried out using the Beckman Coulter Ultracentrifuge Model Optima L-100K at 9,000 rpm and 15 °C. After centrifugation, the cream fraction was collected and redispersed with distilled water followed by addition of SDS 1.0% (w/w). The redispersed cream fraction was stirred for 30 minutes and centrifugation was carried out for the second time. The resulting cream fraction was again collected and redispersed with distilled water to 30% total solid content. The same procedure was repeated for latex treated using 1.0% SDS only and a combination of 0.1% urea with 1.0% SDS respectively.

Characterisation

The protein content in latex samples was determined using the Kjeldahl method which measured the total nitrogen content. About 0.1 g of sample was first weighed and digested in a micro Kjeldahl flask, followed by steam distillation. The distillation result was titrated with concentrated sulphuric acid. The nitrogen content was determined in triplicates and calculated from the titration values.

Particle size and zeta potential of latex were determined using the Brookhaven 90Plus/BI-MAS ZetaPlus. The latex was diluted to 0.01% (w/w) before use. For the Environmental Scanning Electron Microscopy (ESEM), samples were prepared by adding approximately a drop of latex into 1 ml distilled water in Eppendorf tubes. The mixtures were centrifuged and the supernatants discarded. The latex samples were then stained with 1% osmioum tetroxide before viewing under ESEM.

Results and Discussion

Protein contents and zeta potentials

The proteins content and zeta potential characteristic of HA-NRL which were treated with different combinations of either urea, SDS or both denaturants (samples A, B, and C) are tabulated in Table 1. It is evident that the deproteinisation process resulted in a considerable reduction in protein content of the treated latexes.

Evidently, latex treated with urea (sample A) demonstrated approximately 49% protein removal compared to the untreated HA-NRL. In the presence of SDS alone (sample B), only 18% reduction in proteins content was seen. This suggests that SDS might have smaller role and capacity to denature proteins compared to urea.

Urea is found capable to denature proteins by binding onto the protein peptide backbone via hydrogen bonding to the polar moieties of proteins [15-17]. It is also reported elsewhere [18] that urea readily promotes solvation of protein hydrophobic groups whereby partial solubility of hydrocarbon was seen in the presence of aqueous urea. These elements could have contributed to the greater removal of latex proteins, resulted when urea was used, in comparison to SDS in the present study.

Table 1. The effect of protein denaturants on zeta potential and protein content

Treatments	Sample Reference	Proteins Content (%)	Zeta Potential (mV)[1]
High ammonia natural rubber latex (control)	HA-NRL	3.88	-40.78
HA-NRL treated with 0.1% urea	A	1.99	-25.85
HA-NRL treated with 1.0% SDS	B	3.18	-31.32
HA-NRL treated 0.1% urea and 1.0% SDS	C	1.75	-46.32

[1]Zeta potential measured at pH10

From the perspective of SDS, interaction of the anionic surfactant with proteins may also cause denaturation via high affinity binding. SDS is an anionic surfactant which may bind to proteins via sulphate group and positively charged amino side chain, or between the alkyl chain and hydrophobic side chain [19]. An earlier study [19] suggested that the protein unfolding process via SDS might proceed via two different modes which are closely linked to the changes in the micellar structures. That study also established that concentration of surfactants played an important role in the degree of unfolding of the proteins.

This present study shows that the combination of both denaturants resulted in highest protein removal efficacy (55%). However, this is only an increment of about 6% compared to latex treated with urea alone. This slight increment in urea-SDS protein removal indicates a synergistic effect from the two denaturants. Urea may inhibit the effectiveness of SDS to unfold proteins as it is found that in the presence of urea, the SDS hydrocarbon tails readily solvate, aggregation number of SDS micelles reduced and CMC value of SDS increased [18]. Therefore, to further enhance protein removal efficiency, it is suggested that higher than 1% of SDS is required.

With regard to electrostatic stability, the lower protein content resulted from deproteinisation of HA-NRL with urea caused a substantial reduction in zeta potential value from -40.78mV to -25.85mV. Zeta potential analysis gives an indication on surface charge behaviour on rubber particle surface, thus distinct chemical nature of the absorbed layers on the surface of rubber particle is reflected in the difference in the zeta potential value consequently the colloidal stability of natural rubber latex. Adsorbed proteins on the surface of latex particle are reported to contain both acidic and alkaline functional groups that carry positive and negative charge respectively [20]. HA-NRL is composed of phospholipids, carbohydrates, proteins and other non-rubber constituents which contribute charge species that gives high negative zeta potential value [3]. Perturbation of the proteins layer by urea might compensate the surface charge hence compressed the diffuse layer and subsequently reduced the negative zeta potential value [20].

According to the theory of adsorption isotherm [21], charged surfactant like SDS will adsorb onto the surface of latex particles. Reduction in zeta potential value was observed when HA-NRL was treated with 1% SDS. Zeta potential of latex treated with SDS was better than latex treated with urea, suggesting that the former has better colloidal stability than the latter. Interestingly, a higher zeta potential value was observed for sample C which was treated with urea in the presence of SDS whereby its zeta potential surpassed that of HA-NRL alone. This again suggests the synergistic effect of both denaturants when they are used together in deproteinisation of latex.

Factors influencing particle size distribution

Figure 2 depicts particle size distribution of samples HA-NRL, A, B and C. Monomodal size distribution was observed for all samples. Similar size distribution was observed for samples HA-NRL and A, while B and C showed bigger size distributions with sample B recorded the biggest result. Although the proteins content and zeta potential value of sample A were prominently reduced, the particle size distribution was not affected much compared to control (HA-NRL). The narrower and obvious shift to bigger size distribution for sample B (treated with 1.0% SDS) could be due to encapsulation of SDS onto the latex particles which resulted in interference and restricted penetration by photon correlation spectroscopy used in the size measurement method. Moreover due to the

function of SDS as stabiliser, a more distinct and stable domain of rubber particle was formed which restricted inter-particle fusion. This explains the reason why particle size distribution for sample B is narrower and shifted to bigger particle size range.

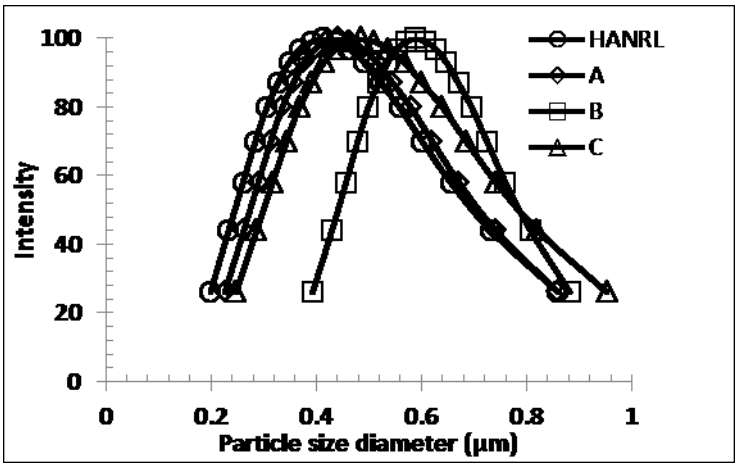

Figure 2. Effect of individual chemical treatment and combination of both chemicals on particle size diameter of deproteinized NRL (A =HANRL treated with 0.1% urea, B = HANRL treated with 1.0% SDS, and C = HANRL treated with 0.1% urea and 1.0% SDS)

Morphological changes in the treated latex samples were studied using ESEM as shown in Figure 3. The micrographs were obtained at 15,000 to 21,000 magnification levels. As observed, rubber particles for all samples exhibited nearly spherical shape. HA-NRL showed strong aggregation of rubber particles with large variation in the size distribution. After the centrifugation process, the smaller rubber particles were removed and the latex particles sizes became more uniformed (Figure 3b and 3d). In the presence of urea alone (Figure 3b), the particles were observed to favour particle inclusion; this may be due to the weakening of the hydrophobic forces when the proteins layers were depleted. In the presence of SDS, the degree of aggregation was less (Figure 3c and 3d). This was due to SDS role which served as a protective layer substituting function of the eliminated proteins. Hence, rubber particles in the presence of SDS were able to preserve their distinctive shape and remained well separated.

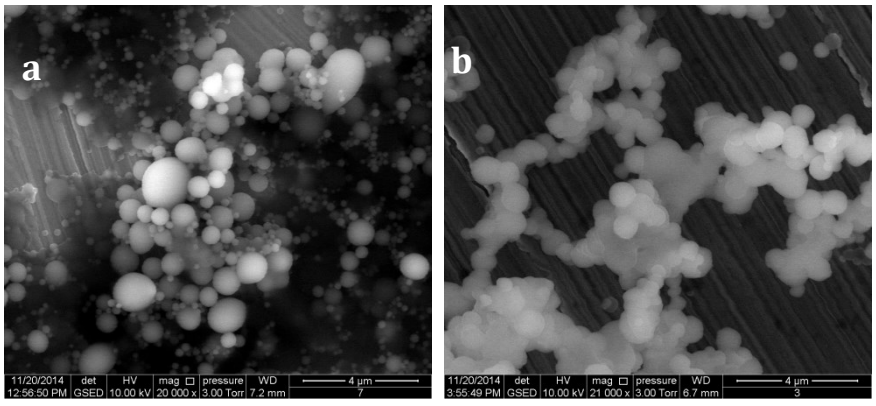

Figure 3. ESEM morphological image of a) HANRL, b) HANRL treated with 0.1% urea, c) HANRL treated with 1.0% SDS and d) HANRL treated with 0.1% urea and 1.0% SDS

It is worth to notify that the primary reason of conducting ESEM analysis is to understand and to have a quick look on the behaviour of rubber particle in a wet condition especially during deproteinisation. This method allows us to gather more information on their shape rather than sizes. The number of particle measured in ESEM is normally small hence it is difficult to collect enough data to give more reliable particle size result. Moreover, it is hard to determine whether or not the particles are merged and aggregated and they will often consider as bigger particle size.

Schematic illustrations on the deproteinisation process using urea, SDS and urea in presence of SDS are shown in Figure 4. It is hoped that this figure will clarify and demonstrate the mechanism of how the rubber particles assemble during deproteinisation process using urea and SDS. The removal of proteins from the surface of rubber particles by urea may create weakens hydrophobic forces of protein layer [15, 22], hence resulting to the merging of rubber particles with adjacent particles (Figure 4a). However, as mentioned earlier, it is uncertain whether the particles are permanently attached together or just in contact with adjacent particle. Treatments with urea will not break the proteins but serves as denaturants which facilitates the removal of proteins from NRL through centrifugation and washing process [23]. When only SDS was used during deproteinisation process, the particle seemed to have an orderly arrangement with a distinct particle shapes and without the particles merging effect (Figure 4b). Interaction of SDS surfactant with NRL surface can be demonstrated as strong interacting systems [24] thus enhance the colloidal stability of rubber particles. This phenomenon will keep the particles away from another therefore particles are well separated. Again, less aggregation was observed when urea and SDS were used mutually (Figure 4c), suggesting the particles protective layer imparted by adsorption of SDS on rubber particle surface.

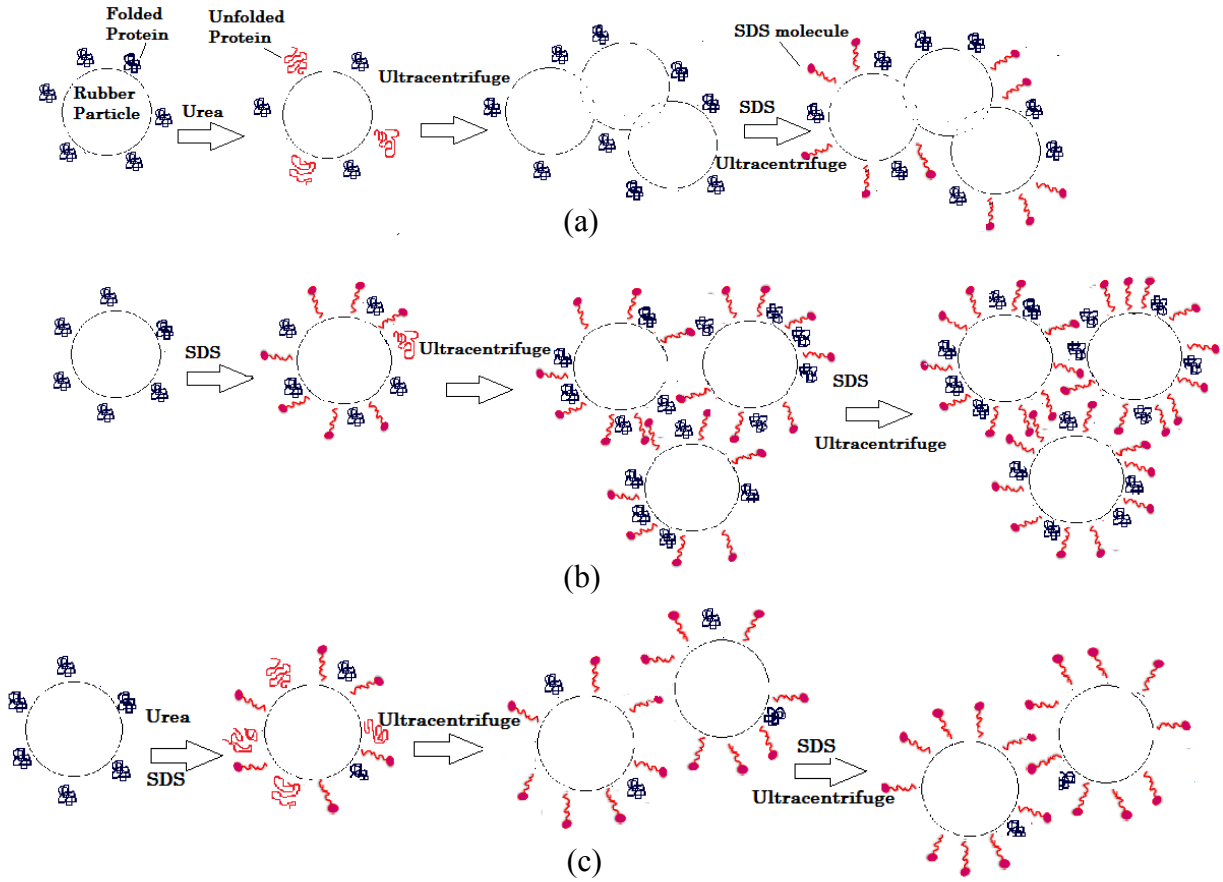

Figure 4. Proposed mechanism and morphological changes during deproteinisation of NRL using a) urea b) SDS and c) urea in the presence of SDS

Conclusion

The function of each denaturant used in the deproteinisation of NRL was examined. This study shows that urea serves as a protein unfolding agent, eliminating the rubber protein protective layer and consequently disrupts the latex colloidal stability, hence promoting particle fusion. The presence of SDS improves the colloidal stability of latex by preserving the colloidal shape of particle and restricting fusion of particle via encapsulation of the rubber particles. This study suggests that in the deproteinisation process, it is most likely that urea functions as a protein unfolding agent whilst SDS serves as a latex stabiliser without distinct effect in the removal of latex proteins.

Abstract

Extracted cellulose from oil palm empty fruit bunch fiber (OPEFB) was subjected to acid hydrolysis in producing microcrystalline cellulose (MCC). The acid hydrolysis was conducted using 1 % (v/v) sulfuric acid (H_2SO_4) at varying temperatures of 120, 130 and 140 °C for an hour. The relationship between the thermal behavior and physical properties was investigated by thermogravimety (TGA/DTG) and differential scanning calorimetry (DSC) as well as x-ray diffractometry (XRD). The hydrolyzed MCC at 120 °C (MCC_A) showed the highest thermal stability temperature and percentage of crystallinity at 250 °C and 65.07% respectively. However, hydrolyzed MCC at 130 °C (MCC_B) and 140 °C (MCC_C) exhibited low thermal stability temperature at 225 °C and 220 °C respectively. The percentage of crystallinity obtained for MCC_B and MCC_C was 61.18% and 60.64% respectively. This study revealed that the degree of crystallinity for cellulose has positive impact on the thermal degradation temperature of the OPEFB-MCC.

Keywords: acid hydrolysis, microcrystalline cellulose, oil palm empty fruit bunch, thermal behavior

Abstrak

Selulosa yang diestrak dari serabut tandan kosong sawit (STKS) dihidrolisis menggunakan asid bagi menghasilkan mikrokristal selulosa (MKS). Hidrolisis berasid dijalankan dengan menggunakan 1 % (v/v) asid sulfurik (H_2SO_4) pada suhu yang divariasikan iaitu 120, 130 dan 140 °C selama sejam. Hubungan antara sifat terma dan sifat fizikal dikaji berdasarkan analisis termogravimetri (TGA/DTG), anlisis kalorimetri imbasan kebezaan (DSC) serta kaedah pembelauan sinar-X (XRD). Peningkatan suhu hidrolisis menunjukkan kesan yang kontra terhadap sifat terma STKS-MKS. MKS yang dihidrolisis pada suhu 120 °C (MKS_A) menunjukkan suhu kestabilan terma dan peratus kehabluran yang paling tinggi iaitu masing-masing pada 250 °C dan 65.07%. MKS yang dihdrolisis pada 130 °C (MKS_B) dan 140 °C (MKS_C) mempamerkan suhu kestabilan terma yang rendah iaitu masing masing pada suhu 225 °C dan 220 °C. Peratus kehabluran yang diperoleh bagi MKS_B dan MKS_C masing-masing adalah 61.18% dan 60.64%. Kajian ini memberi indikasi bahawa darjah kehabluran selulosa memberi kesan positif kepada suhu degradasi terma TKKS-MKS.

Kata kunci: hidrolisis berasid, mikrokristal selulosa, serabut tandan kosng kelapa sawit, sifat terma

Introduction

Oil palm empty fruit bunch (OPEFB) is one of the major agricultural crops generated from palm oil mills in Malaysia. This biomass which is a carbohydrates polymer; comprised of cellulose and hemicellulose and also aromatic polymer called lignin. Despite these three major components, OPEFB also consists of few minor

components such as extractives, inorganic compound and ash [1-3]. Previous study shows that the content of cellulose, hemicellulose and lignin in OPEFB are 44.48%, 27.00% and 17.00% respectively [4]. Figure 1 represents lignocellulosic material structures of the plant cell wall [5].

As a boundless renewable resource, cellulose has a potential on producing environmental friendly and biocompatible products. Cellulose, a glucan polymer that made up from D-glucopyranose units and joined together by β-(1→ 4) - glucosidic bonds [6-8]. Naturally, cellulose resembles in micro fibrils form and composes of crystalline and amorphous region. The 'composite ribbon' micro fibrils bundles are linked by hydrogen bond between the hydroxyl groups and oxygen [9-11]. All native cellulose has been classified as cellulose type I [6]. Studies showed that cellulose type I has intra-molecular hydrogen bond for O(2)H···O(6) and O(3)H···O(5) and the inter-molecular hydrogen bond for O(6)H···O(3') as shown in figure 2 [12-13].

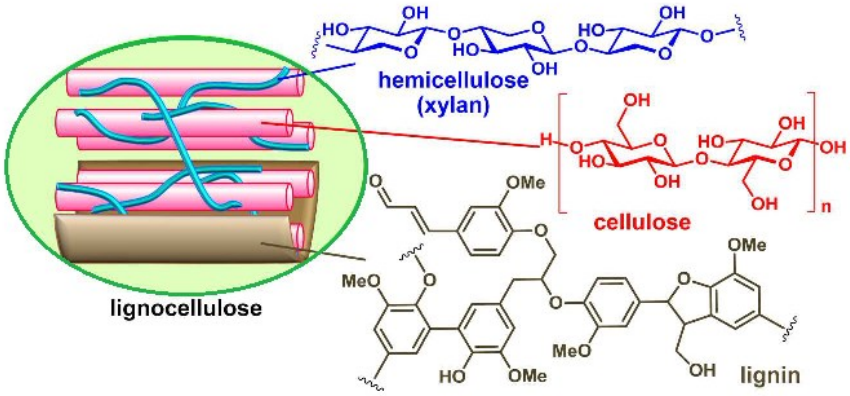

Figure 1. Schematic diagram of lignocellulosic material and their structure

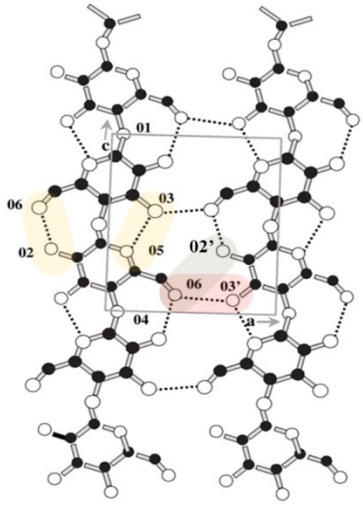

Figure 2. Inter-molecular and intra-molecular hydrogen bonding in cellulose type I

Microcrystalline cellulose (MCC) is defined as a purified, partially depolymerized non-fibrous form of cellulose. MCC is produced by treating cellulose acquired from plant materials using conventional method that is acid hydrolysis. Commercially MCC is produced by woody plants and purified cotton. MCC is white in color, odorless and tasteless crystalline powder. The chemical and physical properties such as crystallinity, moisture content, surface area, molecular weight and porosity are varied depend eloquently on the characteristic of the raw materials and hydrolysis conditions. Commercial MCC produced nowadays have different physicochemical and thermal properties which lead to different functional parameters and applications [7, 14, 15].

MCC is used as a value-added product in food processing, pharmaceutical and cosmetic industries [16]. Today, MCC also being used in producing glucose in order to generate 5-hydroxymethyl furfural (HMF) and levulinic acid as a desirable precursor for catalytic conversion into chemicals and hydrocarbon fuels [17]. Thermal analysis is a technique to prevail the thermal behavior of a material under various conditions. Thermal analysis also determines the changes of a material by noting the temperature at which thermal halt occurred [18, 19]. Azubuike and Okhamafe stated that TGA and DSC analysis also helped to clarify the stability, compatibility and transition of phase of the excipients [7]. In this research, the thermal behavior of MCC from OPEFB was investigated using thermogravimetric analysis (TGA), differential thermal analysis (DTA) and differential scanning calorimetry (DSC). These were employed in order to facilitate the understanding of the possible chemical reactions for the depolymerization of MCC. The MCC was produced by using cellulose extracted from OPEFB through acid hydrolysis at mild concentration and varying hydrolysis temperature of 120, 130 and 140 °C. This work also compared the MCC crystallinity data from X-ray diffraction technique with the thermal stability property.

Materials and Methods

Materials

Oil palm empty fruit bunch fiber (OPEFB) was kindly supplied by Seri Ulu Langat Palm Oil Mills Sdn Bhd, Selangor, Malaysia. The fiber was ground and sieved to obtain fiber size ranging from 315 to 500 μm. Chemicals used for α-cellulose extraction and acid hydrolysis were ethanol (C_2H_5OH; 95% purity, John Kollin Chemicals, UK), sodium chlorite, ($NaClO_2$; 80% purity, Sigma Aldrich, USA) and hydrogen peroxide, (H_2O_2; 30 – 32% purity, Friendemann Schmidt Chemical, Germany). Acetic acid (CH_3COOH; 99.5% purity), sodium hydroxide pellet (NaOH; 99% purity), sulfuric acid (H_2SO_4; 98-99% purity) and toluene (C_7H_8; 99.5%) were purchased from Systerm Sdn Bhd, Selangor, Malaysia. Commercial cellulose microcrystalline powder (Sigma Aldrich, USA) was used as the standard reference.

Method

The prepared OPEFB fibers were dried in a conventional oven at 105 °C for 24 hours and the moisture content was determined. Alcohol-benzene extraction was carried out to remove the extractives such as wax, oil and inorganic substances. This was carried out using ethanol and toluene mixture as the solvent at the ratio of 1:2 by volume for 8 hours following TAPPI T204 cm-97 (Alcohol-benzene solubility of pulp) [20]. The extracted fibre undergone bleaching process to remove lignin by mixing with 25 mL of 10% (v/v) CH_3COOH aqueous solution and 6 g of $NaClO_2$ subsequently under boiling water bath [21]. The mixture was filtered using hardened ash less filter paper (540, Whatman) via Buchner funnel. The whitish yellow filter cake was dried. The filter cake was treated with 75 mL of 17.5% NaOH aqueous solution in a water bath (20 °C). The suspension was filtered and the filter cake was rinsed with 8.3% NaOH aqueous solution followed by 650 mL cold distilled water in order to remove the hemicellulose leaving the α-cellulose in the filter cake. The extracted sample was dried at 105 °C for 24 hours.
Microcrystalline cellulose (MCC) was produced by acid hydrolysis reaction from the dried sample following method proposed by Soom et al. [22]. The reaction was performed by using 1% (v/v) H_2SO_4 diluted solution for an hour at varying temperatures of 120, 130 and 140 °C. The ratio of extracted sample to acid solution was fixed at 1:10. After the reaction was completed, the MCC was rinsed with cold distilled water until it reached pH 7 [7]. The MCC was soaked in 10% (v/v) H_2O_2 diluted solution for 90 min at 60 °C for bleaching purpose [23]. The yield was dried in the oven before further characterization.

Characterizations: X-ray diffraction (XRD)

X-ray diffraction (XRD) analysis was carried out using Bruker X-ray diffractometer (model D8-Advance). The radiation used was Cu-Kα1 at 1.514 Å. All samples were analysed at 2θ of 5° to 60° with the step size of 0.025°/s. The percentage of crystallinity (CrI) was calculated using the following equation (1) [24]:

$$\text{CrI}, \% = \frac{\text{Sc}}{\text{St}} \times 100 \quad (1)$$

where Sc is the area of all crystalline peak and St is the total area including non-crystalline fraction

Thermogravimetric analysis/Differential thermal analysis (TGA/DTA)

Thermogravimetric analysis (TGA) and differential thermal analysis (DTA) were performed using Mettler Toledo model TGA/SDTA 518^e to analyze the thermal behavior of OPEFB, MCC and CMCC samples. The samples were heated from 30 to 600 °C with heating rate of 10 ºC·min^{-1} under nitrogen gas atmosphere [25].

Differential scanning calorimetry

The differential scanning calorimetry (DSC) of the materials was analyzed using Mettler Toledo model DSC 822^e. It was analyzed under nitrogen gas blanket at a flow rate of 20 mL·min^{-1}. The temperature was programmed at 30 to 250 ºC with heating rate of 10 ºC·min^{-1}.

Results and Discussion

X-ray diffraction

The X-ray diffraction (XRD) patterns for all samples are as shown in Figure 3. The main reflection at 2θ=15.0°, 18.0°, 22.6° and 35° were observed for all samples [7,11]. The lattice planes for these reflections were at 101, 10$\bar{1}$, 002 and 040 respectively [7,12]. The free hydroxyl groups present in cellulose are contributed to the rise of various ordered crystal arrangements. This is due to the formation of inter-molecular and intra-molecular hydrogen bonds within the fibrils [26]. Reflections at 15.0°, 18.0°, 22.6° and 35° are typical diffraction signals of polymorph type I which commonly occur in native cellulose [7].

There are two types of natural occurring cellulose called I_α and I_β. Cellulose I_α usually found in bacterial and algae celluloses whereas cellulose I_β is found in higher plant. I_α and I_β exhibited as triclinic and monoclinic unit cells respectively [27]. The changes from polymorph type I to polymorph type II can be seen in the α-cellulose sample. A shoulder around 2θ of 20.4° was observed after alkali treatment was carried out. MCC-OPEFB samples also showed the coexistence of both polymorph types I and II. Two shoulders at 2θ of 20.4° and 12.5° with their respective lattice planes of 110 and 11$\bar{0}$ indicate that acid hydrolysis also contributed in the changes of polymorph type [7, 28].

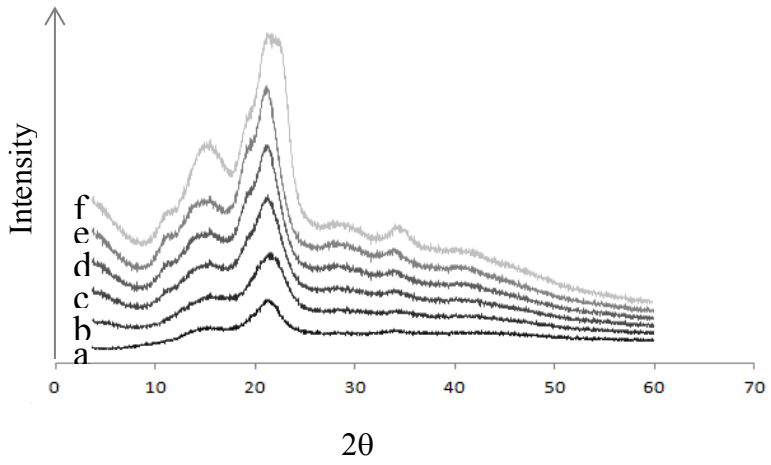

Figure 3. X-ray diffraction patterns of (a) OPEFB; (b) α-cellulose; (c) MCC_A; (d) MCC_B; (e) MCC_C and (f) CMCC

The crystallinity index, CrI (%) of OPEFB, α-cellulose, OPEFB-MCC and CMCC are listed in Table 1. In this study, the crystallinity index was calculated using deconvolution method or curve fitting method. In this method, calculation of CrI is based on the ratio of all crystalline area to the total area [12, 29].

Table 1. Percentage of crystallinity of OPEFB, α-cellullose, OPEFB-MCC and CMCC

Samples	**Crystallinity, CrI(%)**
OPEFB	43.24
α-cellulose	44.78
MCC_A	65.07
MCC_B	61.18
MCC_C	60.64
CMCC	76.19

The crystallinity index increased upon extraction of the α-cellulose. This is possible due to the breakdown of amorphous regions contributed by hemicellulose and lignin [30, 31]. Significant increments of crystallinity index were observed for the acid hydrolyzed samples. This is due to the removal of amorphous part in α-cellulose resulted by the scissoring effect of glycosidic linkages [30]. Higher crystallinity index for CMCC sample was due to the characteristics of the raw material and its hydrolysis condition [14].

Thermal Properties via thermogravimetry analysis (TGA) and differential thermal analysis (DTA)
Figure 3 shows the thermograms of TGA and DTA analyses performed on OPEFB, α-cellulose, OPEFB-MCC and CMCC. Table 2 represents the numerical data from TGA and DTA analyses. The initial weight loss for all samples except CMCC at temperature around 100 °C was attributed to the evaporation of water or moisture [26, 31, 32]. The onset temperature of OPEFB was the lowest compared to other samples. Poletto et al. stated that degradation of hemicellulose which occurs at temperature between 180 to 350 °C [26]. A shoulder in OPEFB DTA curve at 280 °C was suspected belong to hemicellulose since it degrades at a lower temperature compared to lignin and cellulose.

Among the OPEFB-MCC, MCC_A showed the highest onset temperature (250 °C) followed by MCC_B and MCC_C. This is due to the high crystallinity of cellulose in MCC_A. The reorientation of the crystals in cellulose promotes to arise in onset temperature of degradation [33]. According to Poletto et al. (2012), the degradation of cellulose occurs at maximum temperature, (T_{max}) of 350 °C. At this temperature, the scissoring of glycosidic linkage in cellulose happens [26]. The increase in the hydrolytic values lowers both the molecular weight and the T_{max} values. This is attributable to the hydrolytic effect of the crystalline part of the cellulose along with the amorphous hydrolysis [30, 33]. The high onset temperature was observed in CMCC (295 °C) was due to its high percentage of crystallinity [11].

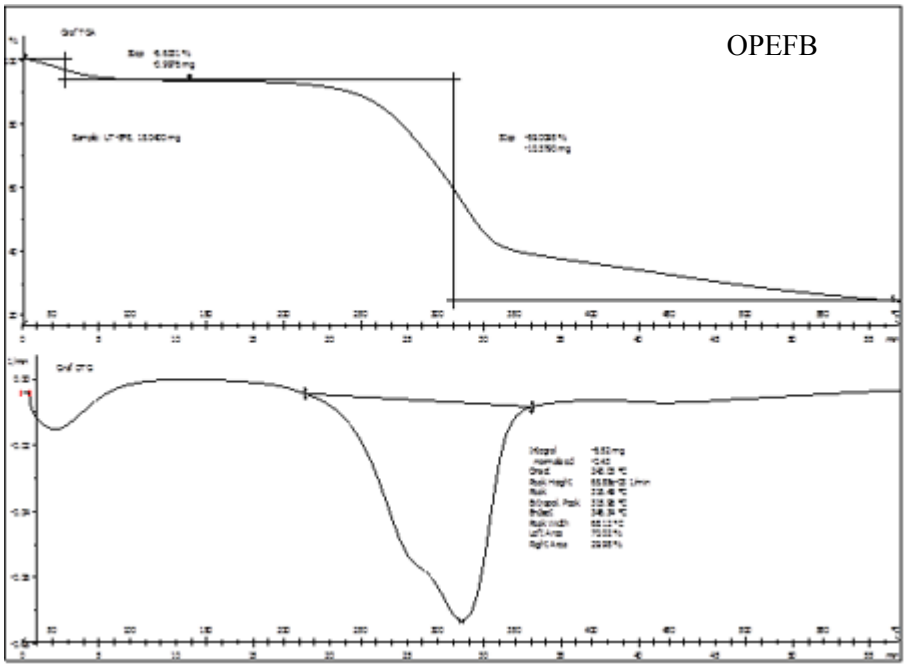

Figure 4 (a). The TGA/DTA curves of OPEFB

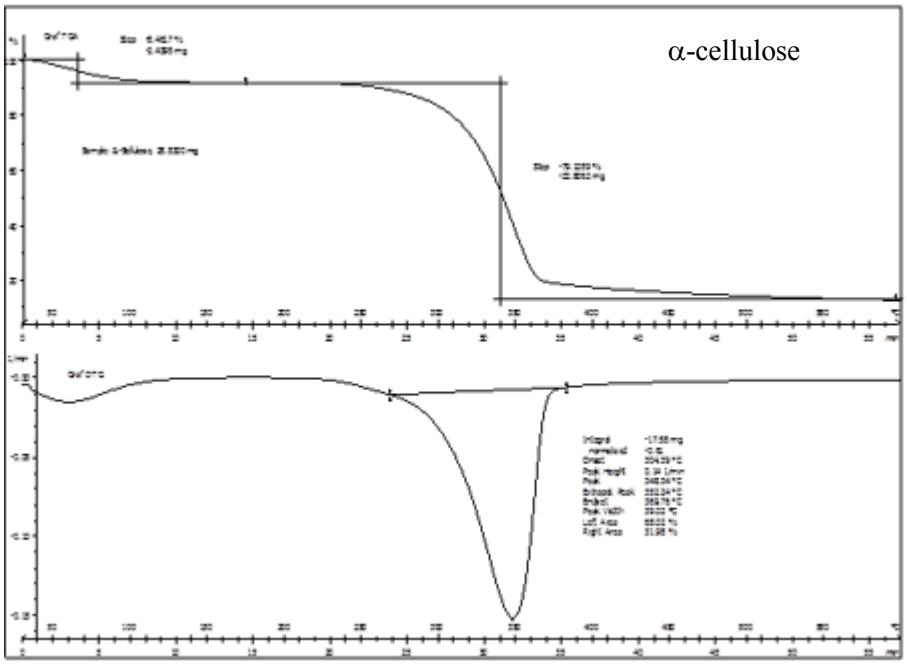

Figure 4 (b). The TGA/DTA curves of α-cellulose

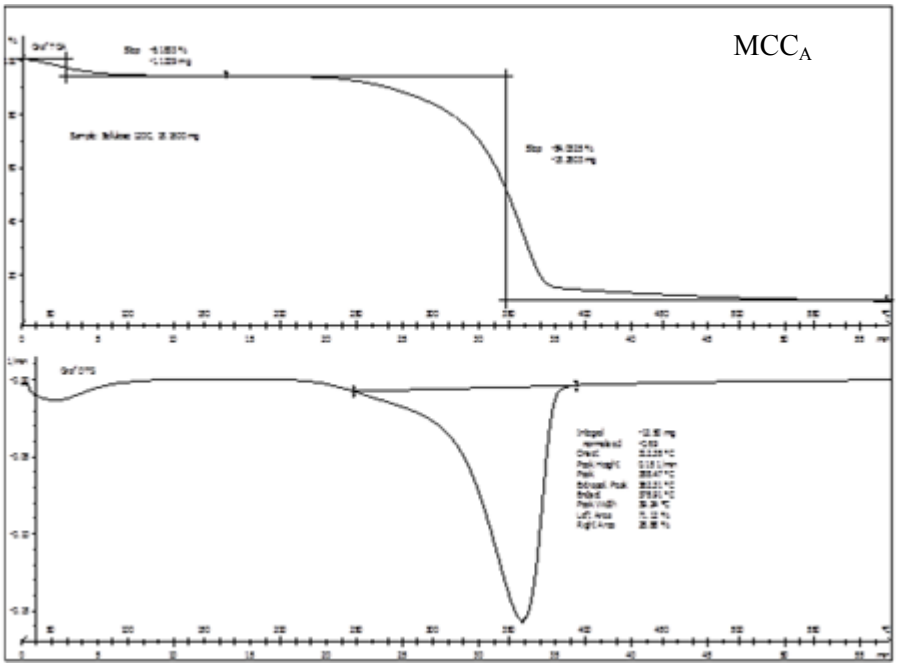

Figure 4 (c). The TGA/DTA curves of MCC_A

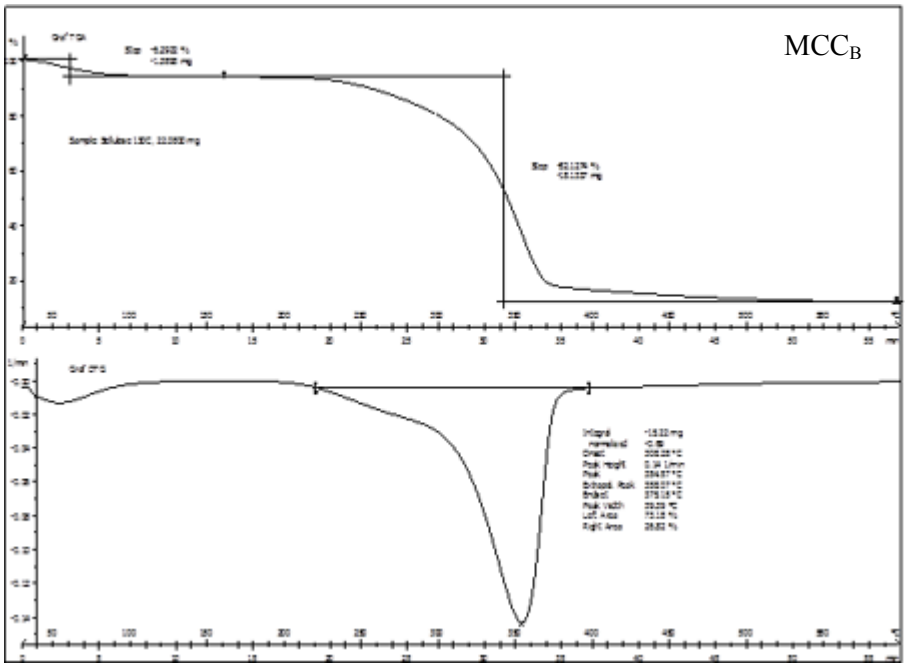

Figure 4 (d). The TGA/DTA curves of MCC_B

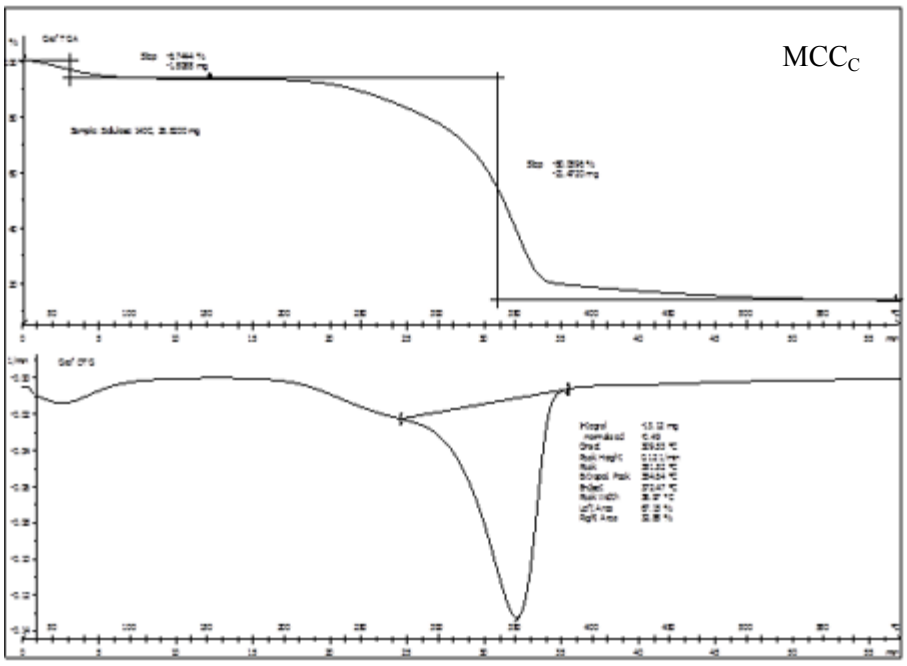

Figure 4 (e). The TGA/DTA curves of MCC_C

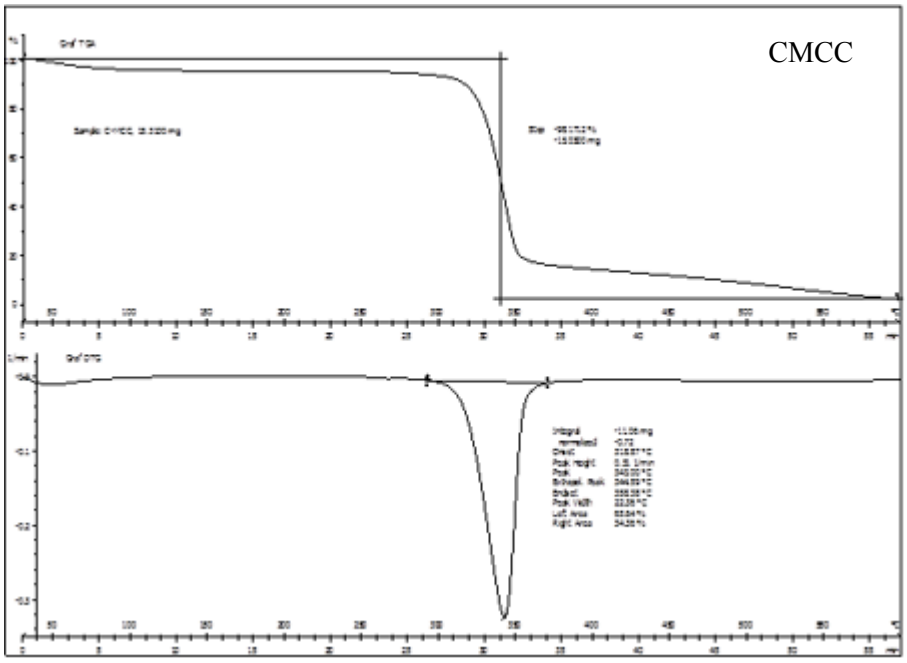

Figure 4 (f). The TGA/DTA curves of CMCC

Differential scanning calorimetry (DSC)

The glass transition temperature, T_g was tabulated in Table 2. The T_g value observed in OPEFB was lower compared to α-cellulose due to the low molecular weight of hemicellulose in OPEFB. Hemicellulose is enriched with many branched structures and also polyose chains [25]. This causes the chain mobility in OPEFB occur at lower temperature. The broad T_g peak on OPEFB was due to the presence of hemicellulose and lignin whereas the broad α-cellulose T_g peak was contributed by the amorphous cellulose. Based on the T_g obtained for the OPEFB-MCC, MCC_A showed high T_g compared to MCC_B and MCC_C. This is due to the acid hydrolysis of the crystalline cellulose at high temperature as discussed earlier. CMMC has the lowest T_g due to its initial physical condition which is powdered form.

Table 2. Thermal properties obtained from TGA and DSC analysis of all samples studied

Samples	T_{onset} (°C)	T_{max} (°C)	T_g (°C)	Weight loss (%)
OPEFB	215	315	182	75.64
α-cellulose	250	349	187	87.57
MCC_A	250	360	178	90.22
MCC_B	225	355	171	88.42
MCC_C	220	350	171	86.80
CMCC	295	345	168	98.17

Conclusion

The thermal behavior of microcrystalline cellulose from oil palm empty fruit bunch (OPEFB) has been investigated. Acid hydrolysis has significantly increased the thermal stability of the OPEFB. However, higher hydrolysis temperature reduced the thermal stability. The MCC_A showed the highest thermal stability and highest percentage of crystallinity.

Abstract

The rubber latex particle morphology, size and also arrangements of various types of natural rubber latex are investigated in the latex state using Environmental Scanning Microscope (ESEM). Subsequently the changes in the morphology after film formation is observed using Field Emission Scanning Electron Microscopy (FESEM). Prior to film formation, in the latex state, epoxidised natural rubber showed marked differences in latex particle morphology and arrangement compared to high ammonia latex. Subsequently, after the films are formed, the microscopy results exhibited certain dissimilarities between high ammonia and epoxidised natural rubber latex films particularly particle clustering. It is revealed that the high ammonia natural rubber latex film showed distinctly larger spherical shaped latex particles at the surface of the films in contrast to the smaller latex particles as observed in the epoxidised natural rubber latex film. The present study provides insight into the differences in the film formation between high ammonia and epoxidised natural rubber latex, which may also influence the properties of the resulting rubber latex films and latex products.

Keywords: high ammonia natural rubber latex, epoxidised natural rubber latex, film formation, latex particles

Abstrak

Morfologi partikel lateks getah, saiz dan juga susunan pelbagai jenis lateks getah asli dicirikan dalam bentuk lateks menggunakan Mikroskop Imbasan Alam Sekitar (ESEM). Selepas itu perubahan morfologi selepas pembentukan filem diperhatikan menggunakan Mikroskop Elektron Imbasan Medan (FESEM). Sebelum pembentukan filem, dalam bentuk lateks, getah asli terepoksi menunjukkan perbezaan yang ketara dalam morfologi partikel lateks dan susunan berbanding lateks getah asli ammonia kandungan tinggi. Selepas itu, setelah filem terbentuk, analisis mikroskop menunjukkan ketidaksamaan tertentu antara filem lateks getah asli kandungan tinggi ammonia dan lateks getah asli terepoksi terutamanya kelompok partikel. Ia mendedahkan bahawa filem bagi lateks getah asli kandungan tinggi ammonia menunjukkan partikel lateks berbentuk sfera jelas lebih besar di permukaan filem berbeza dengan partikel lateks yang lebih kecil sebagaimana yang berlaku di filem lateks getah asli terepoksi. Kajian ini memberi gambaran tentang perbezaan dalam pembentukan filem di antara lateks getah asli kandungan tinggi ammonia dan lateks getah asli terepoksi, yang juga boleh mempengaruhi sifat – sifat yang terhasil filem lateks getah dan produk getah.

Introduction

Natural rubber (NR) is an elastomer which has been commercially available for nearly a hundred years and it comes with unique physical and chemical properties which are suitable for tires, gloves, condoms, adhesives and etc. [1]. The application of NR in such products hinges on its ability to undergo strain-induced crystallisation which results in high tensile, tear and fatigue properties [2].

The introduction of chemical modification in NR is carried generally to improve properties, such as oil resistance in order to extend NR latex areas of application and as a new material [2, 3]. One of the chemical modifications is epoxidation which converts NR to epoxidised NR (ENR). Through epoxidation, oxirane (epoxide) is introduced where oxygen atom is added to the unsaturated NR carbon- carbon double [4]. ENR is commercially available in two grades namely ENR-25 (25 mole % epoxide) and ENR-50 (50 mole % epoxide).

Even though epoxidation of NR has been started in 1922 [5], the literatures on ENR latex state is deemed inadequate. This is probably due to the application of ENR was more towards dry rubber application hence more of the research approaches are focused on dry rubber [6-10]. With regards to ENR latex state, information is still lacking especially on latex particle arrangement and film formation.
With regards to the use of microscopy to study rubber, there are research adequate works which described the use of electron microscopy to study rubber latex particle [11-13], however still much of the work utilised dry state latex thin films in their study. The investigation on latex particles morphology using ESEM in the latex or aqueous state and consequently the latex particles packing in films using FESEM has not been yet attempted so far. Hence, in this preliminary work, visualization of chemically modified NR and the subsequent film was carried out by using ESEM and FESEM. The average of latex particles also calculated in this present work.

Materials and Methods

Materials

Concentrated high ammonia natural rubber latex (HA-NRL) was purchased from Lee Rubber, Malaysia Epoxidised natural rubber (ENR 1) and epoxidised natural rubber (ENR 2) latex were obtained from Development of Specialty Rubbers and New Rubber Program, Malaysia Rubber Board with epoxidation level 25% mole. For dilution purposes, distilled water was used throughout the study.

Latex particle morphology using ESEM

HA-NRL and ENR sample and distilled water were mixed in Eppendorf tube prior shaking for a few minutes. Then, the solution was centrifuged for 10 minutes. After that, sample was collected then osmium tetroxide was used to stain the sample. The sample was left to dry for several hours before washing and centrifugation. Then, the sample was ready for ESEM viewing. The morphology of particles was analysed using an ESEM (FEI Quanta). Then, the average of particle size was calculated using ImageJ software (NIH, Freeware).

Film formation and particles packing using FESEM

HA-NRL and ENR samples were stained with osmium tetroxide prior to FESEM analysis. The sample was then air dried in the desiccators on sample stub before coating with thin layer of platinum. Then, surface area of latex film was analysed using FESEM (JOEL JSM-6701F) at 5000 magnification.

Results and Discussion

Latex particle morphology

The ESEM micrographs in Figure 1(a, c, e) present different latexes at latex state. Figure 1a which represents HA-NRL particles packing showed the existence of both spherical and pear shaped latex particles similar with previous studies on NR latex [11-12, 14] where small particles were in spherical or egg shape and large particles were in pear shape. The latex particles were randomly distributed where agglomeration of latex particles could be observed in a close arrangement of latex particles. The large latex particles which in pear shaped were shown to be clustered by smaller latex particles.

After epoxidation (Figure 1c), the arrangement of latex particles changed and agglomeration of particles appeared to be reduced. The latex particles were no longer closer to each other. As result to epoxidation, based on the

micrographs the shape of latex particles could be observed in circular and smaller size only. The pear shaped particle could not be detected in the micrographs (Figure1c and 1e).

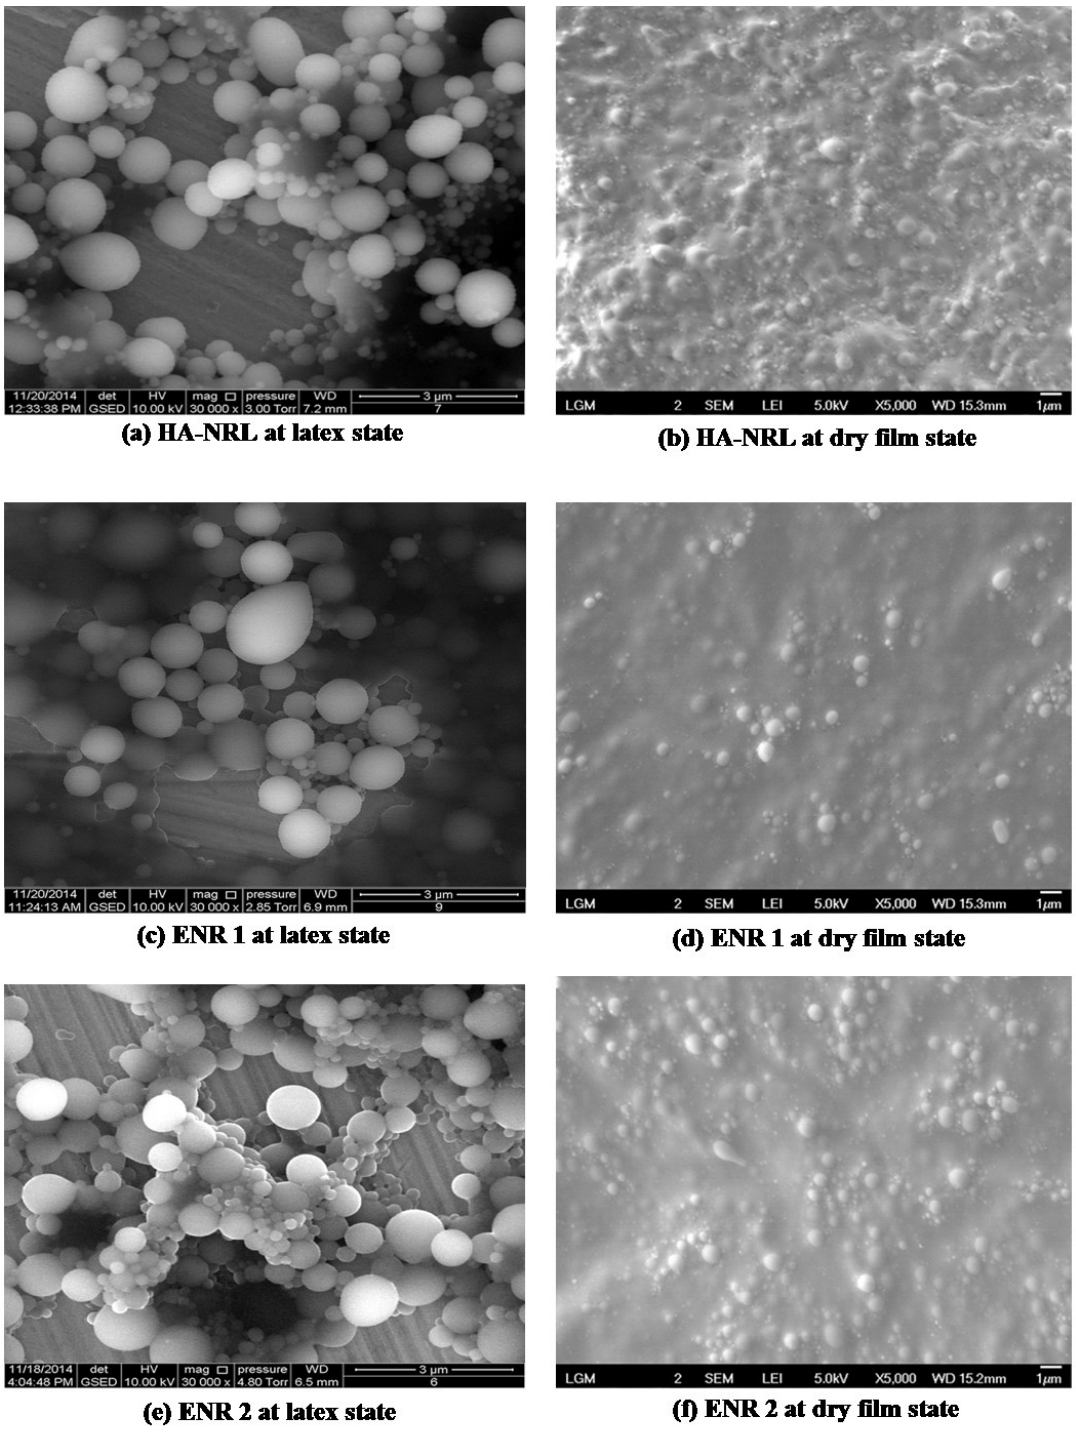

Figure 1. ESEM (a, c, e) and FESEM (b, d, f) micrographs showing of different latexes at various magnification for latex and dry film state.

Meanwhile, for Figure 1e, as could be seen the arrangement of particles was different to Figure 1c where the particles were closer to each other and clustering of smaller particles in between large particles could be seen clearly. The spherical shaped latex particles could be observed whilst the small particles were agglomerated to each other formed larger particles. The similar phenomenon also observed in this micrograph where the pear shaped latex particle could not be observed. This is because ENR 1 and ENR 2 had undergone epoxidation with different propriety processing process. Thus, this could lead to different particle arrangement as seen in the micrographs. So, based on the findings, it is suggested that epoxidation on natural rubber latex has given some effect to latex particles shape and also modified the arrangement of latex particles.

The average of latex particles in the latex state is shown in Figure 2. In the present investigation, average latex size existing in the latex state was measured from the ESEM micrographs. As per stated elsewhere [15], a particle size analysis results merely in 'average' diameter, whether based a number, surface area, volume, is of limited value. The average size of latex particles was in the range of 0.5 to 1.2 μm was taken as the limiting range in this present work because *ImageJ* software has limitation to the smaller size of latex particles. From particle size analysis using laser diffraction the range of particle size for Hevea latex was around 0.01 to 5.0 μm [16] and 0.2 μm to 1.5 μm [17]. Based on Figure 2, the average of particles size between all the latex samples were not much different. This is due to the limitation of measurement by using *ImageJ*. The results were also consistent with result of previous study [15], where the distribution of average particles size based on particles diameter exhibited higher distribution between 700 to 1500 nm. This also explained the average of different latexes exhibited almost similar results to each other.
The average of particles size after drying process for HA-NRL and epoxidation natural rubber latex from FESEM micrographs was measured and the result shown in Figure 2. The trend of latex particles size distribution among HA-NRL, ENR 1 and ENR 2 was similar to result of ESEM micrographs. The size of latex particles after drying showed a reducing trend compared to the ESEM result. This result may have suggested that after drying process, the latex particles size could be reduced in size due to evaporation process at stage I and II which are deformation particles occurred [18].

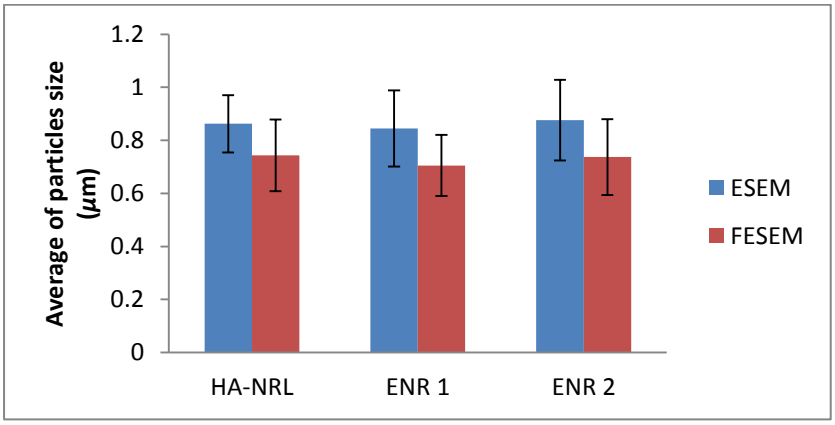

Figure 2. Average latex particles size for different latexes based at latex (ESEM) and dry state (FESEM).

Film formation and particles packing
FESEM micrographs conducted on air dried thin films obtained from HA-NRL, ENR 1 and ENR 2 latex. The features occurred on HA-NRL film were undulation with distinguished latex particles spherical shaped (Figure 1b). Clearly, the polydisperse latex particles distribution could be observed on the surface of formed HA-NRL film even though coalescence of latex particles had already occurred during drying. The core shell structure of HANRL latex particles almost diminished due to occurrences inter-particle diffusion of NR molecules. It is essential in order for

inter-particle mixing of rubber molecules takes place to ensure complete coalescence of the particles as per seen in micrograph. In this case, suggested coalescence and film formation were occurred in same time.

After epoxidation, the surface morphology the film was shown to be in different features compared to HA-NRL latex film. Based on FESEM micrographs (Figure 1d and 1f), the undulation feature on HA-NRL latex film is no longer observable. ENR 1 films exhibited a more coherence films with less distinguishable latex particles. However, in ENR 2 (Figure 1f), clusters of spherical shaped latex particles can be seen on the film surface clearly. The packing of particles could not be observed on the surface morphology in contrast with HA-NRL. This suggested that the changes in latex particles surface morphology are dependent on the type of modification. This is consistent to the ENR 1 and ENR 2 different surface morphology due to the effect processing process. It also could be suggested that inter-particle diffusion process which lead to the coalescence of the particles could be reacted different with HA-NRL.

Conclusion

The interesting findings have been observed using combination of ESEM and FESEM techniques in relation to the elucidation of latex particles arrangement in aqueous latex state and particles packing after the drying of latex to form films. In latex state, it can be suggested that epoxidation contributed to smaller size of latex particles. Subsequently after drying and when films are formed, ENR exhibited a more coherence and less undulating surface in contrast to HA-NRL film.

Abstract

An epoxidized palm oil-based hydrogel (HPEPO) was synthesized by using ring opening polymerization (ROP) in the presence of fluoroantimonic acid hexahydrate catalyst ($HSbF_6 \cdot 6H_2O$), followed by chemical hydrolysis catalyzed with sodium hydroxide (NaOH). The structural characterization and thermal property of synthesized hydrogel were studied. The successful ring opening of EPO was confirmed by disappearing of epoxy functional group at 833 cm^{-1} in the Fourier transform infrared (FTIR) spectrum. The formation of HPEPO was detected at 2500 cm^{-1} to 3400 cm^{-1} which represents the O-H stretching of carboxylic acid. Based on nuclear magnetic resonance (NMR), the disappearance of epoxy ring group at 2.8 – 3.0 ppm has indicated the completely reacted oxirane ring with the presence of peak at 3.7 ppm corresponded to hydroxyl group. Meanwhile, HPEPO exhibited low thermal stability by having melting temperature around 45 °C to 60 °C in Differential scanning calorimetry (DSC) and as showed by the great percentage of weight loss in thermogravimetric analysis (TGA) curve. However, the formation of char residue was slow, probably due to the formation of hydrogen linkages in hydrogel.

Keywords: hydrogel, epoxidized palm oil, ring opening polymerization, chemical hydrolysis

Abstrak

Hidrogel berasaskan minyak sawit terepoksidasi (HPEPO) telah disintesis menggunakan polimerisasi pembukaan cincin (ROP) dengan kehadiran asid fluoroantimonik heksahidrat ($HSbF_6.6H_2O$) sebagai pemangkin, diikuti dengan hidrolisis kimia yang dimangkinkan oleh natrium hidroksida (NaOH). Pencirian struktur dan sifat termal hidrogel yang disintesis telah dikaji. Kejayaan pembukaan cincin minyak sawit terepoksidasi (EPO) telah disahkan melalui kehilangan kumpulan berfungsi epoksi pada 833 cm^{-1} dalam spektrum Fourier inframerah (FTIR). Pembentukan HPEPO dikesan pada 2500 cm^{-1} hingga 3400 cm^{-1} yang mewakili regangan O-H daripada asid karboksilik. Merujuk kepada resonans magnetik nuklear, kehilangan cincin epoksi pada 2.8 – 3.0 ppm menunjukkan cincin oksiran telah bertindakbalas sepenuhnya dengan kewujudan puncak pada 3.7 ppm sepadan dengan kumpulan hidroksil. Sementara itu, HPEPO telah mempamerkan kestabilan haba yang rendah dengan mempunyai suhu lebur antara 45 °C to 60 °C daripada kalorimetri pengimbasan pembezaan (DSC) dan seperti yang ditunjukkan dalam kehilangan peratusan berat yang besar melalui lengkung analisis Termogravimetri (TGA). Walau bagaimanapun, pembentukan sisa arang didapati perlahan, berkemungkinan disebabkan oleh pembentukan ikatan hidrogen dalam hidrogel.

Kata kunci: hidrogel, minyak sawit terepoksidasi, polimerisasi pembukaan cincin, hidrolisis kimia

Introduction

Natural oil-based materials have been widely used in many industries due to environmental legislation and sustainability. They are used as precursors for many chemical materials such as alcohols (polyols), glycols, olefenic compounds, lubricants, plasticizers and stabilizer for polymers [1,2]. Researchers have successfully synthesized epoxidized natural oils from soybean oil [3], rubber seed oil [4], rapeseed oil [5] and linseed oil.

As one of the major producers of palm oil, Malaysia too has successfully developed epoxidized palm oil as starting materials for various industrial areas [6]. The production of macromonomer polyols through ring opening polymerization of EPO with Lewis acid in tetrahydrofuran [7] and with glycerol [8] has been reported. The benefit of EPO as a starting material is necessary to be explored progressively in order to expand the palm oil commercial value in various industrial areas. A research work completed by Ang et al. [9] have successfully synthesized polyol with high molecular weight and low hydroxyl functionality which is potentially to be used in wood adhesive applications. Clark and Hoong [7] have reported to derive macromonomer polyols from EPO by Lewis acid ring opening reactions in tetrahydrofuran (THF) solvent and reacted with MDI to furnish elastomeric polyurethanes.

This research has utilized EPO due to high reactivity of epoxy ring which can be subsequently converted into many products including polyols. An effort has been made to expand the use of EPO into new area such as hydrogel. Palm oil generally has the average 2.0 – 2.5 functionality as compared to ESO that has higher epoxy functionality. This drawback limits the use of palm oil polyol in the area that need longer molecular chain or higher molecular weight. However, the idea to introduce palm oil polyol with crosslinking network has brought the exploration of polyol into hydrogel.

Hydrogel, can be derived from many synthetic and natural polymers, possess high water absorption capacity and biocompatibility. These attractive properties contribute to wide applications such as in tissue engineering, pharmaceutical, and biomedical fields [10]. Liu et al. [11] have successfully synthesized epoxidized soybean oil (ESO) hydrogel via hydrolysis reaction.This study has adopted ring opening polymerization of EPO to prepare polymeric hydrogel in chemical hydrolysis reaction with the presence of sodium hydroxide (NaOH). The proposed reaction scheme is shown in Fig. 1. To date, no work has been done on the synthesis of hydrogel-based EPO.

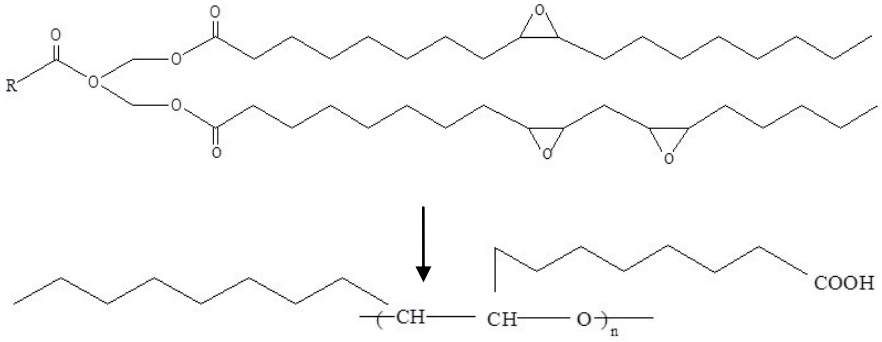

Figure 1. Scheme outlining the synthesis of HPEPO polymers

Materials and Methods

Materials

EPO with 2.7 – 2.9 % oxirane oxygen content (OOC), molecular weight of 1049 g/mol and iodine value of 0.58 eq/100 g value was supplied by Budi Oil (M) Sdn. Bhd. Fluoroantimonic acid hexahydrate catalyst ($HSbF_6 \cdot 6H_2O$) was purchased from Sigma Aldrich while methylene chloride, sodium hydroxide, hydrochloric acid and acetic acid were obtained from Qrec Chemical Co. Ltd.

Sample preparation: *Ring opening polymerization*

EPO was reacted with methylene chloride in the presence of fluoroantimonic acid hexahydrate as catalyst for 3 hours at room temperature to obtain polyol (PEPO) under nitrogen gas environment.

Hydrolysis reaction
PEPO was refluxed in sodium hydroxide for 24 hours before filtered and cooled down to room temperature. The obtained gel was precipitated with hydrochloric acid and washed with water for several times, then washed with acetic acid twice afterwards. The resulting hydrogel (HPEPO) was dried in the oven at 80 °C overnight and further dried in vacuum oven at 70 °C and the weight was measured for every 20 minutes until it reached a constant weight.

Characterization: *FTIR measurements*
Samples of the EPO, PEPO and HPEPO were analyzed using KBr plates. The IR spectra of these samples were recorded on Perkin Elmer IR spectrometer at room temperature with scanning range of 4000 to 400 cm^{-1} for 16 scans.

NMR measurements
The ^{1}H NMR spectrum for the EPO, PEPO and HPEPO samples were recorded quantitatively using a NMR spectrometer model of a Bruker Avance II 400 MHz UltraShield.

DSC measurements
The test was conducted using a DSC-6 Perkin-Elmer on PEPO Aand HPEPO. Samples were placed in the aluminium pan and were scanned from - 60 ^{o}C to 150 ^{o}C and the heating rate of 10 ^{o}C/min.

TGA measurements
A thermogravimetric analysis of the PEPO and HPEPO was carried out on TG (Mettler Toledo, TGA/SDTA851) under nitrogen atmosphere from 30 °C to 600 °C at heating rate of 10°C/min.

Results and Discussion

FTIR analysis
FTIR spectra of EPO, PEPO and HPEPO are presented in Fig. 2. The epoxy group of EPO at 833 cm^{-1} was disappeared in PEPO and HPEPO, indicated the ring opening reaction of epoxy was successfully achieved. Meanwhile, the ester carbonyl band of PEPO (1737 cm^{-1}) has shifted to the lower band in HPEPO (1710 cm^{-1}), implying the formation of strong hydrogen bonding of carboxylic acids dimers in HPEPO. Denisov et al. [12] found that hydrogen bonding and resonance have weaken the C:O bond, resulting in absorption at a lower frequency. Furthermore, a very broad peak observed at around 2500 cm^{-1} to 3400 cm^{-1} which represented the O-H stretching of carboxylic acid, supported the formation of HPEPO hydrogel.

NMR analysis
NMR was done to confirm the formation of polyol. Figures 3, 4 and 5 exhibit the ^{1}HNMR spectrum of EPO, PEPO and HPEPO respectively. From Fig. 3, the highest peak at 1.00 – 1.30 ppm belongs to the CH_2 proton in the fatty acid moiety. The presence of epoxy ring was detected by the peaks at 2.8-3.0 ppm. Meanwhile, the peaks that appeared at 2.7-2.9 ppm were corresponding to the proton adjacent to epoxy cyclic ring groups. Fig. 4 shows the ^{1}HNMR spectrum of PEPO produced. The proton peaks at epoxy cyclic ring group at 2.8-3.0 ppm disappeared and a new small signal at 3.7 ppm has emerged which indicated the presence hydroxyl group of the opened epoxy ring. Similarly, the spectrum of HPEPO in Fig. 5 has shown that there were no peaks from epoxy groups detected, indicating that the epoxy ring has completely reacted.

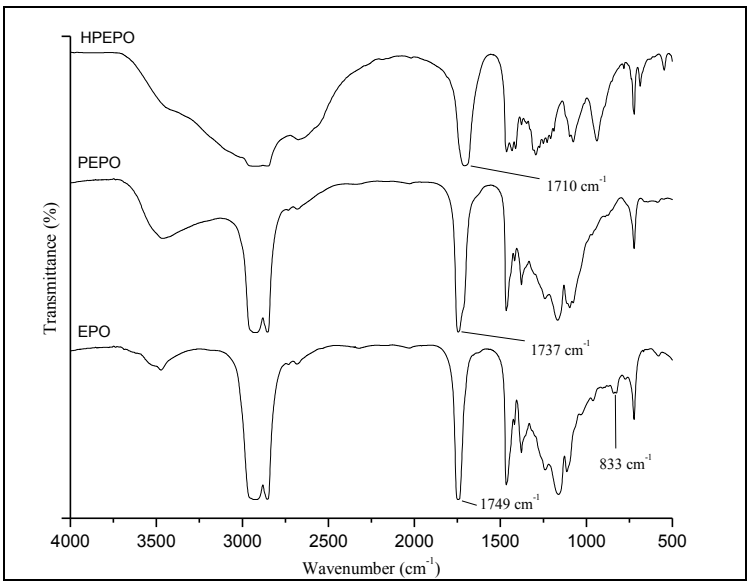

Figure 2. IR spectra for EPO, PEPO and HPEPO

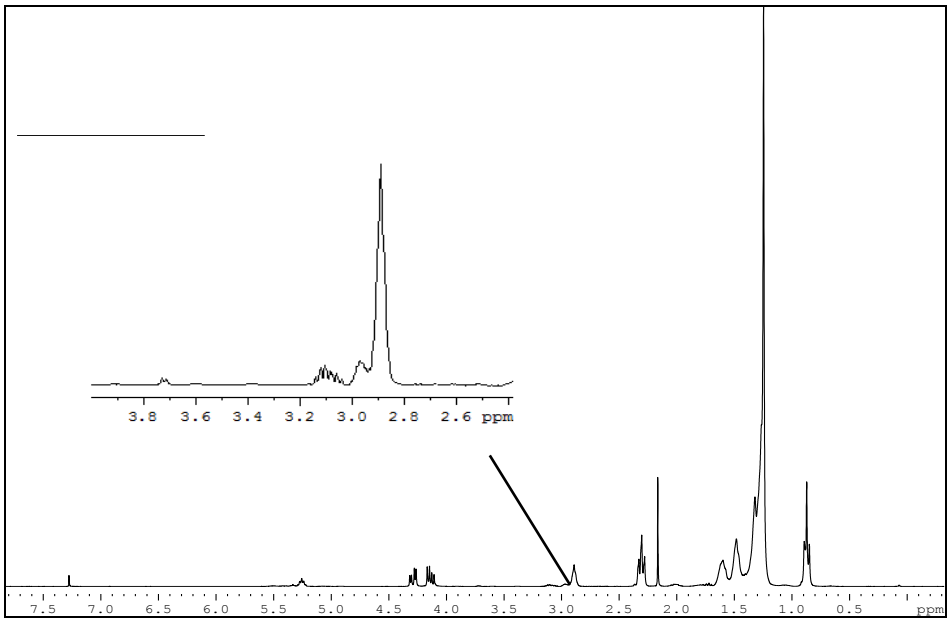

Figure 3. [1]HNMR spectra of EPO

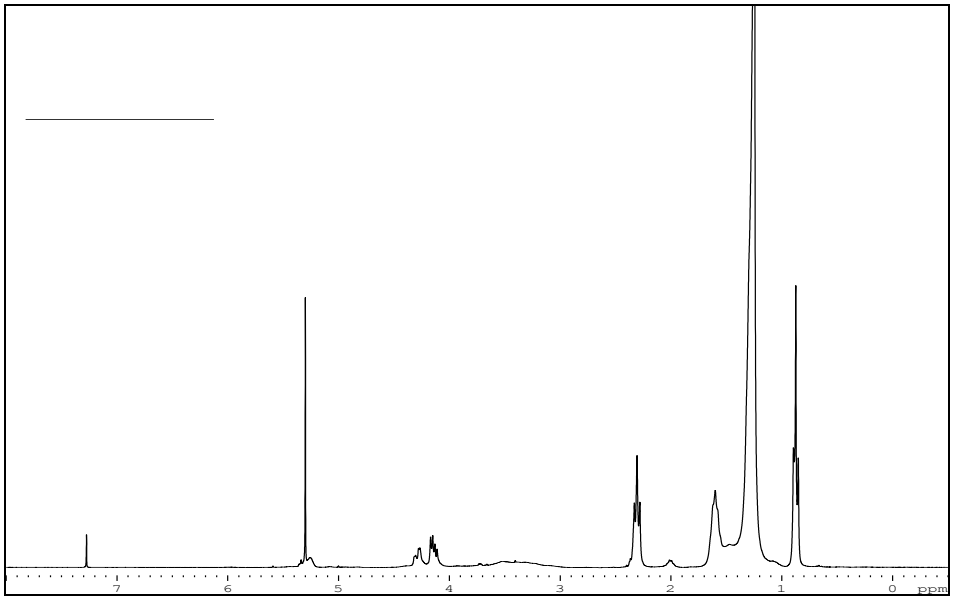

Figure 4. ^{1}HNMR spectra of PEPO

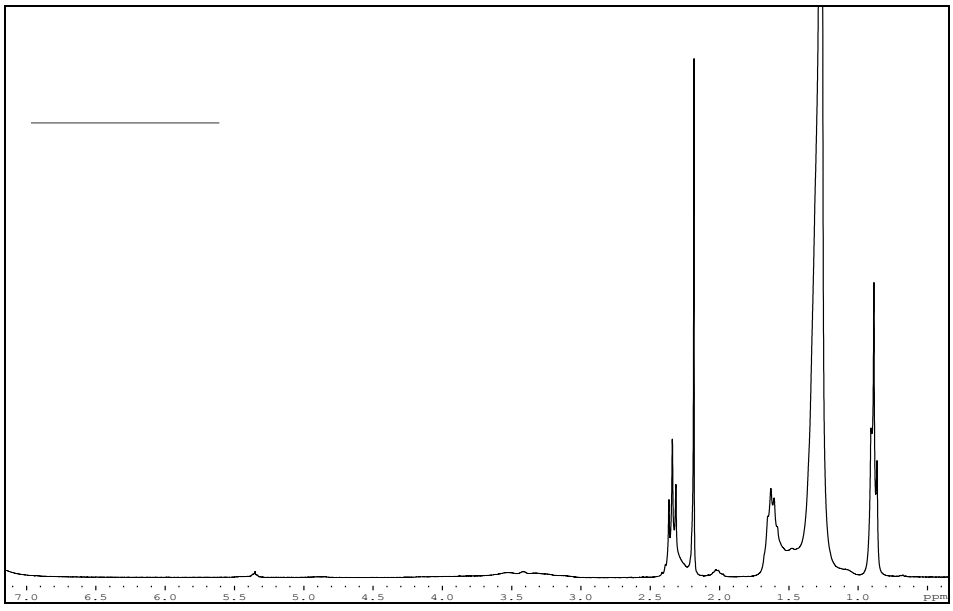

Figure 5. ^{1}HNMR spectra of HPEPO

Differential Scanning Calorimetry

Figure 6 shows the DSC thermograms of PEPO and HPEPO samples. Corresponding to an endothermic process, it can be seen that the DSC heating thermograms of the PEPO and HPEPO samples have shown positive peaks. From the graph, the melting temperature, T_m for PEPO was observed to be at 10 °C while HPEPO has higher in a range between 45 to 60 °C . As related to previous findings reported by Zhang et al.[13] and Rashmi et al. [14], bio-based polyols are typically have low melting temperature due the domain that consists of soft segments that crosslink to

each other. According to Wang and Schuman [15], the composition of the polymer within the cross linked structure plays an important role in thermal behavior, with the inherently flexible structure of fatty acid chain in PEPO reducing the crosslink density to form a less compact crosslinked structure compared to HPEPO. As a result, a polymer with low crosslink network increased its free volume and reduced its viscosity, leading to the decrease in T_m.

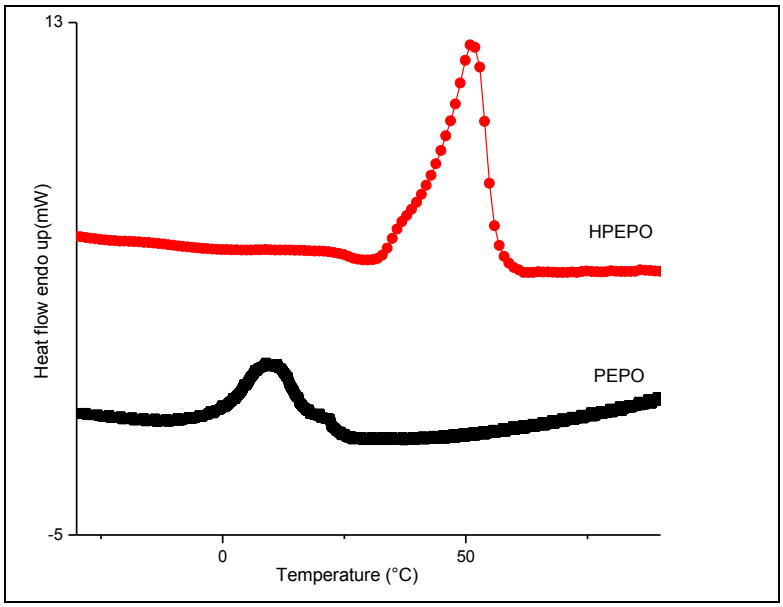

Figure 6. DSC thermograms of PEPO and HPEPO

Thermogravimetric analysis

Fig. 7 shows the TGA curves of PEPO and HPEPO. It can be seen both PEPO and HPEPO exhibited three degradation steps, related to the decomposition of polyunsaturated, monounsaturated and saturated fatty acids as both are palm oil based products, similar to most edible oils [16]. The decomposition in PEPO was not that obvious in the first region with a gradual reduction of weight loss at 5 wt%. On the contrary, HPEPO showed a sharp drop of plateau at about 40 wt%. This is thought due to the synthesis of HPEPO which involves hydrolysis reaction that caused the breakdown of ester linkage [17]. Furthermore, the release of volatile compounds such as hydrocarbon and carboxylic acid also contributes to the great weight loss of the sample [16]. In the second step, PEPO exhibited higher weight loss at 50 wt% compared to 40 wt% weight loss in HPEPO in the temperature ranges from 270 to 390 °C. As illustrated in Fig. 8, the weight loss fell sharply in PEPO as showed by a resolved peak of derivative TG (DTG) curve. In the third step, the char residue formed at above 400 °C, where about ca. 90 wt% and 95 wt% losses occurred in HPEPO and PEPO. However, the rate of degradation of HPEPO was slightly slower than PEPO, probably due to more hydrogen linkages that formed in the hydrogel apart from saturated fatty acids.

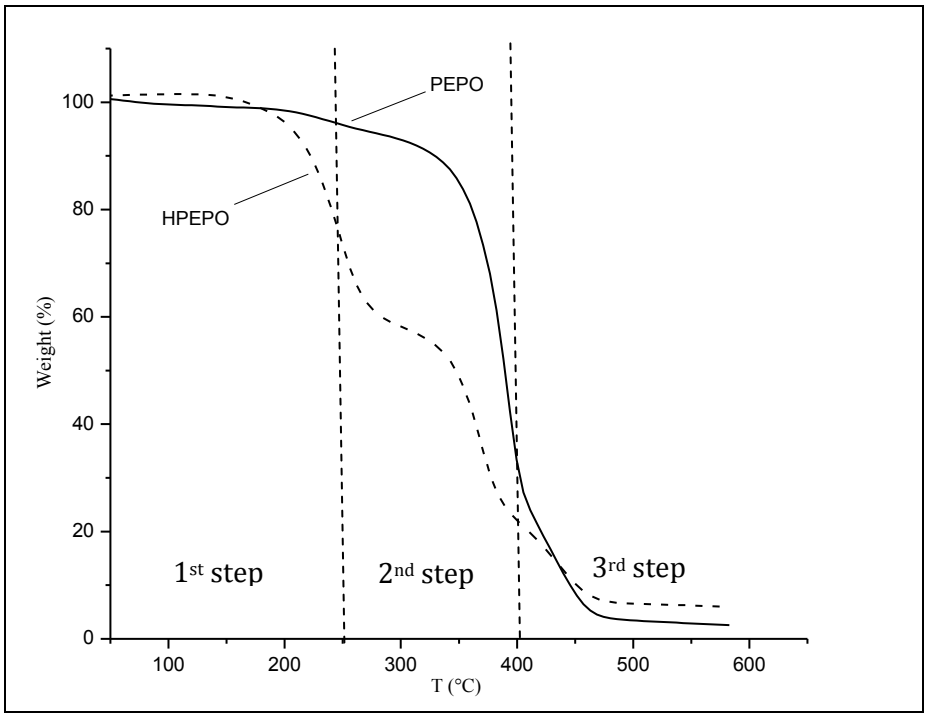

Figure 7. TGA thermogram of PEPO and HPEPO weight loss versus temperature

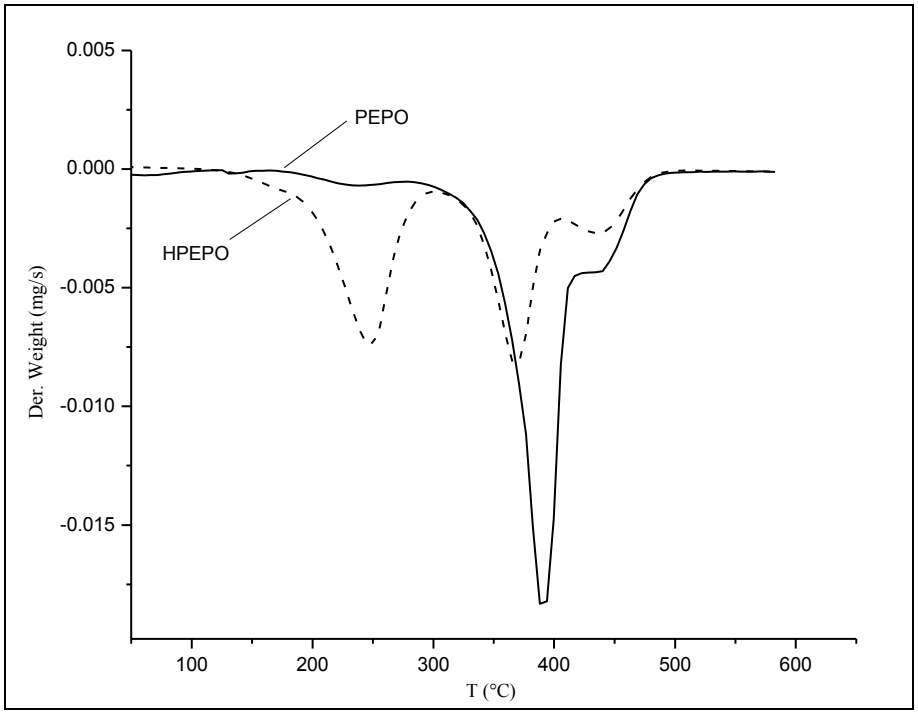

Figure 8. Derivative TG of PEPO and HPEPO versus temperature

Conclusion

The structural and thermal characteristics of epoxidized palm oil based hydrogel were studied. The epoxy ring in EPO had been successfully opened; evidently form the disappearance of 833 cm^{-1} epoxy characteristic band from FTIR spectrum. The formation of hydrogel HPEPO was confirmed with the detection of –OH stretching peaks of carboxylic acid at 2500 cm^{-1} to 3400 cm^{-1}, respectively. This is supported in NMR analysis where the disappearance of epoxy ring group at 2.8 – 3.0 ppm has indicated the completely reacted oxirane ring with the presence of peak at 3.7 ppm corresponded to hydroxyl group. Meanwhile, HPEPO exhibited melting temperature around 45 °C to 60 °C with low thermal stability in the first and the second degradation regions as showed by the great percentage of weight loss against PEPO. However, the formation of char residue was slower in HPEPO, probably due to hydrogen linkages that need higher temperature to be broken.

Abstract

The study investigates the vibration and mechanical properties of rice husk silica (RHS) in enhancing the properties of Polydimethylsiloxane (PDMS). The PDMS/RHS composites panel were fabricated by using casting technique and cured at room temperature. PDMS panels were filled with 2 – 12 wt% of RHS. Vibration analysis of PDMS/RHS composites panel were guided by ISO 8662 standard in evaluation of hand arm vibration for hand grinder machine. The vibration exposure analysis showed that application of PDMS/RHS as a vibration absorber successfully decreased the vibration exposure to 46%. Tensile properties analysis conducted using ASTM D412 standard showed that the PDMS/10 wt% RHS properties increased to 9.6% compared to PDMS without RHS. Thus it is concluded that the addition of RHS had improved both properties of PDMS. RHS has successfully acts as a reinforcement when load is applied to the panel and during vibration exposure, RHS has acts as an absorber and distributed the vibration.

Keywords: polydimethylsiloxane, vibration exposure, rice husk silica, tensile properties

Abstrak

Kajian ini dijalankan untuk mengenalpasti sifat – sifat getaran dan tegangan silika sekam padi (RHS) yang digunakan untuk meningkatkan sifat – sifat polidimetilsiloksana (PDMS). Panel komposit PDMS/RHS dihasilkan menggunakan kaedah tuangan dan dirawat pada suhu bilik. Panel PDMS di isi dengan RHS sebanyak 2 – 12 wt%. Analisa getaran panel komposit PDMS/RHS dikendalikan menurut piawaian ISO 8662 bertujuan menilai pendedahan getaran pada tangan bagi penggunaan mesin canai tangan. Keputusan analisa terhadap pendedahan getaran menunjukkan bahawa penggunaan PDMS/RHS sebagai penyerap getaran telah berjaya menurunkan pendedahan getaran sebanyak 46%. Analisa sifat – sifat tegangan yang dijalankan berpandukan piawaian ASTM D412 menunjukkan sifat - sifat PDMS/10 wt% RHS telah meningkat sebanyak 9.6% jika dibandingkan dengan PDMS tanpa RHS. Ini menunjukkan bahawa penambahan RHS telah meningkatkan kedua – dua sifat PDMS. RHS telah berjaya bertindak sebagai penguat apabila beban dikenakan pada panel dan bertindak sebagai penyerap dan penyebar apabila getaran dikenakan.

Kata kunci: polidimetilsiloksana, pendedahan getaran, silika sekam padi, sifat terikan

Introduction

The importance of improving the PDMS vibration properties is to offer a new invention or solution in decreasing the transmitted vibration to human body. Powered tools such as hand powered tools will expose the operators to hand arm vibration syndrome (HAVS) which lead to neurological and/or vascular disorders separately or

simultaneously. Exposure to hand-transmitted vibration can also occur from vibrating work pieces held in the hands of the operator, and from hand-held vibrating controls such as hand grinder [1].

Particulate polymer composites offer interesting mechanical, physical, mixing process and rheological properties resulting from polymer matrix and filler dispersed phase interaction. Polymer matrix and filler requires specific equipment in order to achieve uniform dispersion of fillers in the polymer matrix [2]. The importance of filler addition on polymer is to modify latter properties, either mechanical properties for example stiffness, modulus, etc. or physical properties for conductivity or density or rheological properties such as viscoelasticity or viscosity [3]. This study focuses on improving PDMS properties by usage of silica filler. PDMS or so called as silicone rubber will be filled with naturally derived silica produced *via* rice husk burning. Several previous studies have shown that filling PDMS with reinforced filler will enhance PDMS in terms of its vibration absorption, mechanical and chemical properties [4].

Materials and Methods

RHS derivation

The derivation of the RHS starts by cleaning the rice husk using tap water to remove impurities. Next, wet rice husk was dried in the sun. Dried rice husk converts to RHS by burning process at 700˚C using furnace.

Composites fabrication

PDMS (Dow Jones Xiameter, USA) was applied as matrices and RHS as the reinforcement. Closed mold casting technique had been used to fabricate the composites panel. The PDMS/RHS composites panels were cured at room temperature.

Molecular analysis

Fourier transform infrared spectroscopy (FTIR) was conducted by using Perkin Elmer FTIR Spectrum 100 Spectrometer, USA to analyze the molecular in PDMS/RHS composite panels. Testing specimen preparation and procedures were conducted as per ASTM D2702 - Standard practice for rubber chemicals - determination of infrared absorption characteristics.

Tensile test

Tensile properties as tensile strength, modulus was determined via tensile testing as per ASTM D412 standard test methods for vulcanized rubber and thermoplastic elastomers. Shimadzu AG-1 10kn, Japan was used to conduct the testing. Figure 3.15 shows the Shimadzu AG 10kn universal testing machine attached with tensile jig.

Vibration Test

The vibration properties of PDMS/RHS composite panels were evaluated under BS ISO EN 8622 for testing procedure and BS ISO EN 5349 for Hand Arm Vibration (HAV) measurement. This test method used to determine the average sum frequency weighted acceleration of X, Y, and Z axis and measure the limit of daily vibration exposure of Bosch GWS 8-1 100CE hand grinder to operator. Figure 1. shows the PDMS/RHS composite panels and accelerometer were attached to hand grinder grip. Human vibration meter of Larson Davis's HVM100 were used to measure the hand arm vibration.

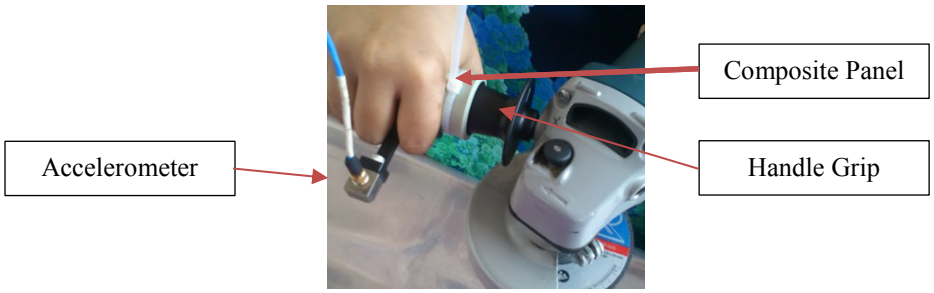

Figure 1. Hand grinder grip attached with composite panels and accelerometer

Results and Discussion

Molecular analysis

Molecular analysis *via* FTIR used to determine and confirm the existence of molecular bonding in the PDMS/RHS composite. The infrared spectra according to the RHS content ranged from 0 to 12% is shown in Figure 2. It was found that the range of wavelength observed referring to presence of PDMS and RHS is from 2963 cm^{-1} to 788 cm^{-1}. The four main peaks have a wavelength of 2968 cm^{-1}, 1260 cm^{-1}, 1012 cm^{-1} and 791 cm^{-1}. The bonds corresponding to the peaks are C-CH_3, Si-CH_3, Si-O-Si and SiO_4 bond respectively similar to observation by Shah et al. and Duo et al. [5, 6]. Those four main peaks have a wavelength of 2968 cm^{-1}, 1258 cm^{-1}, 1008 cm^{-1} and 788cm^{-1} which almost similar to previous studies [5, 6].

The trend of peaks and bonds shows the presence of hydroxyl and silanol group bonding which refer to PDMS and silica bonding respectively. The existence of –CH_3 in first peak (2968 cm^{-1}) and second peak (1260 cm^{-1}) indicated that the reaction between hydroxyl groups on the surface of RHS and PDMS has occurred. The presence of Si in third (1012 cm^{-1}) and fourth peak (791 cm^{-1}) corresponding to silanol groups on the surface of silica decreases after curing [7].

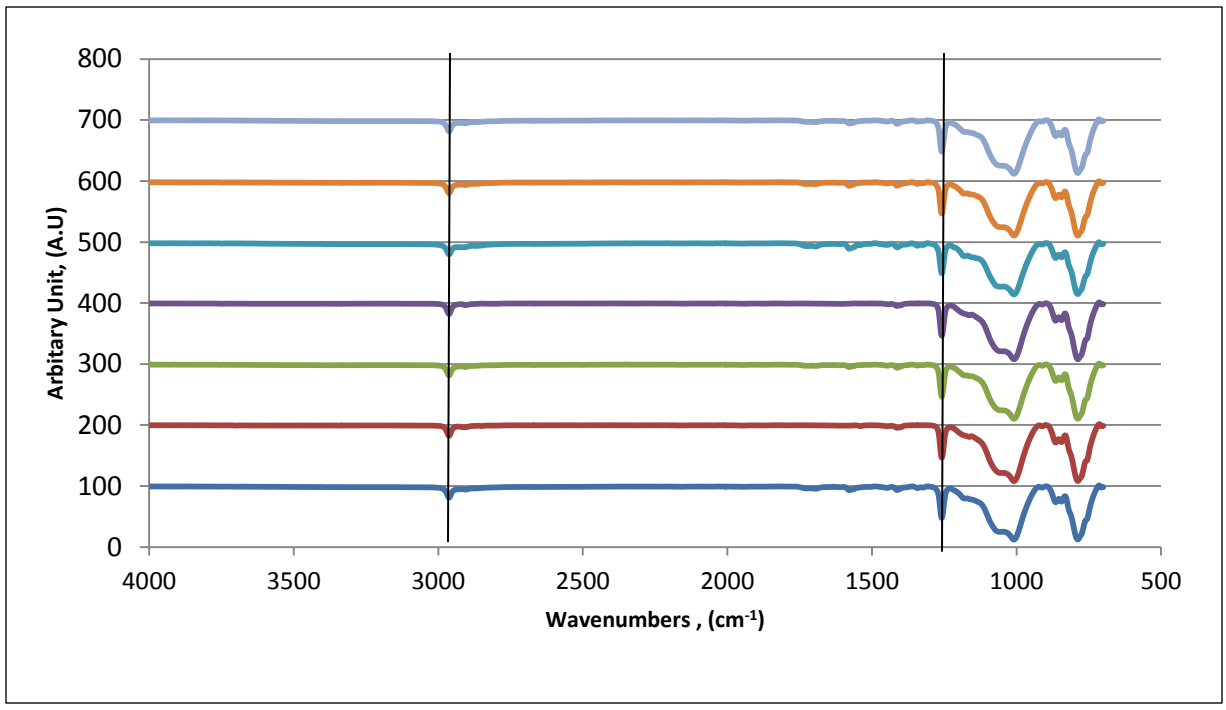

Figure 2. Infrared spectra of PDMS/RHS composite panels

Tensile properties

Tensile properties of PDMS/RHS composites were analyzed in terms of the tensile strength and modulus of elasticity. Figure 3 and Figure 4 shows the results of tensile strength and modulus of PDMS/RHS composites modulus gradually increase with increasing RHS loading. The addition of RHS had increased the tensile strength and modulus properties of PDMS from 5.311 MPa to 5.819 MPa and 1.408 MPa to 2.842 MPa respectively.

Tensile strength and modulus elasticity of composites tend to increase with increment of RHS loading up to 10 wt%. This is ascribed to the greater reinforcing ability by the RHS that may be due to excellent bonding adhesion

between matrix and filler [8]. However, a decline in tensile behavior was observed as the RHS content reaches 12 wt%. This may be due to formation of large SiO_2 aggregates caused by agglomeration of the high SiO_2 content. Subsequently these aggregates contribute to poor an inhomogeneous distribution of SiO_2 in PDMS [9].

The tensile strength and modulus shows a similar trend because of the increment of the RHS loading increased the tensile strength. The elasticity of the composites are indeed proportional to the tensile strength value. Higher tensile strength yields higher modulus of elasticity. However, the strain rate of the composites did not much improve as the addition of RHS caused the composites become stiffer [10].

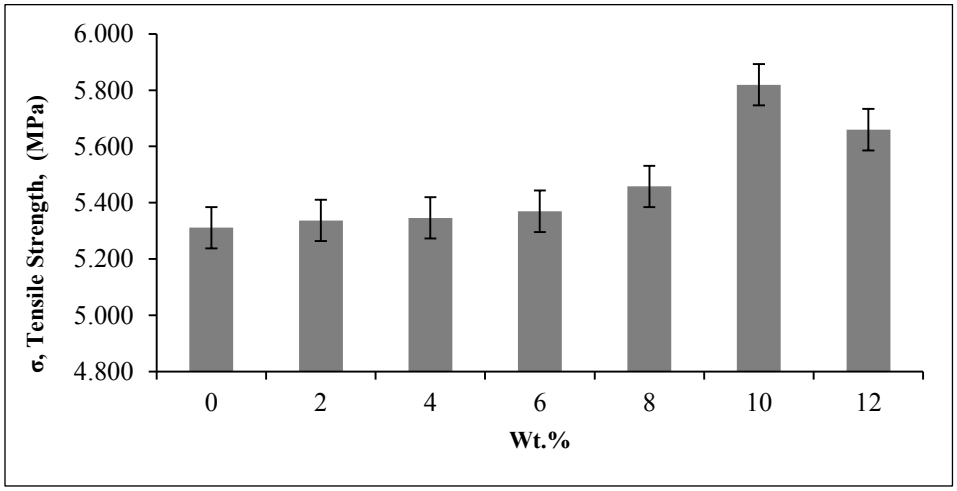

Figure 3. Tensile strength of PDMS/RHS composites

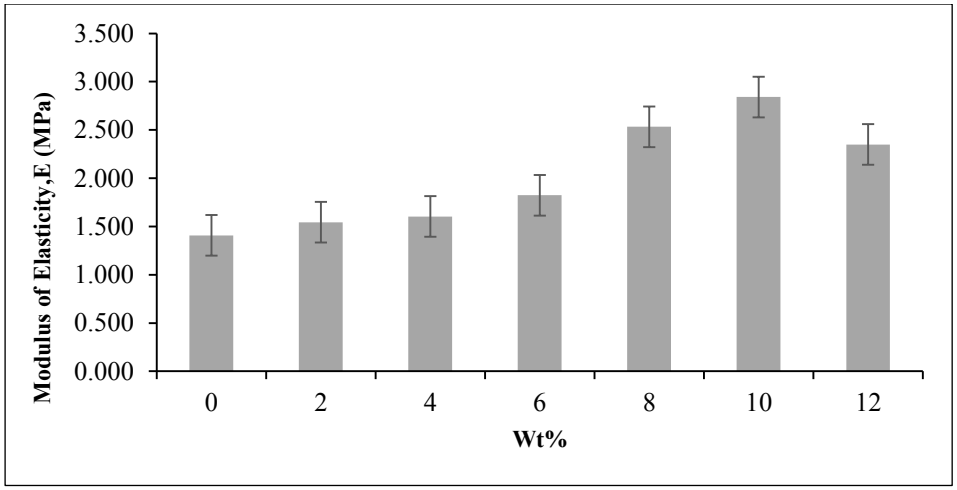

Figure 4. Modulus of PDMS/RHS composites

Vibration properties

Frequency weighted acceleration and vibration exposure time were observed in hand grinder's hand arm vibration measurement. Each measurement used different type of composite panels attachments which ranged from 0 wt% to

12 wt%. The measurement without composite panels attachment also had been studied as a reference. Fig. 5 and Fig. 6 show the results of sum average frequency weighted acceleration and vibration exposure time respectively.

The frequency weighted acceleration values were present the amount of vibration generated during measurement. From the Figure 5 the frequency weighted acceleration were progressively decreased as the filler loading increase. Maximum frequency weighted acceleration decrement occurred at PDMS/4 wt% RHS. However, the frequency weighted acceleration tends to increase at PDMS/6 wt% RHS.

Results showed that the use of PDMS composite panels had significantly decreased the frequency weighted acceleration or vibration of hand arm. The attachment of PDMS without RHS filler hand decreased the frequency weighted acceleration from 11.700 ms^{-2} to 6.360 ms^{-2}. This is due to PDMS properties itself which able to absorb the transmitted vibration [11]. The used of RHS as a filler had improve further the vibration absorption. RHS act as a filler in order to help to distribute the transmitted vibration to every surface in the composite panels body [12]. Compared to unfilled PDMS, the vibration localized at the vibration source, this lead to weak vibration distribution [13]. However, when the used of RHS exceed its limitation and above, 6wt% for this study, its turn out to be insignificant in reducing the vibration due to agglomeration and distribution of filler in the composite panels.

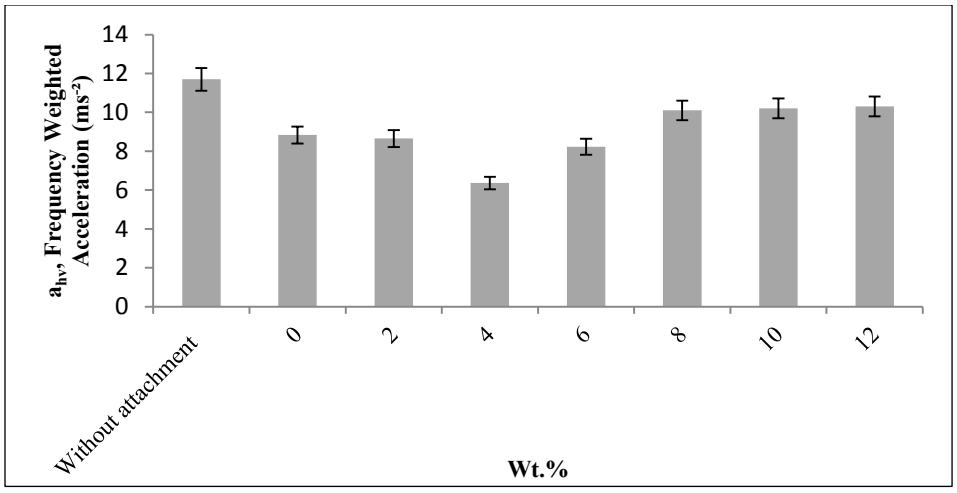

Figure 5. Sum average frequency weighted acceleration

The decrement in frequency weighted acceleration lead to lower hand arm vibration of hand grinder during operation. The lower vibration rate will helps the operator to work at longer time with less hazardous effect. Figure 6 shows the vibration exposure time as per measured during HAV measurement. Without an attachment to hand grinder grip, in 8 hours working duration per day, the operator only allowed to expose with hand grinder vibration for only 0.46 hour. By applying the PDMS/RHS composites panel the vibration exposure time had increased. The maximum vibration exposure time achieved was 1.55 hours with addition 4wt% of RHS. This enhancement will allow the operator to working or expose to the hand grinder vibration in longer duration and improve the productivity.

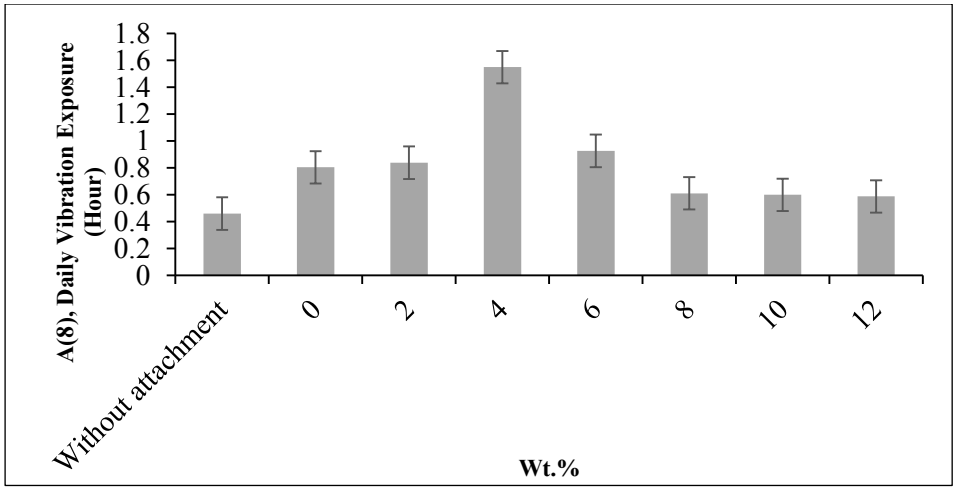

Figure 6. Vibration exposure time

Conclusion

PDMS filled with RHS were successfully fabricated via casting method and cured at 100˚C. Tensile tests revealed that RHS had improve the tensile strength and modulus with the significant enhancement at 10wt% RHS addition. PDMS/4wt%RHS composite panels also improved the productivity of hand grinder operator working hours up to 1.55 hours by reduce the vibration transmitted. This improvement had decreased health effects to the hands-transmitted vibration.

Abstract

Malaysian Rubber Board has developed a new process deprotenised natural rubber (Pureprena™) by treating fresh natural latex with an industrial enzyme which hydrolyses all naturally-occuring proteins in the latex into water-soluble forms. Further research is carried out to determine the processability performance of Pureprena™ by Mooney viscometer, rubber process analyser and capillary rheometer. The Pureprena™ in bale form has low nitrogen, low ash and volatile matter contents as well as being lighter in color compared to commercial Standard Malaysian Rubber. The rheological results indicate that the Pureprena™ has a comparable rheological behavior with synthetic polyisoprene at low shear rate as determined by RPA and capillary rheometer curves. The measurement by viscometer confirms the rheological behavior at low shear rate. However, Pureprena™ has a faster mill breakdown rate compared to synthetic polyisoprene and SMR at 60 °C. All rubbers were compounded using the soluble efficient vulcanisation system especially for manufacturing engineering rubber products. It was found that Pureprena™ vulcanisate has comparable tensile strength, modulus, resilience and volume swelling in water compared to synthetic polyisoprene vulcanisate.

Keywords: deprotenised natural rubber, soluble efficient vulcanisation cure system, tangent delta, capillary rheometer, rubber process analyser

Abstrak

Lembaga Getah Malaysia telah membangunkan proses baru getah asli nyah protein (Pureprena™) dengan merawat getah asli segar menggunakan enzim perindustrian yang akan menghidrolisis semua protein semulajadi di dalam susu getah kepada bentuk larut-air. Penyelidikan lanjut dijalankan bagi menentukan prestasi kebolehprosesan Pureprena™ menggunakan viskometer Mooney, penganalisa proses getah dan reometer kapilari. Bandela Pureprena™ mempunyai kandungan nitrogen yang rendah, kandungan abu yang rendah dan kandungan jirim meruap serta warna yang lebih cerah berbanding getah komersial Getah Standard Malaysia. Keputusan reologi menunjukkan bahawa Pureprena™ mempunyai kelakuan reologi setanding dengan poliisoprena pada kadar ricih yang rendah dari ujian RPA dan keluk kapilari reometer. Pengukuran dari viskometer mengesahkan kelakuan reologi pada kadar ricih yang rendah ini. Walau bagaimanapun, Pureprena™ mempunyai kadar pecahan yang lebih pantas berbanding sintetik poliisoprena dan SMR pada suhu 60 °C. Penyebatian getah adalah menggunakan sistem pemvulkanan cekap larut khas bagi produk – produk getah kejuruteraan. Ia didapati bahawa Pureprena™ vulkanisat mempunyai kekuatan tensil, modulus, daya tahan dan pembengkakan dalam air yang setanding dengan vulkanisat sintetik poliisoprena.

Introduction

Rheological and processability properties of polymer melt are very important in processing of rubbers especially in extrusion and injection molding process due to the high shear rate and pressure involved during the process but are complicated by a number of factors such as flow rate, pressure and temperature. All these factors can affect the rheological properties of polymer and rubber melts [1, 2]. The rheology of polymer melts is considered to be one of the most important factors in determining the processability of a polymer especially for those which required good flow properties such as in calendaring, extrusion and moulding in tyre manufacturing process. Uniformity and consistency in the flow behaviour and processability of rubber are essential in providing the solution to the rubber industries in order to improve productivity, products quality and energy conservation [3]. Thus rubbers with good consistent flow and processability properties for extrusion process can improve productivity and product quality as well as reduce waste and rejects.

The new process deprotenised natural rubber (Pureprena™) has been produced through treating fresh natural latex with an industrial enzyme which hydrolyses all naturally-occuring proteins in the latex into water-soluble forms [4]. The rheological property of Pureprena™ was compared with Standard Malaysian Rubber (SMR), SMR CV which has been produced by Malaysian Rubber Board (LGM) and also synthetic polyisoprene. Both SMR grades of natural rubber were prepared from the same clonal of latex collected from the same field in Kota Tinggi Research Station, Kota Tinggi, Johor and then processed at LGM, Sg Buloh.

Therefore, this research is aim to evaluate the raw properties and processability performance of Pureprena™, SMR CV and synthetic polyisoprene in terms of raw and compound properties. Both rubbers were compounded based on a soluble efficient vulcanisation (EV) typical formulation.

Materials and Methods

Pureprena™ and SMR CV rubbers were produced by LGM. Synthetic polyisoprene, SK1-3 was supplied by Galin Enterprise. Zinc oxide, Permanax TMQ, sulphur, accelerator 1 and 2 were used as the compounding ingredients which act as activator, antioxidant, curing agent and accelerator respectively. Zinc-2-ethylhexanoate (ZEH) and Carbon black N774 were used as activator and filler purchased from Struktol and Cabot (Malaysia) Sdn Bhd., respectively.

Raw rubber properties

The raw rubber test was carried out according to Rubber Research Institute Malaysia (RRIM) internal procedure [5]. The testing were dirt content, ash content, volatile matter and nitrogen content. Ash and dirt content are a measurement of soluble and insoluble impurities in rubber. The presence of large amount of ash and dirt will affect the final rubber properties. Volatile matter determined moisture in raw rubber includes the amount of any material in the rubber which is volatile at 100 °C. A nitrogenous material in the rubber that occurs chiefly as proteins is determined through its nitrogen content. This parameter can provide an estimation of the protein content in the rubber even though it does not give a precise indication.

Processability of raw rubber

The processability study was carried out by using viscometer, Rubber Process Analyser (RPA) and capillary rheometer. The Mooney viscosity was known to be one of the instruments to measure the quality and processability of rubber by using Monsanto automatic Mooney viscometer (MV2000) at 100 °C conducted according to American Standard Testing Method (ASTM D 1646-06) [6, 7]. The viscosity was also measured after mill breakdown for 10 minutes. The effect of viscosity on high shear rate has been carried out by using capillary rheometer Rheograph 75. The capillary rheometer sample was collected after the raw rubber was passed through two roll mill for six times for homogenization and then sheeting out to 6 mm thickness. While for RPA study, the raw rubber in bale form was cut and determined based on frequency sweep mode at 100 °C, 7% strain and ranging of frequency from 0.1 to 20 Hz.

Preparation of compounds

The compounds used in this study are shown in Table 1. The compound with the soluble EV cure system were mixed in two stages in a Banbury internal mixer, BR1600 of capacity 1.6 liters at 70 rpm rotor speed and starting

temperature of 70 °C and additives were added to the master batches by using a two-roll mill at roll temperature of 50 °C. Table 1 shows the formulation used throughout this study. For the evaluation of physical properties, all compounds were cured to their respective optimum cure time, t_{95} at 150 °C by using compression moulding process.

Table 1. Typical formulation for soluble EV formulation

Ingredients	PHR
Rubber	100
N774 black	20

ZEH[1]	2
Permanax TMQ[2]	2
Accelerator 1	1.44
Accelerator 2	0.7
Sulphur	0.7

[1]Zinc-2-ethylhexanoate,
[2]Polymerised 2,2,4-trimethyl-1,2-dihydroquinoline

Physical properties
All testing is done according to the International Organisation of Standardisation (ISO) procedure by using equipment available in the laboratory. The measurements are hardness (ISO 48), tensile properties (ISO 37), resilience (ISO 4662), compression set (ISO 815) and volume swelling (ISO 1817).

Results and Discussion

Raw rubber properties
The raw rubber properties were analysed and the data obtained are summarised in Table 2. It can be seen in Table 2 that Pureprena™ has a low dirt contents compared to synthetic polyisoprene rubber. Synthetic polyisoprene rubber which based on petroleum has low nitrogen content and volatile matter. A nitrogenous material in the rubber that occurs chiefly as proteins is determined through its nitrogen content. This parameter can provide an estimation of the protein content in the rubber. Result indicates that synthetic polyisoprene rubber has slightly lower protein level. It confirms that deprotenised process brings down the nitrogen content and also produced clean rubber compared to SMR rubber.

Table 2. Raw rubber properties

Property	Pureprena™	Synthetic polyisoprene	SMR
Dirt retained on 44um aperture sieve (% wt, max)	0.003	0.015	0.008
Ash content (%)	0.14	0.26	0.12
Nitrogen content (% wt, max)	0.07	0.04	0.38
Volatile matter (%wt, max)	0.12	0.015	0.23

Mooney viscosity determination
Table 3 shows the Mooney viscosity (V_R) of the rubbers measured by MV2000 at temperature of 100 °C. The results show all rubbers exhibited comparable viscosity at 78.5 ± 1.5 MU. These Mooney viscosity results are in agreement with the viscosity results obtained from RPA discussed above which show that the rubbers did not show a significant difference in viscosity at low shear rate.

Table 3. Mooney viscosity of rubber

Rubber	Mooney viscosity, ML(1+4)@100 °C, MU
Pureprena™	79
Synthetic polyisoprene	77
SMR	80

The effect of viscosity after mastication for 30 minutes showed in Figure 1. It can be seen that Pureprena™ exhibited lower viscosity for all tested time which indicates of easier processing even though, all rubbers have a similar initial viscosity.

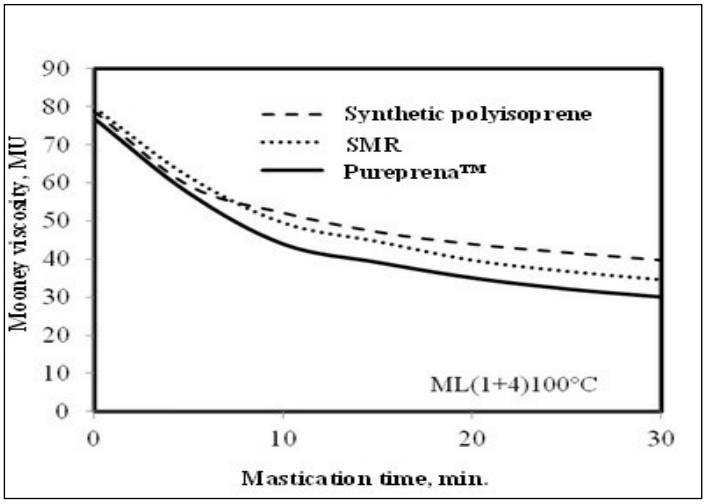

Figure 1. Mill breakdown viscosity of raw rubber determined using viscometer

Viscosity determination by RPA at low shear rate

The effect of shear rate on viscosity determined by RPA is showed in Figure 2. At low shear rate (0.05 – 9sec^{-1}) Pureprena™ , synthetic polyisoprene and SMR exhibited comparable viscosity. This confirms the viscosity behavior as measured by viscometer in Table 3.

Tan delta and elastic modulus determination

The processability characteristics of rubbers can also be assessed by the results of tan delta and elastic torque properties obtained from RPA test. For this test, the values and trend of tan delta and elastic torque with variation in the applied frequency (Hz) was studied. Although the frequency was set from 0.1 to 20 Hz, due to the limitation of the instrument, the actual shear rates applied during the RPA testing was still considered very low that is less than 25 sec^{-1} as compared to those obtained by using capillary rheometer (> 10,000 sec^{-1}). It is known that, the higher the tan delta value the better the processability of the rubber and *vice versa* [8]. It can be seen in Figure 3 that Pureprena™ and synthetic polyisoprene exhibited no significance difference in tan delta at low frequency and become significance as the frequency increased. The higher tan delta value for Pureprena™ indicates better processability than synthetic polyisoprene.

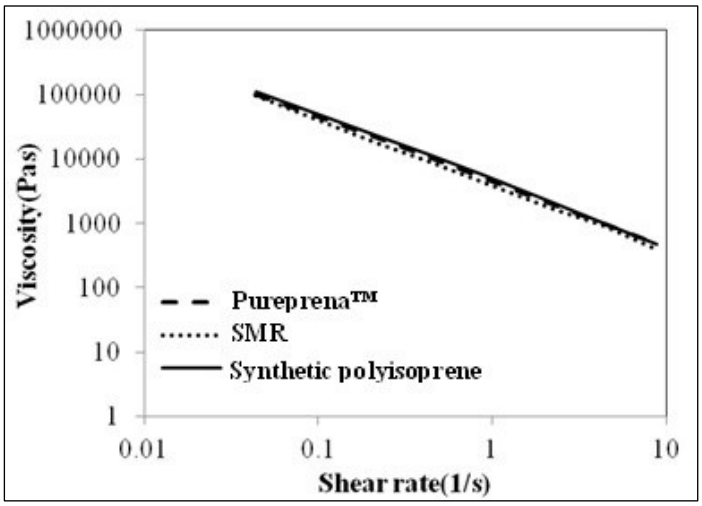

Figure 2. Viscosity responses from frequency sweep of rubbers at 7% strain at temperature of 100 °C

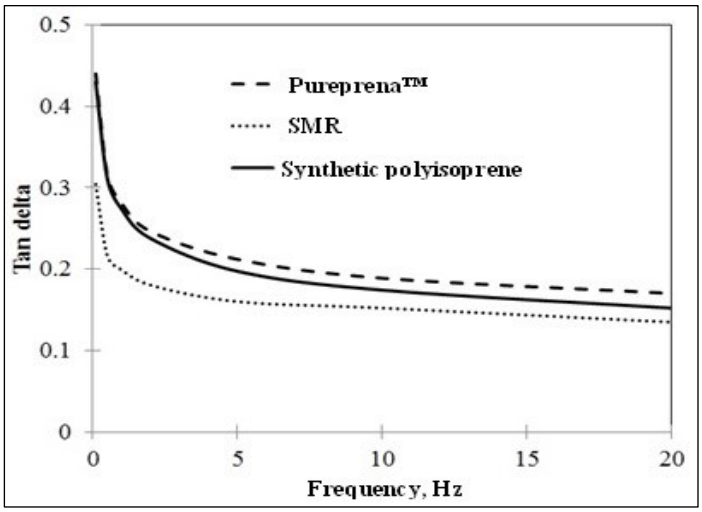

Figure 3. Tan delta response from frequency sweep of rubbers at 7% strain at temperature of 100°C

The elastic torque is the rotational force needed to deform the rubber shape. Normally, high values in elastic torque indicates poor processability of rubber and high energy is needed in its processing due to its high elastic property. As can be observed from the RPA results on raw rubbers as shown in Figure 3 Pureprena™ exhibits lower tangent delta for the range of shear rates tested as compared to synthetic polyisoprene. This is also due to lower elastic modulus of Pureprena™ compared to synthetic polyisoprena as seen in Figure 4.

Viscosity determination by capillary rheometer

The viscosity test was conducted using the capillary rheometer at 100 °C test temperature and employing high shear rates ranging from 100 to 100000 shear rate to study the actual flow behavior of rubbers when shear rate is increased. Viscosity is a measure of the resistance of a fluid (polymer) which is being deformed by shear stress. Low viscosity values indicate good processability and vice versa. For the viscosity results of raw rubber as shown

in Figure 5, it can be observed that all rubbers possess comparable viscosity at low shear rate. However, at high shear rate, synthetic polyisoprene exhibits a lower viscosity curve as compared to Pureprena™ and SMR rubber. Due to its lower viscosity results, it can be deduced that synthetic polyisoprene has lower resistance to flow and hence better flow properties compared to Pureprena™ and SMR rubber.

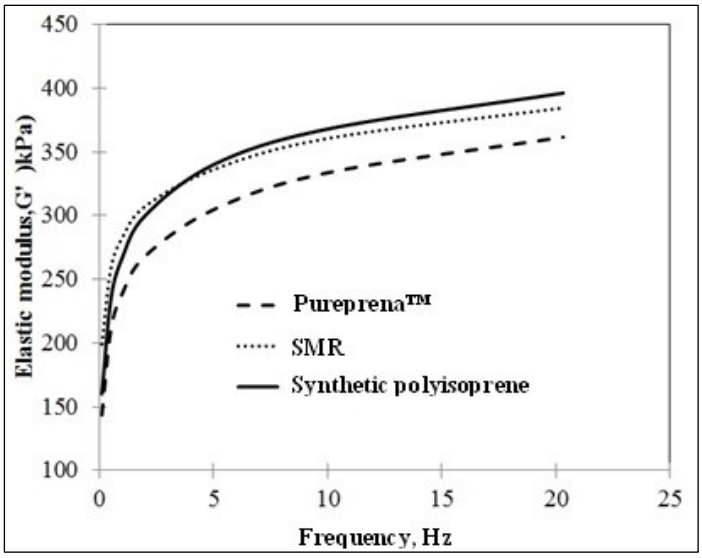

Figure 4. Elastic modulus response from frequency sweep of rubbers at 7% strain at temperature of 100 °C

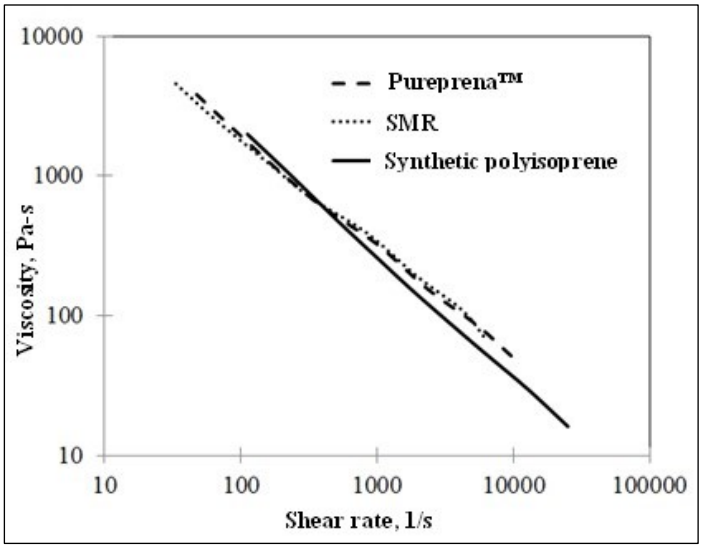

Figure 5. Viscosity of raw rubber determined using capillary rheometer

Basic physical properties of soluble EV vulcanisates

The Pureprena™ and SMR CV compounds were cured at temperature of 150 °C for 12 minutes at cure rate of 2.7 and 2.4 dNm/min, respectively. While, synthetic polyisoprene compound was cured at temperature of 150 °C for 18

minutes at cure rate of 1.6 dNm/min. The basic physical properties of the vulcanisates are shown in Table 4. It was observed that the Pureprena™ and synthetic polyisoprene exhibits almost similar tensile strength, hardness, modulus at 100% elongation, resilience and volume swelling in water. However, Pureprena™ exhibit slightly poor elongation at break and recovery behavior compared to synthetic polyisoprene. The Pureprena™ and SMR exhibited comparable basic physical properties.

Table 4. Basic physical properties of vulcanisates (cured to t_{95} at 150 °C)

Property	**Pureprena™**	**Synthetic polyisoprene**	**SMR**
Hardness, IRHD, 23°C	42	40	41
M100, MPa	0.82	0.83	0.81
M300, MPa	2.60	2.52	2.59
Tensile strength, MPa	24.29	22.64	26.10
Elongation at break, %	700	730	700
Dunlop resilience, % at 23 °C	84	84	85
Compression set, % at 22h/70 °C	12	5	11
Swelling in water, Vol. change, %			
168h/RT	0.1	0.2	0.4
72h/100°C	1.7	1.5	3.8

Conclusion

From the observations and results obtained in this study it showed that deprotenised process brings down the nitrogen content, dirt and volatile matter in the natural rubber. It also found that the new process deprotenised natural rubber produced a low dirt and ash contents compared to synthetic polyisoprene rubber. The RPA study determined that Pureprena™ exhibits better processability compared to synthetic polyisoprene through their higher tangent delta and lower elastic modulus at low shear rate. However, at high shear rate as measured by capillary rheometer, synthetic polyisoprene displayed slightly low viscosity that assumed to be better flow behaviour for the subsequent process. The Pureprena™ and synthetic polyisoprene vulcanisates exhibits comparable basic physical properties such as tensile strength, hardness, modulus at 100% elongation, resilience and water immersion.

Abstract

Petrochemical based polymers used in packaging materials are causing various environmental problems. Therefore, biopolymers prepared from renewable sources have high potential to substitute the commercially available non-degradable polymer. Poly(lactic acid) (PLA) is one of the biodegradable polymers that can be used to substitute in the application of petrochemical-based polymers. Environmental friendly and biodegradable epoxidized palm oil (EPO) was used as plasticizer in this study and it was incorporated into PLA matrix through solution blending method. The mechanical properties were determined through three-point flexural test and tensile test. Tensile results revealed that the flexibility of PLA can be improved by the addition of epoxidized palm oil (EPO) as plasticizer in the polymer. PLA/EPO blend at ratio 100:10 showed significant flexibility among the other PLA/EPO blends. The thermal properties of neat PLA and PLA/EPO blends were characterized by using Differential Scanning Calorimetry (DSC). The glass transition temperature (Tg) decreased by addition of plasticizer, indicated the chain mobility of PLA increased in the PLA/EPO blends system. The improved flexibility of PLA by using EPO as plasticizer showed that it has high potential to be used as environmental-friendly packaging material.

Keywords: biodegradable polymer, green polymer, poly(lactic acid), environmental friendly packaging material

Abstrak

Barangan dari sumber yang boleh diperbaharui boleh mewujudkan satu platform untuk menggantikan polimer berasaskan petroleum yang diketahui tidak mampu terbiodegradasi. Poli(laktik asid) (PLA) adalah antara polimer yang boleh biodegradasi secara semula jadi dan dipercayai boleh menjadi pengganti bagi penggunaan polimer petrokimia. Pemplastik yang terbiodegradasi boleh digunakan untuk meningkatkan fleksibiliti PLA. PLA/EPO telah dicampurkan dengan nisbah tertentu dan sifat mekanikal dan haba bahan ini telah dikaji. Sifat mekanik polimer/pemplastik ditentukan melalui ujian lenturan mekanik dan ujian tegangan. Hasil kajian tegangan bahan menunjukkan bahawa fleksibiliti PLA boleh dipertingkatkan dengan penambahan minyak kelapa sawat terepoksi (EPO) sebagai pemplastik dalam polimer. Ia telah membuktikan bahawa kandungan 100:10 PLA/EPO adalah nisbah yang paling sesuai untuk campuran PLA/EPO. Ciri – ciri haba diperolehi dengan menggunakan Kalorimeter Pengimbasan Perbezaan (DSC). Pemplastik didapati mengurangkan suhu peralihan kaca PLA. EPO didapati meningkatkan tekanan tegangan dan pemanjangan di dalam PLA/EPO. Peningkatan fleksibiliti PLA menerusi penggunaan EPO membuktikan bahawa PLA/EPO boleh digunakan untuk pengunaan bungkusan mesra alam.

Kata kunci: polimer terbiodegradasikan, polimer hijau, poli(laktik asid), bungkusan mesra alam

Introduction

Flexible materials for packaging industry have been second largest contributor in the industries from way back. Ease of handling and storage, overall cost savings and convenience are among the advantages of flexible packaging. Therefore, these are the keys for its success in packaging industry. There are many polymers that are used in flexible packaging industry but mostly the polymers are non-degradable. The most common polymers utilized in the industry are polypropylene (PP), polyethylene (PE), polyvinyl chloride (PVC), polyethylene terephthalate (PET), and bi-axially oriented polypropylene (BOPP) [1].

At present, most polymeric products are derived from fossil fuels, and these products become non- degradable waste materials and remain in the environment. Consequently, extensive researches are conducted globally to create green polymers from renewable resources which are biodegradable and compostable. Biodegradable polymer is an environmental friendly polymer and has low toxicity. But, it has lower strength, brittle, flammable and high permeability to most of gases and solvents as compared to metals and ceramics, which limits its applications in industry [2, 3]. Reinforcement with additive polymers such as plasticizer and filler can overcome these problems, where the fillers need to be evenly distributed in the polymer matrix to maximize its function [3].

Biodegradable products have been used widely in food, furniture and clothing industries [5]. Therefore, the biopolymers have been researched extensively which can expand potential applications. According to Avérous and Pollet [4], biodegradable polymer is a material that decomposes into other resources such as carbon dioxide, methane, water, inorganic compounds and biomass. There are various types of biodegradable polymer which derived from renewable sources such as natural polymer (agro-polymer), microbial polymer (synthesis from microbial fermentation) and synthetic polymer (renewable bio-derived monomers) [4,5,6].

Poly(lactic acid) (PLA) is a synthetic polymer that derived from renewable sources such as starch derivative. PLA is non-toxic and has high mechanical performance compared to other commercial polymers [7]. PLA can be used for disposable packaging industry as it has good mechanical properties and processability [8,9]. However, the brittleness of PLA causes main drawback in the packaging industry [8]. Thus, many researches have been conducted to improve mechanical properties by addition of plasticizer and fiber in the polymer matrices [9]. For this research, properties of PLA had been improved by the addition of epoxidized palm oil (EPO) as plasticizer through solution blending method. Different types of solvents were utilized to solubilize PLA, in which the solvents have closest solubility parameter with PLA. Therefore, the optimum solvent was chosen to be used for mixing PLA to EPO in various ratios. The optical, thermal and mechanical properties of PLA/EPO blends were reported and discussed.

Materials and Methods

Screening Process

For screening process, the PLA beads were solubilized in different type of solvents such as chloroform, methylene chloride (DCM), dimethylformamide (DMF), tetrahydrofuran (THF) and toluene. The solvents were selected based on the solubility parameter. The PLA/EPO blends were blended at constant speed for overnight.

Samples preparation

Firstly, an amount 0.5 g of PLA was solubilized in five different solvents (chloroform, DCM, DMF, THF, and toluene). Then, 0.05 g of EPO was added into each sample and stirred overnight. The polymer blends were poured slowly into petri dishes and left evaporated at fume hood for 24 hours.

Optimization and sample preparation

Once the optimum solvent was chosen, 30 g of PLA was used to prepare PLA/EPO blends in five different ratios of PLA to EPO (100:5, 100:10, 100:15, 100:20, and 100:30) and neat PLA as reference.

Characterization

XH-406B Tablet Press Machine was used to prepare samples in 0.1 cm thickness of film at 150 °C. Shimadzu Autograph AGS-X Series was used to measure the elongation-at-break of the samples. Differential Scanning Calorimetry (DSC 822) was used to obtain the thermal properties of the samples.

Results and Discussion

Solubility of PLA/EPO blend in different solvents

Samples prepared in five different solutions was shown in Figure 1. This step is to identify the most optimum solvent that can be used for mixing and diffusivity of plasticizer in the PLA solution. Through optical observations, sample prepared from chloroform showed transparency and this indicated homogeneity of PLA and EPO in the solvent. Therefore, chloroform was chosen as the solvent and continued for next step of preparing PLA/EPO blend in different ratios.

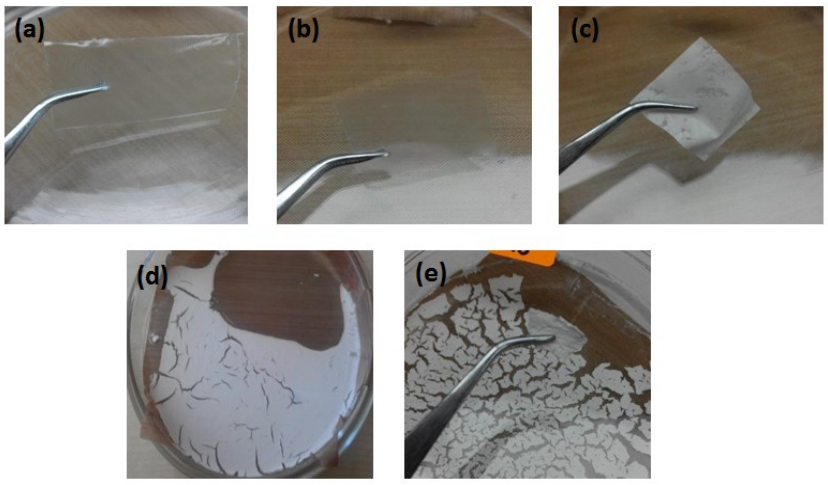

Figure 1. PLA/EPO (100:10) blends in different solutions (a) chloroform, (b) DCM, (c) THF, (d) DMF, and (e) toluene.

Flexural properties of PLA/EPO blends

Flexural strength is the limit of a material to withstand flexural stress without fail. The effects of EPO on the bending stress in the PLA/EPO blends was presented in Figure 2. The bending stress was increased from EPO 5 to EPO 10 and then reduced gradually to EPO content of 15 and 20 wt%. And then, the stress increased again when the EPO content was 30 wt%. This showed that by addition of EPO as plasticizer, it reduced the stress that the blend can endure except for PLA/EPO (100:10). At EPO content of 30 wt%, the increased stress exhibited reduced plasticizing effect at higher loading of EPO. The stress also reflected the ability of PLA/EPO blend (100:10) to resist compression and tension stress simultaneously as shown in Figure 3.

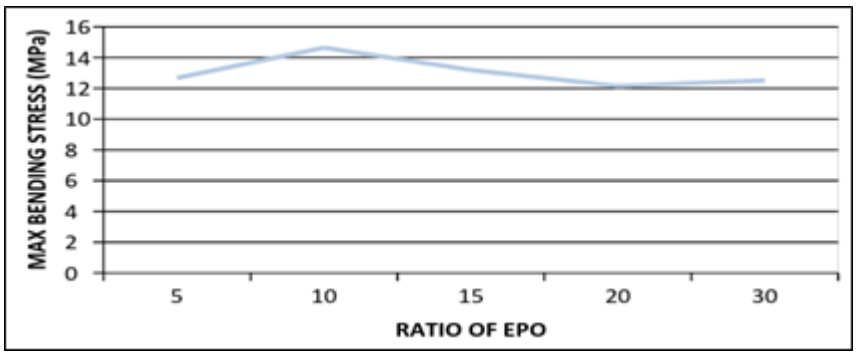

Figure 2. Bending stress of PLA/EPO blends at different ratios

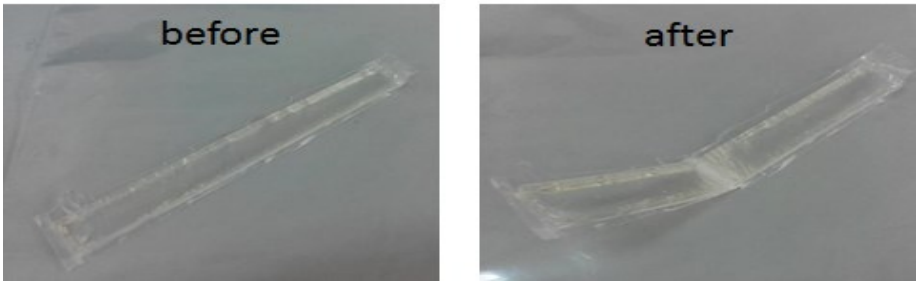

Figure 3. PLA/EPO blend (100:10) sample before and after the bending stress

Tensile properties of PLA/EPO blends

The tensile strength and elongation at break were determined at room temperature (25 °C). The stress-strain curves of neat PLA and PLA/EPO blends was shown in Figure 4. It showed that neat PLA was fractured at low strain whereas the PLA/EPO blends exhibited a ductile behavior with yield indicating plastic deformation behavior. PLA/EPO blends exhibited stress whitening behavior as shown in Figure 5. The similar stress whitening behavior was also observed in other plasticized PLA sample which was due to formation of voids in the samples [10].

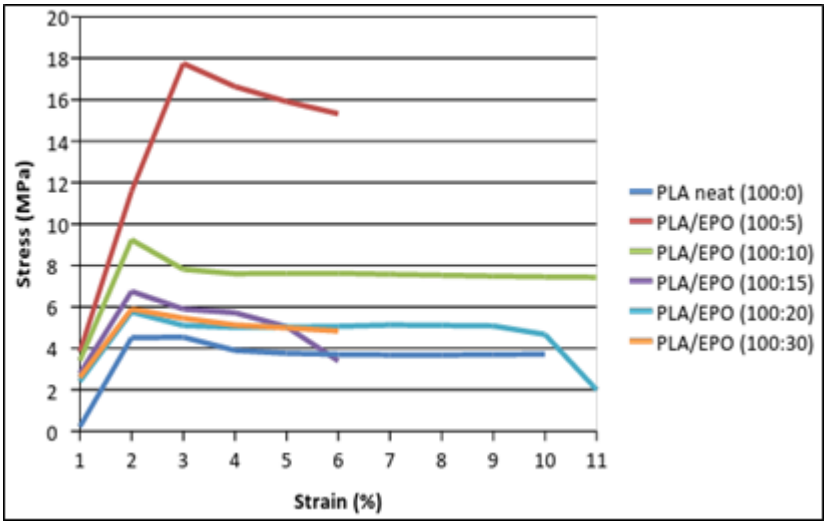

Figure 4. Stress-strain curves of neat PLA and PLA/EPO blends

The elongation-at-break of PLA/EPO blends increased due to plasticization effect of low molecular weight EPO and dispersion of EPO micro droplets in the PLA matrix [10]. The increased flexibility of the PLA/EPO blends was accompanied with decreased in tensile strength, yield stress and modulus. The yield stress of neat PLA decreased from 18.0 MPa to 9.0 MPa for 5 wt% EPO. Addition of 5 wt% EPO significantly improved the tensile strength of PLA/EPO by approximately 50%. Hence, as ratio of EPO increased, the yields stress decreased as reported by Chieng et. al [11]. Meanwhile, at EPO content of 30 wt%, the yield stress decreased to 4.3 MPa and elongation-at-break of 6%. The plasticizing effect reduced at higher loading of EPO, in this case, at 30 wt% the plasticizer has not much effect in the PLA matrix.

Figure 5. Visualization of deformed samples under tensile test

Thermal properties of PLA/EPO blends

The DSC heating thermograms of neat PLA and plasticized PLA blends was illustrated in Figure 6. The DSC curves exhibited three thermal transitions; glass transition (T_g), crystallization (T_c), and melting (T_m) temperatures. The glass transitions of PLA/EPO blends appeared at a lower temperature compared to neat PLA. The glass transition temperatures gradually decreased with increasing EPO content. The T_g of neat PLA decreased from 60.7 °C to 54.9 °C for PLA/EPO (100:15). However, for PLA/EPO (100:30), the glass transition temperature was increased to 60.84 °C. Ali et al. [10] mentioned that there will be no more decrease of T_g at greater amount of epoxidized soybean oil (ESO) in the PLA matrix. In addition, the declination of T_g also exhibited mixing of EPO soft segments into the hard segment phase of PLA. The decrease in T_g showed that there was penetration of EPO segment into the PLA hard segments and increased the chain mobility of PLA.

The crystallization temperature (T_c) of PLA also decreased by addition of EPO which indicated higher chain mobility after the incorporation of EPO. This finding was consistent with plasticized PLA reported by Ali et al. [10], that the cold crystallization temperature of PLA decreased with higher plasticizer content.

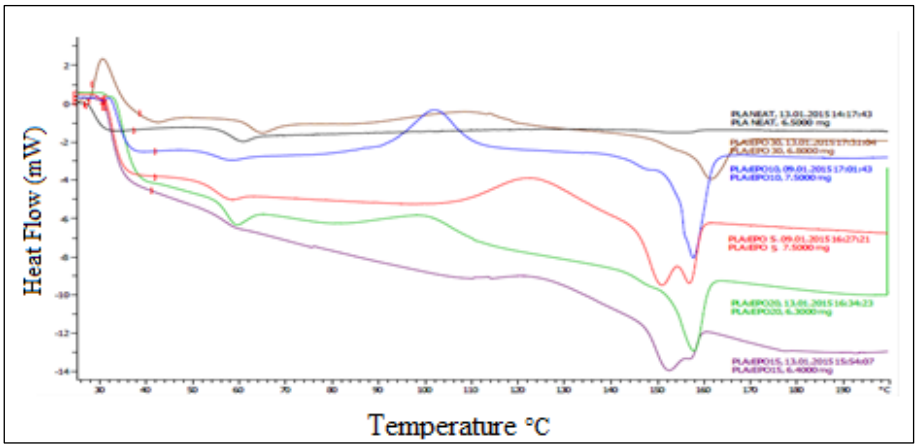

Figure 6. DSC thermograms of neat PLA and PLA/EPO blends

Conclusion

Biodegradable PLA/EPO blend film was successfully prepared through solvent blending method by using chloroform. The flexibility of plasticized PLA increased by addition of EPO and the optimum ratio of EPO was 10 wt%. Thermal properties of PLA/EPO blends showed that the glass transition (T_g), crystallization (T_c), and melting (T_m) temperatures were decreased and the chain mobility of PLA increased. The improved thermal properties of PLA using EPO eased the processability of the blend and this to ensure the blend to be used as environmental friendly packaging material.

Abstract

The urbanization in Klang Valley, Peninsular Malaysia over the last decades has induce the atmospheric pollution's risk resulted to negative impact on the environment. The aims of this paper are to identify the spatial-temporal relationship of particulate matter (PM_{10}), to determine the characteristic of each location and to classify hierarchical of the location in relation to their impact on PM_{10} concentration in Klang Valley. The Spearman correlation test indicate that there was strong significant relationship between all the locations (> 0.7; $p < 0.001$) and moderate relationship between Petaling Jaya-Kajang and Kajang-Shah Alam (< 0.7; $p < 0.001$). The principal component analysis (PCA) identifies all four locations have been affected by PM_{10} which were determined as one of the pollutant that deteriorated the air quality. Cluster analysis (CA) has classified the PM_{10} pattern into three (3) different classes; Class 1 (Klang), Class 2 (Petaling Jaya and Kajang) and Class 3 (Shah Alam) based on location. Further analysis of CA would be able to classify the PM_{10} classes into groups depending on their dissimilarities characteristic. Thus, possible period of extreme air quality degradation could be identified. Therefore, statistical and envirometric techniques have proved the impact of the various location on increasing concentration of PM_{10}.

Keywords: particulate matter, Spearman correlation test, principal component analysis, cluster analysis

Abstrak

Proses pembandaran di Lembah Klang, Semenanjung Malaysia sedekad lalu telah mendorong kepada risiko pencemaran atmosfera yang memberi impak negatif kepada alam sekitar. Kajian ini dilakukan bertujuan untuk mengenalpasti hubungkait antara ruang dan tempoh bagi partikel terampai (PM_{10}), menentukan ciri – ciri setiap lokasi dan menentukan pengkelasan hirarki lokasi berhubungan dengan impak kepekatan PM_{10} di Lembah Klang. Ujian korelasi Spearman menunjukkan hubungkait yang kuat antara semua lokasi (> 0.7; $p < 0.001$) dan hubungan

yang sederhana antara Petaling Jaya-Kajang dan Kajang-Shah Alam (< 0.7; $p < 0.001$). Analisis komponen utama (PCA) menentukan semua empat lokasi yang telah terjejas dengan PM_{10} iaitu antara bahan pencemar yang menjejaskan kualiti udara. Analisis kluster (CA) mengelaskan pola PM_{10} kepada tiga (3) kelas berlainan; Kelas 1 (Klang), Kelas 2 (Petaling Jaya dan Kajang) serta Kelas 3 (Shah Alam) berdasarkan lokasi. Analisis lanjutan CA membolehkan pengkelasan kelas PM_{10} kepada kumpulan bergantung kepada ketidaksamaan ciri. Justeru, kemungkinan tempoh kemerosotan kualiti udara yang melampau dapat dikenalpasti. Oleh itu, teknik statistik dan envirometrik telah membuktikan impak pelbagai lokasi terhadap peningkatan kepekatan PM_{10}.

Introduction

Particulate matter is one of the aerosol particles in the atmosphere [1, 2] which has an aerodynamic diameter of less than 10 μm and well known as PM_{10}. PM_{10} has been discovered as major air pollutant in Southeast Asia including Klang Valley, Malaysia [3, 4, 5]. A long term study over 5 decades regarding to air pollution brings up an implication not only to human health but also to the environment [6, 7]. Particulate matter specifically PM_{10} affects human health via inhalation due to its smaller in size and the ability to reach and settle in human respiratory tract which could induce chronic pulmonary disease and asthma [8, 9].

Asia region encounter a major problem due to air particulate matter pollution with the annual average value of total suspended particulate (TSP) which exceeding 300 μgm^{-3} [10]. In Malaysia without the haze issue, the level of PM_{10} is mostly influence by the vehicular and industrial emission [4]. Therefore, this study will define the PM_{10} level in Klang Valley region under normal condition without severe haze issue as the main focus.

Multivariate analysis has been chosen as the final statistical method to analyze, classify and interpret huge number of datasets and has become the most applicable in various field of study recently [11 - 19]. These types of analysis include the application of Principal Component Analysis (PCA) and Hierarchical Agglomerative Cluster Analysis (HACA). The PCA was applying to identify the most significant parameter which relates to spatial and temporal variation [11 - 17, 20, 21, 22]. Meanwhile, HACA was applying to group large data into cluster with differing characteristic between the groups but similar characteristic within the group [23]. Therefore, the aim of this study is to identify the spatial-temporal relationship of PM_{10}, to determine the characteristic of each station and to classify hierarchical of the station that give an impact to PM_{10} concentration in Klang Valley.

Materials and Methods

Background of sampling location

Klang Valley region involves several districts in Selangor and is located in central part of west coast Peninsular Malaysia by the Strait of Malacca to west [24, 25]. Alam Sekitar Malaysia Sdn. Bhd. (ASMA) was appointed by Malaysian Department of Environment (DOE) in establishing, operating and maintaining the continuous air quality monitoring stations. All the stations (S1, S3 and S4) were located within residential area except for Petaling Jaya (S2) which located within industrial area. All the stations within Klang Valley region were affected by heavy traffic which consequently affected by vehicles emissions and the details were shown in the Table 1. The Klang Valley Region which is situated in the central part of Selangor state is illustrated in Figure 1.

The air quality data

The daily-recorded air quality data of PM_{10} at the selected stations within the year of 2000 – 2009 were obtained from Malaysian Department of Environment (DOE). A total of 480 observation data of PM_{10} (12 observations x 4 stations x 10 years) were involved in this study.

Data cleaning

Data treatment technique has been used to treat the missing data in order to obtain a better continuous air quality monitoring data. The missing data in this study has been treated with the method of mean substitution. All the missing data are replacing with the value of mean available neighboring data [27]. Furthermore, other studies stated

that mean substitution method is better and more accurate rather than eliminating the missing value with list wise and pairwise deletion method [28, 29, 30].

Table 1. Continuous air quality monitoring stations within Klang Valley region

Station ID	Air Monitoring Station	Representative Station ID	Representative Name	Coordinates		Background

Source: Department of Environment [26]

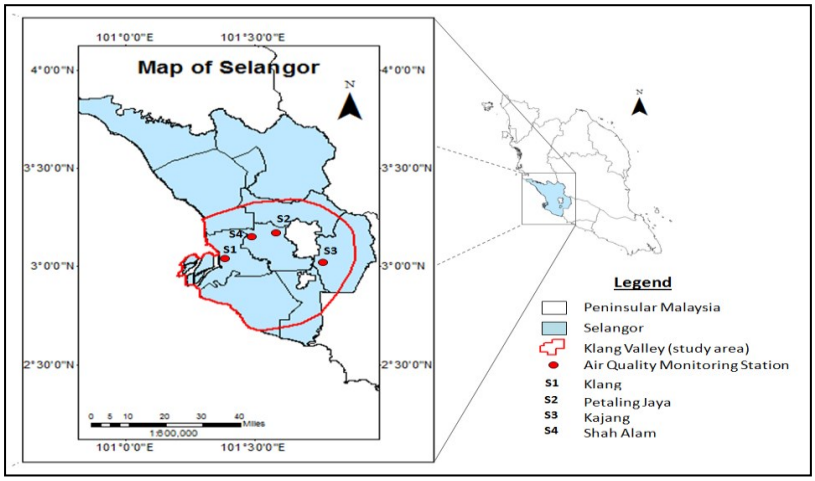

Figure 1. Map of Selangor district which include Klang Valley region

Data analysis

Several types of statistical approach include descriptive analysis, Spearman correlation analysis, principal component analysis (PCA) and cluster analysis (CA) via XLSTAT software has been used in achieving the objective. XLSTAT software has been used as a tool because of its flexibility, multidimensionality and ability to synthesize complex data sets [15]. Any missing value had been treated using mean substitution method.

Spearman correlation test

Spearman correlation test is used for determination of relationship between two variables and also known as Spearman Rho test [31, 32, 33]. This test is one of the non-parametric approaches which is suitable for not normally distributed data and would prefer monotonic graph instead of linear graph. Monotonic relationship shows that the score of variable increases with decreasing the other variables' score either in similar or different rate. The correlation values are in the range between -1 and +1 where the value only shows the strength of correlation between two variables without showing cause and consequence between those two variables [34]. However, the influence and the impact of each other variables can be described. Mathematical formula for calculating Spearman correlation is as follows;

$$r = 1 - \left(\frac{6\,\Sigma\, p^2}{N\,(N^2-1)}\right) \quad (1)$$

where p^2 is define as square root of the variable, and N is a sample size

Principal component analysis (PCA)

Principal component analysis is a procedure for identifying, reducing and arranging items into groups depending on dependent variables and the strength of correlation between those items [12, 15, 16, 35 – 39]. Linear combination of original data set is being generated by the ability of PCA in reducing large amount of data into new sets of variables where the number of principal components is not more than number of original variables [37]. Identification and observation of variation's source taking place after reduction of data set and generally written in the following mathematical equation 2;

$$PC_i = l_{1i}\,X_1 + \, l_{2i}\,X_2 + \, \ldots \, + \, l_{ni}\,X_n \quad (2)$$

where PC_i is define as i^{th} principal component, l_{ji} is define as variable loading and X_j is define as observed variable

Cluster analysis (CA)

CA is an unsupervised pattern recognition identification method, used to split a large group into smaller ones [12] based on homogeneity data. The homogeneous sub-groups will be obtained within the population and gather them into clusters based on similarity of the data [38, 40, 41]. In this study, CA was used for clustering data with the similarities in a group. CA is employed on the normal distribution dataset through the Ward's method by means of Euclidean distances, as a measure of the relationship [11, 12, 16]. The outcome of this method will be demonstrated in a dendrogram form.

Results and Discussion

Statistical analysis of PM_{10}

The monthly values of PM_{10} data in Klang Valley, Selangor have been analyzed and summarized in box plots. The PM_{10} distribution in the air is higher in Klang and Shah Alam compare to Petaling Jaya and Kajang with the range of 154.65μg/m^3 and 104.19μg/m^3 respectively. The mean of PM_{10} is also higher in Klang and Shah Alam compare to the other two stations with the value of 79.97μg/m^3 and 63.32μg/m^3 respectively. Major activities and heavy populated with residential and industrial activities are the main contributors to the higher PM_{10} value in Klang Valley region (Klang and Shah Alam). The details of descriptive statistic of PM_{10} distributions in Klang Valley region for 2000 to 2009 is shown in Table 2 and expressed by box plot in Figure 2.

Determination of air quality relationship

The monthly PM_{10} data in Klang Valley region for 10 years period (2000 to 2009) showed the result is not normally distributed. Parametric test has been used for transformation process via log method. However, the negative result still not normally distributed form. Therefore, the non-parametric test was chosen for the PM_{10} data instead of parametric test. Thus, the Spearman correlation was chosen as the non-parametric approach for determining the relationship between two variables.

Table 2. Descriptive statistic of monthly PM_{10} distributions in Klang Valley region for year 2000-2009

Station	Obs	Min	Max	Range	Q1	Median	Q3	Mean	Var (n)	Std. dev. (n)
Klang	120	39.25	193.90	154.65	55.14	68.39	95.02	79.97	1149.72	33.91
Petaling Jaya	120	26.82	116.97	90.15	45.34	54.06	67.45	58.28	316.60	17.79
Kajang	120	31.01	124.48	93.48	42.30	49.87	61.73	54.03	283.27	16.83
Shah Alam	120	29.67	133.86	104.19	44.71	58.71	80.07	63.32	535.08	23.13

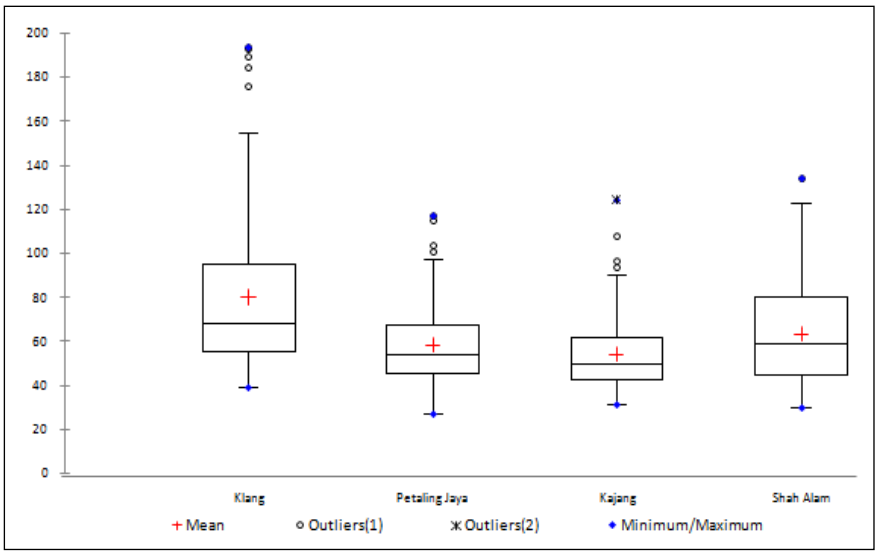

Figure 2. Box Plot of PM_{10} distributions in Klang Valley region for 10 years period (2000 – 2009)

Table 3 showed that all the stations have significant relationship. However, only Klang-Petaling Jaya, Klang-Kajang, Klang-Shah Alam and Petaling Jaya-Shah Alam prove for strong correlation between two stations with the value of 0.732($p < 0.0001$), 0.753($p < 0.0001$), 0.845($p < 0.0001$) and 0.776($p < 0.0001$) respectively. The rest, Petaling Jaya-Kajang and Kajang-Shah Alam showed moderate correlation with the value of 0.678($p < 0.0001$) and 0.602($p < 0.0001$), respectively (Table 4). Klang (S1) was shown to be the main contributor to the PM_{10} level and variation within 10 years period. Based on Malaysian Environmental Quality Report 2004 by Department of Environment, PM_{10} were originating from stationary sources where industries as the highest contributor followed by power plants and the mobile sources from motor vehicles activity [42].

Table 3. Spearman correlation of PM_{10}between Klang Valley regions for 10 years

Year	Variables	Klang	Petaling Jaya	Kajang	Shah Alam
2000-2009	Klang	**1**			
	Petaling Jaya	**0.732**	**1**		
	Kajang	**0.753**	**0.678**	**1**	
	Shah Alam	**0.845**	**0.776**	**0.602**	**1**

Values in bold are different from 0 with a significance level alpha = 0.05

Table 4. Probability value of the spearman correlation of PM_{10} between Klang Valley regions for 10 years

Year	Variables	Klang	Petaling Jaya	Kajang	Shah Alam
2000-2009	Klang	**0**			
	Petaling Jaya	**< 0.0001**	**0**		
	Kajang	**< 0.0001**	**< 0.0001**	**0**	
	Shah Alam	**< 0.0001**	**< 0.0001**	**< 0.0001**	**0**

Values in bold are different from 0 with a significance level alpha = 0.05

Air quality classification using principal component analysis (PCA)

PCA has been applied for identifying the most and less significant location that contributes to air quality in Klang Valley region. Two types of test; Keiser-Meyer-Olkin Measure (KMO) and Barlett's Test of Sphericity have been used in order to assess the sufficiency of the data [13, 37, 38]. KMO test shows the multicolinearity or in simple words, identification of similarity in correlation value exists between two or more items [15]. If there is a similarity in correlation between the items, those items will be measured in similar aspect. The benchmark's value for KMO test is agreed to be more than 0.5 [37, 38]. The KMO value for this study is 0.726 which indicate that there is no serious multicolinearity problem for the Klang Valley's PM_{10} data and suitable to construct PCA. Besides, Barlett's sphericity test also used in identification of the correlation between items and sufficiency of the data to construct the PCA with the benchmark value of less than 0.05 [13, 37, 38]. The result of Barlett'stest showed that the observed PM_{10} data are sufficient to construct PCA with the obtained p-value less than 0.0001. These two sets of test are shown in Table 5.

Table 5. Keiser-Meyer-Olkin Measure (KMO) and Barlett's Test of Sphericity

Types of PCA Test	Test's Variable	Value
Keiser-Meyer-Olkin measure of sampling adequacy		0.726
Barlett's Test of sphericity	Chi-square (observed values)	467.771
	Significant (p-value)	$p < 0.0001$

The Eigenvalue of these data is 3.391 and meet the PCA criterion because of the value larger than one (Eigenvalue > 1). The Eigenvalue shows the proportion of variance in every factor where the variance is significantly increase with increasing number of Eigenvalue [38]. Only 1 Eigenvalue was observed for the PCA analysis as shown in Table 6 because only PM_{10} observation data were used in this study. The scree plot in Figure 3 can prove that only single Eigenvalue involve in this PCA interpretation and the factor that give a large different in variance will be shown clearly by the scree plot [38].

From this study, all of the air quality stations in Klang Valley affected by anthropogenic activity as seen in the F1. From Table 6, it shows that all of the stations gave the positive and strong factor loading [Klang (0.994), Petaling Jaya (0.902), Kajang (0.914) and Shah Alam (0.923)]. Therefore, over past 10 years period (2000 – 2009), particulate matter less than 10 micron (PM_{10}) is one of the most air pollutant that contributed to air quality problem in Klang Valley region. Strong positive factor loading lead to the source of particulate matter from traffic emission in which be the major source of PM_{10} from automobiles' fuel combustion activity [37, 43]. Figure 4 shows the dot matrix position base on factor loading of each air quality stations.

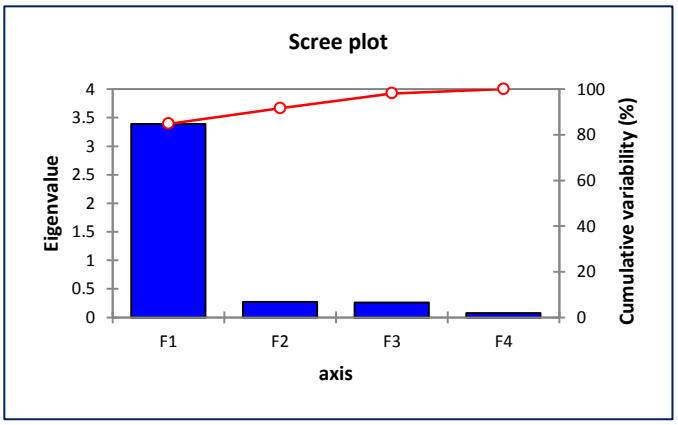

Figure 3. Scree plot of eigenvalue vs cumulative variability (%)

Table 6. Principal component analysis (PCA) interpreted result of PM_{10} data in Klang Valley

Air Quality Station	Factor Loading			
	F1	F2	F3	F4
Klang	0.944	0.141	-0.234	0.185
Petaling Jaya	0.902	-0.246	0.347	0.076
Kajang	0.914	0.356	0.152	-0.123
Shah Alam	0.923	-0.256	-0.250	-0.142
Eigenvalue	**3.391**	0.273	0.261	0.076

The principal components were then being rotated to gain better understanding and interpretation of the data. Varimax rotation was used as a criterion [37] as proposed by other author [44], with only involve the consideration of component with an eigenvalue larger than 1. The variability and cumulative variability for rotated principal component scored both 84.773%. Table 7 shows the percentage of variability and cumulative variability of the PM_{10} data after being rotated with Varimax rotation. On the other hand, Table 8 shows the percentage contribution of PM_{10} in Klang, Petaling Jaya, Kajang and Shah Alam, which are 26.27%, 23.99%, 24.62% and 25.10% respectively. Therefore, it proved that the above statement can be accepted with the average percentage contribution of 25% for each area.

Table 7. Rotated percentage of variability and cumulative variability after Varimax rotation

	F1	F2	F3	F4
Variability (%)	84.773	6.818	6.516	1.893
Cumulative variability (%)	84.773	91.591	98.107	100.000

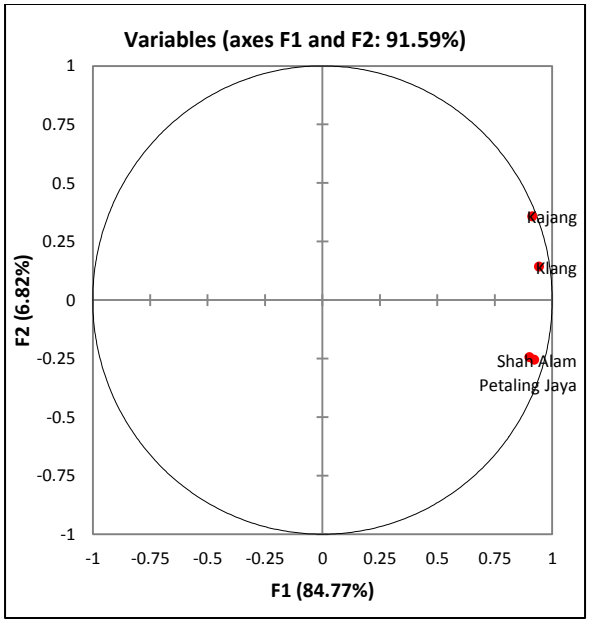

Figure 4. Dot matrix position base on factor loading of each air quality stations in Klang Valley region.

Table 8. Contribution of the variables after Varimax rotation

Contribution (%)	D1
Klang	26.27
Petaling Jaya	23.99
Kajang	24.62
Shah Alam	25.10
Average contribution	25.00
Total contribution	100.00

Air quality pattern using cluster Analysis (CA)

This study focused on four monitoring stations around Klang Valley region, where particulate matter less than 10 microns (PM_{10}) has been chosen for analysis.CA was used as an approach to find and put them into groups depending on their dissimilarity characteristics. PM_{10} pattern which obtained from PCA output have been classified into three (3) different classes; Class 1, Class 2 and Class 3 based on location and can be illustrated in dendrogram such as in Figure 5.

Class 1 refers to air monitoring station in Sekolah Menengah Perempuan Raja Zarina, Klang (CA0011) representative as Klang air monitoring station. This station contributes highest number of dissimilarity to the graph where it is performed alone and giving significant indicator of air quality. In other words, Klang can be represented as a not good air condition. Class 2 covered two different air quality stations which are located in Sekolah Kebangsaan Seri Petaling, Petaling Jaya (CA0016) represent as Petaling Jaya air monitoring station and Country Height, Kajang (CA0023) represent Kajang air monitoring station. Class 3 refers to Sekolah Kebangsaan Taman Tun Dr. Ismail, Shah Alam (CA0025) which represents Shah Alam air monitoring station.

Klang (Class 1) is located near to industrial area and a busy port area originated at Port Klang, while the other two clusters are situated near to both industrial and residential area. The study showed that the sources of pollutant in all stations are affected by motor vehicles, industrial and factories activity. The level of PM_{10} in Klang showed slightly higher concentration due to the port activity which was not found in the other stations [45].

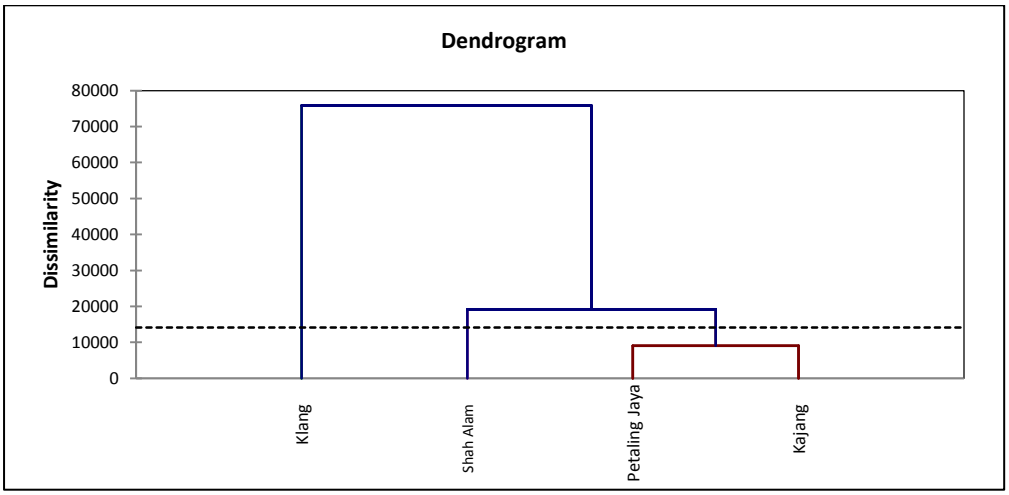

Figure 5. Dendrogram view of cluster analysis for particulate matter (PM_{10}) in Klang Valley

Characteristic of PM_{10} pattern within the Klang Valley region can be identified more using this CA method. This further analysis was discussed based on classes and the groups that might be produced. Figure 6 shows the pattern of $PM_{10}$for three different clusters in Klang Valley based on year.

Throughout the 10 years period from 2000 to 2009, Class 1 (Klang) produces three patterns of group; Group 1 (2008 and 2009) and Group 2 (2002 and 2005). Meanwhile Group 3 (2000, 2001, 2003, 2004, 2006 and 2007) had shown the highest similarity within the year. Based on year 2000 to 2009, Class 2 which refers to Petaling Jaya and Kajang produces four different patterns of group; Group 1 (2008), Group 2 (2009), Group 3 (2003, 2004 and 2005) and lastly Group 4 (2000, 2001, 2002, 2006 and 2007). Class 3 (Shah Alam) produce 3 patterns, Group 1 (2000, 2001, 2006 and 2007), Group 2 (2008 and 2009) and Group 3 (2002, 2003, 2004 and 2005). The above finding shows that the concentration of PM_{10} in the air were the highest at each station; Klang, Petaling Jaya, Kajang and Shah Alam at year 2008 and 2009.

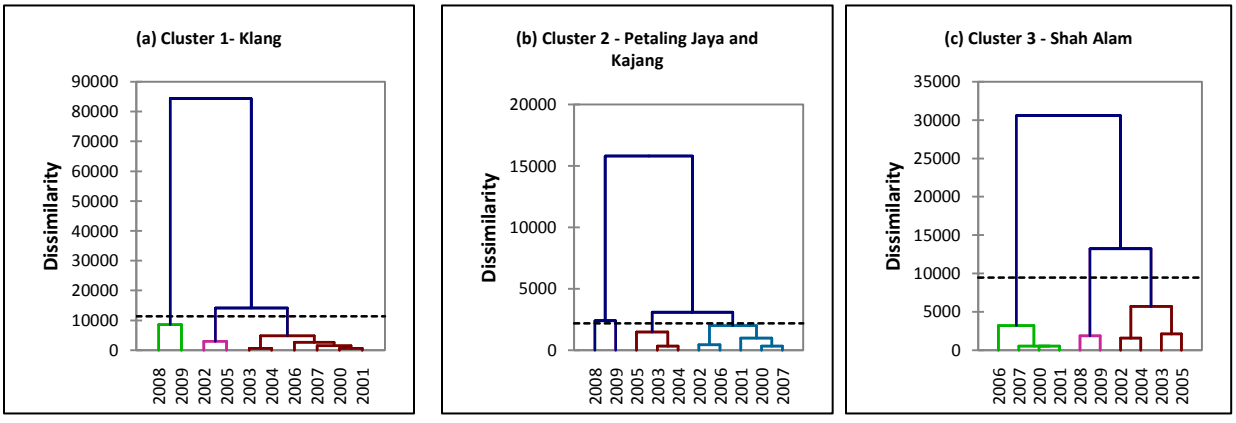

Figure 6. Dendrogram (a – c) view of PM_{10} pattern for three different clusters in Klang Valley based on year

Conclusion

Based on the result, significant relationship of particulate matter (PM_{10}) in Klang Valley, Malaysia and its pattern can be identified using statistical and envirometric technique. The relation between two variables can be determined by using Spearman Correlation Test. Strong correlations (> 0.7 with the p-value < 0.001) were obtained for all stations in determination of significant relationship between 2 stations except for Petaling Jaya-Kajang and Kajang-Shah Alam which recorded moderate correlation value 0.678($p < 0.001$) and 0.602 ($p < 0.001$) respectively. Principal component analysis (PCA) was able to identify the most and less significant location which contributing to the level of PM_{10}. The study found that all four location have been affected by PM_{10} which was determined as one of the air pollutant that contributes to the deterioration of air quality in Klang Valley. On other hand, Cluster analysis (CA) on the other hand was able to classify the PM_{10} into three groups depending on their dissimilarities characteristic. PM_{10} pattern which obtained from PCA output have been classified into three (3) different classes, Class 1 (Klang), Class 2 (Petaling Jaya and Kajang) and Class 3 (Shah Alam) based on location and possible period of extreme air quality degradation could be identified. These statistical and envirometric techniques have proved the impact of the various location on increased concentration of PM_{10}.

Acknowledgement

Gratitude and appreciation to Malaysian Department of Environment (DOE) for their provision of air quality data, and also to supervisor, committee members and colleagues for their efforts in assisting and completing this article.

Abstract

Masalah sedimentasi merupakan masalah utama sungai di Malaysia. Analisis saiz partikel sedimen di sungai menyediakan maklumat yang berguna dalam menilai kadar dan corak hakisan, pengangkutan dan pemendapan pada sesuatu masa. Bahan-bahan sedimen dikelaskan mengikut saiz seperti pasir, kelodak dan liat. Kajian ini membincangkan hasil kajian mengenai analisis sedimentasi yang dijalankan di Sungai Pahang pada 3 hingga 6 Jun 2015. Sebanyak 13 stesen persampelan telah dipilih. Parameter yang telah diguna bagi tujuan kajian ini berdasarkan kepada jenis taburan saiz partikal sedimen (g). Pengelasan mengikut saiz bahan telah dikira dan ditentukan melalui nilai skala Phi (ø) bagi mengira pelbagai parameter penentuan sedimen seperti min (M), sisihan piawai (D) dan pencongan (S). Di dalam kajian ini, teknik envirometrik digunakan untuk mengelaskan setiap parameter sedimen yang telah dianalisis. Hasil pengelasan mendapati setiap parameter min, pencongan dan sisihan piawai mempunyai tiga kelas utama yang mendominasi iaitu pasir kasar, pasir sederhana dan pasir halus. Analisis saiz partikel sedimen (M) menunjukkan bahawa, di bahagian tebing kanan kiri dan tengah sungai adalah didominasi pasir bersaiz butiran halus dengan nilai phi 2 ke phi 3. Tahap keseragaman sedimen atau sisihan piawai (D) di kawasan kajian mempunyai butiran pasir yang halus dengan skala keseragaman yang buruk direkodkan iaitu phi 1 ke phi 2. Bagi nilai pencongan (S), saiz sedimen yang terdapat di kawasan kajian adalah bersaiz kasar dan sangat kasar iaitu di antara phi -0.1 ke phi -0.3 dan phi -0.3 ke phi -1. Oleh yang demikian, kawasan Sungai Pahang merupakan kawasan yang mudah mengalami perubahan geomorfologi akibat daripada struktur tanihnya yang bersifat mudah dihakis oleh hujan dan perubahan kadar luahan sungai.

Kata kunci: sedimentasi, saiz partikel sedimen, teknik envirometrik, skala phi, Sungai Pahang

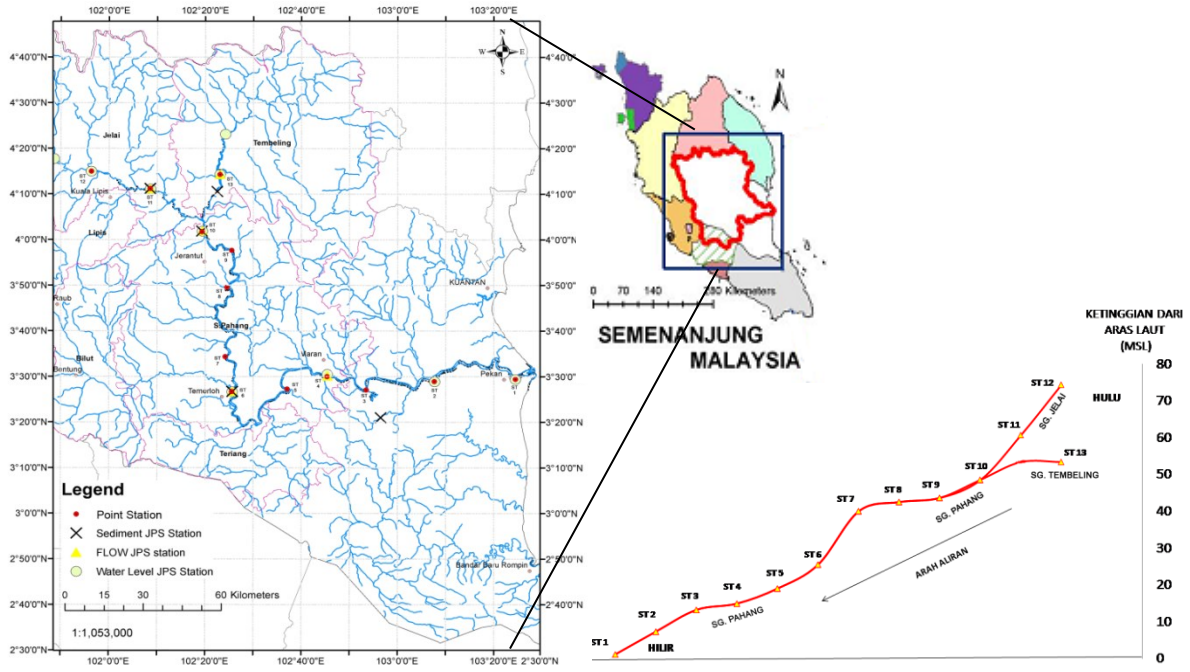
Abstract

Sedimentation is a main river problem in Malaysia. Particle size sediments analysis the river provides useful information to evaluate the rate and pattern of erosion, transportation and deposition at a time. The sediments sizes are classified according to sand, silt and clay. This study discusses about the results of sedimentation analysis at the Pahang River from 3 until 6 June 2015. 13 sampling stations were selected. The parameters used in this study are based on grain size distribution (g). Total of different sizes of material classifications were calculated using Phi scale (ø) in older to statistically calculate their mean (M), standard deviation (D) and skewness (S). In this study, envirometrics technique were used to analyzed the classify parameter of this sediments. The classify results for each parameters mean, skewness and standard deviation has dominated by three main class like coarse sand, medium sand and fine sand size. Analysis of particle size sediment (M) shows the middle, right and left bank river is dominated by fine grain size with the phi 2 to phi 3. The uniformity of sediment or standard deviation (D) on the study

areas has a worst with the fine grain sand with the phi 1 to phi 2. For the skewness (S), sediment size in study areas is coarse and very coarse size with phi -0.1 to phi -0.3 and phi -0.3 to phi -1. Therefore, Pahang River areas is an easily to change as a geomorphology landscape that are easily eroded by rain and change of the discharge rate.

Keywords: sedimentation, particle size, envirometrics technique, phi scale, Pahang River

Pengenalan



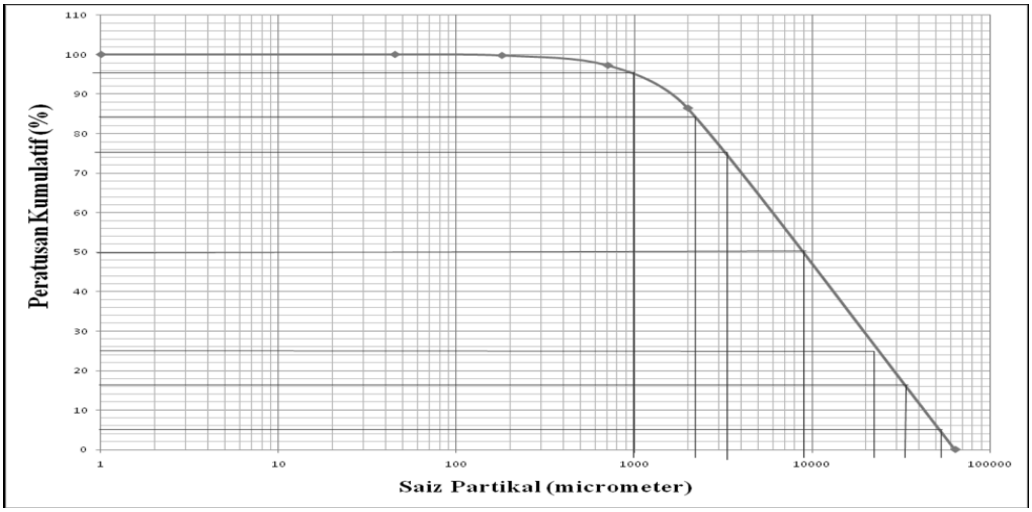
Sedimen atau sedimentasi merupakan sebahagian daripada proses sedimentologi yang berlaku ke atas suatu kawasan lembangan. Sedimen ialah bahan yang terhasil daripada proses luluhawa dan hakisan batuan yang biasanya diangkut oleh agen angin, air dan ais serta diendapkan secara berlapis [1,2]. Sedimen terampai biasanya mempunyai bahan koloid yang bersaiz mikro memerlukan hanya halaju sungai yang rendah untuk mengangkut dari satu titik ke satu titik. Manakala beban dasar sedimen merupakan beban yang bergaris pusat antara 0.2 mm hingga ke 2 mm, bergantung kepada struktur asas batuan dan tanih di sekitar kawasan tersebut [3]. Struktur sedimen pula merupakan struktur yang terbentuk semasa pengenapan atau sejurus selepas bahan sedimen itu dienapkan serta sebelum sedimen termampat [4]. Dengan itu, sedimen memainkan peranan yang penting dalam kitaran yang berkaitan dengan unsur dalam akuatik sekitaran [5]. Sedimen bertanggungjawab bagi mengangkut nutrien dan bahan pencemar yang penting masuk ke dalam sungai. Selain itu, kebanyakan sedimen dalam permukaan air adalah berpunca daripada permukaan hakisan dan mengandungi komponen galian, hakisan batuan dasar dan komponen organik semasa proses pembentukan tanah berlaku [6].

Proses pengangkutan merupakan salah satu dari faktor utama pemendapan sedimen di sepanjang dan muara sungai. Aliran sungai dikatakan mempunyai pengaruh yang besar terhadap pemendapan sedimen terutamanya dalam proses pengangkutan pelbagai jenis beban dari bahagian hulu ke hilir sungai. Terdapat beberapa proses pengangkutan sedimen yang boleh mempengaruhi kadar pemendapan di sesuatu kawasan, antaranya ialah proses golekan, seretan, loncatan, apungan, ampaian dan proses larutan [2,7]. Proses golekan, seretan dan loncatan melibatkan beban sungai yang agak besar dan sederhana besar. Proses ini berlaku disebabkan oleh halaju air yang kuat dan beban ini kebanyakannya dimendap di bahagian hulu sungai yang melibatkan kawasan air terjun dan jeram. Selain dari proses di atas, proses apungan, ampaian dan proses larutan pula boleh mempengaruhi pemendapan sedimen di sepanjang sungai dan muara sungai. Proses ini berlaku disebabkan oleh keadaan dasar sungai yang semakin landai dan menyebabkan aliran air sungai mulai perlahan. Keadaan ini boleh menyebabkan pemendapan sedimen berlaku, biasanya melibatkan sedimen atau bahan mendak yang lebih kecil seperti pasir, lumpur, kelodak dan kerikil yang halus [8]. Masalah sedimentasi yang serius berlaku di Sungai Pahang mendorong kajian ini dijalankan. Bagi mengetahui punca utama berlakunya masalah sedimentasi, kajian analisis sedimentasi ini dilakukan untuk mengetahui struktur tanih yang terdapat di sepanjang Sungai Pahang.

Bahan dan Metodologi

Kajian ini dijalankan pada 3 hingga 6 Jun 2015 dan sebanyak 13 stesen telah dipilih disepanjang Sungai Pahang iaitu bermula dari Sungai Jelai di bahagian Barat Laut Negeri Pahang dengan koordinat 101° 55'49.472" E dan 4° 15'34.355" N. Manakala Sungai Tembeling dibahagian Timur Laut dengan koordinat 102° 28'27.324" E dan 4° 31'14.986" N yang terus mengalir kebawah melalui Bandar Termeloh, Bera, Mentiga dan terus ke pekan dan berakhir di Pahang Tua Muara Sungai Pahang di koordinat 103° 28'16.529" E dan 3° 31'33.478" N (Rajah 1). Bagi memudahkan analisis yang akan dijalan, kawasan kajian akan dipecahkan kepada tiga peringkat iaitu hulu, tengah dan hilir. Peringkat hulu iaitu di Sungai Jelai (Stesen 12 dan Stesen 11), Sungai Tembeling (Stesen 13), Hulu Sg. Pahang (Stesen 10). Peringkat tengah adalah Jerantut, Temerloh dan Bera (Stesen 9, Stesen 8, Stesen 7 dan Stesen 6). Manakala peringkat hilir pula bermula dari Bandar lama Chenor sehingga ke Pekan Pahang (Stesen 5, Stesen 4, Stesen 3, Stesen 2 dan Stesen 1).

Alatan yang digunakan dalam kajian ini adalah seperti pencekup sedimen dan beg plastik bagi tujuan pengambilan sedimen. Tiga replikasi sampel telah di ambil bagi tiap-tiap stesen dan hasil kajian ditunjuk mengikut purata replikasi tersebut. Meter arus, tolok penyukat kedalaman, pita pengukur dan pancang digunakan bagi mengukuran keratan rentas dan had laju air disetiap stesen [9,10]. Kesemua sampel yang diambil kemudiannya dianalisis di dalam makmal.



Rajah 1. Peta kawasan kajian melalui pandangan atas dan tepi

Proses pengayakan sedimen akan dijalankan di dalam makmal dengan menyerakkan sedimen di atas plastik bersih dan dibiarkan kering pada suhu bilik. Semasa proses pengeringan yang dijalankan, gumpalan sampel sedimen dipecahkan kepada bahagian-bahagian yang lebih kecil untuk mempercepatkan proses pengeringan. Sampel sedimen dibiarkan kering kemudian dihancurkan dengan menggunakan penumbuk lesung. Sampel tanih tersebut ditimbang sebanyak 100 g dan diayak selama 15 minit dengan menggunakan penggoncang mekanikal. Saiz dulang pengayak yang digunakan di dalam kajian ini adalah 2.0 mm, 0.250 mm, 0.125 mm, 0.063 mm dan pan. Setelah semua sampel tanih dikelaskan serta diasingkan mengikut saiz, sampel tanih tersebut akan dipindahkan ke dalam piring petri dan ditimbang dengan menggunakan neraca eletronik dua titik perpuluhan [11,12]. Berat setiap saiz sampel tanih akan memberikan peratusan saiz tanih. Skala yang akan digunakan di dalam kajian ini adalah mengikut skala Udden-Wentworth.

Menurut kaedah Udden-Wentworth [13,14] untuk memudahkan penganalisisan, pembinaan satu graf arimetik ordinat dengan menggunakan nilai berat yang didapati haruslah dibuat. Skala paksi-x adalah dalam nilai micrometer (µm). Paksi-y adalah nilai skala peratus kumulatif (0 hingga 100%) menggunakan satu skala linear (Rajah 2). Lengkung kumulatif digunakan untuk menentukan nilai micrometer (µm). Saiz phi kemudian ditentukan dengan melihat jadual pengredan saiz partikel sedimen untuk mengetahui setiap nilai phi: (phi pada 5%, phi pada 16% dan sebagainya. Dimana % merujuk untuk peratus kumulatif. Kertas graf yang menggunakan skala log telah digunakan bagi tujuan kajian ini [15].

Bagi kawasan tebing kiri sungai pula, hasil analisis mendapati tiga kelas utama iaitu butiran halus merupakan kelas pertama, diikuti kelas kedua bersaiz butiran kasar dan ketiga bersaiz sederhana. Lokasi yang berada pada kelas pertama iaitu stesen 1, 4, 5, 6, 9, 11 dan 13 dengan saiz butiran antara 125 micrometer hingga 65 micrometer (halus). Stesen 2 dan 3 merupakan kawasan yang mempunyai saiz butiran yang kasar iaitu 1000 micrometer hingga 500 micrometer. Manakala kelas ketiga yang mempunyai saiz butiran antara 500 micrometer hingga 250 micrometer (sederhana) adalah stesen 7, 8, 10 dan 12. Bagi kawasan tengah sungai pula, kelas pertama adalah stesen 1, 9, 10, 11, 12 dan 13 iaitu saiz butiran yang halus, diikuti oleh stesen 2, 6, 7 dan 8 yang bersaiz butiran sederhana dan stesen 3, 4 dan 5 bersaiz kasar.

Rajah 2. Graf Arimetik Ordinat

Beberapa nilai phi akan ditentukan untuk mengira pelbagai nilai statistik bagi Min (M), Sishan Piawai (D), Pencongan (S) dan Kurtosis (K) (Rajah 2) dengan menggunakan persamaan 1 hingga 4 seperti yang ditunjukkan pada Jadual 1 dan 2. Namun begitu, kajian ini lebih membincangkan tentang analisis bagi Min, Sisihan Piawai dan Pencongan pada setiap sampel kajian.

Jadual 1. Nilai phi yang didapati melalui pengiraan daripada analisis pengayakan

Peratus	**ø5**	**ø 16**	**ø 25**	**ø 50**	**ø 75**	**ø 84**	**ø 95**
Nilai Phi	-5.72	-5.14	-4.72	-3.21	-1.84	-1.42	0.0

$$\text{Min (M)} = \frac{\text{ø16} + \text{ø50} + \text{ø84}}{3} \quad (1)$$

$$\text{Sishan Piawai (D)} = \frac{\text{ø84} - \text{ø16}}{4} + \frac{\text{ø95} - \text{ø5}}{6.6} \quad (2)$$

$$\text{Pencongan (S)} = \frac{\text{ø84} + \text{ø16} - 2(\text{ø50})}{2(\text{ø84} - \text{ø16})} + \frac{\text{ø95} + \text{ø5} - 2(\text{ø50})}{2(\text{ø95} - \text{ø5})} \quad (3)$$

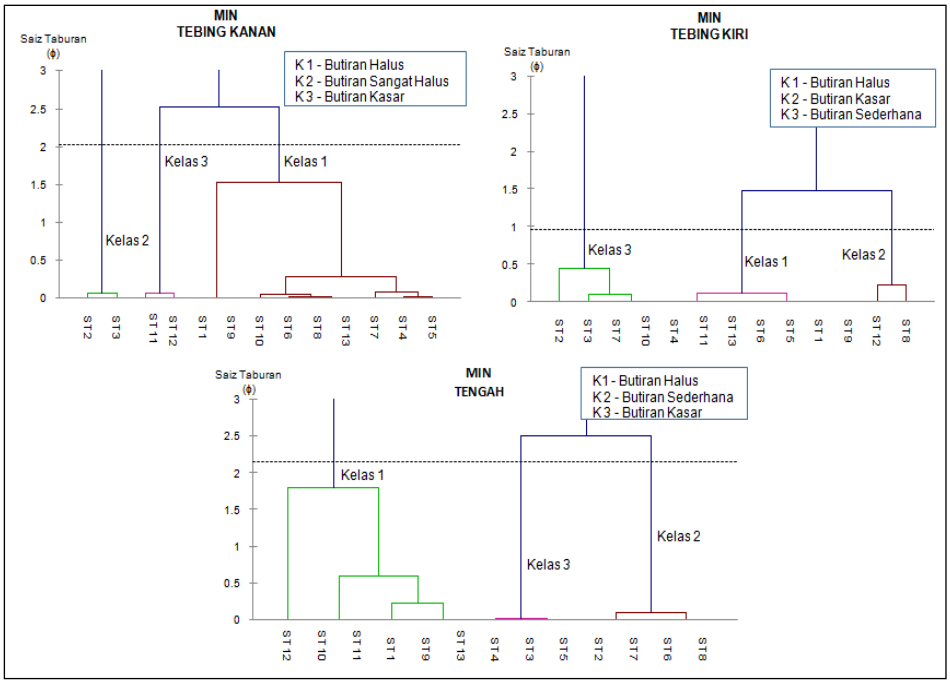
Seterusnya, teknik envirometrik yang digunapakai adalah dengan menggunakan perisian tambahan XLStat yang disesuaikan ke dalam perisian Microsoft Excel. Bagi tujuan pengelasan dalam kajian ini, kaedah analisis kluster agglomeratif hierarki (HACA) digunapakai untuk menterjemahkan data mengikut kelas – kelas sedimen yang diperolehi berdasarkan kelas kehomogenan [16]. Aplikasi kaedah ini juga dijangka mampu untuk memperkenalkan dan mengenalpasti ciri sedimen yang sama dan juga masalah yang sama di dalam sub-plot yang akan dibahagikan mengikut kriteria utama dalam pengelasan ini.

Jadual 2. Taksiran bagi saiz taburan, tahap keseragaman dan saiz sedimen untuk skala ukuran Min, Sisihan Piawai dan Pencongan [12]

Skala Ukuran (Min)		**Skala Ukuran (Sisihan Piawai)**		**Skala Ukuran (Pencongan)**	
Saiz Taburan (min)	**Nilai phi**	**Tahap Keseragaman**	**Nilai phi**	**Saiz Sedimen**	**Nilai phi**
Batu besar	-12 ke -8	Sangat baik	< 0.35	Sangat halus	+1.00 ke +0.30
Batu	-8 ke -6	Baik	0.35 ke 0.50	Halus	+0.30 ke +0.10
Batu kecil	-6 ke -2	Sederhana baik	0.50 ke 0.71	Sederhana	+0.10 ke -0.10
Pasir	-2 ke -1	Sederhana	0.71 ke 1.0	Kasar	-0.10 ke -0.30
Butiran sangat kasar	-1 ke 0.0	Buruk	1.0 ke 2.0	Sangat kasar	-0.30 ke -1.00
Butiran kasar	0.0 ke 1.0	Sangat buruk	2.0 ke 4.0		
Butiran sederhana	1.0 ke 2.0	Buruk ekstrem	> 4.0		
Butiran halus	2.0 ke 3.0				
Butiran sangat halus	3.0 ke 4.0				
Kelodak kasar	4.0 ke 5.0				
Kelodak sederhana	5.0 ke 6.0				
Kelodak halus	6.0 ke 7.0				

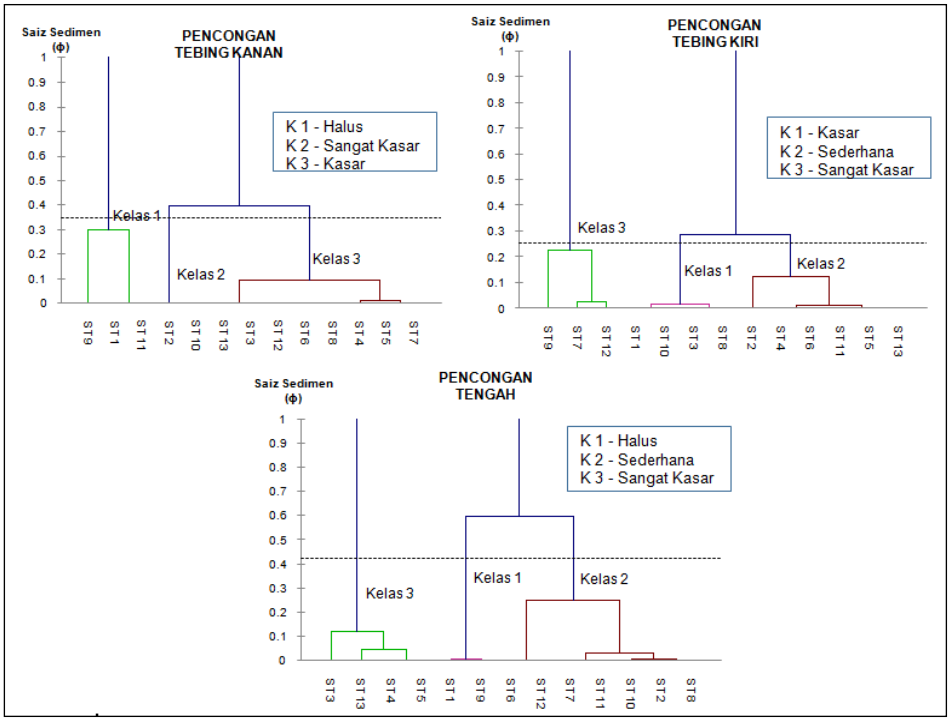
Hasil dan Perbincangan

Analisis sedimen dalam kajian ini adalah dengan menggunakan ukuran nilai phi (ø) dan micrometer yang diperkenalkan oleh Udden dan Wentworth [13,14]. Parameter yang digunakan bagi menganalisis sampel kawasan tebing kanan, tebing kiri dan tengah sungai adalah min, sisihan piawai dan pencongan.



Min (saiz taburan butiran)

Min merupakan saiz taburan butiran sampel tanih yang diperolehi semasa di lapangan. Skala saiz taburan sampel ini terbahagi kepada batu, pasir dan kelodak. Berdasarkan Rajah 3 hasil analisis saiz butiran tanih menggunakan teknik analisis envirometrik mendapati tiga kelas utama saiz butiran yang terdapat di tebing kanan sungai iaitu butiran sangat halus, butiran halus dan butiran kasar. Hasil analisis pengkelasan saiz butiran tanih mendapati bahawa butiran halus iaitu nilai phi 2.0 hingga phi 3.0 merupakan jenis butiran yang paling dominen di semua lokasi persampelan. Antara lokasi yang mempunyai saiz butiran yang halus adalah stesen 1, 4, 5, 6, 7, 8, 9, 10 dan 13, manakala saiz butiran yang sangat halus (phi 3.0 hingga phi 4.0) direkodkan di stesen 11 dan 12. Seterusnya stesen 2 dan 3 pula mencatatkan saiz butiran yang kasar iaitu antara phi 0.0 hingga phi 1.0.



Dapat dirumuskan melalui pengkelasan tersebut bahawa, kawasan di peringkat hulu dan sebahagian kawasan pertengahan Sungai Pahang akan lebih giat berlaku hakisan kerana sifat butirannya yang bersaiz halus, Sungai Pahang di peringkat hulu sehingga sebahagian pertengahan sungai akan mudah mengalami hakisan dan gelongsoran tebing. Saiz butiran yang halus dan sangat halus akan mudah dihakis oleh agen-agen hakisan seperti hujan dan tindakan turbulen arus sungai [17]. Manakala di bahagian hilir pula, jenis butiran yang kasar menunjukkan proses sedimentasi yang giat berlaku kerana arus di kawasan tersebut suda semakin perlahan berbanding di kawasan hulu dan pertengahan Sungai Pahang.

Pencongan (saiz sedimen)

Pencongan merupakan parameter yang digunakan oleh Udden dan Wentworth dalam menentukan saiz sedimen yang terdapat di sesebuah sungai. Berikut merupakan hasli pengkelasan nilai saiz sedimen (pencongan) menggunakan kaedah HACA (Rajah 4). Hasil pengkelasan mendapati empat jenis saiz sedimen yang terdapat pada kawasan tebing kanan, tebing kiri dan kawasan tengah sungai iaitu bersaiz halus, sederhana, kasar dan sangat kasar.

Rajah 3. Hasil pengkelasan saiz butiran (Min) tebing kanan, kiri dan tengah Sungai Pahang menggunakan kaedah HACA

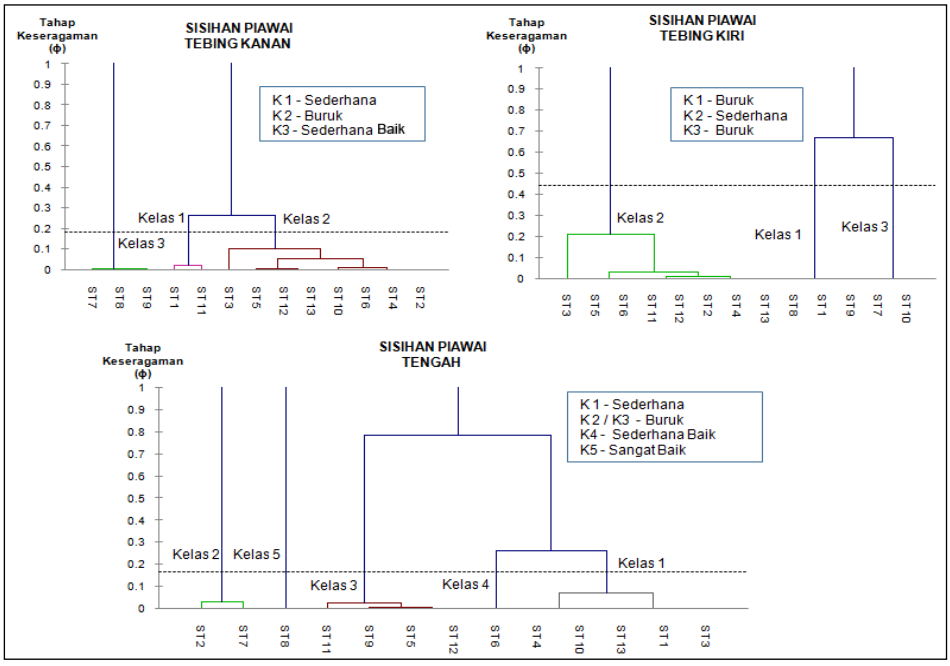
Rajah 4. Hasil pengkelasan saiz sedimen(pencongan) tebing kanan, kiri dan tengah Sungai Pahang menggunakan kaedah HACA

Berpandukan pada Jadual 3, jenis saiz sedimen yang terdapat pada tebing kanan Sungai Pahang adalah didominasi oleh saiz sedimen yang kasar dengan nilai phi antara -0.1 ke -0.30. Stesen-stesen yang mencatatkan saiz sedimen yang kasar adalah stesen 3, 4, 5, 6 7, 8, 10, 12 dan 13. Manakalah stesen 1, 9 dan 11 mencatatkan nilai phi -0.30 ke phi -1.0 iaitu saiz yang sangat kasar. Namun begitu, hanya di stesen 2 sahaja mencatatkan saiz sedimen yang bersaiz halus. Kawasan tebing kiri pula, sedimen yang bersaiz sederhana dengan phi 0 ke phi -0.1 iaitu pada kelas kedua telah direkodkan pada stesen 2, 4, 5, 6, 11 dan 13. Pada kelas pertama pula, dengan saiz sedimen phi -0.1 ke phi -0.3 (kasar) terdapat pada stesen 1, 3, 8 dan 10. Diikuti kelas 3 yang bersaiz sangat kasar, dicatatkan pada stesen 7, 9 dan 12. Seterusnya, di kawasan tengah sungai pula, saiz sedimen bersaiz sederhana iaitu nilai phi 0.1 ke phi -0.1 merupakan saiz yang paling dominen di sepanjang sungai. 8 stesen yang mencatatkan nilai saiz sedimen sederhanan iaitu stesen 2, 6, 7, 8, 10, 11 dan 12. Diikuti kelas 3 dengan nilai phi -0.3 ke phi -1.0 dicatatkan pada stesen 3, 4, 5 dan 13 iaitu bersaiz yang sangat kasar. Saiz sedimen yang halus pula telah didapati di stesen 1 dan 9 dengan nilai phi 0.3 ke phi 0.1.

Jadual 3. Pengkelasan saiz sedimen di lokasi kajian

Pencongan Tebing Kanan	
Kelas 1 (Halus)	ST 1 ST 9 ST 11
Kelas 2 (Sangat Kasar)	ST 2
Kelas 3 (Kasar)	ST 3 ST 4 ST 5 ST 6 ST 7 ST 8 ST 10 ST 12 ST 13
Pencongan Tebing Kiri	
Kelas 1(Kasar)	ST 1 ST 3 ST 8 ST 10
Kelas 2 (Sederhana)	ST 2 ST 4 ST 5 ST 6 ST11 ST 13
Kelas 3 (Sangat Kasar)	ST 7 ST 9 ST 12
Pencongan Tengah	
Kelas 1(Halus)	ST 1 ST 9
Kelas 2 (Sederhana)	ST 2 ST 6 ST 7 ST 8 ST 10 ST 11 ST 12
Kelas 3 (Sangat Kasar)	ST 3 ST 4 ST 5 ST 13

Nilai pencongan bagi suatu sampel berkait rapat dengan bahan mendapan terdapat di dalam sungai. Sebahagian pasir sungai menunjukkan pencongan positif kerana kebanyakan butiran halus yang dimendapkan selepas sungai surut akibat banjir atau hujan, manakala pasir pantai menunjukkan pencongan negatif kerana butiran kasar akan mudah diasingkan oleh pergerakan arus [18]. Bahan enapan bagi kawasan tebing kanan Sungai Pahang adalah berkeadaaan negatif iaitu butiran yang kasar yang mana kawasan tersebut akan mudah mengalami proses hakisan dan pengangkutan serta lebih mudah mengalami perubahan bentuk dan plan sungai.



Bagi kawasan tebing kiri pula, saiz kasar yang direkodkan juga mengalami proses yang sama dengan kawasan tebing kanan sungai. Kedua – dua kawasan tebing juga menunjukkan di stesen 1 iaitu bahagian hilir dan stesen 9 pertemuan antara Sungai Jelai, Sungai Tembeling dan Sungai Pahang menunjukkan saiz butiran yang halus, hal ini disebabkan kadar arus yang semakin berkurangan dan proses pemendapan sedimen yang halus tertumpu di kawasan tersebut. Manakala di kawasan tengah sungai pula, saiz sedimen yang bersaiz kasar (negatif) semakin berkurangan iaitu hanya terdapat di stesen 3, 4, 5 dan 13 sahaja berbanding saiz yang halus dan sederhana (positif) yang banyak tertumpu di bahagia tengah sungai. Hal ini menunjukkan, bahagian tengah sungai mempunyai kadar arus yang rendah membolehkan sedimen jenis ini termendap di dasar tengah sungai.

Sisihan piawai (tahap keseragaman)

Parameter ini digunakan untuk menganalisis tahap keseragaman bahan enapan dan tahap keseragaman saiz butiran sampel yang dianalisis. Jadual 4 dan Rajah 5 menunjukkan hasil yang diperolehi selepas analisis pengelasan dijalankan.

Jadual 4. Pengelasan tahap keseragaman sampel di lokasi kajian

Sisihan Piawai Tebing Kanan								
Kelas 1 (Sederhana)	ST 1	ST 2						
Kelas 2 (Buruk)	ST 3	ST 4	ST 5	ST 6	ST 8	ST 10	ST 12	ST 13
Kelas 3 (Sederhana Buruk)	ST 7	ST 9	ST 11					
Sisihan Piawai Tebing Kiri								
Kelas 1 (Buruk)	ST 1	ST 8	ST 9					
Kelas 2 (Sederhana)	ST 2	ST 3	ST 4	ST 5	ST 6	ST 11	ST 12	ST 13
Kelas 3 (Buruk)	ST 7	ST 10						
Sisihan Piawai Tengah								
Kelas 1(Sederhana)	ST 1	ST 3	ST 4	ST 10	ST 13			
Kelas 2 (Buruk)	ST 2	ST 7						
Kelas 3 (Buruk)	ST 5	ST 9	ST 11	ST 12				
Kelas 4 (Sederhana Baik)	ST 6							
Kelas 5 (Sangat Baik)	ST 8							

Rajah 5. Hasil pengkelasan tahap keseragaman (sisihan piawai) tebing kanan, kiri dan tengah Sungai Pahang menggunakan kaedah HACA

Nilai sisihan piawai endapan diukur untuk mengenalpasti proses hakisan yang berlaku bersifat memilih atau sebaliknya. Proses hakisan yang memilih akan menghasilkan butiran sedimen yang halus berbanding hakisan yang tidak seragam akan menghasilkan butiran yang kasar [12,18]. Selepas membuat pengelasan, didapati bahagian tebing kanan sungai didominasi oleh tahap keseragaman yang buruk dengan nilai phi 1.0 ke phi 2.0 iaitu pada stesen 3, 4, 5 ,6, 8, 10, 12 dan 13, sederhana baik dengan nilai phi 0.5 ke phi 0.71 di stesen 7, 9 dan 12 dan tahap sederhana terdapat di stesen 1 dan 2 dengan nilai phi 0.71 ke phi 1.0. Manakala di kawasan tebing kiri pula, hasil pengelasan mendapati terdapat dua jenis keseragaman iaitu jenis buruk dan sederhana.

Hal ini menunjukkan bahawa, bahagian tebing kiri dan tebing kanan sungai mempunyai butiran sedimen bersaiz sederhana kasar dan halus yang boleh menyumbang kepada proses pengangkutan dan pemendapan oleh faktor hakisan. Namun begitu, terdapat beberapa stesen di bahagian kanan tebing yang mengalami hakisan yang tidak memilih iaitu di stesen 7, 9 dan 12 kerana tahap keseragamannya yang sederhana baik dimana saiz butiran sedimennya bersaiz kasar. Seterusnya di bahagian tengah sungai pula, hasli pengelasan mendapati empat kelas tahap keseragaman yang dicatatkan iaitu tahap sangat baik, sederhana baik, sederhana dan buruk. Tahap keseragaman yang buruk didapati di stesen 2, 7, 5, 9, 11 dan 12, tahap keseragaman sederhana terdapat di stesen 1, 3, 4, 10 dan 13. Bagi tahap keseragaman sederhana baik dan sangat baik masing-masing di stesen 6 dan stesen 8. Keseluruhannya, tahap keseragaman yang direkodkan di sepanjang Sungai Pahang adalah berskala buruk iaitu mengalami hakisan yang bersifat memilih kerana saiz butirannya yang diperolehi dalam analisis saiz butiran (Min) menunjukkan butiran halus mendominasi di sepanjang Sungai Pahang.

Kesimpulan

Sungai Pahang mempunyai partikal sedimen yang bersaiz butiran kecil, sederhana dan bersaiz kasar. Butiran kecil ini menunjukkan kawasan tersebut mudah mengalami proses hakisan, pengangkutan dan pemendapan. Selain itu, tahap keseragamannya yang buruk menunjukkan saiz butiran kecil itu lebih mudah dihakis dan diangkut oleh agen-agen hakisan menjadi bahan endapan. Manakala analisis saiz sedimen pula menunjukkan sedimen bersaiz kasar banyak terhasil di sepanjang Sungai Pahang. Hal ini menunjukkan bahawa Sungai Pahang mempunyai struktur tanih yang bersifat pasir dan mudah mengalami perubahan akibat daripada faktor semulajadi dan antropogenik. Sungai Pahang juga akan menjadi semakin dinamik khususnya di bahagian dasar dan tebing sungai yang boleh menyebabkan pelagai masalah yang timbul seperti bencana banjir dan masalah kualiti air yang akhirnya memberi kesan kepada kesihatan persekitaran di dalam Lembangan Sungai Pahang umumnya.

Penghargaan

Kajian ini telah dijalankan melalui dana geran penyelidikan universiti: (UniSZA/2015/GOT/03) dan *Research Acculturation Grant Scheme* (RAGS): (RAGS/1/2015/WABO5/UNISZA/02/1). Penulis merakamkan ucapan jutaan terima kasih kepada Kementerian Pendidikan Malaysia (KPM), Universiti Sultan Zainal Abidin (UniSZA), Universiti Kebangsaan Malaysia dan East Coast Environmental Research Institute (ESERI), UniSZA di atas bantuan yang diberikan.

Abstract

The objective of this research is to conduct the preliminary phytochemical screening, total flavonoid and phenolic contents assays of various solvent extracts of tepal of *Musa paradisiaca*. Phytochemical screening was carried out according to the method of Trease and Evans, total flavonoid content was measured by the aluminium chloride colorimetric assay and total phenolic content was estimated spectrophotometrically by Folin-Ciocalteau method. - Preliminary phytochemical screening reveals the presence of phenolics, flavonoids, alkaloids, tannins, terpenoids in all the three different extracts (methanolic, ethanolic and aqueous). Tepal methanolic extract has the richest content of both phenolics and flavonoids i.e. (4.27 mg GAE/g and 0.25 mg QE/g) respectively, and aqueous extract was the least i.e. (1.32 mg GAE/g and 0.164 mg QE/g). All the extracts were not significantly different with one another ($p > 0.05$). It can be hypothesised that the high contents of phenolic compounds of tepals of *Musa paradisiaca* indicated that these compounds contribute to the antioxidant activity and can be regarded as promising plant species for natural sources of radical scavenging activity with potential value for treatment of many life threatening diseases.

Keywords: phytochemical, flavonoid, phenolics, *Musa paradisiaca*

Abstrak

Objektif kajian ini adalah untuk menjalankan pemeriksaan awal ke atas ketulenan fitokimia, jumlah kandungan fenolik flavonoid dan pelbagai ekstrak pelarut tepal *Musa paradisiaca***.** Penyaringan fitokimia telah dilaksanakan mengikut kaedah Trease dan Evans, dimana jumlah kandungan flavonoid diukur oleh ujian kalorimetrik aluminium klorida dan jumlah kandungan fenolik dianggarkan secara spektrofotometer dengan kaedah Folin-Ciocalteau. Penyaringan awal fitokimia menunjukkan kehadiran fenolik, flavonoid, alkaloid, tannin dan terpenoid dalam ketiga – tiga ekstrak yang berbeza (metanol, etanol dan akueus). Ekstrak metanol Tepal mempunyai kandungan yang paling tinggi di antara kedua-dua fenolik dan flavonoid iaitu sebanyak 4.27 mg GAE/g dan 0.25 mg QE/g, manakala ekstrak akueus adalah mempunyai kandungan terendah iaitu sebanyak 1.32 mg GAE/g dan 0,164 mg QE/g. Semua ekstrak tidak berbeza secara ketara antara satu sama lain ($p > 0.05$). Oleh itu, hipotesis yang boleh dibuat adalah kandungan yang tinggi sebatian fenolik daripada tepal *Musa paradisiaca* menyumbang kepada aktiviti antioksidan dan boleh dianggap sebagai spesies tumbuhan yang berpotensi untuk merawat pelbagai penyakit yang mengancam nyawa.

Kata kunci: fitokimia, flavonoid, phenolic, *Musa paradisiaca*

Introduction

Consumption of medicinal herbs protects and heals a number of ailments and they have been the principal treatment therapy in prehistoric times until the discovery of synthetic drugs in the nineteenth century [1]. This exploration of biologically active natural products has played an important role in finding new chemical entities (NCEs), for example, approximately 28% of NCEs between 1981and 2002 were natural products or natural product-derived [2]. Health benefits has been derived from bioactive compounds that are commonly found in edible plant parts such as fruits, vegetables, flowers, leaves and have been shown to confer protection against various ailments [3]. Interestingly, many of them are known to contain large amounts of phenolic antioxidants [4]. Phytchemicals have become an intense focus of research interest because of their perceived beneficial effects for health, including anticarcinogenic, antiatherogenic, antiulcer, anti-thrombotic, anti-inflammatory, immunemodulating, antimicrobial, varodialatory, and analgesic effects. Therefore, the search for exploitation of natural antioxidants, especially of plant origin, has greatly increased in recent years [1]. For example, chard extract (*Beta vulgaris* L. var. *cicla)* has been used as a hypoglycaemic agent by diabetic mellitus (DM) patients in Turkey [5] and it has been documented that the number of similarly various phytoconstituent such as epicatechin, rutin, quercetin, nymphayol and flavonoid extracts from *Pterocarpus marsupium* have shown to possess β-cells regeneration capacity [6].

Flavonoids represent the most common and widely distributed group of plant phenolics [7] and are abundant in foods; quercetin and rutin are the flavonoids most abundantly consumed [8]. *Musa paradisiaca* is one of the well-known plants of the *Musaeae* family that have been used in traditional medicine since hundred years to alleviate various diseases and health problems. Active constituent presence in the plants materials might be responsible to the beneficial of human health. The most important of these bioactive compounds of plants are alkaloids, flavonoids, tannins and phenolic compounds [9]. Ethnomedicinal survey around the world revealed that the flowers of *Musa spp.* have been used to treat many illnesses. Its flowers have been traditionally used to alleviate menorrhagia, dysentery, diabetes mellitus [10], heart pain, diarrhea, stomach cramps and infantile malnutrition [11]. It was reported that the extracts of the flowers possess medicinal properties for illness such as diabetes mellitus, anaemia [12] and malaria [13]. Phenolics are the largest group of phytochemicals that account for most of the antioxidant activity in plants or plant products [14].

More than 4000 polyphenols (flavonoids, monophenols and poly phenols) are found in vascular plants. Phenolic compounds such as quercetin, rutin, narigin, catechin, caffeic acid, gallic acid and chlorogenic acid are very important plant constituents [15]. Flavonoids are the largest group of naturally occurring phenolic compounds, which occurs in different plant parts in Free State and as glycosides [16]. They are found to have many biological activities including antimicrobial, mitochondrial adhesion inhibition, antiulcer, antiarthritic, antiangiogenic, anticancer, protein kinase inhibition etc. The flavones and flavonols are the most widely distributed of all the phenolics [17]. Flavonoids are particularly beneficial, acting as antioxidants and giving protection against cardiovascular disease, certain forms of cancer and age related degeneration of cell components. Their polyphenolic nature enables them to scavenge injurious free radicals such as super oxide and hydroxyl radicals [18]. A variety of dietary plant flavonoids inhibits tumor development in experimental animal models [19]. The bi-flavonoids have the pharmacological effects like their ability to inhibit the release of histamines, the adhesion of blood platelets and the action of lens aldose reductase, to block the inflammatory effects of hepatotoxins, and to act as a heart stimulant [20]. Therefore, the objective of this paper is to carry out the phytochemical screening, total contents of both phenolics and flavonoids of various solvent extracts of *Musa paradisiaca.*

Materials and Methods

Preparation of plant extract

The tepals were selectively removed from the bracts, oven dried for one week. It was then crush grinded to fine powder using an electrical grinder. This was then divided into three portion and each portion was soaked in methanol, ethanol and distilled water for 3 days respectively. Each sample was later filtered using Whatmann's No. 1 filter paper. The filtrates were then concentrated at 42 °C to yield a dark brown semi solid using a rotary evaporator (N-1100, Shanghai, Eyela. Co. Ltd, Tokyo, China). This was repeated three times. For each extract, the yield was expressed in percentage by dividing the quantity of dry mass obtained after extraction by the dry weight of the powder used before soaking. Dried extracts were weighed and dissolved in 10% dimethylsulphoxide (DMSO)

to yield a stock solution from which lower concentrations were prepared. The filtrate was then concentrated using an electric incubator. The extract appears as semi-solid greenish brown paste. A stock solution to be used was then prepared by dissolving 100 g of the extract in 50 ml of distilled water.

Preliminary Phytochemical Screening
The phytochemical screening of the extracts was conducted using standard procedures described by Trease and Evans [21]. The following qualitative tests were carried out:

Test for saponins
One mL of the tepal extract was diluted with distilled water to 20 mL and shaken in a graduated cylinder for 15 minutes. The formation of one centimeter layer of foam indicates the presence of saponins.

Test for phenols
A small amount of the ethanolic extract was taken with 1 mL of water in a test tube and 1 to 2 drops of Iron III chloride ($FeCl_3$) was added. A blue, green, red or purple color is a positive test.

Test for glycosides
A small amount of alcoholic extract was taken in 1 mL of water in a test tube and a few drops of aqueous NaOH were added. A yellow coloration indicates the presence glycosides.

Test for flavonoids
One to five drops of concentrated hydrochloric acid (HCl) were added to little amount of ethanolic extract of the plant material. Immediate development of a red colour indicates the presence of flavonoids.

Test for alkaloids
Two mL of extract was taken in a test tube and then 0.2 mL dilute HCl was included, followed by 1 mL of Meyer's reagent. A yellowish coloration indicates alkaloid's presence.

Test for tannins
Five mL of the tepal extract was placed in a test tube and then 2 mL of 5 % of $FeCl_3$ solution was added. A greenish-black precipitate indicates the presence of tannins.

Test for terpenoids
In a test tube containing 2 mL of chloroform, 0.5 mL of extract was added. This is then followed by the addition of 3 mL conc. H_2SO_4 which forms a layer. Reddish brown coloration of the interface indicates terpenoids.

Total phenolic content assay
The total phenolic content (TPC) was carried out by using the method of Folin-Ciocalteu. An aliquot (least amount) (1 mL) of extracts or standard solution of gallic acid (100, 200, 300, 400, and 500 µg/mL) was added to 25 mL of volumetric flask, containing 10 ml of decontaminated water. A blank reagent using distilled water was prepared. One mL of Folin-Ciocalteu phenol reagent was added to the mixture and shaken. After 5 mins 10 mL of 7.5% Na_2CO_3 solution was added to the mixture. The volume was then made up to the mark. Upon completion of incubation for 30-45 minutes at room temperature, the absorbance against the reagent blank was determined at 760 nm with an UV-Visible (Shimadzu Japan). TPC was expressed as mg gallic acid equivalents (GAE) [22].

Total flavonoid content assay
In this method, quercetin was used as the standard to make the calibration curve. 3.2 mg of quercetin was dissolved in 95% ethanol and then diluted to 5, 10, 20, 40, 80, 160, and 320 µg/mL. A calibration curve was made by measuring the absorbance of the dilutions at 415 nm (λ_{max} of quercetin) with a UV-1800 spectrophotometer Shimadzu Japan. Aluminium chloride ($AlCl_3$), 10 % and potassium acetate, 1 M solution was prepared. An amount 50 mg of each extract was accurately weighed and transferred to 10 mL volumetric flask and made up the volume with methanol. 50 µL of each extract stock solution, 2.15 ml ethanol, 0.1 mL $AlCl_3$ 0.1 ml potassium acetate solution and 2.8 mL distilled water were added and mixed well. Sample blank was prepared in a similar way by

replacing $AlCl_3$ with distilled water. Sample and sample blank of all extracts were prepared and their corresponding absorbances were measured at 415 nm. All prepared solutions were filtered through whatmann filter paper before measuring. Total flavonoid content (TFC) was expressed as mg of quercetin equivalent (QE) [23]. TFC was computed by using the following formula:

$$TFC = (R \times D.F \times V \times 100) / W. \quad (1)$$

where, R - result obtained from the standard curve, D.F - dilution factor, V - volume of stock solution, 100 - For 100 g dried plant, W - weight of plants used in the experiment.

Results and Discussion

Percentage yield of extracts

The percentage yield for the various solvent extracts of tepal of *Musa paradisiaca* is shown in Table 1. Ethanolic tepal extract (ETE) has the highest percentage yield when compared to the methanolic and aqueous extract of the flower.

Table 1. Percentage yield of various solvent extracts of tepal of *Musa paradisiaca*

Extract	Initial weight	Final weight	% Yeild
Tepal (methanol)	508.9	7.53	1.50
Tepal (ethanol)	508.9	7.54	1.51
Tepal (aqueous)	508.9	7.13	1.40

Preliminary phytochemical screening

Preliminary phytochemical screening shows the presence of phenols, glycosides, flavonoids, alkaloids, tannins and terpenoids in all three extracts i.e. methanol, ethanol and aqueous. MTE has the highest contents of phenols, followed by the ETE and aqueous tepal extract (ATE) the least. Nonetheless, the aqueous extract possesses flavonoids in abundance. Glycosides, alkaloids, tannins and terpenoids were all found to be present. All extracts were tested negative for saponins.

Total phenolic content (TPC)

The TPC of the extracts was determined by extrapolation from the calibration curve ($Y = 0.18x + 0.1039$; $R^2 = 0.994$) prepared from the gallic acid concentrations (Figure 1) and expressed in mg of gallic acid equivalence (GAE) per gram. The amount of phenolic compounds in the various extracts was obtained from regression equation and the values were expressed in gallic acid equivalence (Figure 2). There was no significant difference ($p > 0.05$) in all the three different extracts.

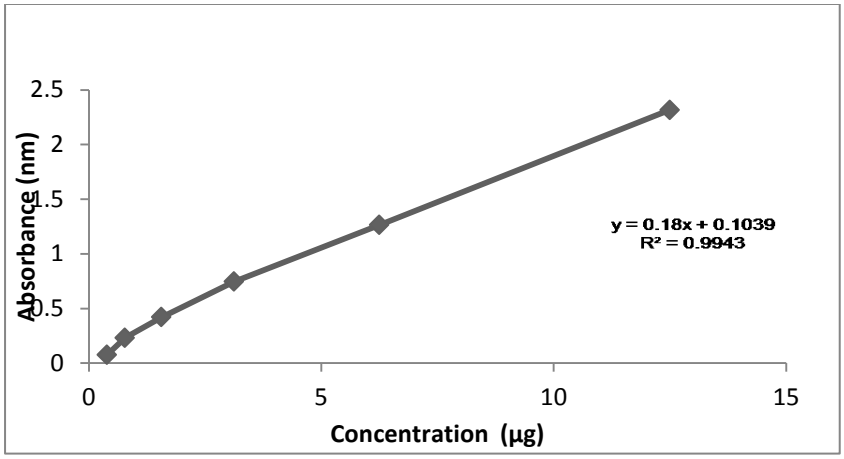

Figure 1. Gallic acid calibration curve

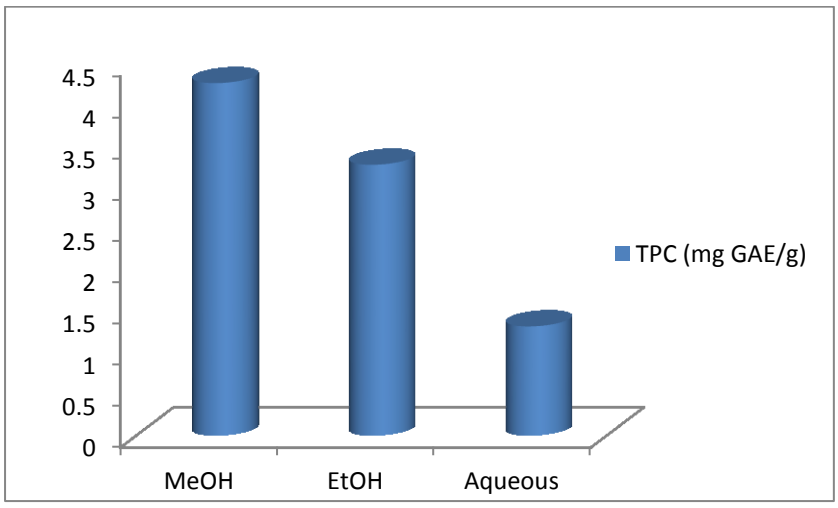

Figure 2. Total phenolic content of various solvent extracts of tepal of *M. paradisiaca*

Total flavonoid content (TFC)

The TFC content of the tepal extracts was also determined by extrapolation from the calibration curve (Y = 0.4638x + 0.0778; R^2 = 0.992) prepared from the quercetin concentrations (Figure 3) and expressed in mg of quercetin equivalence (QE) per gram. The amounts of flavanoid compounds in the various extracts were obtained from regression equation and the values were expressed in quercetin equivalence (figure 4). The values from all the extracts were not significantly different ($p > 0.05$).

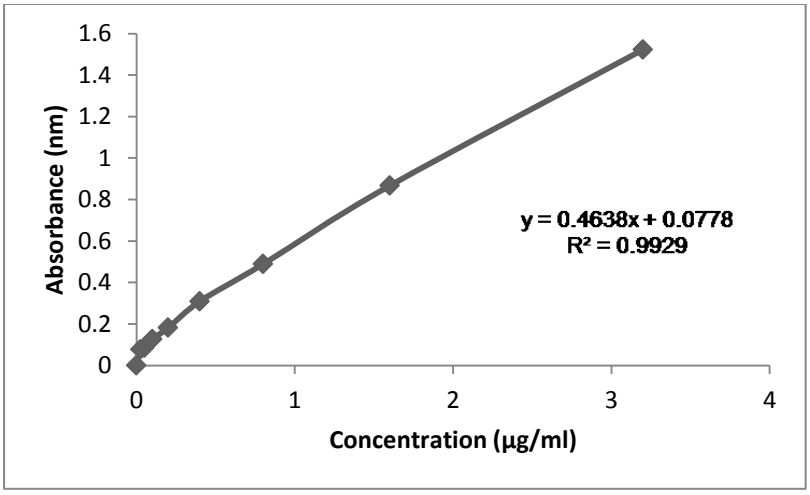

Figure 3. Quercetin calibration curve.

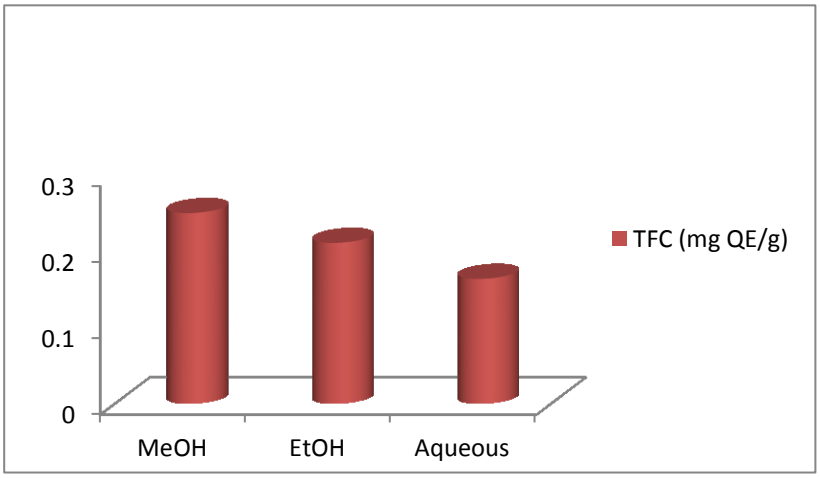

Figure 4. Total flavonoid content of various solvent extracts of tepal of *M. paradisiaca*

Preliminary phytochemical screening reveals the presence of phenols, flavonoids, glycosides, alkaloids, tannins and terpenoids. Saponins were tested negative in all the three different extracts (Table 2). The total phenolic content (TPC) of the tepal (methanolic, ethanolic and aqueous) extracts of *Musa paradisiaca* was determined using the Folin-Ciocalteau method. This method allows the estimation of all the flavonoids, anthocyanins and non-flavonoid phenolic compounds of all the phenolics available in the samples [24]. The results for total phenolic content in the studied plant extracts are presented in the graphs (Figure 2). The results show that MTE has the richest source of phenolics, total phenolic content is 4.272 mg GAE/g while on the contrary, ATE possesses the lowest amount of phenolics i.e. 1.32mg GAE/g. The total phenolic contents did not vary significantly ($p > 0.05$) in different solvent extracts. This is in agreement with the researchers [25,26], who found that yield of total phenolic was dependent on the method and choice of solvent. The recovery of polyphenols from plant materials is influenced by the solubility of the phenolic compounds in the solvent used in the extraction process. Furthermore, solvent polarity will play a key role in increasing phenolic solubility [27]. Thus, it is difficult to produce a standard extraction procedure suitable for phenol extraction of all the plant samples. As the results indicated, it is apparent that the recovery of

phenolic compounds was dependent on the solvents used and their polarity. This may be attributed to the fact that wide range of phenols can dissolve in aqueous methanol mixtures. On the other hand, methanol is a good solvent system for the extraction of polar antioxidants [28]. There is a strong link between phenolic content and free radical scavenging activity [29,30]. Phenolics possess a broad spectrum of biochemical activities such as antioxidant, antimutagenic, anti-carcinogenic and even the ability to modify the gene expression [31]. Polyphenols are the largest group of phytochemicals that account for most of the therapeutic activity in plants or plant products [32]. This plant is generally reported to contain substantial amounts of polyphenols with pharmacological properties which includes flavonoids and tannins [33]. The results obtained in the present study revealed that the level of phenolic compounds in these extracts was considerable and falls within the values of commonly consumed green vegetables. Hence consumption of these plants will enhance the health benefits by absorbing and neutralizing free radicals, quenching singlet oxygen, or decomposing peroxides [3].

Table 2. Preliminary phytochemical screening of various solvent extracts of *Musa paradisiaca*

S.N.	Test	T (MeOH)	T (EtOH)	T (aqueous)
1	Saponin	–	–	–
2	Phenols	+++	++	+
3	Glycosides	++	++	+
4	Flavonoids	+	+	++
5	Alkaloids	+	+	+
6	Tannins	++	+	+
7	Terpenoids	+	+	+

plus (+) indicates the presence and minus (-) signifies absence.

Total flavonoid content (TFC) of different extracts of tepals of *Musa paradisiaca* was determined by $AlCl_3$ method. Determining the total flavonoids by using $AlCl_3$ is based upon the formation of stable complex between $AlCl_3$, keto and hydroxyl groups of flavones and flavonoids. The results for total flavonoid content in the studied plant extracts are presented in the graph (Figure 4). The results show that MTE has the richest source of flavonoids, i.e. total content is 0.25 mg QE/g while on the contrary, ATE possess the lowest amount of flavonoid i.e. 0.164 mg QE/g. this is contrary to the findings of [34] where it was found that ethanolic extract has the highest flavonoid content. Flavonoids display a crucial role in scavenging the free radicals and these are the phyto constituents that should be focused on for investigation of many biological activities. Phytochemicals especially polyphenols constitute a major group of compounds that act as primary antioxidants [15].

More than 4000 polyphenols (flavonoids, monophenols and poly phenols) are found in vascular plants. Phenolic compounds such as quercetin, rutin, narigin, catechin, caffeic acid, gallic acid and chlorogenic acid are very important plant constituents [15]. Medicinal plants are known to produce diverse substances possessing antioxidant properties having ability to protect the human body against cellular oxidation. Anti-oxidation are vital substances which possess the ability to protect the body from damage caused by free radicals inducing oxidative stress [35]. Antioxidant compounds like phenolic acids, polyphenols and flavonoids scavenge free radicals such as peroxide, hydroperoxide of lipid hydroxyl and therefore halt the oxidative mechanism that leads to degenerative diseases [36]. Flavonoids are proactive polyphenolic compounds found in most plants and cannot be synthesized or produced by the humans [37]. It was found to be effective in controlling various biological activities and is anti-inflammatory, anti-angiotic, antimicrobial, antioxidant, reduced hypertension, and has anti-cholesterol properties [38, 39]. In recent times, research interest has been paid to polyphenols and flavonoids as a result of their antioxidant capacity which is principally based on the redox properties of their hydroxyl groups and the structural relationship between different functional groups in their structure which enable them to actively serve as free radical scavengers, reducing agents, singlet oxygen quenchers metal chelators, and hydrogen donors [40].

Conclusion

It can be postulated that the contents of phenolic and flavonoid compounds of tepal of *Musa paradisiaca* contribute to the radical scavenging activity and can be regarded as promising plant species for natural sources of antioxidant with potential value for treatment of many life threatening diseases. The process of extraction and identification of active principles responsible for the free radical scavenging property of tepal extract of *Musa paradisiaca* through bioactivity guided fraction is under progress in order to understand the possible mechanism of action of tepal of *Musa paradisiaca*. Utilization of this tepal will be of advantage to mankind and increased in its consumption will help in prevention of chronic life style diseases.

Abstract

Inflammatory diseases are an important health concern, and the growing rate is on the rise. Finding a safe drug for these diseases remains an important issue. The study aimed to determine the nitric oxide (NO) scavenging as well as anti-inflammatory activities of *Musa paradisiaca* (banana). *Musa paradisiaca* plant parts used in this study namely tepal, skin (peel) and flesh (pulp) were extracted with methanol (tepal, flesh and skin), ethanol (tepal) and water (tepal) using cold maceration technique. Phytochemicals screening of the extracts was carried out. The ability of the extracts to scavenge NO radical was evaluated using Griess reagent. The anti-inflammatory activity of the extracts was assessed by evaluating the ability of the extract to inhibit RAW 264.7 macrophage cell line from generating harmful NO induced by bacterial lipopolysaccharide (LPS). In order to determine the toxicity of the extracts to the cells while exerting its anti-inflammatory activity,cytotoxicity was measured using MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] assay.The extract was found to contain bioactive chemicals like flavonoids, saponins, phenols, etc. Maximum NO radical inhibition of 41.05% was recorded in the tepal aqueous extract, and minimum inhibition of 22.34% was recorded in the flesh extract. All others showed mild inhibition as well. Flesh extract has the highest NO (generated by LP) inhibitory activity, with the maximum inhibition of 52.21% at 250 µg/mL, followed by tepal aqueous extract with maximum inhibition of 48.16% at 62.5 µg/mL. The least inhibition was noted in the tepal methanol extract that has the maximum inhibition of 19.63% at 62.5 µg/mL. The viability of the activated macrophages was not affected by the extracts as confirmed by the MTT assay, thereby indicating that the inhibition of NO synthesis by the extracts was not due to cytotoxic effects. Overall, *Musa paradisiaca* plant parts have the potential as anti-inflammatory and studies in this aspect should be intensified.

Keywords: anti-Inflammation, MTT, *Musa paradisiaca*, RAW 264.7

Abstrak

Penyakit radang merupakan gejala penyakit yang semakin mendapat perhatian dan kadar kedapatan (penyakit) semakin meningkat. Pencarian ubat yang selamat untuk penyakit ini masih menjadi isu penting. Kajian ini bertujuan menentukan aktiviti pemerangkapan nitrik oksida (NO) serta anti radang oleh *Musa paradisiaca* (pisang). Bahagian – bahagian *Musa paradisiaca* yang diguna dalam kajian ini adalah jantung, kulit (kupasan) dan isi (pulpa). Sampel – sampel telah diekstrak dengan metanol (jantung, kulit dan isi), etanol (jantung) dan air (jantung) menggunakan kaedah rendaman sejuk. Penyaringan fitokimia keatas ekstrak telah dijalankan. Keupayaan ekstrak memerangkap radikal NO dinilai menggunakan reagent Griess. Aktiviti anti radang

oleh bahan terekstrak telah ditentukan melalui penilaian terhadap keupayaan menghalang sel makrofaj RAW 264.7 daripada menghasilkan NO yang diaruh oleh lipopolisakarida (LPS) bakteria. Bagi menentukan ketoksikkan ekstrak terhadap sel semasa ianya bertindak sebagai anti radang, tahap sitotiksik telah diukur menggunakan ujian MTT [3-(4,5-dimetiltiazol-2-il)-2,5-difeniltetrazolium bromida]. Kajian mendapati bahawa ekstrak pisang mengandungi bahan kimia bioaktif seperti flavonoids, saponins, fenols, dan lain - lain. Perencatan maksima radikal NO sebanyak 22.34% telah direkodkan bagi ekstrak akueus jantung pisang, dan kadar perencatan minima telah direkodkan pada ekstrak isi pisang. Kesemua ekstrak yang lain menunjukkan perencatan yang rendah. Ekstrak isi pisang mempunyai aktiviti perencatan NO (yang dihasilkan oleh LP) tertinggi dengan perencatan maksima 52.21% pada kepekatan 250 µg/mL, diikuti oleh ekstrak akueus jantung pisang dengan perencatan maksima 48.16% pada kepekatan 62.5µg/mL. Perencatan terendah telah dicatatkan oleh ekstrak metanol jantung pisang, yang mempunyai perencatan maksima 19.63% pada kepekatan 62.5 µg/mL. Kebolehhidupan makrofaj yang diaktifkan tidak terjejas oleh ekstrak sepertimana yang dibuktikan oleh ujian MTT, ia menunjukkan bahawa sintesis NO oleh ektrak bukanlah dari kesan sitotoksik. Secara keseluruhan, bahagian – bahagian *Musa paradisiacal* mempunyai potensi sebagai anti radang dan kajian mengenainya perlu diperluaskan.

Kata kunci: anti radang, MTT, *Musa paradisiaca*, RAW 264.7

Introduction

The body is continuously expose to various noxious agents.This ranges from pathogens (bacteria, viruses, and fungi) to various physical and chemical agents as well as environmental pollutions that result in cell injury or death [1,2]. The body cells resist and eliminate the effect of these agents through an inherent process termed "inflammation".

Recently, the roles of many inflammatory cells and a large number of inflammatory mediators in many pathologies not previously known to be associated to inflammation have been identified. Such pathologies include Alzheimer's disease and cardiovascular disorders including atherosclerosis, as well as cancer [3,4]. For example; acute infection is characterized by elevated myeloperoxidases, ROS and IL-6, which in severe disease serve as an index, in viral and bacterial causes [5], increased nitric oxide (NO) in exhaled air reflected airway inflammation in asthma patients [6,7,8].

Nitric oxide is an important signalling molecule involved in diverse physiological and pathophysiological mechanisms in cardiovascular, nervous and immunological systems. It has contrasting roles in living organisms. It acts as a biological mediator, control blood vessel tone in vascular systems and is an important agent in host defence effector in the immune system. However, it is a free oxygen radical and has cytotoxic effect in pathological processes, particularly in inflammatorydisorders [9-12].Inhibition of iNOS (inducible nitric oxide synthase) may be beneficial for the treatment of inflammatory disease [13,14]. Evidence showed that drugs obtained from natural sources can modulate various inflammatory mediators (arachidonic acid metabolites, peptides, cytokines, excitatory amino acids, *etc*.), the production and/or action of second messengers (cGMP, cAMP, protein kinases, and calcium), the expression of transcription factors such as AP-1, NF-κB, and proto-oncogenes (*c-jun*, *c-fos*, and *c-myc*), and the expression of key pro-inflammatory molecules such as inducible NO synthase (iNOS), cyclooxygenase (COX-2), cytokines (IL-1β, TNF-α), neuropeptides and proteases [15].

Plants have been the basis of many traditional medicine systems throughout the world for thousands of years and remain the primary new source of structurally significant chemical substances that lead to the development of innovative drugs [16,17]. Banana is one of the oldest and well-known fruit worldwide. It has no seeds; it is delicious and available throughout the seasons at an affordable cost. Many traditional uses of banana have been documented. In addition to its nutritional value, a number of biological activities studies have been carried out on banana and these studies prove it to possess bioactivities including anti-hyperglycaemic, anti-ulcerogenic, antioxidant, antihypertensive, cardiac depressant, diuretic, anti-tumoral, bronchodilatory, expectorant, oral contraceptive, antibacterial, antifungal, among others [18].

Hence, the aim of this study is to search for a new safer agent from the medicinal plant that has both NO radical scavenging as well as anti-inflammatory activities is significant to the field of medicine and health sciences.

Materials and Methods

Plant material: Collection and preparation

Musa paradisiaca, fruit and tepal, were obtained from Kuala Terengganu, Malaysia. Samples were identified and authenticated by Dr. Khamsah Suryati Mohd from the Faculty of Bioresources and Food industry, Universiti Sultan Zainal Abidin. The skin (peel) was skinned away and both the skin and the flesh (pulp) were cut and weighed by an electrical balance (1.45kg and 3.28kg) respectively, before dried in a drier at 45 °C, their dry weights were 0.41 kg and 0.21 kg respectively. After drying, samples were blended into powder, using an electrical blender, and the weights were 0.21 kg and 0.10 kg. The tepal was also processed in a similar way and weighed (3kg) and dried at 40 °C and then blended to powder (0.42 kg).

Extraction procedure

The freshly prepared flesh, skin and tepal were extracted twice with methanol (10:2 mL/kg) by cold extraction technique and again with ethanol (for the tepal). The samples were kept in the solvents forthree days at room temperature with regular shaking. Aqueous extraction of the tepal was done by boiling the sample in distilled water at 100 °C on a hot plate. All the extracts were vacuum filtered using Whatman filter paper and made semi-solid by evaporating the solvents using a rotary evaporator.The water extract was concentrated in an oven at 100 °C to obtain the crude extracts. The crude extracts were kept in fresh vials and refrigerated (4 °C) for further use.

Phytochemical screening

The phytochemicals screening of the various solvents extract were carried out using standard procedures as described by Trease and Evans[19]. The following tests were carried out qualitatively.

Test for glycosides

Small amount of the extracts was put in 1 mL of water in a test tube followed by the addition of 1 mL of NaOH. A yellow precipitate indicates the presence of glycosides.

Test for phenols

The extract (5mg) was dissolved in distilled water, and 3 mL of 10% lead acetate solution was added. Bulky white precipitates indicated the presence of phenols.

Test for Flavonoids

A few drops of concentrated hydrochloric acid were added to a small amount of the extract. Immediate development of red color indicates the presence of flavonoids.

Test for Saponins

1 mL of each extract was diluted with distilled water to 20 mL and shaken in a graduated cylinder for 15 min. The formation of foam of about 1cm indicates the presence of saponins.

Pharmacological activities: Nitric oxide (NO) scavenging activity

For the experiment, sodium nitroprusside (10 mM) in phosphate buffered solution (pH = 7.4) was mixed with various concentrations of the extract prepared in 10% DMSO and incubated under light at room temperature for 15 min. The same reaction mixture without the tested extract, but the equal amount of the solvent serves as the control (the last well). After the incubation, 0.05 mL of Griess reagent (1% sulfanilamide, 2% H_3PO_4 and 0.1% N-(1-naphthyl) ethylenediamine dihydrochloride was added. Ascorbic acid was used as positive control. The absorbance was measured at 546 nm and the percentage of NO radical inhibition by the extract was calculated from the formula equation 1 below

$$[(A0–A1) /A0] \times 100. \quad (1)$$

where A0 is the absorbance of the control, and A1 is the absorbance of the extract/standard [20]. IC_{50} value was obtained by drawing the equation of line from the graph of concentration (µg/mL) versus percentage of inhibition.

Anti-inflammatory activity: Materials and reagents

RPMI 1640 media (Gibco), dimethyl sulfoxide (DMSO), lipopolysaccharide (LPS, Escherichia coli) and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) were purchased from Sigma Chemical Company, fetal bovine serum (FBS)(Gibco) and penicillin/streptomycin (Penstrep)(Gibco).

Cell culture (seeding and treatment)

The macrophage cell line, RAW 264.7 was obtained from the cell culture lab, Faculty of medicine, Universiti Sultan Zainal Abidin. The cells were cultured in Roswell Park Memorial Institute (RPMI, 1640) medium supplemented with 1% pen/strep and 10% heat-inactivated fetal bovine serum. The cell was incubated, in a humidified incubator, in an atmosphere of 5% CO_2 at 37 °C and were subcultured twice before the experiment.

RAW 264.7 cells were seeded onto a 96-well plate (1×10^5 cells/well) and incubated for 24 hours for the experiments. The cells were then treated with the samples at concentrations of 250, 125, 62.5, 31.25, and 15.625 µg/mL and incubated for 1 hour. They were then stimulated with 1µg/mL of LPS for another 24 hours. The supernatant was gently transferred to new 96-well plates and used for NO determination, while the cells remained in the old plate were used for the MTT assay of cell viability. Samples (stock) were dissolved in DMSO, and the working samples were prepared in the media. The effects of the tested extracts were compared with those of L-N^6-(1-iminoethyl) lysine hydrochloride), a known inhibitor of NO production.

MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] assay for cell viability

MTT is a pale yellow substrate that is reduced by living cells to yield a dark blue formazan product. This process requires an active mitochondrion, and only freshly dead cells do not reduce significant amounts of MTT. After 24 hours incubation with LPS, MTT was added to the medium for 4 hours. At last, the supernatant was removed, and the formazan crystals were dissolved in DMSO and incubated for more 15 minutes at room temperature. Absorbance was measured at 570nm with reference 630nm. The percentage of dead cells was determined using the formula equation 2.

$$Cell\ viability(\%) = \frac{Test}{Control} \times 100 \quad (2)$$

Nitric oxide assay

Nitric oxide production was assayed by measuring nitrite in the supernatants of cultured RAW 264.7 cells. The assay was carried out as described previously with slight modification [21]. After pre-incubation of RAW 264.7 cells (1×10^5 cells/mL) with LPS (1 µg/mL) for 24 hours, the amount of nitrite, a stable metabolite of NO use as an indicator of NO production, in the culture medium was measured using the Griess reagent (1% sulfanilamide and 0.1% naphthylethylenediamine dihydrochloride in 2.5% phosphoric acid). A volume of 50 µL of the cell culture medium was mixed with 50 µL of the Griess reagent. Subsequently, the mixture was incubated at room temperature for 15 min,and the absorbance was measured at 540 nm in a microplatereader. Fresh culture medium was used as a blank in every experiment. The quantity of nitrite was determined from a sodium nitrite standard curve as expressed in equation 3.

$$Inhibition\ (\%) = \frac{Control-Test}{Control} \times 100 \quad (3)$$

Results and Discussion

Phytochemicals detected in *Musa paradisiaca*

The various solvent extracts of *Musa paradisiaca*, prepared in this work showed the presence of some of the tested phytochemicals like flavonoids, phenols, glycosides among others. Research into natural products often, is aided by ethnopharmacological knowledge and has brought enormous contributions to drug production by providing novel chemical structures and mode of action [22,23]. Methanol and ethanol tepal extracts showed the presence of glycosides and phenols in abundance. Flavonoids and saponins were also detected in these extracts. Tepal aqueous showed the presence of glycosides, phenols, with abundant flavonoids yet saponins are not detected in this extract.

In both skin and flesh methanol extracts, glycosides and phenols were detected with abundant flavonoids in the latter and normal in the former (Table 1).

Table 1. Phytochemicals from the various solvent extracts of *Musa paradisiaca*

Extract	Glycosides	Phenols	Flavonoids	Saponins
Tepal methanol	++	++	+	+
Tepal Ethanol	++	++	+	+
Tepal Aqueous	+	+	++	-
Skin	+	+	++	-
Flesh	+	+	+	-

Note: ++ = present in abundance. + = present. - = Absent

Plant secondary metabolites, are essential sources of many food ingredients and plant chemicals (phytochemicals) [24]. Plants are known to produce many secondary metabolite compounds like alkaloids, cyanogenic glycosides, glucosinolates, flavonoids, saponins, steroids and terpenoids to screen themselves from the attack of naturally occurring pathogens, insect pests and environmental stresses. Recent researches showed that many phytochemicals can protect humans against various diseases [25]. Many phytochemicals are present in herbs, and each has its distinct work. The health benefits attributed to these phytochemicals include; antioxidant, antimicrobial, anti-inflammatory, cancer preventive, antidiabetic and antihypertensive effects [26,27].

Previous studies confirm to the current finding. Research by Jini et al. [28], showed that the flower methanol, ethanol and aqueous extracts of *Musa paradisiaca* containing flavonoids and phenolic compounds. Phytochemical screening of *Musa paradisiaca* flower revealed the presence of glycosides, flavonoids and tannins in ethanolic extract and flavonoids, saponins, glycosides and tannins in ethanol-water extract (1:1) [29]. Preliminary phytochemical screening of dried leaves and fruit peels of *Musa paradisiaca* revealed the presence of some glycosides, anthocyanins, tannins, flavonoids as well as carbohydrates [30,31,32]. These phytochemicals have been reported to play multiple biological and pharmacological roles (antibacterial, antihypertensive, antidiabetic and anti-inflammatory activities) [33].

The obvious roles played by these phytochemicals in both therapeutic and nutritional fields, contribute to the role played by this plant, *Musa paradisiaca* particularly tepal and fruit (skin and flesh) in the field of medicine and health sciences.

Effect of *Musa paradisiaca* on nitric oxide generated by sodium nitroprusside

The extracts showed mild inhibition against the NO produced by the sodium nitroprusside. Maximum inhibition of 41.05% was recorded in the tepal aqueous extract, and minimum inhibition of 22.34% has been registered in the flesh extract; all others showed mild inhibition as well (Table 2).

Table 2. Percentage of NO inhibition by tepal, skin and flesh extracts with the inhibitory concentration

Sample	Maximum inhibition (%)	Concentration (µg/mL)
Tepal methanol	32.36	1000
Tepal ethanol	40.58	250
Tepal aqueous	41.05	1000
Skin	35.94	1000
Flesh	22.34	500
Ascorbic acid	84.43	1000

Nitric oxide is an important chemical mediator produced by endothelial cells, macrophages, neurons, to mention a few and is involved in the regulation of many different physiological processes [34]. An excess amount of NO is associated with several diseases [35], such as its implication in inflammation, cancer and other pathological conditions. It is produced in biological tissues by specific nitric oxide synthases (NOSs), which metabolize arginine to citrulline in which process it is formed via a five electron oxidative reaction [36]. Incubation of solutions of sodium nitroprusside in PBS at 25 $^{\circ}$C resulted in the linear time dependent nitrite production, which is reduced by the tested extracts. Powdered drug of plant parts of Drymariadiandra Blume were separately extracted with methanol-water in ratio 4:1. The extracts from this plant of both hill and plain areas executed very less scavenging power against NO [37].

Effect of *Musa paradisiaca* – tepal, skin and flesh on LPS induced NO (anti-inflammatory activity) and RAW 264.7 cell viability

The Griess reaction, a spectrophotometric determination of nitrite level, was carried out to measure the nitrite levels in the conditioned medium of RAW 264.7 cells treated with LPS. Sodium nitrite ($NaNO_2$) was used as a standard compound for the standard curve (Figure 1). The NO concentrations were obtained using the standard curve equation: $y = 0.005x + 0.0589$, where y is absorbance at 540 nm and x is the NO concentration in µM. The inhibitory activity of the extracts towards NO generated by LPS-activated macrophage was obtained from the calculated value of x.

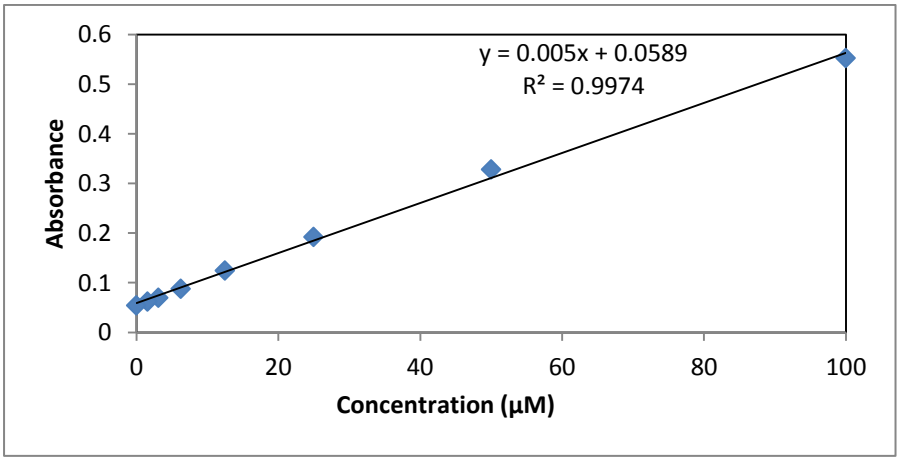

Figure 1. $NaNO_2$ standard curve, use to obtain NO concentration.

The results from this findings showed that flesh extract has the highest NO inhibitory activity, with the maximum inhibition of 52.21% at 250 µg/mL, followed by tepal aqueous extract with maximum inhibition of 48.16% at 62.5 µg/mL. The least inhibition was noted in the tepal methanol extract that has the highest inhibition of 19.63% at 62.5 µg/mL (Table 3). The inhibition of NO, generated by the LPS induced macrophage, by the extracts is similar to that of NO generated by sodium nitroprusside, as discussed in the NO radical scavenging assay. This proves that *Musa paradisiaca* has NO inhibitory activity, which signifies its anti-inflammatory activity.

Table 4 and Figure 2 showed that the number of viable activated macrophages was not altered by the extracts as determined by MTT assay. This indicates that, the inhibition of NO synthesis by the extracts was not due to cytotoxic effects.

The higher NO inhibition by the fruit correspond to the epidemiological data that suggest that lower incidences of certain chronic diseases such as atherosclerosis, arthritis, diabetes, acquired immune deficiency syndrome (AIDS)

are associated with frequent intake of fruits and vegetables [38,39,40]. Flavonoids constituent may also contribute to this activity as many studies prove that consumption of flavonoid-rich foods exhibited regression of inflammatory diseases [41].

Table 3. Maximum NO (generated by LPS) inhibitory concentration of *Musa paradisiaca* tepal, skin and flesh extracts and their concentrations.

Sample	Maximum NO inhibition (%)	Concentration (µg/mL)
Tepal methanol	19.63	62.5
Tepal ethanol	46.08	125
Tepal aqueous	48.16	62.5
Skin	30.6	250
Flesh	52.21	250
Standard	52	250

Table 4. Maximum and minimum percent cell viability of *Musa paradisiaca* tepal, skin and flesh and their various concentrations

	Cell viability (%)			
Sample	Maximum	Concentration (µg/mL)	Minimum	Concentration (µg/mL)
Tepal methanol	102.4	62.5	15	250
Tepal ethanol	119.84	62.5	75	250
Tepal aqueous	83.43	15.625	36	250
Skin	87.14	15.625	43	250
Flesh	100.36	62.5	68	250
Standard	90.97	62.5	80.96	250

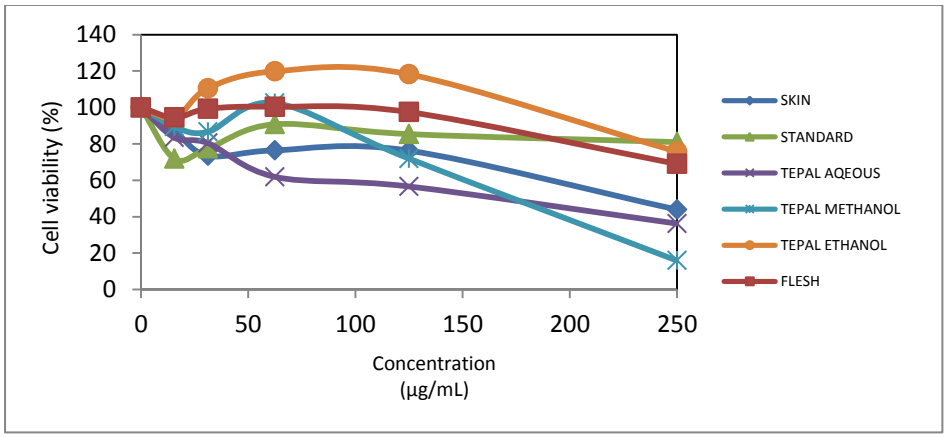

Figure 2. Percent cell viability of the tepal, skin and flesh extracts as determined by MTT

Inflammation is the normal physiological and immune response to tissue injury. More blood supply, enhanced vascular permeability and migration of immune cells occur at the damaged sites. The inflammatory process is a protective reaction that takes place in response to trauma, infection, tissue injury or noxious stimuli [42,43,44]. In this process, activated inflammatory cells (neutrophils, eosinophil, mononuclear phagocytes and macrophages) released abnormal levels of NO, prostaglandin E2 (PGE2) and cytokines, such as interleukin (IL)-1ß, IL-6, and tumour necrosis factor (TNF).These substances not only cause cell and tissue damage but also activate macrophages in diseases like rheumatoid arthritis and chronic hepatitis [45 – 48].

NO is the main product, which formationis regulated by the NOSs. The NOSs include iNOS (inducible nitric oxide synthases), eNOS (endothelial nitric oxide synthases) and nNOS (neuronal nitric oxide synthases). Most significantly, iNOS is highly expressed in macrophages and its activation leads to organ destruction in some inflammatory and autoimmune diseases [49,50]. During inflammation, macrophages play a fundamentalrole in controlling many different immunopathological phenomena, including the overproduction of pro-inflammatory cytokines and inflammatory mediators such as IL-1ß, IL- 6, NO, iNOS, COX-2 and TNF. Indeed, many of inflammatory stimuli, such as LPS and proinflammatory cytokines, activate immune cells to up-regulate such inflammatory states, and these are therefore useful targets in the development of new anti-inflammatory drugs and investigation of the anti-inflammatory molecular mechanisms of a potential drug [51,52]. LPS stimulation alone has been demonstrated to induce iNOS transcription and its protein synthesis, in murine macrophage RAW 264.7 cells, with a corresponding rise in NO production. Moreover, LPS stimulation has also been shown to induce IκB proteolysis and NF-κB nuclear translocation [53,54]. Hence, this cell system is a splendid model for drug screening and the subsequent evaluation of potential inhibitors against iNOS and NO production.

Varieties of phytoconstituents are responsible for anti-inflammatory activity in plants, including phenolics, alkaloids, and terpenoids [55] and phenols are among the phytochemical presents in the extracts. Plants are blessed with many different phytochemical such as, vitamins, phenolics, terpenoids, lignins, tannins, flavonoids, quinones, coumarins, alkaloids, amines, betalains, and other metabolites, which are rich in antioxidant activity [56,57]. Several researches have shown that many of these antioxidant compounds possess anti-inflammatory, anti-atherosclerotic, anti-tumor, anti-mutagenic, anti-carcinogenic, anti-bacterial, and anti-viral activities [58,59]. Saponins present in the tepal ethanol extract may as well, contribute to its anti-inflammatory activity, as soybean saponins were reported to downregulate the expression of PGE2 and NO metabolism at mRNA and protein levels, showing these saponins as chemicals that possess chemopreventive activity through the downregulation of COX-2 or iNOS [60]. Another report also showed that saponins from quinoa possess potent anti-inflammatory activities [61].

Many compounds from medicinal plants origin have been demonstrated as inhibitors of the expression of iNOS in LPS-activated macrophages. Their structures can be categorized as sesquiterpene [62,63], polyacetylenes [64] and lignans [65]. Thus, plants demonstrating inhibitory activity against NO production will be promising candidates for the isolation of active components exhibiting iNOS inhibitory activity, which may have therapeutic potential for the treatment of inflammation accompanying overproduction of NO.

These results indicate that flesh, tepal ethanol and aqueous extracts may suppress NO generation by inhibiting the NOS enzyme activity similar to the NOS inhibitor L-N^6-(1-imino ethyl) lysine hydrochloride (the standard). It is recommended that the extracts, which inhibits NO production through inhibiting iNOS enzyme activity, has beneficial therapeutic effects in the management of inflammatory diseases. These results showed that the tepal ethanol, aqueous and flesh extracts, did not alter the cell viability even at 250 µg/mL. Therefore, inhibition of LPS-induced NO production by these extracts was not due to its cytotoxicity on the cells.

Conclusion

Musa paradisiaca (banana) is a plant that has been used since ancient times both as nutrient and in the treatment of many diseases. The plant is a good candidate for evaluating the nitric oxide scavenging as well as anti-inflammatory potentials due to its proven positive pharmacological activities by many researchers. Both tepal and fruit extracts

demonstrated good nitric oxide scavenging as well as anti-inflammatory activities. Hence, these plant parts need more scientific attention in order to actualize its potentialities in the fields of medicine and health sciences.

Acknowledgement

The researchers acknowledged the effort of chemistry and cell culture labs staff, in the Faculty of Medicine, of Universiti Sultan Zainal Abidin (UniSZA) for their help in this research. The effort of Ainul Syamira, a research assistant at UniSZA, is also appreciated.

Abstract

The current use of ulcer drugs is limited due to its side effects and potentiality of relapse. This study aimed to ascertain the antiulcer potentials of the tepal and skin extracts of banana *Musa paradisiaca*. The parts were processed and extracted using methanol by maceration. Phytochemicals content of both parts were screened. Twenty-five albino mice were used in *in vivo* analysis. The mice were treated with 100 mg/kg of tepal and skin extract as well as cimetidine for seven days followed by administration of indomethacin. The animals were sacrificed, and the removed stomachs were prepared for the evaluation of ulcer index and gastric wall mucus. pH and volume were measured from the gastric juice. The results revealed that banana's tepal and skin extracts contain phytochemicals like phenols, flavonoids and etc. The tepal and skin extracts prevented the IND+PYL induced ulcer by 68.80 ± 20.53% and 43.22 ± 14.82% respectively. Significant rise ($p < 0.05$) in gastric juice pH (3.79 ± 0.24) was noticed in the banana's tepal treated group. However, the decrease in gastric juice volume and increased gastric wall mucus by both tepal and skin were not statistically significant ($p > 0.05$). Findings from this study shows that banana's tepal and skin were able to prevent IND+PYL induced ulcer by strengthening the gastric mucosa and decreasing the gastric juice acidity.

Keywords: banana's tepal, banana's skin, indomethacin, *Musa paradisiaca,* preventive index.

Abstrak

Penggunaan ubat ulser pada masa kini adalah terhad disebabkan kesan sampingan dan potensi kambuh. Kajian ini bertujuan menentukan potensi antiulser dari ekstrak jantung dan kulit pisang *Musa paradisiaca*. Bahagian – bahagian ini telah diproses dan diekstrak menggunakan metanol melalui kaedah rendaman. Kandungan fitokimia kedua – dua bahagian telah disaring. Dua puluh lima tikus albino telah digunakan dalam analisis *in vivo*. Tikus – tikus ini telah diberi rawatan dengan 100mg/kg ekstrak jantung dan kulit pisang serta simetidin selama tujuh hari di ikuti dengan rawatan dengan indomethacin. Haiwan dikorbankan selepas 8 hari rawatan, dan perut dikeluarkan bagi penilaian indeks ulser dan mukus dinding perut. pH dan jumlah jus gastrik juga diukur. Hasil kajian mendapati bahawa ekstrak jantung dan kulit pisang mengandungi beberapa fitokimia seperti fenol, flavonoid, dan lain – lain. Ekstrak jantung dan kulit ini menghalang ulser yang diaruh dengan IND+PYL masing – masing sebanyak 68.80 ± 20.53% dan 43.22 ± 14.82%. Peningkatan yang signifikan ($p < 0.05$) pada pH jus gastrik (3.79 ± 0.24) telah diperhatikan dalam kumpulan yang dirawat dirawat dengan jantung pisang. Walau bagaimanapun, penurunan dalam jumlah jus gastrik dan meningkatkan mukus dinding perut oleh kedua – dua ekstrak adalah tidak signifikan secara statistik ($p > 0.05$). Dapatan dari kajian ini menunjukkan bahawa jantung dan kulit pisang dapat mencegah ulser yang diaruh dengan IND+PYL melalui penambahan mukosa perut dan pengurangan keasidan jus gastrik.

Kata kunci: jantung pisang, kulit pisang, indomethacin, *Musa paradisiaca,* indeks pencegahan

Introduction

Ulcers are simply lesions penetrating the thickness of the gastrointestinal tract (G.I.T) mucosa [1]. The etiology of gastro-duodenal (peptic) ulcer has therefore developed when aggressive factors such as, increased HCL and pepsin secretion, parietal cell mass, and gastrin production, dominate the defensive factors (PGs, increased mucous cells etc) [2,3].

Indomethacin, a NSAID (methylated indole derivative), was introduced in 1963 for the management of inflammatory diseases such as rheumatoid arthritis, degenerative joint diseases, gout, and acute musculoskeletal disorders [4,5]. However it was later found to be injurious to tissues. These injurious effects have been ascribed to the production of reactive oxygen species (ROS) [6,7], which lead to oxidative stress and initiation of lipid peroxidation [7], infiltration of inflammatory cells [8,9]. Pylorus ligation also induced ulcers by increasing the accumulation of gastric acid and pepsin that lead to auto digestion of the gastric mucosa and the breakdown of gastric mucous [10]. Hence, indomethacin and pylorus ligation were used to induce ulcer in this research.

The major idea behind treating ulcers is to lower the amount of acid that the stomach makes, to neutralize the acid and to protect the injured area so it can have time to heal [1]. However, most of the commonly used antiulcer drugs, namely antacids, H2- blockers and proton pump inhibitors, etc. that mainly act by reducing the aggressive factors are reported to have adverse effects, development of tolerance and increased the incidence of relapses during ulcer therapy [11]. The expensive costs and toxic effect of these agents, necessitate efforts to find a suitable protective agent, for the treatment of peptic ulcer disease from natural products of plants, which afford better protection and decrease the incidence of relapse that is affordable by all classes of people. Interestingly, herbal drugs mostly augment the defensive factors such as mucin secretion, cellular mucus, bicarbonate secretion and mucosal blood flow [12].

Banana is one of the oldest and well-known fruit worldwide. The leaf and stem of banana are use to treat diarrhoea; the stem is good for asthenia and wounds, and the leaf for the treatment of inflammation, headache and rheumatism [13]. Besides to its nutritional value, a number of biological activities studies have been carried out on banana and these studies prove it to possess bioactivities including anti-hyperglycaemic, antiulcerogenic, antioxidant, antihypertensive, cardiac depressant, diuretic, anti-tumoral, bronchodilatory, expectorant, oral contraceptive, abortifacient, antibacterial, antifungal and etc. [14]. Therefore, this study was carried out to evaluate the antiulcer effect of *Musa paradisiaca* tepal (a part mostly considered as a waste) and skin, against indomethacin plus pylorus ligation induced gastric injury in mice.

The economy of developing countries has a lot to do with the health status of its citizen. The rising incidence of ulcer has involved both adults and children. The solution to ulcer will help in controlling health status, societal and physical well-being as well as economic uplift of individuals, families, companies and nation at large.

Materials and Methods

Collection and preparation

Banana fruit and tepal, were purchased from Kuala Terengganu, Malaysia; samples were identified and authenticated by Dr. Khamsah Suryati Mohd from the Faculty of Bioresources and Food industry, Universiti Sultan Zainal Abidin. The skin (peel) was removed from the fruit, sliced, and weighed using electrical balance (1.45kg). It was then dried in a drier at 45°C; the dry weight is 0.41 kg. After drying, it was blended to powder, using an electrical blender, and the weight is 0.21 kg. The tepal was also prepared in a similar way and weighed (3kg) and dried at 40 $^{\circ}$C and then blended to powder (0.42 kg).

Extraction procedure

The prepared skin and tepal were extracted twice with methanol (10:2 mL/kg) by cold extraction technique. The samples were put in the solvents for about 3 days at room temperature with regular shaking. All the extracts were

vacuum filtered using Whatman number one filter paper and concentrated at 40 °C using a rotary evaporator. The crude extracts were kept in a fresh vials and refrigerated at 4°C for further study.

Phytochemical screening of the extracts
The phytochemicals screening of the various solvents extract were carried out using standard procedures [15].

Test for glycosides
Small amount of the extracts was put in 1 mL of water in a test tube followed by the addition of 1 mL of NaOH. A yellow precipitate indicates the presence of glycosides.

Test for phenols
The extract (5mg) was dissolved in distilled water and 3 mL of 10% lead acetate solution was added. A bulky white precipitates indicated the presence of phenols.

Test for Flavonoids
A few drops of concentrated hydrochloric acid were added to a small amount of the extract. Immediate development of red colour indicates the presence of flavonoids.

Test for Saponins
An amount 1 mL of each extract was diluted with distilled water to 20 mL and shaken in a graduated cylinder for 15 min. The formation of foam of about 1cm indicates the presence of saponins.

Evaluation of antiulcer activity
Swiss albino mice of both sexes (30-35g), obtained from UniversitI Sains Malaysia Pinang, were utilized in this experiment. The animals were kept in cages with proper bedding. The bedding was regularly changed to prevent coprophagy. The animals were put up in an ambient temperature of 22 ± 1ºC in a 12 hours light–dark bicycle. They were fed a standard balanced diet and given free access to water *ad libitum*. All animals were fasted for 24 hours [16] to ensure an empty stomach before use in the experiment. The experiments were designed and conducted to meet the ethical norms approved by University Sultan Zainal Abidin, Malaysia, animal ethical committee (UniSZA/AEC/14/006).

Study design
The experimental models were acclimatized for one week. They were then randomly grouped into five groups comprising of five mice each. Group I served as normal control, which received 0.3ml/30g distilled water for 7 days. Group II or IND+PYL group was induced with indomethacin at a single dose of 48 mg/kg [17] body weight (b.wt) on the 7th day of the experiment. Group III or TPM group was also orally administered methanol extract of the tepal at a dose of 100 mg/kg b. wt and then indomethacin at a single dose of 48 mg/kg on the 7th day, one hour after the last treatment. Group IV or SKM and V or CIM were treated in the same manner as group III. All animals were allowed to fast overnight. On the 8th day, pylorus was ligated using silk sutures as per the method [18] under light ether anaesthesia, taking care not to temper with the blood vessels. Then after the abdominal wall was closed by suturing and the animals were allowed to recover from the anaesthesia for 4 hours, ketamine was used to euthanize it. Each stomach was removed and opened along the greater curvature, washed with 0.9% saline and examined for macroscopic mucosal lesions, with the aid of magnifying glass (x10), and then put inside a container containing 10% formasaline and kept for histopathological studies. The gastric content was carefully collected for analysis.

Calculation of macroscopic ulcer index (U.I)
The severity of the ulceration was graded according to the scale that is a modification of the score [19].

(0 - Normal gray colored stomach), (0.5 - Pink to red coloration of the stomach), (1 - Spot ulcer), (1.5 - Haemorrhagic streak), (2 - Number of ulcers less than 5), (3 - Number of ulcers more than or equal to 5), (4 - Ulcer with bleeding) and (5 - Perforation of the gastric/duodenal wall).

Ulcer Index was calculated by summing the entire number of ulcers plus the severity of the ulcer. The preventive index (P.I) of the extract administered was obtained by using the equation 1[20].

$$P.I = \frac{U.I\ of\ indomethacin\ group - U.I\ of\ test\ group}{U.I\ of\ indomethacin\ group} \times 100 \quad (1)$$

Determination of gastric juice volume and pH

After the gastric contents were collected and centrifuged at 1000 rpm for 10 min. The volume of the supernatant was determined in mL. The pH of the supernatant was measured using a pH meter [21,22].

Assessment of gastric wall mucus

Alcian blue binding to gastric wall mucus was determined by a modified method of Corne [23]. The stomach of each mice was weighed and immediately transferred to 10 mL of 1% (w/v) alcian blue solution (in 0.16 M sucrose solution, buffered with 0.05 mL sodium acetate, pH 5) for 2 hours at room temperature. After 2 hours, the stomachs were removed, rinsed with 0.25 M sucrose solution to remove excess dye after 15 and 45 minutes, and the dye complexed with gastric wall mucus was extracted with 10 mL of 0.5M $MgCl_2$ solution by intermittent shaking for 1 minute at 30 minutes' intervals for 2 hours. The stomachs were removed and 5 mL of each aliquot of $MgCl_2$ solution containing the alcian blue eluted from each stomach was shaken with 4 mL of diethyl ether. The aqueous phase was separated out, centrifuged at 4000 x g for 16 min and the absorbance of the supernatant was measured at 580 nm. The amount of alcian blue bound per stomach in micrograms was determined using a standard calibration curve. Alcian blue was the standard compound used.

Histopathological studies: Tissue preparation

After the lesions seen in the stomachs had been noted, each stomach was then placed in 10% formasaline. After 24 hours of fixation followed by embedding, using closed type automated embedding machine, in a paraffin block, it was then trimmed and cut into sections of 5 microns, the ribbon obtained was put in a water bath (56^oC), fished out onto a glass slide and stained with haematoxylin-eosin stain for histological assessment of the gastric mucosa [24].

Results and Discussion

Phytochemicals present in *Musa paradisiaca* tepal and skin

The tepal and skin methanol extracts of *Musa paradisiaca*, prepared in this work showed the presence of the tested phytochemicals like flavonoids, phenols and glycosides.

Investigations into natural products often, is guided by ethno-pharmacological knowledge, and has brought tremendous contributions to drug production by providing novel chemical structures and mechanisms of action [25,26]. Tepal methanol extract showed the presence of glycosides and phenols in abundance. Flavonoids and saponins were also detected in this extract. Skin methanol extract also contains glycosides and phenols yet saponins are absent (Table 1).

Table 1. Phytochemicals from the tepal and skin methanol extracts of *Musa paradisiaca*

Extract	Glycosides	Phenols	Flavonoids	Saponins
Tepal	++	++	+	+
Skin	+	+	++	-

Note: ++ = present in abundance. + = present. - = Absent

Plant secondary metabolites, are important sources of many food ingredients and plant chemicals (phytochemicals) [27]. Recent researches showed that many phytochemicals can protect humans against various diseases [28]. Many phytochemicals are present in herbs, and each has its distinct work. The health benefits attributed to these

phytochemicals include; antioxidant, antimicrobial, anti-inflammatory, cancer preventive, antidiabetic and antihypertensive effects [29,30].

Preliminary phytochemical screening of dried leaves and fruit peels of *Musa paradisiaca* unveil the presence of some glycosides, anthocyanins, tannins, flavonoids as well as carbohydrates [31-33]. These phytochemicals have been reported to play multiple biological and pharmacological roles (antibacterial, antihypertensive, antidiabetic and anti-inflammatory activities [34].

Several phytochemicals in different parts of banana from different solvent extracts have been reported by several researchers. Many flavonoids and related compounds (Leucocyanidin, quercetin, and its 3-O-galactoside, 3-O-glucoside and 3-O-rhamnosyl glucoside) were isolated from the unripe pulp of plantain [35,36]. Serotonin, norepinephrine, tryptophan, indole compounds, tannin, starch, iron, crystallizable and non-crystallizable sugars, vitamin C, B-complex vitamins, fats, mineral salts were detected in the fruit pulp of *M. paradisiaca var. sapientum* [37]. The preliminary phytochemical screening carried out indicated *M. paradisiaca var. sapientum* peels contain some secondary metabolites such as glycosides, alkaloids, saponins, volatile oil, flavonoids and tannins [38]. The phytochemical screening of ethanolic and methanolic extracts of *Musa paradisiaca* confirmed the presence of some secondary metabolites. Ethanolic extract was found to have alkaloids, flavonoids, steroids, tannins, glycosides etc., whereas the methanolic extract revealed the presence of alkaloids, saponins, xanthoproteins and glycosides [39].

The roles of these phytochemicals as both therapeutics and nutrients makes these parts (tepal and skin) of the plant have medicinal and nutritional values. This work confirmed the presence of most of these phytochemicals in the parts above.

Effect of *Musa paradisiaca* tepal and skin on ulcer index

Ligation of pylorus causes erosion due to stimulation of acid and pepsin in the abdomen [18], leading to autodigestion of the gastric mucosa and the breakdown of the gastric mucosal barrier [40]. Prostaglandins (PGs) shows a protective effect on the stomach mucosa and causes an increase in bicarbonate secretion, maintain mucosal blood flow and repair. Hence, the increase in mucosal lesions is caused by suppressing PGs synthesis by NSAIDs. For this reason, indomethacin plus pylorus ligation model was used in our study to induce severe ulceration in mice. The number of lesions seen on the gastric mucosa is an indication of the severity of ulcer disease [41]. Non-parametric Kruskal-Wallis followed by Mann-Whitney tests were used for the statistical analysis.

According to this result (Table 2), administration of indomethacin coupled to ligation of the pylorus in IND+PYL group showed significant increase in ulcer index (16.20 ± 5.70) when compared to the normal control group ($p = 0.005$). Pre-treatment with cimetidine significantly ($p = 0.009$) decreases the ulcer index. Tepal pre-treatment also significantly decreases ($p = 0.027$) the ulcer index when compared to the induced group. However, the decrease in ulcer index in skin pre-treated group is not significant ($p = 0.074$). The cimetidine pre-treated group decreased the ulcer index to 3.6 ± 1.20 giving 72.14% protection. Meanwhile, the tepal and skin extracts reduced the ulcer index to 3.60 ± 1.20 and 6.90 ± 2.10 giving 68.80% and 43.22% protection respectively. This protection (preventive index) observed in both the tepal and skin is not statistically significant from the protection observed in cimetidine ($p = 0.249$).

The gastric mucosal integrity depends on the balance between HCL, pepsin (aggressive factors) and the protective factors as mucus and bicarbonate secretion, prostaglandins, mucosal blood flow, nitric oxide [42]. Hence, the main guidelines for the treatment are aimed not only at blocking the acid secretion, but also on the increased production of factors responsible for protecting the gastric mucosa, thus preventing epithelial damage [43]. The present study proves the preventive effect of *Musa paradisiaca* tepal and skin methanol extracts, as they significantly decreased the induced ulcer.

Table 2. Effect of tepal and skin pre-treatments on ulcer index and preventive index in IND+PYL induced ulcer

Sample (n=5)	Ulcer Index (Mean ± SE)	Preventive index (Mean ± SE)
Control	0.00±0.00[c]	Nil
IND+PYL	16.20±5.70[a,d]	Nil
Tepal pre-treated	3.80±1.60[b]	68.80±20.53[e]
Skin pre-treated	6.90±2.10[a]	43.22±14.82[e]
Cimetidine pre-treated	3.60±1.20[b]	72.14±13.49[e]

[a,b]Man-Whitney U test showed that, tepal methanol and cimetidine showed significant decrease in ulcer index. However, the decrease in skin extract is not statistically significant, when compared to the induced group (IND+PYL) [a]. [c,d]Man-Whitney U test showed a significant formation of ulcer in IND+PYL group when compared to the normal control group. [e]Kruskal-Wallis test showed no significant difference in ulcer prevention (Preventive ulcer index) exerted by the tepal, skin as well as the standard cimetidine drug.

Effect of Musa paradisiaca tepal and skin on gastric juice volume and pH

The current study showed that, the methanolic skin and tepal extracts of *Musa paradisiaca,* as well as cimetidine, lower the volume of the gastric juice compared to the induced group (IND+PYL). The volume of the gastric juice was found to be 0.86 ± 0.13mL in the induced (IND+PYL) group, but tepal brought it down to 0.40 ± 0.04mL. Cimetidine and skin also reduced the volume to 0.46 ± 0.08 mL and 0.64 ± 0.13 mL respectively (Figure 1), although not statistically significant.

Significant increase in pH was observed in the tepal and cimetidine pre-treated groups as presented in Fig. 1. The pH value in the induced group (IND+PYL) was found to be 2.48 ± 0.2. This is significantly (p = 0.012) increased to 3.79 ± 0.24 by the tepal extract in a similar way to the standard drug, cimetidine, 3.98 ± 0.11 (p = 0.009) when compared to the induced group. The increase in pH by the skin extract is not statistically significant (p = 0.203) when compared to the induced group. This may be due to its less chemical components than the tepal or may be higher dosage is needed. However, it also increases the gastric juice pH to 2.99 ± 0.32 (Figure 1).

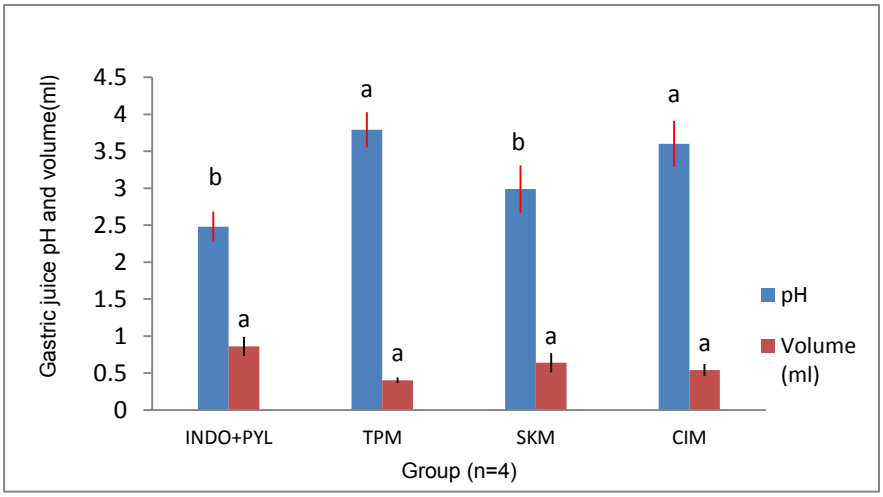

Figure 1. Gastric juice pH and volume

Tepal methanol (TPM), cimetidine (CIM) and skin methanol (SKM) pre-treated groups showed no significant gastric juice volume reduction when compared to the induced group (INDO+PYL).

CIM and TPM showed a significant rise in pH when compared to the induced group (INDO+PYL). SKM showed no statistical significance when compared to the induced group.

Effect of Musa paradisiaca tepal and skin on gastric wall mucus

Figure 2 showed the impact of the tepal and skin extracts on the measured gastric wall mucus. Both the tepal and skin showed increased gastric mucus but not statistically significant ($p = 0.339$) when compared to the induced group (IND+PYL). The group pre-treated with the standard cimetidine drug also decreases the gastric mucus in a similar way to the tepal and skin.

The research shows the effects of tepal and skin against indomethacin plus pylorus ligation induced gastric ulcers. The gastric ulcers in the pylorus ligated animal are mainly due to increased gastric HCL secretion leading to the destruction of mucosal barrier and autodigestion of the gastric mucosal layer. In ulcer induced models there is, normally, a significant increase in the level of acid and pepsin [44]. Indomethacin also increases pepsinogen secretion [45].

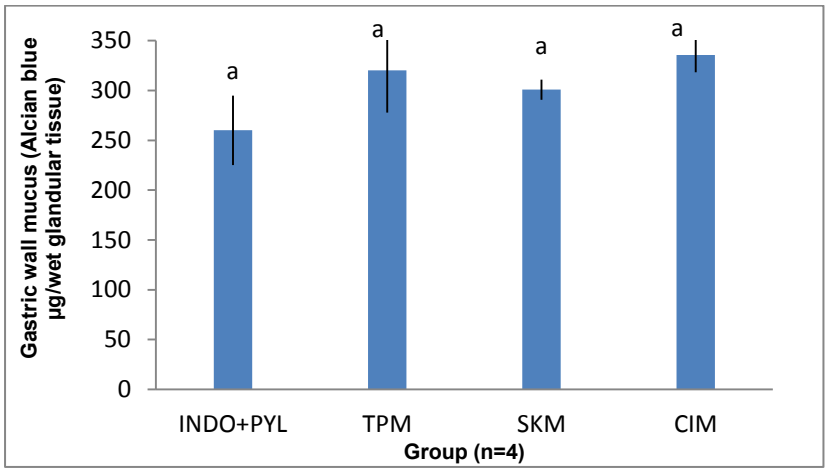

Figure 2. Increase in gastric wall mucus by the extracts.

The rise in the gastric wall mucus (GWM) by both the TPM and SKM is not statistically significant when compared to the induced group (INDO+PYL).

The volume of acid present in gastric secretion which comprises HCL, pepsinogen, mucus, bicarbonate, intrinsic factor and protein reflects acid volume. Exposure of the open lumen of the stomach to accumulating acid could facilitate ulceration [46]. Another aggressive factor responsible for ulcers is the amount of "acid present in the gastric juice. Over secretion of histamine contributes to increased secretion of gastric juice" [47]. When the concentration of hydrogen ions in gastric juice decreases, it indicates high pH. The genesis of ulcer and gastric damage is made easy by hydrogen ions that serve as another aggressive factor [48].

Administration of tepal, skin and cimetidine at a dose of 100 mg/kg decreased gastric juice volume and increased gastric the juice pH when compared to the ulcer induced group. The increase in pH implies a decrease in gastric acidity which can occur through the decline in pepsin activity. Hence, the extracts prevent ulcer possibly by preventing overproduction of gastric acid.

Mucus serves as the first line of defence against ulcerogenic agents. It is secreted by the mucous neck cells and shields the gastric mucosa. Mucus secretion is an essential factor in the protection of the gastric mucosa from the gastric erosions and has been regarded as a significant defensive entity in the gastric mucus barrier [49]. Increased mucus secretion by the gastric mucosal cells can protect gastric ulceration by several mechanisms, like decreasing of stomach wall friction during peristalsis and gastric contractions, increasing the buffering of acid in gastric juice and by acting as an effective barrier to back diffusion of H^+ ions [50]. *Musa paradisiaca* skin and tepal was found to augment the gastric mucus by decreasing the gastric juice acidity and lowering its volume, which are all evident in this work.

Topical and systemic effects of NSAIDs in the gastrointestinal mucosa are associated with mucosal damage in both the upper and lower GIT [51]. The systemic effects of NSAIDs involve the inhibition of prostaglandin production (by affecting COX-1 function), which defect bicarbonate and mucus secretion. Indomethacin induce a direct irritation effect by increasing free radical formation and H^+ ion transport [52]. Indomethacin causes ulcer mainly on the glandular (mucosal) part of the stomach [53]. The extracts (100 mg/kg) may also offer gastroprotection by enhancing the mucus wall thickness and antioxidant activity, since it was found to have an excellent DPPH radical scavenging activity [54] as well as the augmentation of the gastric wall mucus. It is possible that the cytoprotective action *M. paradisiaca* is mediated via the action of endogenous prostaglandin, which stimulate mucus secretion and plays an important role in ensuring mucosal integrity against the actions of various deleterious agents [55].

Several studies on the antiulcer efficacy of different parts of *Musa paradisiaca* var. *sapientum* were carried out, and it conforms to the current finding. A study conducted by Koffuor [56], showed that, the aqueous extract of *Musa paradisiaca* (0.2 – 0.8 mg/kg) treated mice gave a significant ($P < 0.001$) reduction in the gastric ulceration, induced by acetic acid, similar to the esomeprazole treated group. The flower extract of *Musa paradisiaca* has been described to possess antioxidant as well as antiulcer activity [57,58]. Methanolic extract of *M. sapientum var. paradisiaca* showed antiulcer and mucosal defensive factors in normal and non-insulin dependent diabetes mellitus rats [59]. Studies with *M. paradisiaca var. sapientum* have shown its ulcer protective and healing activities through its predominant effect on various mucosal defensive factors and they resolved that its antioxidant activity may be implied in its ulcer protective activity [57]. A previous study reported that dried unripe banana powder contains flavonoid leucocyanidin and a significant protective role against aspirin-induced erosions was seen [55].

The significant increase in the antiulcer activity of *Musa paradisiaca* skin and tepal, could also be attributed to the presence of flavonoids and glycoside, which are shown to be present in the both tepal and skin extracts. In this study, the tepal extract showed better antiulcer activity as well as more abundant glycosides and phenols than the skin extract. The skin extract that showed antiulcer activity and also contains abundant flavonoids (Table 1). Among the phytochemicals present in the extracts, saponins and flavonoids are referred to as antiulcer compounds [60]. These phytochemical constituents of the extracts could explain its antiulcer activity. Furthermore, several plants containing high amounts of saponins have been shown to possess antiulcer activity in several experiments [61,62], probably acting as an activator of mucus membrane protective factors [63]. Moreso, the gastroprotective effect of flavonoids has been previously reported [64].

Phenolic compounds cause the augmentation of mucus production and anti-inflammatory action due to their free radical scavenging activity [65]. The tepal and the skin extracts of *Musa paradisiaca* were found to have a large amount of total phenolic content [54]. The presence of phenolic compounds in the extracts may be a contributing factor towards the significant reduction of ulcer index observed in the pre-treated groups. *Musa paradisiaca* contains a glycoside called “aucubin” which has antihistaminic activity [66]. Thus, the antihistaminic activity may be one of the mechanisms through which plant extracts prevent ulcer progression.

Mucosal defence and repair mechanisms are relevant in protecting the integrity of the mucosal layer, and resultant inhibition of these mechanisms could lead to necrosis. Examples of such defense mechanisms include preepithelial factors (mucus-bicarbonate-phospholipid barrier), surface epithelial cells connected by tight junctions, bicarbonate and mucus production, prostaglandins, heat shock proteins and blood flow through the mucosal vessels [67]. The extracts in effect, may directly protect the mucosal layer from harmful substances such as NSAIDs (indomethacin), acids and alcohol and stimulate mucosal regeneration.

Macroscopic observation

Figure 3 showed the representative stomachs of mice after indomethacin plus pylorus ligation induced gastric ulcer. Oral administration of indomethacin (48 mg/kg) and ligation of pylorus produced superficial or deep erosions, bleeding, and antral ulcers. This is similar to the reports of Zhu and Kaunitz [3] and Lanza [68] in which prostaglandin and protective mucus function were inhibited by NSAIDs.

Nevertheless, pre-treatment with *Musa paradisiaca* skin and tepal significantly reduced the ulcer severity. Tepal and cimetidine were able to cause a significant reduction in ulcer indices compared to the ulcer induced group which caused a significant increase in the ulcer indices. Moreover, tepal and cimetidine have the same protective action against the induced ulceration. The decrease in ulcer indices is in line with those of Goel [69] who reported the reduction in ulcer indices on treatment with vegetable *Musa paradisiaca* in aspirin induced rats [69].

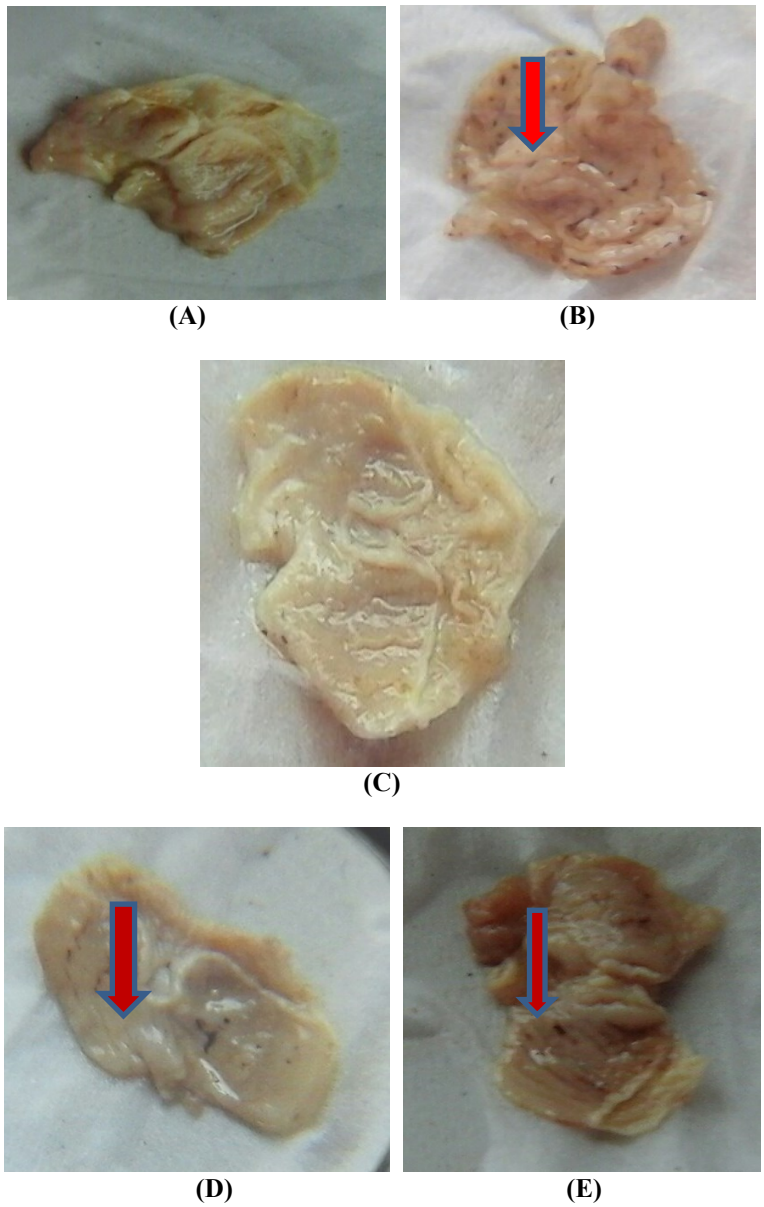

Figure 3. Gross view of mice stomachs after pre-treatment and ulcer induction.

A: control stomach, showing normal gastric mucosa. B: ulcer induced stomach, showing various lesions and some inflammation. C: Tepal pre-treated stomach, showing a highly significant preventive effect against the IND+PYL induced ulceration. D: Skin pre-treated stomach, showing a mild preventive effect against IND+PYL induced ulceration. E: Cimetidine pre-treated stomach, showing prevention against the IND+PYL induced ulcer in the similar way as in C.

Histopathological studies

This study also showed that, the administration of indomethacin at 48 mg/kg body wt. and the ligation of the pylorus, induced histological lesions in mucosal and submucosal regions as revealed by histological examinations compared to control group (Figure 4). This finding conforms to that of several studies in which ulcer was induced using indomethacin [8, 70,71].

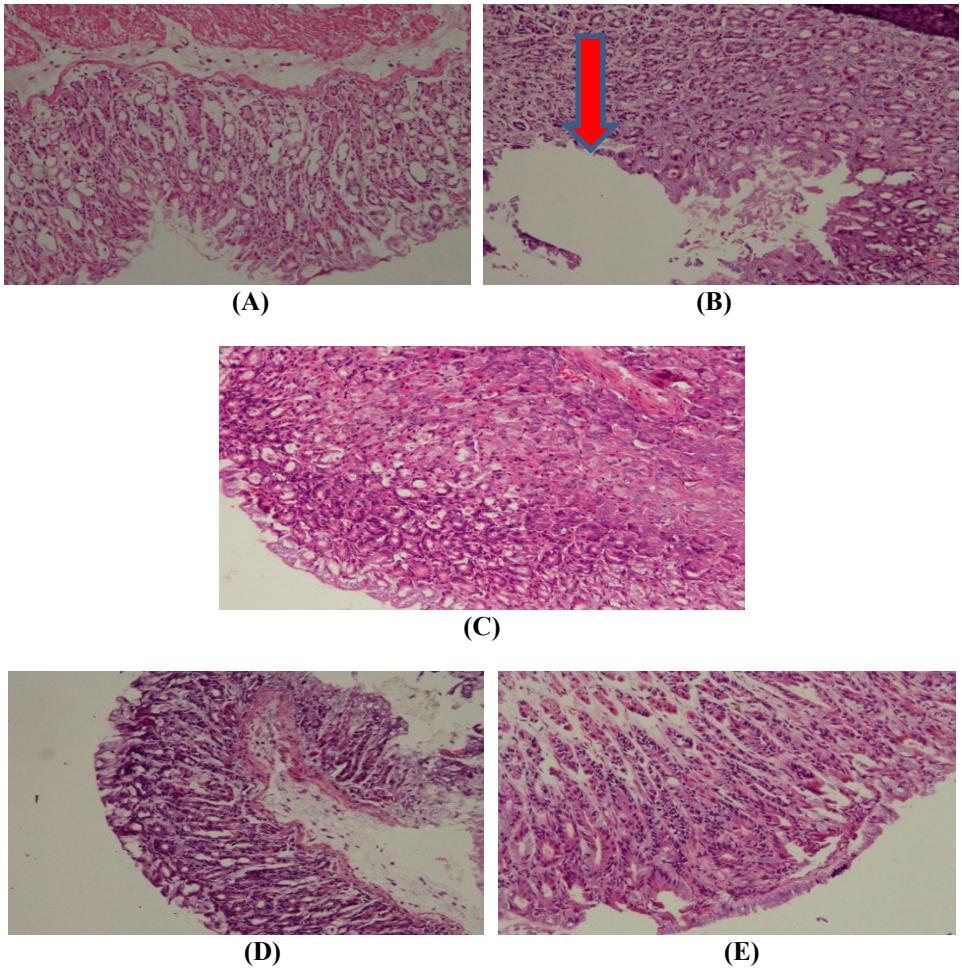

Figure 4. The histological view (x 100) of the stomach of mice

Control group showing intact mucosa (A). IND+PYL (B) induced highlighting the areas of congestion and erosions. Tepal pre-treated (C) showing intact mucosa. Skin pre-treated (D), with intact mucosa and decreased oxyntic cells in superficial half of mucosa and cimetidine (reference drug) pre-treated (E) also showing intact mucosa.

Conclusion

In the present study, it was found that, the tepal extract has the highest preventive ulcer index that is statistically not significant when compared to standard drug (cimetidine), against the indomethacin plus pylorus ligation induced ulceration. Also the same tepal and the skin extract showed a promising reduction of gastric juice volume, increasing pH and strengthening of the gastric wall mucus. Phytochemical screening revealed the presence of flavonoids, saponins, glycosides and phenols in the extracts, which are especially higher in the tepal extract, which could be the reason for its higher antiulcerogenic action recorded in this work. Further investigations are needed to confirm the use of these parts of banana for ulcer treatment.

Acknowledgement

The researchers acknowledged the effort of Chemistry lab and animal house staff, in the Faculty of Medicine and Faculty of Bioresources and Food Industry, of Universiti Sultan Zainal Abidin (UniSZA) for their help in this research. The effort of Mrs. Ummi Akrimmah Binti Yim, a technician in Histopathology lab, Faculty of Medicine, UniSZA, is also appreciated. Regard to Eng. Dr. Rabiu Musa Kwankwaso (Kwankwasiyya) for sponsoring the study.

Abstract

The levels of airborne microbe in hospital are unknown previously in Terengganu. Typically, fungi and bacteria are usually presented in indoor environments and cause of human health effects. The aim of this descriptive study was to investigate the level of airborne microbial pollution in the indoor air of the selected hospital rooms. A total of 8 rooms were investigated for this study. Sampling was conducted with an Eco-Mas 100 Single-Stage Microbial Air Impactor and counting plates containing two selective media, Rose Bengal Chloramphenicol Agar (RBCA) and Sabouraud Dextrose Agar (SDA). Air sampling was taken for 5 min at an airflow rate of 28.3 L/min. A medium-low level of bacterial and fungal concentrations (8 to 38 CFU/m^3 for RBCA and 2 to 149 CFU/m^3 for SDA), respectively were found in indoor air quality of the hospital. The highest microbe air levels for RBCA was measured in the washing room, while the highest microbe air levels for SDA was measured in the reprocessing room of hemodialysis unit. The culturable airborne bacterial and fungal concentrations on SDA agar were higher than those on RBCA. The most common culturable airborne microbes were *Penicillium* and *Cladosporium*. In addition, the use of RBCA rather than SDA significantly improved the fungal yield. The study also revealed that no indoor atmosphere in the hospital is completely free from microorganisms.

Keywords: hospital, indoor air quality, airborne microbe, colony counts

Abstrak

Tahap mikrob bawaan udara di hospital tidak di ketahui sebelum ini di Terengganu. Lazimnya, kulat dan bakteria terdapat dalam persekitaran dalaman dan menyebabkan kesan terhadap kesihatan manusia. Tujuan kajian deskriptif ini adalah untuk menyiasat tahap pencemaran mikrob bawaan udara di dalam bangunan bilik – bilik yang terpilih di hospital. Sejumlah 8 buah bilik telah disiasat untuk kajian ini. Pensampelan telah dijalankan dengan menggunakan Eco-Mas 100 Impaktor Udara Mikrob Tahap Tunggal dan plat yang mengandungi dua media terpilih iaitu *Rose Bengal Chloramphenicol Agar* (RBCA) and *Sabouraud Dextrose Agar*. Pensampelan udara dijalankan selama 5 minit pada kadar aliran udara 28.3 L/min. Satu tahap kepekatan sederhana rendah bakteria dan kulat (8 hingga 38 CFU/m^3 untuk media RBCA dan 2 hingga 149 CFU/m^3 untuk media SDA) masing – masing ditemui dalam kualiti udara dalam bangunan hospital tersebut. Tahap udara mikrob yang tertinggi untuk RBCA diukur di bilik cuci, manakala tahap udara mikrob yang tertinggi untuk SDA diukur di bilik pemprosesan semula unit hemodialisis. Kepekatan bakteria dan kulat bawaan udara yang dikultur pada agar SDA adalah lebih tinggi daripada agar RBCA. Mikrob bawaan udara lazimnya yang didapati dari media kultur ialah *Penicillium* and *Cladosporium*. Penggunaan media RBCA adalah ketara lebih baik berbanding media SDA dalam penghasilan kulat. Kajian juga mendedahkan bahawa tiada keadaan persekitaran tertutup di dalam hospital yang bebas sepenuhnya dari mikroorganisma.

Kata kunci: hospital, kualiti udara dalam bangunan, mikrob bawaan udara, pengiraan bilangan koloni

Introduction

Indoor air quality resulting from high levels of fungi (mold) and bacteria become a critical issue in the world and are therefore ubiquitous [1]. This is because of people spend most of their time indoors which is about 90 percent exposure to many types of pathogens [2,3,4]. Recently, an increasing number of people have experienced adverse health effects because of their indoor environments like infections, toxic reactions and hypersensitivity pneumonitis [5,6,7]. This is due to indoor microbial exposure has been related to a range of serious public health hazard and well-being of the population [8].

Hospital is an important facility of public place associated with the environmental exposure of humans. Besides, hospital is referred as a special public place [9]. In addition, the number of people is much higher in hospital every day compared to other public places. The effect of hospital in indoor air quality to humans is more significant, therefore this study has forwarded because there are very little studies that focused on the indoor airborne microbial in hospital in Malaysia especially in Terengganu. Fungi are common in indoor environments and about 10% of people have affected with fungal allergy like allergic bronchitis, chronic obstructive pulmonary disease and asthma [1,10]. Therefore, the airborne in indoor environment of the hospital is essential for the health of patients and medical personnel.

The culturable methods are still widely used generally with impactors and it is a sterile method [11]. The plates have been put in the impactor and grows as a colony, it is then counted as a colony-forming unit, or CFU [12]. This method is easy to implement and low cost thus reproducing the most common culturable conditions regarding total airborne microbial from a particular procedure [13]. According to study by Pasquarella et al. [14], bacterial levels less than 39 CFU/dm^2/h with passive sampling were considered as acceptable values for the air microbial contamination. While the recommended maximum limits set by the American Conference of Governmental Industrial Hygienists with the culturable count for total bacteria is not to exceed 500 CFUs/m^3 [15]. Meanwhile, the hospital was considered as a middle risk in which 50 CFUs/m^3 identified an acceptable microbiological quality in the operative areas [16].

The objective of this study is to calculate the number of colony as CFU/m^3 on two cultivated media, RBCA and SDA and to identify the types of colonies grows on the respective media through their specific colour, and morphology. This study is in line with the study by Yassin and Almouqatea [1], which state that the growth behavior and patterns on different agar need to be evaluated.

Materials and Methods

Study sites

Sampling was performed in eight selected rooms in the Hospital Sultanah Nur Zahirah (HSNZ) namely washing room, endoscopy room, isolation C (haemodialysis unit), isolation B (haemodialysis unit), CAPD room, ward 7A, and negative pressure room.

Media

Media used for sampling included RBCA and SDA (Hi Media Company Limited, India). Sabouraud Dextrose Agar consist of peptone 10 gl^{-1}, glucose 40 gl^{-1}, agar 15 gl^{-1} and Rose Bengal Chloramphenicol Agar consist of agar 15.5 gl^{-1}, chloramphenicol 0.1 gl^{-1}, dextrose 10 gl^{-1}, magnesium sulfate 0.5 $gl^{-1,}$ monopotassium phosphate 1 gl^{-1}, mycological peptone 5 gl^{-1} and rose bengal 0.05 gl^{-1} were prepared.

Sampling procedure

Air was sampled using a MAS-100 Microbial Air Sampler (Merck) for standard 90 mm petri dishes which contain Rose Bengal Chloramphenicol Agar (RBCA, Merck) and Sabouraud Dextrose Agar (SDA) to collect air sample. The microbial air sampler was located at a height of about 1.1 m to 1.5 m from the floor of the sampling sites to simulate location of the breathing zone of a seated person [9,17]. The air sampler was sterilised with 70% ethanol before using. Air sampling was taken for 5 min at an airflow rate of 28.3 L/min. Duplicates of each plate were used

in each stations. After the sampling, the petri dishes contained RBCA and SDA were incubated in an inverted position for a period of 3 to 7 days at room temperature (25 – 27 ^{o}C) as per standard procedures [18,19]. After the desired duration of agar incubation, the colonies formed on each plates were counted and the counts obtained were averaged. According to the standard conversion table for accounting particles at single impaction sites, the transformed colony forming units (CFU) appeared to be similar to the original counted which were expressed in CFU/m^3 [17].

Identification of fungi and bacteria

Isolates with different colony morphologies were selected from RBCA and SDA for identification. A stereoscopic light microscope with a magnification of 40x and 100x was used for identification of the fungi and bacteria. The fungi and bacteria were identified due to their typical colony and morphology characters based on [18, 20-23].

Results and Discussion

The levels of occurrence of the bacteria and fungi identified in the indoor air from eight different rooms in the hospital are represented in Tables 1 and 2. As stated from Table 1 and Table 2, the high CFU/m^3 is found after incubation of 7 days which this is the optimum time different species need to grow. Additionally, the trend of growth of colony counts illustrated that as times increases there is progressively more time for microbial to divide new cells. In this study, it shows that longer incubation times were associated with the highest CFU count obtained in the washing room and reprocessing room which were 38 CFU/m^3 and 149 CFU/m^3 respectively. On the other hand, negative pressure room can be classified as a clean area but there also has a growth of colony on both media; RBCA media and SDA agar which the counts were 25 CFU/m^3 and 11 CFU/m^3 respectively. However, the values obtained for negative pressure room were within the acceptable levels of microbial count.

In the present study the air quality of all of the selected rooms were found to be good, with acceptable values for the air microbial counts, since the microbial levels were lower than 50 CFU/m^3 which in the range from 8 – 38 CFU/m^3 for RBCA media and 2 – 149 CFU/m^3 for SDA media except for the microbial level in reprocessing room of hemodialysis unit Figure 1.

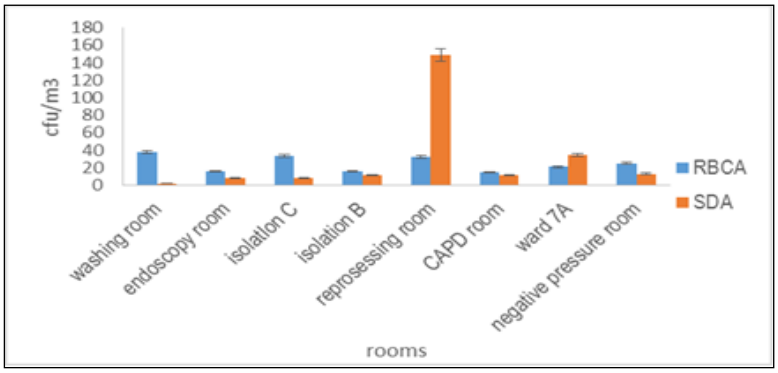

Figure 1. Mean value of microbial counts in each room for RBCA media and SDA media

In this experiment the plates were incubated for a distinct period of time. Figure 2 shows RBCA agar after three, five and seven days of incubation. After incubating the plate, a variety of organism species are grown with increasing times of days of incubation. In this study, it shows that average numbers of fungi on RBCA media was the highest in washing room because it is the place where chemicals most widely used for the purposes of washing medical apparatus before and after operation and preparation for the operation procedures. Figure 3 shows SDA

agar plate after three, five and seven days of the air sampling in reprocessing room. The reprocessing room at hemodialysis unit shows the highest number of colony. The viable cells counted in the reprocessing room and washing room were significantly higher than those found in other rooms because of inadequate ventilation and air filtration system in those rooms.

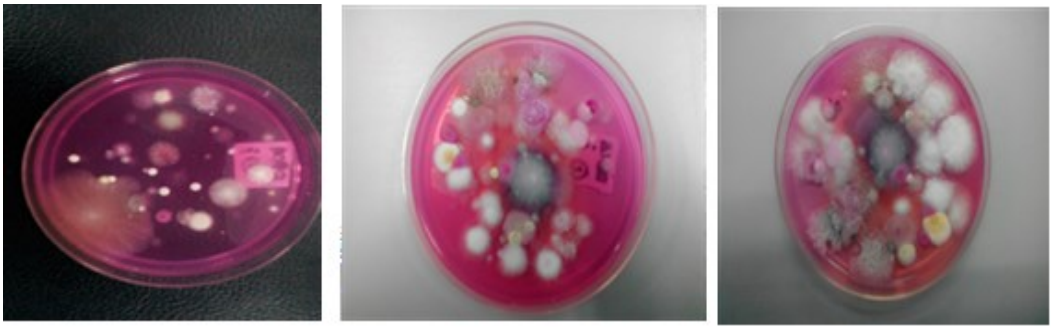

Figure 2. RBCA agar plate after 3, 5 and 7 days of the air sampling in washing room (the highest concentration of fungi on RBCA) of the hospital HSNZ

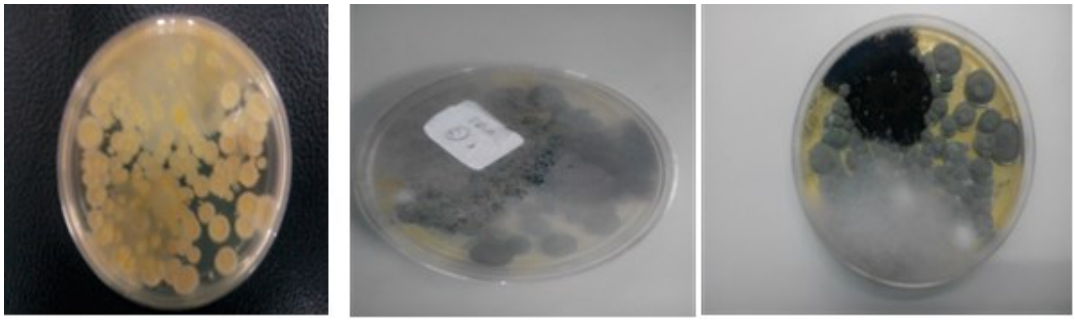

Figure 3. SDA agar plate after 3, 5 and 7 days of the air sampling in reprocessing room (hemodialysis unit) (the highest concentration of fungi on SDA) of the hospital HSNZ

In the present study, totally five different fungi were collected. The most dominant fungi were identified as *Cladosporium* sp. (85%), *Penicillium* sp. (48%), *yeast* sp. (28%), *Mucor* sp. (25%), and *Aspergillus* sp. (12 %). This indicated that indoor environment of each selected location in the hospital provides more favorable conditions for the survival of fungi. In addition, chloramphenicol used in RBCA media was included for the elimination of bacterial colonies in fungal culture while rose Bengal reduced the growth of fungi which eased identification of individual colonies [24]. This result is in line with the finding of earlier researcher by Guiamet et al. [25], who studied in indoor air sampling showed the similar identification of fungi that were *Aspergillus* sp. and *Penicillium* sp. as the most abundant microorganisms because of the microbes can be easily cultivated in the indoor environments.

Conclusion

The current study clearly indicates that there have a growth of airborne fungi and bacteria on two cultivated medias in the hospital even the room environment is clean. Bacteria show higher growth on SDA media while slow growing of fungi on RBCA media. The use of RBCA rather than SDA significantly improved the fungal yield. The lowest detection level of the colony counts was calculated as 2 CFU/m^3 in washing room while the highest detection level of the colony counts was calculated as 149 CFUs/m^3 in reprocessing room of hemodialysis unit respectively.

The evaluation of colony counts in the hospital rooms provides a continuous control for airborne microbial growth and it is important to identify the level of bacterial and fungal in the hospital work environment over the time for the health reassurance of patients and hospital team.

Abstract

Coastal aquifer groundwater is vulnerable to saltwater contamination as it is located near the coastline. Therefore, a study is conducted to confirm all the major source of pollutants on coastal groundwater based on 13 sampling wells that located close to Terengganu coastline as well as to assess the intensity of saltwater intrusion into the wells. Measurements of selected water quality parameters such as dissolve oxygen (DO), electrical conductivity (EC), total dissolve solid (TDS), salinity, pH, turbidity and total suspended solid (TSS) were obtained from each well by using certified scientific instruments. Data were analysed by using multivariate techniques which involves principle component analysis (PCA) and cluster analysis (CA). CA was performed by using hierarchical agglomerative cluster analysis (HACA) technique. PCA yielded two PCs where PC1 forms composite factor loadings of TDS, salinity and EC that represented the saltwater intrusion meanwhile, PC2 formed composite factors of turbidity, TSS and TDS that represented the anthropogenic pollutions. CA successfully classified sampling wells into seven clusters; Extreme High (EH), Very High (VH), High (H), Moderate (M), Low (L), Very Low (VL) and Extreme Low (EL) where each cluster represented the saltwater intrusion intensity in decreasing order.

Abstrak

Air bawah tanah dari akuifer pantai terdedah kepada pencemaran air masin kerana ia terletak berhampiran pantai. Oleh itu, satu kajian dijalankan untuk mengesahkan sumber utama pencemaran kepada air bawah tanah pantai berdasarkan 13 telaga pensampelan yang terletak berhampiran kawasan pantai Terengganu serta untuk menilai keamatan pencerobohan air masin ke dalam telaga.Pengukuran parameter kualiti air seperti oksigen terlarut (DO), kekonduksian elektrik (EC), jumlah pepejal terlarut (TDS), kemasinan, pH, kekeruhan dan jumlah pepejal terampai (TSS) diambil dari setiap telaga dengan menggunakan peralatan saintifik. Data dianalisis menggunakan teknik multivariat iaitu analisis komponen utama (PCA) dan analisis kelompok (CA). CA dilakukan menggunakan teknik analisis kelompok hierarki agglomeratif (HACA). PCA menghasilkan dua PC yang mana, PC1 membentuk faktor komposit TDS, kemasinan dan EC yang mewakili pencerobohan air masin manakala, PC2 membentuk faktor komposit kekeruhan, TSS dan TDS yang mewakili pencemaran antropogenik. CA berjaya mengelaskan telaga pensampelan kepada tujuh kelompok; Tinggi Ekstrem (EH), Sangat Tinggi (VH), Tinggi (H), Sederhana (M), Rendah (L), Sangat Rendah (VL) dan Rendah Ekstrem (EL) yang mana setiap kelompok mewakili keamatan pencerobohan air masin dalam urutan berkurangan.

Kata kunci: air bawah tanah, akuifer pantai, kemasukan air masin, teknik multivariat

Introduction

Water plays a critical role in human life because human need water to stay alive and to carry out daily activities either as in domestic uses or economic uses. As human population keeps growing over times, the demands for water keep increasing as well. For Malaysia, it is a tropical country and thus, receiving an adequate amount of rainfall throughout the year. Supposedly, available water should be enough to cater the needs of its people. However, there are still some states that are experiencing a water shortage crisis [1]. Another alternative for freshwater supply is from groundwater. Groundwater is defined as subsurface water and can be either stored in confined or unconfined aquifer. These aquifers can be distinguished by the water components and type of surface and subsurface water interaction [2]. Water stored as groundwater is originated from surface water that seep slowly into the ground. It takes a long time to fill up the groundwater storage. In contrast, groundwater can be extracted easily by drilling a well into aquifer. Extraction of groundwater without a proper management may lead to imbalance rate of recharge and discharge. As a result, it causes threat to this valuable water resource.

Besides, groundwater aquifer is also vulnerable to saltwater contamination [3]. This kind of threat is generally related to aquifers that located close to coastline. These aquifers are known as coastal aquifers. Theoretically, freshwater and saltwater are of different density and thus, these waters should not mix up. Instead, freshwater and saltwater was separated by a zone known as transition zone containing brackish water. This zone kept freshwater and saltwater in natural equilibrium [4, 5]. The location of the transition zone is not fixed as it is can either move further inland or towards the sea depending on several factors. The movement can be map or visualize by adopting hydrogeochemical and geophysical technique [6]. In a normal condition, freshwater will be flowing into the sea. A reversed situation can occur where the saltwater is flowing into the freshwater under the influences of natural events and anthropogenic activities [7 - 9].

This unfavourable situation caused a great concern to peoples living along the coast since long time ago. This is because of a further movement of saltwater toward the land will lead to saltwater intrusion into coastal aquifer that containing their main freshwater supply [7 - 11]. Contamination of 2 – 3% of saltwater into coastal aquifer will increase the waters salinity and resulting in water quality degradation [8]. This problem is also experienced by residence living along Terengganu coastline which is the area of this study. Most of the residents in this area still use groundwater withdrawn from the drilled wells. Some of them use the water only for basic uses such as for watering crops and livestock drinking water. The rest of them used the well water as their main water supply due to financial issues. In conjunction to this problem, a study is carried out to confirm the major sources of groundwater quality pollutants based on sampling wells that located along Terengganu coastline and to assess the intensity of saltwater intrusion into the wells.

Materials and Methods

Study area

Terengganu is located on the east coast of Peninsular Malaysia [12]. Specifically, it is located between longitudes 102.25 °E to 103.50 °E and latitude 4 N to 5.50 °N. The size of Terengganu is approximately 1,295, 638.3 hectares with coastline bordered by South China Sea and stretching 225 km from Besut to Kemaman [12]. It received an average rainfall of ± 400 mm per annum during the northeast monsoon season from November to March, meanwhile ± 190 mm per annum during the other months [12, 13]. Its average temperature is from 29 °C to 32 °C throughout the year [14]. Sampling areas were located along the Terengganu coastline (Figure 1).

Generally, Terengganu coastline is dominated by Quaternary rock of marine and continental deposits [15]. It is specifically known as Holocene beach ridges derived from Matang Gelugor Member. It is comprises of sand, gravel and sandy clay deposits in littoral and marine environment [16, 17]. In the hydrogeology perspective, Quaternary sediment is characterized by high porosity and excellent permeability that allowed water to be stored in between the grains [18]. Carboniferous rock and minor intrusive rock also present along the centre and south of Terengganu coastline.

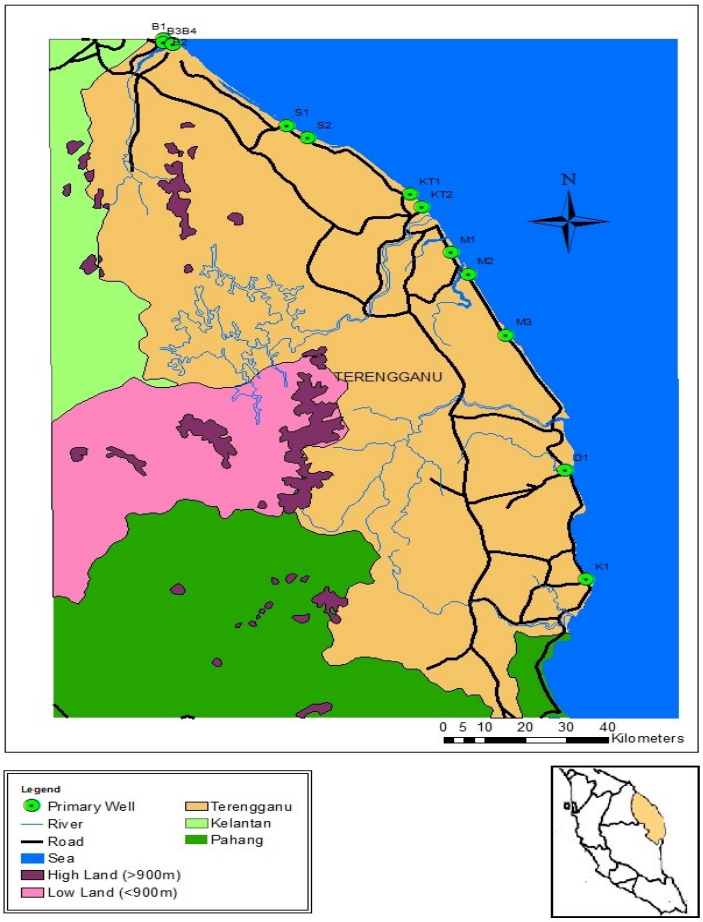

Figure 1. Location of sampling wells (Primary Well) along Terengganu coastline

Data collection

Samplings were carried out at 13 private wells, located closely to Terengganu coastline from July to August 2015 (Table 1). Samplings were conducted monthly by performing in situ measurements of selected water quality parameters such as dissolve oxygen (DO), electrical conductivity (EC), total dissolve solid (TDS), salinity, pH, turbidity and total suspended solid (TSS) . DO, EC, TDS, salinity and pH were measured using YSI 556 Handheld Multiparameter meter. Turbidity was measured using 2100Q Portable Turbidimeter and TSS was measured using HACH DR 900 Multiparameter Handheld meter. Global Positioning System (GPS) was used to locate the exact coordinates of sampling wells.

Multivariate analysis

A numbers of physiochemical parameters can be used to determine the groundwater quality namely total dissolve solid (TDS), dissolve oxygen (DO), total suspended solid (TSS), salinity, electrical conductivity (EC), chloride, biochemical oxygen demand (BOD) and pH value. However, it is difficult to define the main factors that control groundwater quality since there are too many data. Multivariate analysis such as principal component analysis and cluster analysis is suggested to be one of the best solutions to re-define the meaning of a mass of data. Therefore, multivariate analysis is employed to achieve the objective of this study.

Table 1. Coordinate location of sampling wells

Sampling Well	Latitude	Longitude
B1	5.8339°	102.5553°
B2	5.8241°	102.5566°
B3	5.8216°	102.5754°
B4	5.8202°	102.5774°
S1	5.5951°	102.8262°
S2	5.5605°	102.8736°
KT1	5.4039°	103.0992°
KT2	5.3686°	103.1241°
M1	5.2435°	103.1872°
M2	5.1825°	103.2256°
M3	5.0135°	103.3096°
D1	4.6387°	103.4383°
K1	4.3361°	103.4858°

Principal component analysis (PCA)

PCA identify the principle components (PCs) of data sets by transforming the original variables into new variables [19 – 23]. The input data matric (variables x cases) used for this method was [7 x 52]. PCs with eigenvalues more than 1.0 computed from PCA process is considered as significant PCs. These PCs were then rotated and the count of PCs was used as rotation factor in varimax normalization process. Two significant varifactors (VFs) of eigenvalues more than 1.0 explaining 67.44% of the total variance of water quality data set were yielded [24]. Each VF contains a list of factor loadings that explains the major sources of groundwater pollutant.

Cluster analysis (CA)

Cluster analysis is technique for data classification based on their similarities or closeness [22, 23, 25]. It is done by performing hierarchical agglomerative cluster analysis (HACA) on selected parameters spatially or temporally. In this study, spatial cluster analysis is applied onto selected parameters to group the sampling wells into a few clusters. Sampling wells that grouped as a cluster are homogenous to each other meanwhile, sampling wells between clusters were heterogeneous.

Results and Discussion

Identification of source of pollutant

Corresponding VFs, loadings and variance resulted from PCA are presented in Table 2. Bolded values in Table 2 indicated the strong and moderate factor loadings with absolute loading values of >0.75 and 0.75 – 0.50, respectively. These factor loadings were considered as important factors that influence water quality [26]. The un-bolded values represent the weak factor loadings with absolute loading values of 0.50 – 0.30 and have minor contribution for this water quality study.

VF1, explaining 48.66% of total variance, has strong positive loadings on EC, TDS and salinity. This composite factor represents the saltwater intrusion into coastal aquifer. These factors combination proposed that the dissolved solid engaged in PC1 was dissolved salts supplied by high salt contents of seawaters through saltwater intrusion process. Thus, it can be emphasized that groundwater samples from study area are highly susceptible to saltwater intrusion as it is located near to coastline.

Table 2. Factor loadings after Varimax rotation from PCA of sampling wells.

Variables	VF1	VF2
Turbidity (NTU)	-0.281	**0.743**
TSS	0.273	**0.577**
DO (mg/L)	-0.109	**-0.598**
EC (mS cm^{-1})	**0.956**	-0.035
TDS (mg/L)	**0.975**	0.0004
Salinity (ppt)	**0.976**	-0.002
pH	0.649	-0.259
Eigenvalue	3.424	1.297
% Total variance	48.66	18.78
Cumulative % variance	48.66	67.44

Values in bold indicate strong and moderate loadings

VF2, explaining 18.78% of total variance, has positive moderate loading on turbidity, positive moderate loading on TSS and negative moderate loading on DO. This composite factor is proposed to represent the anthropogenic pollution such as waste dumping into wells. The small suspended solid originated from the waste act like a barrier for the direct light entering the wells. It would be able to reach the well base only by scattering through the small spaces in between the particles. The measure of amount of light scattered of these particles is known as turbidity. This explains the association of total suspended solid with turbidity. If the amount of total suspended solid is high, the turbidity would be high as well. In contrast, increasing amount of turbidity and total suspended solid has inverse relationship with dissolved oxygen. The oxygen is suggested to be used up by microorganism for decay process [27].

Spatial clustering

A further analysis on saltwater intrusion which was identified from the VF1 composite factor is done by applying spatial clustering. Parameters included in VF1 composite factor are EC, TDS and salinity. The aim of this application is to cluster the sampling wells according to the range of EC, TDS and salinity readings. Results of this analysis revealed six main clusters. The results of cluster analysis of each parameter are shown in Figures 2, 3 and 4, respectively. Interestingly, all parameters have classified the sampling wells into seven statistically significant clusters. The count and the sampling wells listed under each cluster were also similar. As stated before, EC, TDS and salinity were related to each other. Therefore, it could explain why sampling wells that listed below each cluster is the same for all parameters.

The result of EC, TDS and salinity cluster analysis is suggested to represent the intensity of saltwater intrusion and is shown as a summary in Figure 5. Overall, CA revealed that sampling well B3 is intruded by extremely high (EH) saltwater intrusion compared to other stations followed by very highly (VH) intruded well B4, highly (H) intruded well KT1, moderately (M) intruded well B1, low or less (L) intruded well M3, and very low (VL) intruded well S2, KT2, M1 and D1. EH cluster is characterised by extremely high EC (3965.25 µS/cm), extremely high TDS (2384.5 mg/L) and extremely high salinity (1.89 ppt) compared to other clusters. VH cluster has very high EC (1278.6 µS/cm), very high TDS (1161.88 mg/L) and very high salinity (0.905 ppt).

H cluster has high EC (1094.75 µS/cm), high TDS (608.05 mg/L) and high salinity (0.52 ppt). M cluster is characterised by moderate EC (556.25 µS/cm), moderate TDS (326.14 mg/L) and moderate salinity (0.24 ppt). L cluster has low EC (331.95 µS/cm), low TDS (175.52 mg/L) and low salinity (0.18 ppt). VL clusters has very low EC (246.9 – 321.68 µS/cm), very low TDS (147.89 – 194.01 mg/L) and very low salinity (0.10 – 0.14 ppt). On the other hand, the least or extremely low (EL) intruded sampling wells are B2, S1, M2, K1. This cluster has extremely

low EC (140.15 – 189.15 µS/cm), extremely low TDS (84.34-111.96 mg/L) and extremely low salinity (0.06 – 0.09 ppt).

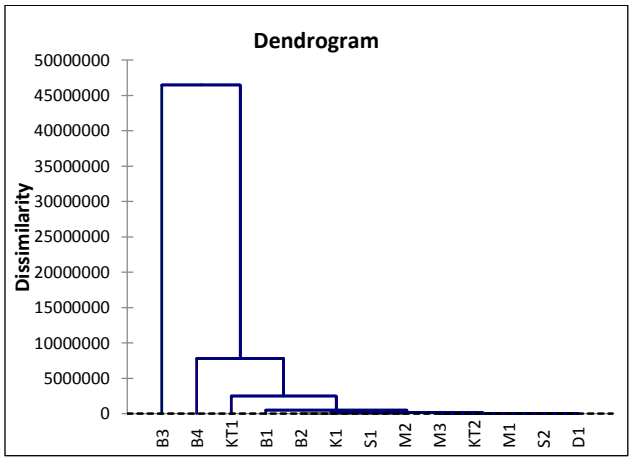

Figure 2. Dendrogram of spatial classification for EC of sampling wells along Terengganu coastline

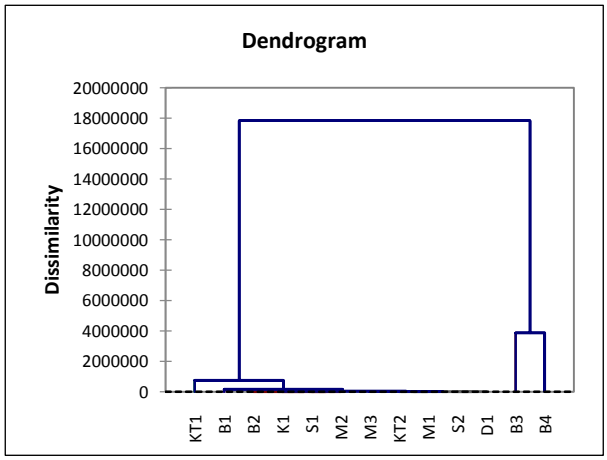

Figure 3. Dendrogram of spatial classification for TDS of sampling wells along Terengganu coastline

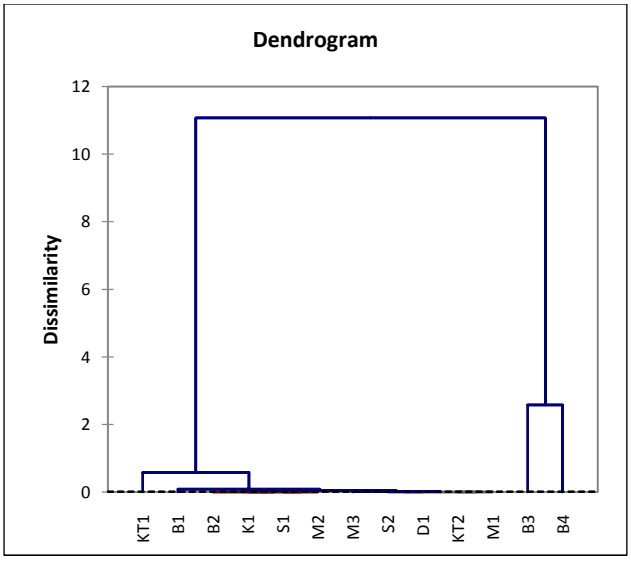

Figure 4. Dendogram of spatial classification for salinity of sampling wells along Terengganu coastline

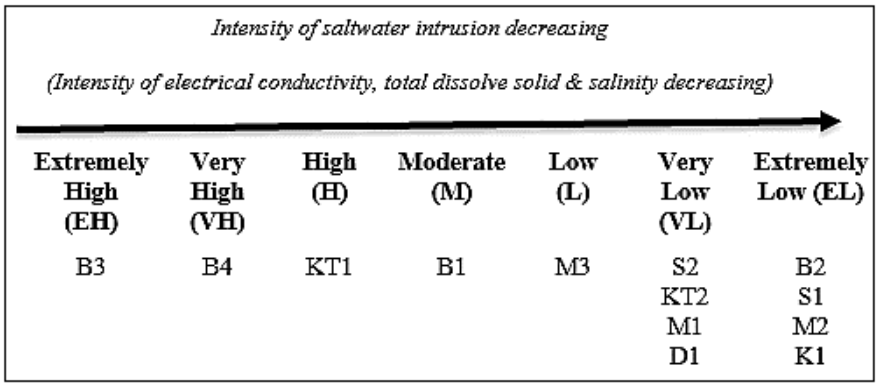

Figure 5. Saltwater intrusion intensity based on EC, TDS and salinity cluster analysis of sampling well along Terengganu coastline

Conclusion

According to principle component analysis (PCA) technique, two pollutants that affect the groundwater quality of sampling wells that located along Terengganu coastline are the saltwater intrusion and the anthropogenic pollutions such as waste dumping into the wells. Next, cluster analysis performed on EC, TDS and salinity has grouped sampling wells into seven clusters; EH, VH, H, M, L, VL, EL. The extremely high (EH) intruded by saltwater is groundwater of sampling well B3 compared to other wells, very highly (VH) intruded well is B4, highly (H) intruded is KT1, moderately (M) intruded is B1, less or low (L) intruded is M3, very low intruded sampling wells are S2, KT2, M1 and D1 meanwhile, extremely low intruded wells are B2, S1, M2 and K1.

Abstract

The interaction of tetrabutylammonium bromide (TBABr)-based deep eutectic solvents (DESs) with calf thymus DNA (ct-DNA) was investigated by fluorescence and circular dichroism (CD) spectroscopy. The influences of hydrogen bond donors (HBDs), with respect to chain lengths and the presence of OH group were determined through ethidium bromide (EB) fluorescence quenching. Based on the quenching process, it was concluded that hydrophobic interactions were responsible for the DES ability to quench EB from EB-bound DNA. The strong electrostatic attraction between TBA^+ cation on DES and negative charge phosphate DNA was proved from fluorescence and CD spectroscopy. DNA was able to maintain its double helical structure at 25 °C with a concentration of 25% DES.

Keywords: binding, deep eutectic solvent, tetrabutylammonium bromide, fluorescence quenching, circular dichroism spectroscopy

Abstrak

Ikatan antara pelarut eutektik mendalam berasaskan tetrabutilammonium bromida (TBABr) dengan 'calf thymus' DNA (ct-DNA) telah diuji dengan spektroskopi pendarfluor dan edaran dikroisme (CD). Pengaruh penderma ikatan hidrogen (HBDs) berdasarkan panjang rantai dan kehadiran kumpulan OH telah ditentukan melalui pelindapkejutan pendarfluor etidium bromida (EB). Berdasarkan proses pelindapkejutan, dapat dirumuskan bahawa ikatan hidrofobik berperanan dalam menentukan keupayaan DES untuk menyingkirkan EB daripada EB-terikat DNA. Tarikan elektrostatik yang kuat antara kation TBA^+ pada DES dengan cas negatif fosfat DNA telah dibuktikan daripada kedua-dua spektroskopi pendarfluor dan CD. DNA berupaya mengekalkan struktur heliks berganda pada suhu 25 °C dan kepekatan DES pada 25%.

Katakunci: ikatan, pelarut eutektik mendalam, tetrabutilammonium bromida, pelindapkejutan pendarfluor, spektroskopi edaran dikroisme

Introduction

DNA is a biomacromolecule that plays an important role in the living organism because it stores the genetic information for cell replication and transcription. The potentials of DNA were increasingly recognized especially in the applications of biosensors, catalytic membranes, absorbing membranes and support for catalysts [1,2]. However, DNA is unstable in aqueous solution, resulting in denaturation of nucleic acid structure after 1 month of storage at ambient temperature [3]. Over the past few years, new solvents that can retain the DNA helical structure has been researched. Mamajanov et al. were among the first to propose deep eutectic solvent (DES) as an alternative solvent to maintain DNA helical structure and it was found that choline chloride: urea can maintain the DNA native structure [4]. However, the stability of DNA in the DES depends on the ability of DNA to maintain its helical structure, that could change during the interaction of DNA with other molecules. Recently, Sharma et al. found that hydrogen bonding and electrostatic interactions between bio-ionic liquids and DNA were found to be responsible for the long-term stability of DNA [5]. This finding enhanced the importance of studying the mode of interaction between DNA-DES to provide a stable medium for DNA.

Herein, the study of binding between tetrabutylammonium bromide (TBABr)-based DES and DNA by fluorescence quenching and CD spectroscopy was reported. The capability of DESs to quench EB from EB-bound DNA was explored using different HBDs with varying chain lengths and the number of OH group. In previous literature, it was reported that increasing the alkyl chain length of the cation in ionic liquid (IL) aided the quenching process [6]. In this study, the effect of HBDs chain length in DES on the quenching process was studied. The mode of interactions as well as stability of DESs in DNA were investigated.

Materials and Methods

Materials

Tetrabutylammonium bromide (TBABr), 1,3-propanediol and 1,5-pentanediol were supplied by Fluka Chemical (Reidstr, Steinheim, Germany) with 98% purity. Ethylene glycol was purchased from R&M (Essex, UK) and glycerol was from J.T. Baker (Phillipsburg, NJ, USA). All chemicals were used without further purification. Deoxyribonucleic acid extracted from calf-thymus in the sodium salt form was purchased from CalBioChem. Ethidium bromide (EB) was purchased from Sigma-Aldrich (USA). Deionized water type III was used throughout the experiments.

Synthesis of deep eutectic solvent (DES)

TBABr salt was mixed with four different hydrogen bond donors (HBDs); ethylene glycol, 1,3-propanediol, 1,5-pentanediol and glycerol. The formation of DES mixture between TBABr and HBDs were done at molar ratio of 1:3. The mixtures were heated at 60 °C and stirred at 250 rpm until colourless solution was observed. The mixtures were cooled to room temperature and sealed tightly in vials. DES mixtures were prepared accordingly to the method reported by Yusof et al. [7].

Preparation of reagent solution

Ethidium bromide (EB) stock solution (1.27×10^{-3} mol L^{-1}) was prepared by dissolving 0.01 g of EB in 20 mL volumetric flask and stored in a cool and dark place. The dilution of EB stock solution was done for fresh preparation of 0.5 μM EB.

Preparation of DNA stock solution

A stock solution of DNA was prepared by dissolving an appropriate amount (about 250 mg) of the solid DNA in deionized water type III and stored at 4 °C for about 24 hours. The solution was stirred until homogeneous DNA solution was produced. The solution was sonicated at a 40% amplitude, with setting of 30s on and 50s off for 20 minutes by the Digital Sonifier (Branson).

The final concentration and purity of the DNA stock solution was measured using UV–vis spectrophotometer (AV-650). Diluted DNA stock solution (3 mL) in 1 cm pathlength cuvette was placed in the instrument. The absorbance at 260 nm was measured and corrected with the corresponding deionized water as a blank. The absorbance of the DNA was measured three times to obtain the average absorbance. The sample was scanned from 1000 nm to 290 nm. The concentration of DNA stock solution was calculated from Beer's Law equation 1:

$$A = \varepsilon cl \quad (1)$$

where A is the absorbance value, ε is an extinction coefficient constant (6600 $M^{-1} \cdot cm^{-1}$ at 260 nm expressed in terms of base molarity), c is the concentration of solution (M) and l is a light path length (cm).

The purity of DNA solution was determined by measuring the ratio of the absorbance of the DNA stock solution (at 260 nm) to that of the absorbance of protein (at 280 nm)[6]. The DNA solution was considered pure if the ratio of A_{260}/A_{280} was above 1.8.

Fluorescence measurements

Fluorescence emission of the solution was measured by using Cary Eclipse fluorescence spectrophotometer. In this study, EB was used as an intercalator. About 3 mL of 0.5 μM EB was placed into 1 cm cuvette. The fluorescence spectra of the mixtures were recorded in the wavelength range of 550 to 750 nm with excitation wavelength at 510 nm. Both the excitation and emission slits were set at a diameter of 5 nm. A solution of DNA (0.83 μM) was titrated into the cuvette, and allowed to reach equilibrium for 3 minutes. The emission spectrum was recorded. The DNA was titrated continuously into EB by increasing the DNA concentration from 0.83 μM to 12.5 μM, while the concentration of EB was at 0.5 μM.

The prepared solution of DNA-bound EB was titrated with DES. The titration was done by increasing the concentration of the DES: 0.025, 0.075, 0.175, 0.30, 0.45, 0.63, 0.83, 1.08, 1.38 and 1.73 M into the same cuvette, while maintaining the concentration of DNA-bound EB. The solution was incubated for 3 minutes before the emission spectra were measured. The fluorescence emission spectra were recorded after each addition of the DES solution into the EB-bound DNA. This procedure was repeated for all the newly synthesized DES; TBABr:EG, TBABr:1,3-PD, TBABr:1,5-PD and TBABr:Gly.

Circular dichroism measurements

Circular dichroism spectroscopic measurements were performed by JASCO J-810 spectrophotometer equipped with a Peltier temperature controller (PTC-423s) and a water circulation unit. A fixed amount of DNA (300 μM) was solubilized in 25% hydrated DESs at room temperature, 25 °C. A quartz cuvette with a pathlength of 1.0 cm was used with a bandwidth at 1.0 nm and set at standard sensitivity. The measurements were taken at 320 to 200 nm wavelengths. Three scans were collected for each sample with a scan speed of 50 nm/min and the average value taken. A spectrum of blank solution was recorded and subtracted from the spectra of DES and DNA complexes.

Results and Discussion

The synthesis of DES

TBABr salt was mixed with different HBDs; ethylene glycol (EG), 1,3-propanediol (1,3-PD), 1,5-pentanediol (1,5-PD) and glycerol (Gly) at 60°C with a molar ratio of 1:3. A clear homogenous liquid was observed after 2 to 3 hours of heating. Figure 1 shows the structures of the newly synthesized TBABr-based DES.

The concentration and purity of DNA stock solution

Figure 2 shows a broad absorption spectrum of DNA at 210 to 310 nm in the UV region with a maximum absorption at 260 nm. The final concentration of DNA stock solution was estimated to be 0.0133M with the calculated A_{260}/A_{280} as 1.8. This high ratio ensures a purity of DNA used for the experiments, as it was sufficiently free from protein contamination. The maximum absorption at 260 nm is an indicator of the chromophoric groups present in purine (adenine and guanine) and pyrimidine (cytosine and thymine) moieties that is responsible for the electronic transitions [8].

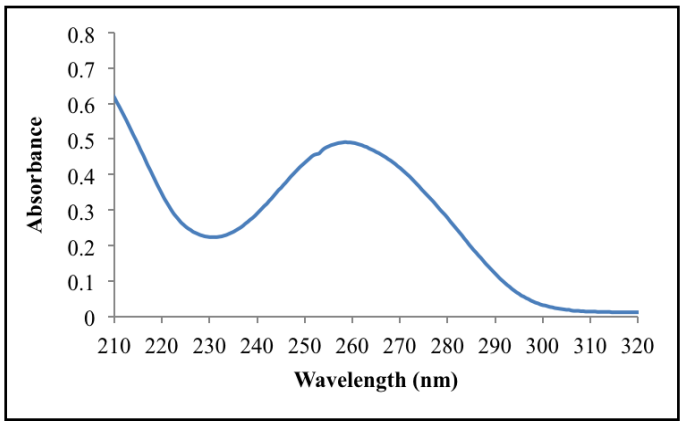

Figure 2. Absorbance spectrum of DNA in the UV region with a maximum absorption at 260 nm

Fluorescence quenching measurements

Fluorescence spectroscopy is one of the most common methods used to study DNA binding. The high sensitivity of fluorescence able to detect the polarity changes causes spectral shifts in both the excitation and emission spectra of molecules [8]. In this work, a known intercalator, ethidium bromide (EB) was used as a fluorescence probe to intercalate the double helix of DNA. EB can be easily intercalated into the adjacent base pairs and stretch the double helix structures of DNA as it is made up of polycyclic, aromatic and planar structure [6, 8, 9]. Through intercalation, the DNA has to unwind in order to let the intercalator fit between the two base pairs. This process causes the DNA helix lengthening by 3.4 Å as the bases are pushed apart hence resulting in conformational changes of the sugar group [10].

Figure 3 shows the emission intensity of free EB at 610 nm when excited at 510 nm. The addition of DNA into free EB has increased the emission intensity with the peak shifted to a shorter wavelength (595 nm). The planar hydrophobic EB was shielded from the aqueous bulk solvent upon intercalation, which resulted in the increase of emission intensity.

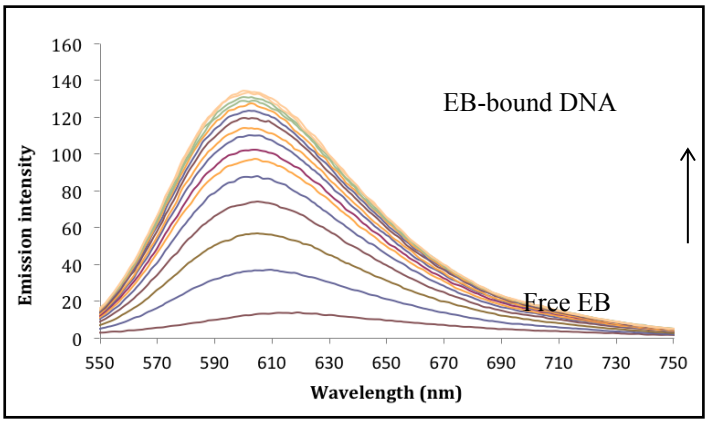

Figure 3. Emission intensity of free EB (610 nm) and EB-bound DNA (595 nm)

The effect of increasing DNA concentration towards the emission intensity was plotted in Figure 4. The emission intensity rapidly increased with the addition of 0.83 µM to 9.17 µM DNA. The intercalation of EB into empty space between the base pairs of DNA happens at this point. The emission intensity increased very slowly during the addition of 11.6 µM up to 12.5 µM DNA, hence suggesting that the base pair on DNA was fully packed with EB at 11.6 µM DNA. The numbers of empty spaces were reduced and the intercalation of EB into DNA base pair was almost saturated.

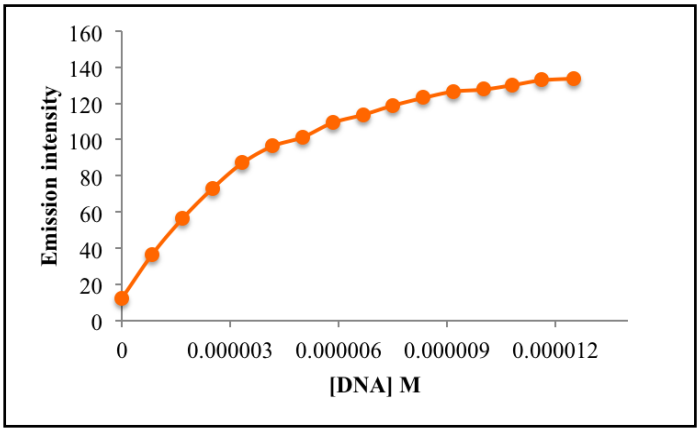

Figure 4. Emission intensity of free EB (0.5 µM EB) with addition of 0.83 µM to 12.5 µM DNA

The strength of newly synthesized DESs to quench EB-bound DNA was determined. DES was titrated into saturated EB-bound DNA in increasing DES concentration; 0.025, 0.075, 0.175, 0.300, 0.450, 0.630, 0.830, 1.080, 1.380 and 1.730 M. Figure 5 shows that the emission intensities steadily decreased with the addition of four different DESs from 0.025M to 0.830 M. During titration, TBA^+ from DES, condensed the DNA and formed

compact molecular structures through electrostatic interaction between TBA^+ and the negative charge of phosphate on DNA [11]. DES acts as a competing molecule that inhibits the intercalation of EB. This process caused the EB to dissociate from DNA and move into the aqueous solvent, resulting in the decrease of emission intensity. Then, the continuous addition of DES from 1.08 to 1.73 M into EB-bound DNA resulted in no observable change of the emission intensity, indicating the complete removal of EB from DNA base pairs.

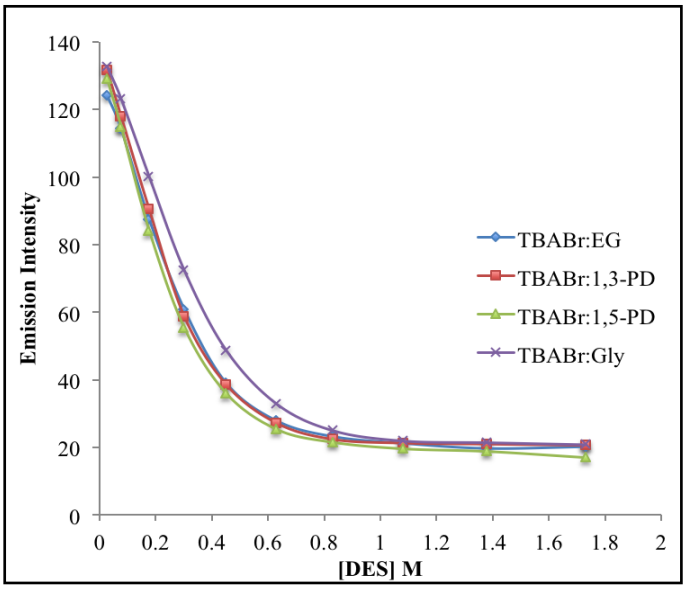

Figure 5. The quenching of EB-bound DNA by addition of different DESs (0.025 to 1.73M)

All synthesized DESs are sufficiently strong to quench the intercalation of EB from EB-bound DNA. From this study, the effect of HBD in quenching was observed, in terms of chain length and presence of OH group. The highest quenching efficiency of DES was shown in order of TBABr:1,5-PD, followed by TBABr:1,3-PD, TBABr:EG to TBABr:Gly. TBABr:1,5-PD has the longest chain length of HBD contributing to the largest hydrophobic effect. The quenching process was caused by the hydrophobic interactions between hydrophobic part of DNA bases and hydrocarbon chain of DES [6]. TBABr:1,5-PD contains five $–CH_2$ groups on 1,5-pentanediol compared to the TBABr:1,3-PD and TBABr:EG which contain of three and two $–CH_2$ groups, respectively. The less number of $–CH_2$ groups reduces the hydrophobic effect, hence decreasing the ability to quench EB. This quenching study suggested that length of HBD has affects the ability of DES to quench EB from EB-bound DNA. This trend is in agreement with the previous reported literature on the binding studies of ILs and DNA, which claimed the quenching efficiency increased with longer alkyl chain lengths of cation in IL[11]. The presence of OH group on DES also plays an important role in the quenching process. Both TBABr:1,3-PD and TBABr:Gly have a similar number of $–CH_2$ groups on HBD. However, TBABr:Gly shows a weaker ability to quench EB from DNA when compared to TBABr:1,3-PD. The presence of three OH groups on glycerol compared to the two OH groups on 1,3-propanediol reduces the hydrophobic effect on DES, in turn decreasing the ability of the TBABr:Gly to remove EB from EB-bound DNA. These results confirmed the importance of hydrophobic effect of DES in destabilizing the DNA-bound EB complex.

Circular dichroism spectroscopy

Circular dichroism (CD) spectroscopy is an optical technique that is usually used to analyze the conformational structures of macromolecules, such as DNA. DNA normally exists as double stranded with two polynucleotide chains in opposite directions to form a double helical structure of Watson-Crick base pairs. DNA can exist in many different conformations; right-handed double helical structure of A- and B-conformation of DNA as well as left-

handed of Z-conformation of DNA. However, the most common and stable DNA structure in solution is the B-conformation of DNA. In order to study the conformation of DNA in DES, the secondary structure on one of the synthesized DES; TBABr:1,5-PD was analyzed by CD. The DES was diluted in aqueous system at fixed concentration of 25%. The effect of DESs concentration to DNA will be studied in the next publication. The study of DNA stability in DES was carried out as DNA is very sensitive towards any changes in its environment such as pH, temperature or concentration [12].

Figure 6 shows the secondary structure of DNA at 25 °C in 25% hydrated TBABr:1,5-PD and its control, DNA in aqueous solution at 25 °C. The positive band at 275 nm and the negative band at 245 nm are due to the π- π base stacking and the helicity of DNA, respectively, indicating the characteristics of B-conformation DNA [3]. When DNA was added into 25% of TBABr:1,5-PD, the magnitude of positive and negative bands increased and decreased respectively. The shift at both the positive and negative bands indicates an electrostatic mode of interaction between the cationic TBA^+ in DES and anionic phosphate charge of DNA [11]. This observation agreed with the flouorescence results and concluded that DNA in 25% of TBABr:1,5-PD maintained its B-conformation as both positive and negative bands were observed at the same wavelength. This hypothesis was supported by the UV-vis absorbance graph as shown in Figure 6(b), where the curves of DNA in DESs are similar to the control.

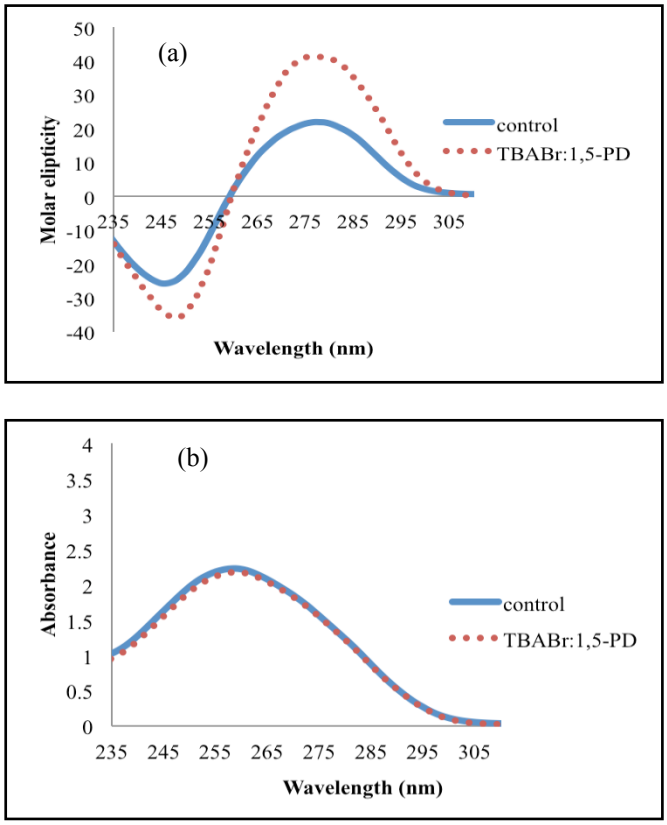

Figure 6. (a) CD spectra (b) absorbance spectra of DNA in 25% hydrated TBABr:1,5-PD as compare to the control at 25 °C. The control was DNA in aqueous solution.

Conclusion

All synthesized DESs; TBABr:EG, TBABr:1,3-PD, TBABr:1,5-PD and TBABr:Gly were strong enough to displace the intercalation of EB from DNA. The strongest DES that quenched EB from DNA was the one that was most

hydrophobic with the longest HBD and the least OH group, TBABr:1,5-PD. Hydrophobic interactions contributes to the ability of DESs to quench DNA from EB. The affinity of DESs toward DNA was due to the electrostatic interactions between the TBA^+ cation of DES and phosphate backbone of DNA. These hypotheses were confirmed by fluorescence and CD spectroscopy. DNA was able to maintain its B-conformation in TBABr:1,5-PD at 25 °C with 25% concentration.

Abstract

The development of environmentally friendly methodologies for pericyclic reactions such as Diels Alder reaction is astonishing. Nevertheless, this is still scarce for the rest of pericyclic reactions. In this work, diastereosiomeric cycloadducts were formed via 1,3-dipolar cycloaddition between *N*-4-Tert-Benzylidene nitrone and maleimide in imidazolium-based ionic liquids (ILs) at 25 °C. Cycloaddition between nitrone **1** and maleimide **2** give diastereoisomeric adducts with 1:1 and 1:2 *trans*/*cis* ratio in two ionic liquids, [Bmim][PF_6] and [Bmim][BF_4], respectively. [Bmim][PF_6] give the desired cycloadducts in 43% yield compared to only 18% yield in [Bmim][BF_4]. In comparison, when the similar reaction was conducted in chloroform, the diasteroeisomeric mixture favoured *trans* isomer in 6:0.2 ratio. We reasoned that the repulsive van der Waals interactions favouring *exo* transition state was assisted by imidazolium ionic liquids. Thus, ILs have shown great potential as second reaction media in dipolar cycloaddition reactions.

Keywords: pericyclic reactions, 1,3-dipolar cycloaddition, imidazolium ionic liquids

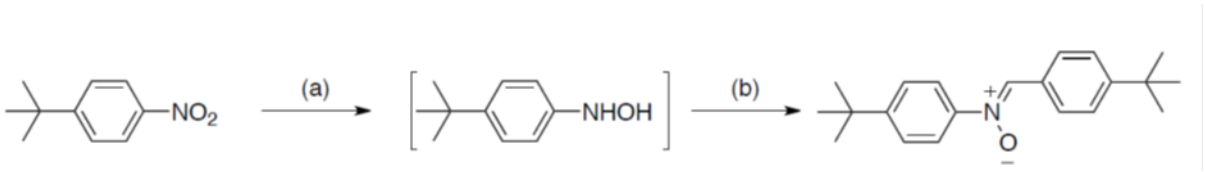
Abstrak

Tindak balas Diels Alder merupakan contoh tindak balas perisiklik yang mesra alam serta mendapat perhatian ramai. Namun begitu, contoh lain tindak balas perisiklik masih lagi terhad. Melalui kajian ini, tindak balas 1,3-dwikutub pensiklotambahan di antara *N*-4-Tetra-Benzilidina nitron dan maleimida dalam cecair ionik imidazolium pada suhu 25 °C telah dijalankan. Pensiklotambahan antara nitron **1** dan maleimida **2** telah menghasilkan sikloaduk diastereoisomerik dengan nisbah *tran/cis* 1:1 dan 1:2 bagi kedua-dua cecair ionik, [Bmim][PF_6] dan [Bmim][BF_4]. Hasil sikloaduk dalam cecair ionik [Bmim][PF_6] adalah sebanyak 43% berbanding hanya 18% di dalam [Bmim][BF_4]. Apabila tindak balas yang sama dijalankan dalam pelarut kloroform, ianya memberikan sikloduk diastereosiomerik dalam nisbah 6:0.2 dengan menyebelahi isomer *trans.* Kami beranggapan bahawa interaksi repulsif Van der Waals mendorong keadaan peralihan ekso dengan bantuan cecair ionik imidazolium. Oleh yang demikian, cecair ionik mampu memainkan peranan penting sebagai media kedua di dalam tindak balas dwikutub pensiklotambahan.

Kata kunci: tindak balas perisiklik, 1,3-dwikutub pensiklotambahan, cecair ionik imidazolium

Introduction

Cycloaddition reactions belong to an important group of organic reactions called pericyclic, that are characterized by concerted mechanism proceed *via* cyclic transition states [1]. Woodward-Hoffman rules are used to predict the



stereochemical features of this pericyclic reaction [2]. In cycloaddition reactions, two or more unsaturated systems react to give a cycle with one less unsaturation. Ionic liquids (ILs) have proved to be alternative solvents and catalysts for the development of the pericyclic reactions [3]. In most cases, an important improvement on the yields and reaction rates has been observed. Hazra et al. observed a good yield in the formation of tetracyclic pyrrolidine/isoxazolidine fused pyrano[3,2-h]quinolines via intramolecular 1,3-dipolar cycloaddition in [Bmim][PF_6] [4].

Thus, the 1,3-dipolar cycloaddition (1,3-DC) reactions has been considered as versatile protocol to generate new C-C bonds, leading to five-membered heterocycles, an essential skeleton in the synthesis of natural products [5]. This reaction furnishes pairs of racemic diastereoisomeric cycloadducts, labelled as *trans* and *cis* with respect to the endo and exo transition states. These two products have markedly different geometries with *trans* diastereoisomer possess an open geometry compared to closed geometry of cisdiastereoisomer. In the case of *cis* isomer, all protons are positioned on the same side with regards to the isoxazolidine ring while in the *trans* isomer, the nitrone-derived hydrogen atom is rendered *trans* to the two hydrogen atoms originally located on the maleimide group.

Not only being regioselective, 1,3-DC also can be highly stereoselective [6]. The mixture of diastereoisomers are obtained depending on the electronic nature of the substituents appended on the two reagents. This outcome originated from the interplay of two generally opposing forces in the transition states, whereby attractive π orbital overlap of unsaturated substituents will favour an endo transition state leading to the formation of isoxazolidine trans. On the other hand, repulsive van der Waals steric interactions favour an exo transition state.

Typically, many cycloaddition reactions conducted in ionic liquids (ILs) was Diels-Alder reaction [7]. Nonetheless, the 1,3-dipolar cycloaddition reaction in ILs has not much received attention. The early attempt was reported by Dubreuil and Bazureau in 2000 [8]. Significant rate accelerations and improved yields of cycloadducts were observed for the reaction of imidate and 2-ethoxybenzaldehyde in [Emim][BF_4], [Emim][PF_6] and [Emim][NfO] respectively. Olga and co-workers have studied extensively the $Er(OTf)_3$ catalyzed 1,3-DC reaction in [Bmim][OTf] which also significantly increase the yield of cycloadducts [9]. Recently, more studies are carried out with the effort to synthesize spiroheterocycles using azomethineylides via catalyzed 1, 3-DC reactions [10, 11, 12].

Herein, we described the 1,3-DC reaction between nitrone **1** and maleimide **2** in room temperature ILs. Initially, the nitrone **1** were prepared in two steps synthesis, starting from 4-Tert-Butylnitrobenzene, which first reduced to hydroxylamine derivatives using Rh/C and hydrazine monohydrate. Subsequently, condensation reaction takes place with 4-Tert-Butylbenzaldehyde (Scheme 1). Maleimide **2** was synthesized by simple condensation reaction of maleic anhydride and *p*-toluidine in acetic acid.

Scheme 1. Synthesis of nitrone **1**. Reagents and yields: (a) Rh/C, NH_2NH_2•H_2O, THF, rt, 4 h; (b) 4-Tert-Butylbenzaldehyde, EtOH, rt, 16 h, 44%.

Materials and Methods

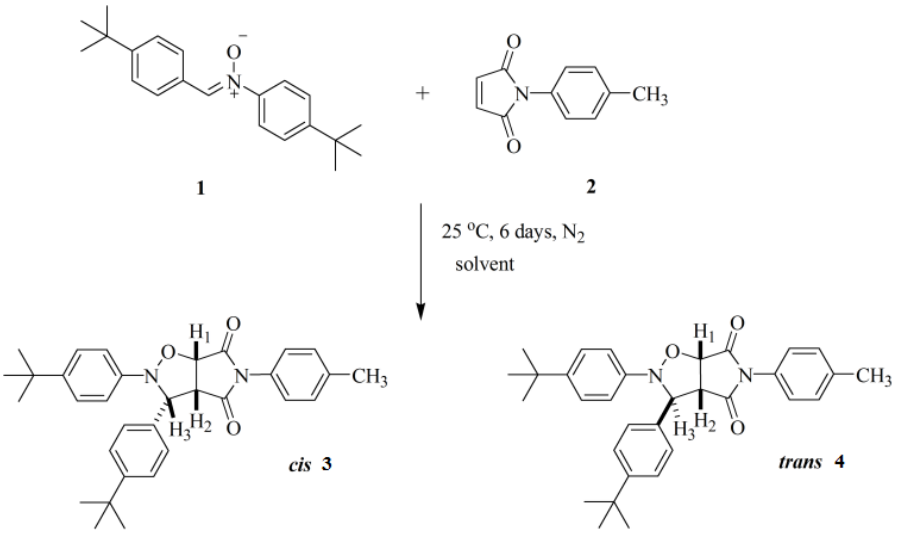
Chemical and reagent

Starting materials and reagents used in the reactions were obtained commercially from Sigma Aldrich, Acros Organic and Friendemann Schmindt, were used without purification, unless otherwise indicated. All other reagents and solvents were purified after receiving from commercial suppliers.

Instrument

^{1}H nuclear magnetic resonance (NMR) spectra were recorded with a JEOL spectrometer (400 MHz) using tetramethylsilane (TMS) as internal standard. ^{13}C NMR spectra were recorded on the same instrument at 100 MHz.

The coupling constant (J) are given in Hz. IR spectra were obtained with a Perkin Elmer Spectrum GX machine as film or as KBR pellets for all the products. Mass spectroscopy (MS) spectra were recorded with a Bruker instrument. The progression and/or completion of the reactions were monitored by thin-layer chromatography (TLC) using 0.25 mm silica gel plates (Merck Kieselgel $60F_{254}$ UV indicator),while column chromatography was performed with silica gel (Merck Kieselgel) 600-200 mesh.



Synthesis of (Z)-4-Tert-Butyl-N-(4-Tert-Butylbenzylidene)aniline oxide 1

4-Tert-Butylnitrobenzene (0.56 g, 3.12 mmol) was dissolved in THF (15 mL). Rhodium (20 mg, 30 wt.% on carbon, wet) and hydrazine monohydrate (0.19 mL, 3.75 mmol) was added and the progress of the reaction was monitored by TLC. After completion, the solution was filtered through Celite pad and concentrated under reduced pressure to obtain the intermediate hydroxylamine which was directly used in the next step without further purification. The hydroxylamine was dissolved in EtOH (15 mL) and 4-Tert-Butylbenzaldehyde (0.51 mL, 3.12 mmol) was added dropwise to the solution. The reaction mixture was left stirred in the absence of light for 16 hours at ambient temperature. The solvent was concentrated *in vacuum* and the residue was purified by column chromatography (SiO_2, gradient Cyclohexane:EtOAc:Et_3N) to give nitrone **1** as yellow solid (44%).

Synthesis of novel diasteromeric isoxazolidine derivatives (3 & 4) in ionic liquid

The 1,3-DC reaction between nitrone **1** and maleimide **2** was carried by stirring out at room temperature under inert atmosphere in the absence of light for six days. The progress of the reaction was monitored using thin layer chromatography. The cycloadducts were carefully isolated using diethyl ether and cyclohexane and concentrated by evaporation under reduced pressure. The residue was purified by column chromatography (SiO_2, gradient hexane: ethyl acetate) affording both diastereoisomers *cis* and *trans* as colourless solid. [Bmim] with anion BF_4 and PF_6 were used as recyclable solvents for 1,3-dipolar cycloaddition reaction of nitrone **1** with maleimide **2** to produce novel isoxazolidine derivatives. The synthesis of the diastereoisomeric adducts were also conducted in chloroform for comparison (Scheme 2).

In a typical procedure, 1 mmol of nitrone **1** was mixed with an equivalent of maleimide **2** in [Bmim][BF_4] (2 ml) under stirring at room temperature and the progress of the reaction was monitored by TLC. After completion of reaction, the reaction mixture was washed with diethyl ethers (3 × 10 ml). The combined organic layers were concentrated *in vacuum* and the resulting product was directly charged on silica gel column and eluted with a mixture of ethyl acetate:hexane to afford pure isoxazolidines.

Scheme 2. Synthesis of diastereoisomeric cycloadducts 3 and 4 via cycloaddition between nitrone **1** and maleimide **2** at 25 °C

Results and Discussion

[Bmim][PF_6] was found to give better yield of 43% as to compare with only 18% in [Bmim][BF_4] (Table 1). This results is in agreement from previous observation from other studies involving cycloaddition reactions in imidazolium based ILs. Chakraborty and Luitel have demonstrated the application of imidazolium ILs as solvents in their cycloaddition reaction of *N*-Benzyl fluoronitrone with maleimide derivatives. In all cases, they found the ratio of the diastereoisomer is 3:1, favouring *cis* cycloadduct [13]. Ganesh et al. also observed similarly the exclusive formation of *cis* fused products in highly stereoselectivity intramolecular 1,3-dipolar cycloaddition of azomethineylides as well as nitrones[14].

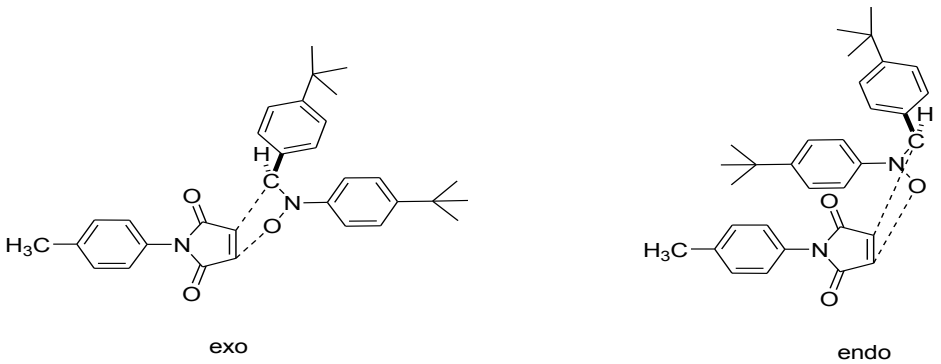


Table 1. 1,3-Dipolar cycloaddition reactions of nitrone **1** with maleimide **2**

Entry	Solvent[a]	*cis* (3)/*trans* ratio(4)[b]	Yield (%)
1	[Bmim][BF_4]	2:1	18
2	[Bmim][PF_6]	1.1:1	43
3	$CHCl_3$	0.2:6	36

[a]Reaction conditions: nitrone **1** (1 mmol), maleimide **2** (1 equivalent), 2 mL of respective ILs or 4 mL of $CHCl_3$, N_2 atmosphere, rt, [b]Cycloadducts were characterized by IR, ^{1}H NMR, ^{13}C NMR and MS spectral data

In the case of *cis* cycloadduct, the prominent signal for proton H_3 and H_1 are both doublet, while triplet for H_2. By contrast, *trans* cycloadducts, signal for proton H_3 is singlet while doublet for H_1 and H_2. It is shown that [Bmim][BF_4] and [Bmim][PF_6] gave cycloadducts in 1:2 and 1:1.1 ratio, respectively, favouring *cis* diastereoisomer. This results is staggering given that a typical uncatalyzed 1, 3-DC of nitrone and maleimide in chloroform leads to the solely formation of *trans* cycloadduct with the ratio of 6:0.2. In addition, mass spectral analysis of the cycloadducts provided evidence for the success of the cycloaddition reactions. The mass spectrum shows the present of molecular ion peak at the base peak m/z = 519.26, 497.27 and 332.20, respectively.

For the formation of major cycloadduct, these results can be rationalized by an exo approach of nitrone which has Z configuration while an endo approach leads to the formation of minor cycloadduct (Scheme 3).

Scheme 3. Exo/ endo approach of nitrone to maleimide in cycloaddition reaction

ILs have shown powerful catalytic properties to accelerate the Diels Alder reaction due to its ionic features. We do believe that ILs contribute to the accessibility of exo transition state, which in return give more *cis* diastereoisomer.

In the meantime, we are trying to investigate further this kind of reactions with elongated 1,3-dipole compounds and dipolarophiles.

Characterization

Representative data for synthesis of (Z)-4-Tert-Butyl-N-(4-Tert-Butylbenzylidene)aniline oxide 1: M.p. = 152.5 – 154.4 °C; ^{1}H NMR (300.1 MHz, $CDCl_3$): δ_H 8.35 - 8.30 (2H, m, ArH), 7.88 (1H, s, CH), 7.72 – 7.67 (2H, m, ArH), 7.52 – 7.46 (4H, m, ArH), 1.35 (18H, s, CH_3); ^{13}C NMR (75.5 MHz, $CDCl_3$): δ_c154.4 (ArC), 153.3 (ArC),146.8 (ArC), 134.2 (CH), 129.1 (ArCH), 128.3 (ArC),126.1 (ArCH), 125.7 (ArCH), 121.4 (ArCH), 35.2 (qC), 35 (qC), 31.4(CH_3), 31.$_3$(CH3); MS (ES^+) m/z 332.0 ([M+Na]$^+$, 95), 641.0 (100); HRMS (ES^+) *m/z* calculated for $C_{21}H_{27}NONa$ 332.1990 [M+Na]$^+$, found 332.1994.

Conclusion

Considering the environmental pollution by using conventional organic solvents, ILs have become an alternative reaction media for the development of green synthetic strategies in 1,3-DC. Two ionic liquids, [Bmim][BF_4] and [Bmim][PF_6] has facilitated the course of 1,3 DC of nitrone and maleimide with improved results on the yield of the cycloadducts. In the future, we would like to explore the use of microwaves as conventional heating sources. ILs will be heated very quickly, thus, providing shorter reaction times and efficient reaction due to microwave irradiation.

RADIOLOGICAL RISK ASSESSMENT FROM THE INTAKE OF VEGETABLES AND FRUITS IN MALAYSIA

(Penilaian Risiko Radiologi dari Pengambilan Sayur-Sayuran dan Buah-Buahan di Malaysia)

Abstract

The activity concentration of natural radionuclides ^{226}Ra, ^{232}Th and ^{40}K in vegetables and fruits in central zone of Malaysia were measured using gamma spectrometry. This is for the purpose of assessing the radiological risk in term of ingestion dose and cancer risk. The total ingestion dose from the consumption of vegetables were found to be 0.469 ± 0.003, 0.326 ± 0.005 and 0.232 ± 0.003 mSv/y for infants, children and adults respectively. Whereas the total ingestion dose from the consumption of fruits for infants, children and adults were 0.349 ± 0.005, 0.283 ± 0.007 and 0.195 ± 0.004 mSv/y respectively. The estimated cancer risk from the consumption of vegetables and fruits were 8.13×10^{-4} and 6.83×10^{-4} respectively for adults. The results obtained for activity concentration, dose and risk were found to be below the internationally recommended level. This indicates that the vegetables and fruits consumed in Malaysia would not pose any significant radiological impact to the population.

Keywords: activity concentration, gamma spectrometry, ingestion dose, natural radionuclides, risk assesment

Abstrak

Kepekatan aktiviti radionuklid semulajadi ^{226}Ra, ^{232}Th and ^{40}K dalam sayur-sayuran dan buah-buahan di Malaysia bahagian tengah telah diukur menggunakan spektrometer gama. Ini bertujuan untuk menilai risiko radiologi dalam istilah dos dimakan dan risiko kanser. Didapati jumlah dos dimakan dari pengambilan sayur-sayuran adalah 0.469 ± 0.003, 0.326 ± 0.005 and 0.232 ± 0.003 mSv/tahun masing-masing bagi bayi, kanak-kanak dan dewasa. Manakala jumlah dos dimakan dari pengambilan buah-buahan bagi bayi, kanak-kanak dan dewasa adalah masing-masing 0.349 ± 0.005, 0.283 ± 0.007 and 0.195 ± 0.004mSv/tahun. Risiko kanser dari pengambilan sayur-sayuran dan buah-buahan bagi orang dewasa masing-masing dijangkakan sebanyak 8.13×10^{-4} dan 6.83×10^{-4}. Kesemua hasil yang diperolehi dalam kajian ini bagi kepekatan aktiviti, dos dan risiko didapati berada di bawah aras yang dibenarkan oleh badan antarabangsa. Ini menunjukkan bahawa sayur-sayuran dan buah-buahan yang diambil di Malaysia tidak menimbulkan bahaya radiologi yang ketara terhadap manusia.

Kata kunci: kepekatan aktiviti, spektrometer gama, dos dimakan, radionuklid semula jadi, penilaian risiko

Introduction

The total annual radiation dose received by a member of the population each year is 3.01 mSv. About 79.73% of this number is contributed by natural radiation sources (2.4 mSv/y) and the rest 20.27% by man-made radiation sources (0.61 mSv/y) [1]. It is clear that the natural radiation sources is the main contributor to the total annual radiation dose. One component of this natural radiation sources is the ingestion dose (0.29 mSv/y) that are mainly contributed by ^{238}U and ^{232}Th series (0.12 mSv/y) and ^{40}K (0.17 mSv/y) [2].

Ingestion dose was received by human beings from the consumption of food contaminated with different radionuclides [3]. One of important food that can contributes to better health of human is vegetables and fruits [4]. According to Ministry of Health Malaysia, vegetables and fruits are categorized into the most second important food after rice and grains. Therefore, it is recommended to take these kind of food for at least 5 servings a day (approximately 400 g/d) [5].

Since the amount of recommended intake is quite big, it is important to monitor the radiological effect from the consumption of vegetables and fruits. This matter has become a great concern as has been reported by many researchers in different part of the world. From eleven different countries, 58 types of vegetables have been studied with seven common types namely spinach, carrot, cucumber, tomato, pumpkin, green bean and potato [6-16]. However in Malaysia, only 16 types of vegetables have been studied with spinach and cucumber as the common type [17, 18]. Studies conducted in ten different countries reported that 26 types of fruits have been studied with eight common types namely apple, pear, orange, mango, banana, papaya, grapes and watermelon [6-16]. Whereas in Malaysia, only nine types of fruits have been studied i.e. apple, orange, mango, banana, papaya, star fruit, pineaple, rambutan and durian [17].

The present work is intended to (a) to determine the activities of ^{226}Ra, ^{232}Th and ^{40}K; (b) to assess the ingestion doses (due to these three radionuclides) incurred to the infants (1–2 years), children (7–12 years) and adults (> 17 years), (c) to compare these activities and doses with the previous local and international results, and (d) to estimate the consequent health risk due to the presence of those radionuclides in the vegetables and fruits. This work is also conducted to complete the precedent researches carried out by the authors on some food products such as milk and water [19, 20].

Materials and Methods

Sample collection

Twelve different samples of commonly eaten vegetables and fruits were collected. All the samples were purchased from the local market in central zone of Malaysia. All vegetables and three fruits sample (banana, papaya and mango) were locally produced in Malaysia whereas the remaining three fruits sample i.e. apple, orange and pear were imported from China, Korea and Australia respectively.

Sample preparation

All vegetables and fruits samples were prepared following the IAEA procedure [21]. They were made into powder to follow the geometry of standard silica powder (4 cm height in 10 cm polyethilene beaker). First, they were washed and minced to get a small size. The unused part such as skin and seeds were discarded. Samples were then oven dried at 80 ^{o}C for 48 hours or until they reached constant mass. The dried sample were pulverized and sieved until they become 500 μm homogen powder. The powdered samples were then kept in a sealed tight polyethilene beaker for 30 days to achieve secular equilibrium. For every types of samples, three samples were prepared to obtained the average activity concentration. This means, 36 samples (= 12 × 3 samples) has been prepared for these two categories of samples.

^{226}Ra, ^{232}Th and ^{40}K measurement

The radionuclides ^{226}Ra, ^{232}Th and ^{40}K count, N in the vegetables and fruits sample were measured using gamma ray spectrometry system with high purity germanium detector (HPGe). The detector was connected to MCA card (Accuspec B) and Genie-2000 analysis software. The detector energy resolution was 1.8 keV at 1.33 keV of ^{60}Co gamma ray peak and the relative efficiency was 30% at the same energy peak [22]. Each measurement was carried out for 43,200 second (12 hours). The count of each radionuclides were resulted from the line energy peaks emited directly by the corresponding radionuclide (1460 keV for ^{40}K) or by the radionuclides daughter (352 and 609 keV for ^{226}Ra and 239, 583 and 911 keV for ^{232}) [17]. The equation 1 used to calculate the activity concentration, A and its uncertainty was expressed below [21, 23]:

$$A = \frac{N}{\varepsilon \times t \times P_{\gamma} \times M_s} \quad (1)$$

where ε is the detector efficiency, t is measurement time, P_γ is the γ-ray emission probability (%) and M_s is the mass of the sample (kg). To conceal the minor photopeaks for each sample, the minimum detectable activity (MDA) was calculated using the formula originally defined by Currie [24].

$$\text{MDA} = \frac{2.71 + 4.66\,\sigma}{t \times \varepsilon \times P_\gamma} \quad (2)$$

where σ is the uncertainty of background count. The present measuring system recorded the MDA of 0.30, 0.34 and 2.88 Bq/kg for ^{226}Ra, ^{232}Th and ^{40}K respectively.

Dose and risk calculation

From the ^{226}Ra, ^{232}Th and ^{40}K activities, the ingestion dose D (mSv/y) can be calculated using the following relationship (equation 3) [25]:

$$D = A \times I \times E \quad (3)$$

where I (kg/y) is the annual intake of the vegetables and fruits [26] and E (Sv/Bq) is the ingestion dose conversion factor of the radionuclide [27]. The values of I and E for the three age categories are given in Table 1. The dose contributed from three radionuclides ^{226}Ra, ^{232}Th and ^{40}K were summed to obtain the total dose, D_T. If it is assumed that the life-span of an average individual, L is 70 years [28, 29] and the the cancer risk factor for low doses, RF is 5 × 10^{-5} (1/mSv) [1], the cancer risk R can be estimated from:

$$R = D_T \times L \times RF \quad (4)$$

Table 1. The annual intake, I and the ingestion dose conversion factor, E for infants, children and adults

Age Category	I (kg/y)		E (× 10^{-8} Sv/Bq)		
	Vegetables	Fruits	^{226}Ra	^{232}Th	^{40}K
Infants (1–3 years)	12.96	23.01	96	45	4.20
Children (7–12 years)	25.92	46.02	80	29	1.30
Adults (> 17 years)	38.88	69.03	28	23	0.62

Results and Discussion

The measured activity concentration, A of ^{226}Ra, ^{232}Th and ^{40}K in six samples of vegetables and six samples of fruits, their ranges and their average values were shown in Table 2. It was shown that the activity concentration in some samples of vegetables and fruits were not detectable. For vegetables, the detected activity concentration ranged from 0.60 ± 0.57 to 5.64 ± 0.65 Bq/kg for ^{226}Ra, 0.41 ± 0.32 to 4.40 ± 0.49 Bq/kg for ^{232}Th and 398.85 ± 6.89 to 1072.59 ± 10.25 Bq/kg for ^{40}K. The average activity concentration of ^{226}Ra, ^{232}Th and ^{40}K were found to be 1.38 ± 0.21, 1.06 ± 0.12 and 791.51 ± 3.66 Bq/kg respectively. For fruits, the detected ^{226}Ra activity concentration ranged from 0.90 ± 0.64 to 3.83 ± 0.56 with an average value of 1.22 ± 0.17, ^{232}Th activity concentration ranged from 0.56 ± 0.48 to 2.22 ± 0.38 with an average value of 0.77 ± 0.12 and the ^{40}K activity concentration ranged from 75.39 ± 4.78 to 651.64 ± 9.75 with an average value of 288.63 ± 2.83, all in Bq/kg.

For both types of sample, the highest activity concentration were found to be ^{40}K followed by ^{226}Ra and ^{232}Th. This same pattern has also been reported by many previous work as shown in Table 3. The activity concentration of previous results for vegetables samples ranged from 0.049 to 48.80, 0.001 to 25.36 and 0.79 to 1190.45 Bq/kg for ^{226}Ra, ^{232}Th and ^{40}K respectively. For fruits samples, they ranged from 0.009 to 8.15, 0.001 to 32.30 and 20.94 to 439.53 for ^{226}Ra, ^{232}Th and ^{40}K respectively. In comparison with this range, the present results are in agreement with the previous results. This is because all the averaged value of the present results lie clearly within the range of the previous results.

Table 2. ^{226}Ra, ^{232}Th and ^{40}K measured activity concentration, A from vegetables and fruits

Sample	Name	Activity concentration, $A \pm \Delta A$ (Bq/kg)		
		^{226}Ra	^{232}Th	^{40}K
Vegetables	Spinach	5.64 ± 0.65	4.40 ± 0.49	998.04 ± 9.13
	Carrot	ND[a]	ND	398.85 ± 6.89
	Broccoli	1.29 ± 0.62	ND	664.54 ± 8.75
	Pumpkin	ND	0.41 ± 0.32	682.90 ± 6.92
	Tomato	0.76 ± 0.63	ND	932.11 ± 11.02
	Cucumber	0.60 ± 0.57	1.55 ± 0.44	1072.59 ± 10.25
	Range	0.60 – 5.64	0.41 – 4.40	398.85 – 1072.59
	Average	2.07 ± 0.31[b]	2.12 ± 0.24[b]	791.51 ± 3.66
Fruits	Apple	2.58 ± 0.58	1.84 ± 0.42	151.49 ± 5.69
	Banana	ND	ND	401.59 ± 5.85
	Orange	ND	ND	279.74 ± 7.70
	Pear	3.83 ± 0.56	2.22 ± 0.38	75.39 ± 4.78
	Papaya	0.90 ± 0.64	0.56 ± 0.48	651.64 ± 9.75
	Mango	ND	ND	171.95 ± 6.61
	Range	0.90 – 3.83	0.56 – 2.22	75.39 – 651.64
	Average	2.44 ± 0.34[b]	1.54 ± 0.25[b]	288.63 ± 2.83

[a)]ND = Not detectable (MDA for ^{226}Ra, ^{232}Th and ^{40}K were 0.30, 0.34 and 2.88 Bq/kg respectively). [b)]Due to the ND, respectively two and three out of six ^{226}Ra and ^{232}Th activities of vegetables and respectively three and three out of six ^{226}Ra and ^{232}Th activities of fruits were undetected. Therefore, this average was calculated from detected values only.

Table 4. Calculated ingestion dose, *D* from the intake of ^{226}Ra, ^{232}Th and ^{40}K in vegetables and fruits for three age categories

Type	Age Category	Ingestion Dose (mSv/y)			
		$D \pm \Delta D$			$D_T \pm \Delta D_T$ [(a)]
		^{226}Ra	^{232}Th	^{40}K	
Vegetables	Infants	0.026 ± 0.004	0.012 ± 0.001	0.431 ± 0.002	0.469 ± 0.003
	Children	0.043 ± 0.006	0.016 ± 0.002	0.267 ± 0.001	0.326 ± 0.005
	Adults	0.023 ± 0.003	0.019 ± 0.002	0.191 ± 0.001	0.232 ± 0.003
Fruits	Infants	0.054 ± 0.008	0.016 ± 0.003	0.279 ± 0.003	0.349 ± 0.005
	Children	0.090 ± 0.013	0.021 ± 0.003	0.173 ± 0.002	0.283 ± 0.007
	Adults	0.047 ± 0.007	0.024 ± 0.004	0.124 ± 0.001	0.195 ± 0.004

[(a)] $D_T = D_{\text{Ra-226}} + D_{\text{Th-232}} + D_{\text{K-40}}$

Upon comparing these two values, it was found that for vegetables: (a), the *D* due to intake of ^{226}Ra and ^{232}Th for three age categories were below the UNSCEAR annual ingestion dose. Hence, it was automatically below the annual radiation dose from natural sources, (b) only the *D* due to intake of ^{40}K for children and adults were below the UNSCEAR annual ingestion dose, whereas for infants, the *D* value were higher. However, it is still below the value of annual radiation dose from natural sources, (c) the *D* due to total intake of three radionuclides for infants and children are higher than the UNSCEAR annual ingestion dose by a factor of 1.57 and 1.04 respectively, however they are still below the value of annual radiation dose from natural sources.

The comparison results for fruits: (a) the *D* due to intake of ^{226}Ra, ^{232}Th and ^{40}K for three age categories were below the UNSCEAR annual ingestion dose. Hence, it was automatically below the annual radiation dose from natural sources, (b) the *D* due to total intake of three radionuclides were also below the UNSCEAR annual ingestion dose except for infants (higher by a factor of 1.08). However, it is still below the value of annual radiation dose from natural sources. To provide a better understanding of these results, the dose comparison were shown in Figure 1.

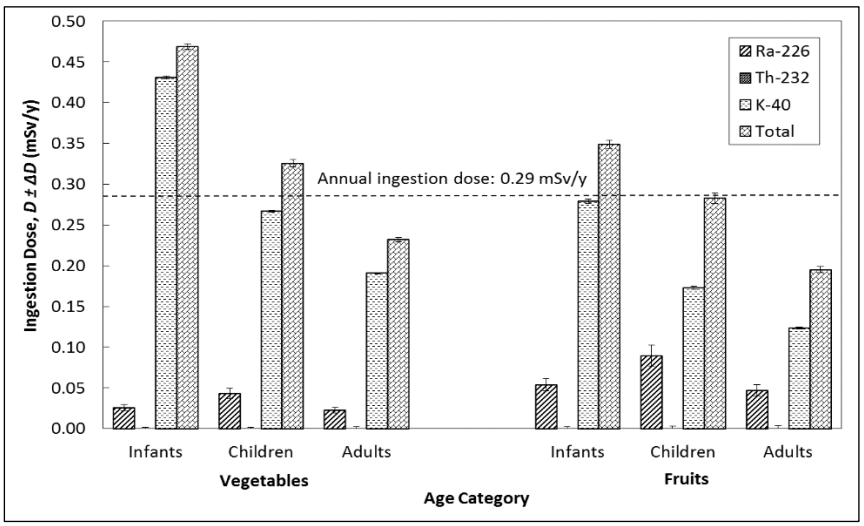

Figure 1. Ingestion dose of infants, children and adults from the intake of radionuclides ^{226}Ra, ^{232}Th and ^{40}K in vegetables and fruits. The dose contributed by ^{232}Th is in the range of 0.012 – 0.019 mSv/y for vegetables and 0.016 – 0.024 mSv/y for fruits, therefore they hardly can be seen.

The *D* for infants and children for both vegetables and fruits were found to be higher than adults despite the lower value of intake *I* (Table 1). This is due to the higher value of *E* (ingestion dose conversion factor) for each radionuclide. The *E* value for infants were found to be higher by adults in the range of 1.96 – 6.77, whereas for children in the range of 1.26 – 2.86. Following the formula of $D = A \times I \times E$, for the same *A*, it makes sense that the *D* is higher when the *E* is higher.

The cancer risk *R* of 8.13×10^{-4} and 6.83×10^{-4} were estimated corresponding to the adult total ingestion dose of 0.232 and 0.195 mSv/y for vegetables and fruits respectively. These risk are significantly lower than the risk estimated by UNSCEAR from total natural radiation dose of 2.4 mSv/y i.e. 8.4×10^{-3}. The reduction by a factor of 10.34 and 12.31 respectively for vegetables and fruits deduces that the vegetables and fruits in Malaysia are safe for human consumption.

Another approach from Cohen and Lee [32] were also used to estimate the health risk posed from the intake of vegetables and fruits. The avoid confusion, these authors estimated the health risk in terms of day loss. It is estimated that an average loss of 9.9 days from continuos exposure of 1 mSv/y throughout life. Based on the total dose of 0.215 and 0.159 mSv/y, the estimated life expectancy for adults is shorten by only 2.13 and 1.57 days due to the consumption of vegetables and fruits respectively. It is therefore concluded that the vegetables and fruits consumed by Malaysian population would not pose any significant radiological impact on health and cancer risk to the population.

Conclusion

The ingestion dose due to the activity concentration of ^{226}Ra, ^{232}Th and ^{40}K in vegetables and fruits in Malaysia were found to be below natural radiation exposure reported by UNSCEAR. It was also comparable to published value reported by other researchers. The estimated risk has no significant health hazard as they were also below the UNSCEAR cancer risk factor. Therefore, it is concluded that the vegetables and fruits available in Malaysia are radiologically safe for human consumption. The data reported here will provide a baseline radiometric values for natural radionuclides in vegetables and fruits and also the radiological risk indices associating with them.

Abstract

A cyclic voltammetry (CV) and differential pulse cathodic stripping voltammetry (DPCSV) studies of RB5 in Britton-Robinson buffer (BRB) at a hanging mercury dropping electrode (HMDE) are described. CV was carried out by cathodic and anodic potential scan over the range of +200 mV to -800 mV with no accumulation time and three well-defined pH-dependent cathodic peaks were observed. The effects of different scan rates, pH of BRB, repetitive cycle and increasing concentrations on the peak height and peak potential of the analyte were studied. The results showed that RB5 dye was adsorbed and irreversibly reduced at the mercury electrode, mainly under diffusion controlled in the optimum pH 4.0 of BRB. By using DPCSV, pH of BRB and various instrumental parameters such as scan rate, accumulation time, accumulation potential and pulse amplitude that may affect the peak height of RB5 were investigated and optimized for RB5 determination. Under the optimized parameters, the peak height was found to be linear with RB5 concentration in the range from 2.5 x 10^{-7} mol L^{-1} to 2.0 x 10^{-6} mol L^{-1}. A detection limit (3SD/m) of 1.3 x 10^{-8} mol L^{-1} was achieved. The precision of the developed method in terms of RSD was 0.55% for intra-day measurement and 0.55%, 0.24% and 0.40%, for inter-day measurements, respectively. The developed method was successfully applied in the determination of RB5 in batik wastewaters with the mean recovery of 83.97 ± 4.78% to 97.93 ± 5.45% (0.5 x 10^{-6} mol L^{-1}), 95.91 ± 2.68% to 103.49 ± 1.32% (1.0 x 10^{-6} mol L^{-1}) and 99.17 ± 0.75% to 105.12 ± 0.28% (2.0 x 10^{-6} mol L^{-1}). The developed method is considered sensitive, precise, accurate, rugged, robust, fast and low cost for routine analysis of RB5 dye in batik wastewaters over the UV-VIS spectrometry method.

Keywords: Reactive Black 5, differential pulse cathodic stripping, Britton-Robinson buffer, hanging mercury dropping electrode, batik wastewater samples

Abstrak

Kajian voltammetri berkitar (CV) dan voltammetri perlucutan denyut kebezaan (DPCSV) terhadap pewarna RB5 dalam larutan penimbal Britton-Robinson (BRB) menggunakan elektrod jatuhan raksa tergantung (HMDE) dihuraikan. CV dijalankan dengan mengimbas potential kathodik dan anodik dari +200 mV ke -800 mV tanpa masa pengumpulan dan tiga puncak diperhatikan selepas imbasan. Kesan perbezaan kadar imbasan, pH BRB, imbasan berkitar yang berulang dan peningkatan kepekatan RB5 ke atas ketinggian dan nilai keupayaan puncak dikaji. RB5 yang dijerap dan diturunkan secara tidak berbalik pada permukaan elektrod merkuri adalah dibawah kawalan difusi pada pH BRB yang optimum iaitu 4.0. Dengan menggunakan DPCSV, pH BRB dan parameter-parameter peralatan yang memberi kesan kepada ketinggian puncak seperti kadar imbasan, masa pengumpulan, keupayaan pengumpulan dan amplitud denyut telah dioptimumkan untuk analisis RB5. Ketinggian puncak berkadar terus dengan kepekatan RB5 dalam julat dari 2.5 x 10^{-7} mol L^{-1} hingga 2.0 x 10^{-6} mol L^{-1}. Had pengesanan adalah 1.3 x 10^{-8} mol L^{-1}. Ketepatan (RSD) kaedah yang dibangunkan adalah 0.55% untuk hari yang sama, manakala 0.55%, 0.24% dan 0.40% untuk tiga

hari yang berbeza. Kaedah yang dibangunkan berjaya diuji bagi penentuan RB5 dalam air sisa batik dengan purata kebolehdapatan 83.97 ± 4.78% sehingga 97.93 ± 5.45% (0.5 x 10^{-6} mol L^{-1}), 95.91 ± 2.68% sehingga 103.49 ± 1.32% (1.0 x 10^{-6} mol L^{-1}) dan 99.17 ± 0.75% sehingga 105.12 ± 0.28% (2.0 x 10^{-6} mol L^{-1}). Kaedah yang dibangunkan adalah sensitif, tepat, lasak, teguh, cepat dan menjimatkan bagi analisis rutin kandungan RB5 dalam air sisa batik berbanding kaedah spektrofotometri UV-VIS.

Introduction

The textile industry is considered as one of the major water consumers. It utilizes a large volume of water and chemicals for the wet processing of the textiles and can contribute to the water bodies pollution [1, 2]. Homemade batik industry is a part of the textile industry and preliminary studies have shown that wastewaters discharged from this particular industry contain dyes, heavy metals, grease, wax and also suspended solids with high chemical oxygen demand (COD) [3, 4].

Azo dyes are considered as the oldest and the largest class of synthetic organic dyes. They are also considered as dyes with the largest shade range and are commonly used [5]. They account for 60% to 70% of the total organic dyes, have bright and high colour intensity, extensively used in textile, food, drug, cosmetic, automobile, leather and in the paper making industries [6, 7, 8].

Reactive Black 5 (RB5) or [2,7-naphthalenedisulfonic acid, 4-amino-5-hydroxy-3,6-bis ((4 - ((2 (sulfooxy) ethyl) sulfonyl) phenyl) azo)-tetrasodium salt], which chemical structure is shown in Figure 1, is categorized in the reactive vinyl sulphonate azo dye due to the presence of –N=N- bonds combined with vinylsulphone as the reactive groups [9]. The two azo groups which act as chromophores enable the dyes to absorb light in the visible spectrum and are also responsible for the corresponding colours. These reactive groups are covalently bonded to –OH or –NH_2 groups that are present in the materials to give excellent wash fastness property [10, 11, 12].

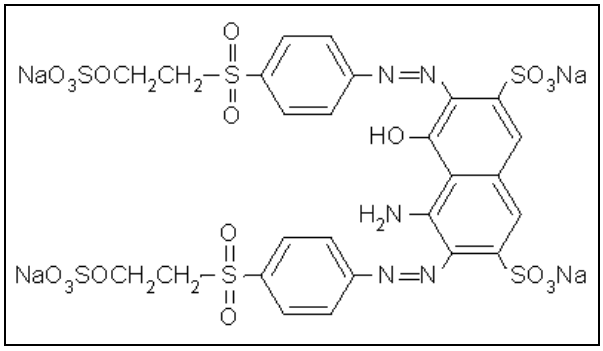

Figure 1. Chemical structure of RB5

Several analytical methods for the analysis of azo dyes and their intermediates in various samples have been developed and most of the methods are based on the electrophoresis, chromatographic and spectroscopic method [13, 14]. The voltammetric method allows for an analysis without or with minimal samples pre-treatment, has comparable selectivity and sensitivity over the chromatographic method, applicability over a wide concentration range, fast analysis, low cost on instrumentation and maintenances and is able to perform both individual and simultaneous analyses [15, 16].

This paper describes the cyclic voltammetric (CV) studies of RB5 dye using a hanging mercury dropping electrode (HMDE) as the working electrode in the Britton-Robinson buffer (BRB) to obtain qualitative information on the

electrochemical reactions such as reversibility, adsorption and diffusion characteristics of a system. Differential pulse cathodic stripping voltammetric (DPCSV) studies of RB5 dye using the same HMDE and in the same BRB had then been carried out for RB5 dye determination in the wastewaters from local batik factories. With regards to the voltammetry method, no DPCSV technique for RB5 dye determination has been reported so far. It is also rarely reported for the analysis of azo dyes containing two azo groups in their chemical structures.

Materials and Methods

Materials

All chemicals used in this study were of analytical grade reagent and all solutions were prepared in deionized water. The RB5 dye standard (MW = 991.82 $gmol^{-1}$) was obtained from Sigma Aldrich, UK. For the preparation of 2.0 x 10^{-4} $molL^{-1}$ RB5 dye stock solution, 20 mg of the RB5 dye standard was dissolved in 100 mL volumetric flask. The standard working solution of 2.0 x 10^{-5} $molL^{-1}$ was prepared by the appropriate dilution of the stock solution. BRB solution as the supporting electrolyte was prepared in 1000 mL deionized water, composed of a mixture of 2.47 g boric acid (R&M Chemicals, Canada), 2.30 mL glacial acetic acid (R&M Chemicals, Canada) and 2.70 mL ortho-phosporic acid (R&M Chemicals, Canada). Sodium hydroxide (Systerm, Italy) with the concentration of 0.1 M was used to adjust the pH of the BRB solution to the desired value. High purity mercury, 99.99% (Merck, Germany) was used for HMDE.

Instrumentations

The voltammetric experiments were carried out using VA 757 Computrace Metrohm Voltammetric Analyzer with 663 VA Stand (Metrohm, Switzerland), consisted of Multi-Mode Electrode (MME) and a 40 mL capacity voltammetric cell. The MME consisted of a HMDE as the working electrode (WE), a platinum wire as the auxiliary electrode (AE) and an Ag/AgCl as the reference electrode (RE). The VA 757 was connected to a computer for data processing and for all pH measurements, the pH meter (Hanna Instruments, UK) was employed.

Voltammetric measurement:

Cyclic voltammetry

BRB solution with the volume of 9 mL was placed into a voltammetric cell and purged by a stream of purified nitrogen for at least 15 minutes. RB5 dye standard solution (2.0 x 10^{-3} $molL^{-1}$) with the volume of 1 mL was then spiked to give a final concentration of 2.0 x 10^{-4} $molL^{-1}$ and the solution was repurged for 2 minutes. The RB5 dye was scanned from +200 mV to -800 mV (cathodic direction) and switched to +200 mV (anodic direction) with a scan rate (v) of 25 mV/s in various pH of the BRB solution (pH 2.0 to 12.0). The effect of various v (25 to 200 mV/s), the effect of repetitive cycle (1 to 5 cycles) and the effect of dye concentrations on the peak height (I_p) and peak potential (E_p) of RB5 dye were investigated.

Differential pulse stripping voltammetry

BRB solution with the volume of 9 mL was placed into the voltammetric cell and purged by a stream of purified nitrogen for at least 15 minutes. RB5 dye standard solution (2.0 x 10^{-5} $molL^{-1}$) with the volume of 1 mL was then spiked to give the final concentration of 2.0 x 10^{-6} $molL^{-1}$ and the solution was repurged for 2 minutes. The initial operational parameters applied for the voltammetric measurements were the initial potential (E_i) = +150 mV, final potential (E_f) = -700 mV, v = 15 mV/s, accumulation time (t_{acc}) = 0 s, accumulation potential (E_{acc}) = 0 mV and pulse amplitude = 50 mV. Parameters such as v, t_{acc}, E_{acc} and pulse amplitude were optimized to increase the response of the developed method.

The developed method was validated for linearity, limit of detection (LOD), limit of quantification (LOQ), precision, repeatability, accuracy, ruggedness and robustness to verify the suitablity for the extended purposes according to the approach proposed by Miranda et al. [17]. The LOD and LOQ were calculated by the equations; LOD = 3 SD/m and LOQ = 10 SD/m, where SD is the standard deviation of the three replicate determinations of the RB5 dye at the lowest concentration on the calibration curve and m is the slope of the regression equation [18]. The RB5 dye standard solution at the concentration of 2.0 x 10^{-6} $molL^{-1}$ was applied for intra-day and inter-day precision, ruggedness and robustness with five replicate (n=5) measurements. The ruggedness of the developed method was investigated using the same voltammetry analyzer (VA 757), but had been conducted by two different analysts [19] and was also analyzed by using two different voltammetry analyzers (VA 757 and VA 797) but only

conducted by one analyst [20] under the same optimum parameters. The robustness was carried out by examining the effect of a small variation of v, t_{acc}, time interval analysis after RB5 dye standard preparation and pH of BRB solution on the response.

Collection, preservation and analysis of wastewaters from the batik industry

Wastewaters from the batik industry were obtained from nine batik factories, located at Kota Bharu and Pantai Cahaya Bulan, Kelantan, Malaysia. The wastewaters were collected from two different dyebaths at each factory. The wastewaters were analyzed using the developed DPCSV technique without the prior samples pre-treatment and extraction by spiking 1 mL of the wastewater samples into the 9 mL BRB solution.

Recovery studies of the RB5 dye in wastewaters from the batik industry

To study the accuracy and reproducibility of the developed DPCSV technique, recovery experiments were carried out using the standard addition method.

UV-VIS Spectrophotometry analysis of the RB5 dye

The results obtained by the developed DPCSV technique were compared with the UV-VIS Spectrophotometry method using Spectrophotometer Cary 100, USA. The double beam mode was employed for the overall analysis from the start wavelength of 700 nm to the stop wavelenghth of 300 nm with the rate of 600 nm/min.

Results and Discussion

Electrochemical behaviour of the RB5 dye

Cyclic voltammetric studies of the RB5 dye were carried out in 0.04 M BRB solution from pH 2.0 to 12.0 with v of 25 mV/s. From the cyclic voltammogram obtained, BRB solution at pH 4.0 was observed to be the optimum condition with I_p of 298 nA for RB5 dye reduction at the HMDE, as shown in Figure 2. Three well-defined reduction peaks at -79.80 mV, -258 mV and -568 mV were obtained for the first, second and third peak, respectively. No oxidation peaks were observed which confirmed that the RB5 dye was irreversibly reduced at the mercury electrode. The second reduction peak was referred to as the analytical signal due to its higher sensitivity compared to the first and third reduction peak of the RB5 dye [21].

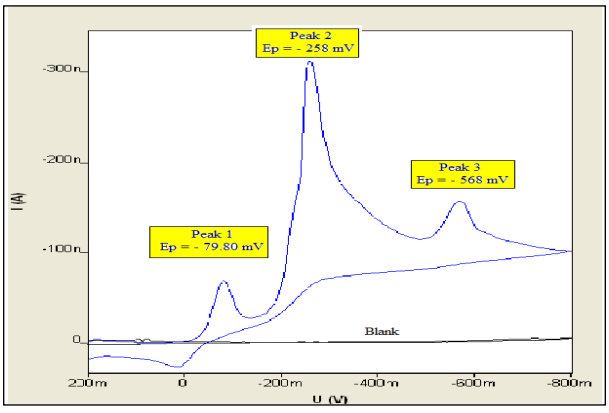

Figure 2. Cyclic voltammogram of 2 x 10^{-4} $molL^{-1}$ RB5 dye in BRB solution at pH 4.0.Experimental condition: E_i = +200 mV, E_{switch} = -800 mV, E_f = +200 mV and v = 25 mV/s

The first two obtained reduction peaks were suggested due to the subsequence reduction process of the two azo groups to amines. Both hydroxyl and amino groups were electron donating substituents in the RB5 dye compound. The first reduction peak was suggested from the reduction process of the azo with the hydroxyl group and followed by the reduction process of the other azo with amino group, which gave the second reduction peak on the

voltammograms. The reduction process of the azo with amino group was more difficult due to the electron distribution in this functional group [22].

The effect of pH of BRB solution on the E_p was studied from pH 2.0 to 12.0. The results showed that the E_p of RB5 dye was shifted to the more negative potentials with the increased pH indicating that the electron transfer was accompanied by proton transfer in the reduction process [23, 24]. The reduction process was easier to take place in a medium rich with H^+ ions and more difficult in a medium with low H^+ ions [25] and the reduction process of RB5 dye was pH dependent [26, 27].

The effects of scan rate (v) from 25 to 200 mV/s on the E_p and I_p of the RB5 dye were observed under the same experimental conditions. The results showed that by increasing the v, the E_p shifted to more negative potentials and accompanied with the increase of the I_p. The increase of I_p indicated an adsorption phenomenon of the RB5 dye at the surface of the mercury electrode [28, 29]. A linear relationship was observed between log I_p against log v with a slope of 0.5282 (R^2 = 0.9982, n = 6), as shown in Figure 3. The slope of 0.5282 was close to the theoretical value of 0.5, which indicated that the reduction process of RB5 dye was mainly controlled by diffusion [30, 31].

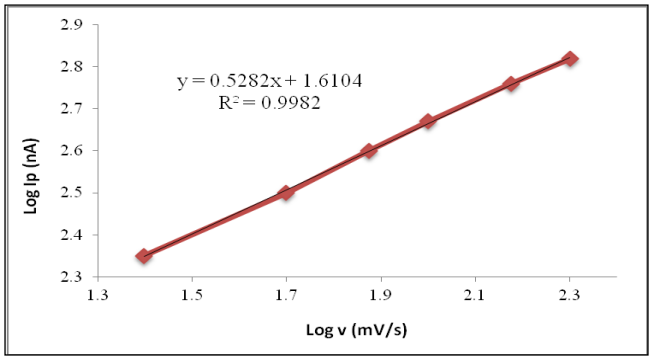

Figure 3. Plot of I_p to the log v for 2 x 10^{-4} molL^{-1} RB5 dye in BRB solution at pH 4.0

The effect of the RB5 dye concentrations was investigated and the results showed that the E_p of RB5 dye at -258 mV showed no significant change in the peak position and the I_p of the RB5 dye increased with the increasing concentration of RB5 dye. This phenomenon confirmed the adsorption of the RB5 dye at the mercury electrode surface [32]. No new peak was observed with the increasing RB5 dye concentration at both the cathodic and anodic directions, which indicated that the obtained reduction peaks were due to respective RB5 dye and not from other electroactive species that may be present in the BRB solution [33].

The effect of repetitive cycles on the I_p of the RB5 dye was studied with five cycles. The I_p decreased in the second cycle and was almost constant for the third, fourth and fifth cycle, as shown in Figure 4. This meant that the variation of I_p was controlled by diffusion in the experimental condition [34] and RB5 dye had the adsorption behaviour at the surface of the mercury electrode [35].

Differential pulse stripping voltammery of the RB5 dye: The effects of pH of BRB solution

Differential pulse cathodic stripping voltammetry of 2 x 10^{-6} molL^{-1} RB5 dye was studied in 0.04 M BRB solution from pH 2.0 to 12.0. BRB solution at pH 2.5 was considered as the optimum pH since the highest I_p and well-defined shape of the first reduction peak were obtained. The voltammogram of RB5 dye in BRB solution at pH 2.5 is shown in Figure 5. The E_p of RB5 dye peak shifted to more negative potentials as the pH of BRB solution increased, indicating the involvement of H^+ in the reduction process of RB5 dye [36].

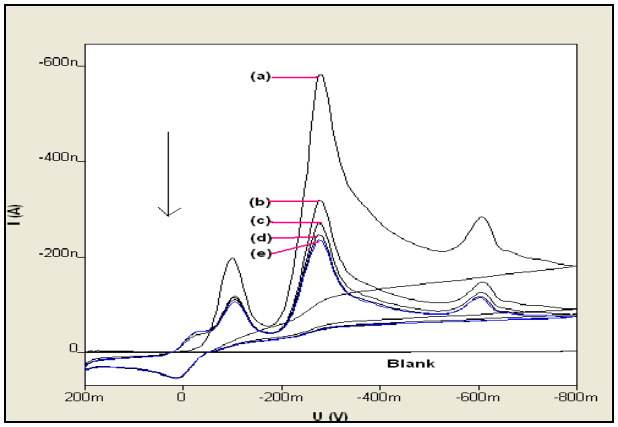

Figure 4. Cyclic voltammograms of repetitive cycles of 2 x 10^{-4} $molL^{-1}$ RB5 dye in BRB solution at pH 4.0. (a) First (b) second (c) third (d) fourth and (e) fifth cycle

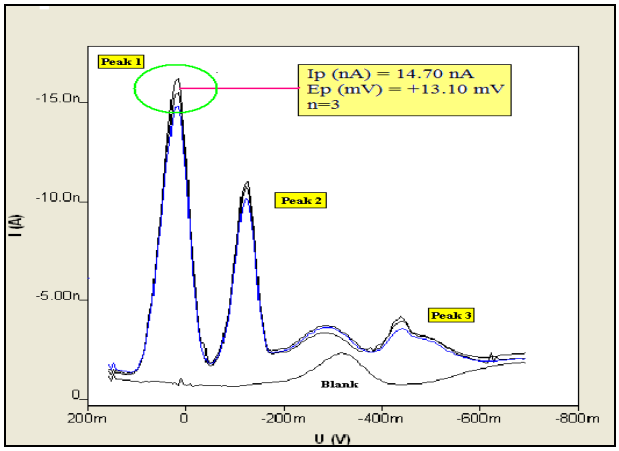

Figure 5. Voltammogram of 2 x 10^{-6} $molL^{-1}$ RB5 dye in BRB solution at pH 2.5. Parameters conditions: E_i = +150 mV, E_f = -700 mV, v = 15 mV/s, t_{acc} = 0 s, E_{acc} = 0 mV and pulse amplitude = 50 mV

Optimization of the operational parameters

It is very important to optimize all the parameters that may influence the measurements in order to obtain the optimum response [37]. The effects of scan rate (v), accumulation time (t_{acc}), accumulation potential (E_{acc}) and pulse amplitude on the I_p of 2 x 10^{-6} $molL^{-1}$ RB5 dye were studied in the BRB solution at pH 2.5.

The effect of scan rate (v)

The relationships of I_p of the RB5 dye to various v such as 5, 10, 15, 30 and 40 mV/s were observed using the unoptimum parameters. The v of 5 mV/s was chosen as the optimum condition since it gave the highest I_p of the first reduction peak of the RB5 dye which was 16.10 nA.

The effect of accumulation time (t_{acc})

Accumulation of electroactive species at the electrode contributed to a high response in the electroanalytical measurements [38]. Accumulation time (t_{acc}) is the period of time given for the RB5 dye to accumulate onto the mercury electrode surface before being analyzed. The dependence of I_p on the t_{acc} was studied at concentration of 2 x 10^{-6} $molL^{-1}$ RB5 dye over the range from 0 to 110 s.

At t_{acc} of 0 s, the first reduction peak of RB5 dye gave a higher I_p compared to the second reduction peak. The I_p of the second reduction peak had become dominant, starting from t_{acc} of 10 s and onwards. The second reduction peak was referred as the analytical signal for further optimization since it showed higher I_p as the t_{acc} increased. From Figure 6, the I_p increased with the increasing t_{acc} from 0 to 80 s, then became constant with the longer times. The t_{acc} of 80 s was chosen as the optimum condition with I_p of 121 nA at E_p of -88 mV.

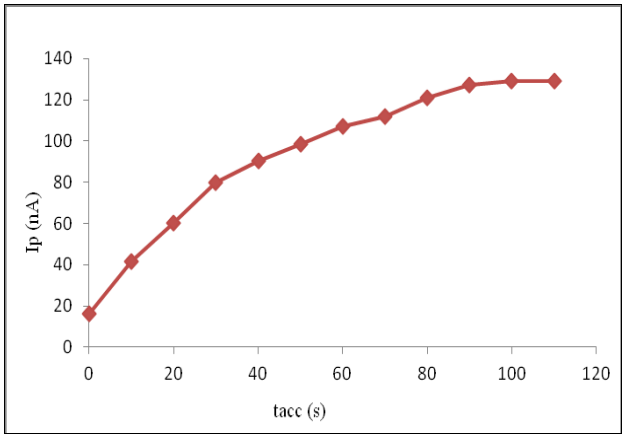

Figure 6. Effect of various t_{acc} on the I_p of second reduction peak of 2 mg/L RB5 dye in BRB solution at pH 2.5. Initial instrumental parameters were E_i = +150 mV, E_f = -650 mV, v = 5 mV/s, E_{acc} = 0 mV and pulse amplitude = 50 mV

As suggested by Tavares et al. [39], the increase of I_p with t_{acc} was due to the accumulation of RB5 dye at the mercury electrode surface in a larger amount, since longer time was given for the accumulation process to occur. The constant I_p that was obtained at longer 90 s had been suggested due to the saturation of the accumulated RB5 dye at the electrode surface [40].

The effect of accumulation potential (E_{acc})

Accumulation potential (E_{acc}) was the potential for the RB5 dye to be accumulated at the surface of mercury electrode, whereas an optimum E_{acc} was the most appropriate potential for the accumulation process to take place. The effect of E_{acc} on the I_p of the second reduction peak was evaluated over the range of 0 to -100 mV for 2 x 10^{-6} $molL^{-1}$ RB5 dye. The maximum response was observed at E_{acc} of 0 mV with I_p of 120 nA at E_p of -82.10 mV. It indicated that the accumulation of RB5 dye at the electrode surface effectively occured at 0 mV.

The effect of pulse amplitude

According to De Lima et al. [41], pulse amplitude is one of the factors that affect the sensitivity of voltammetric measurements. The effect of pulse amplitude on the I_p was studied by measuring 2 x 10^{-6} $molL^{-1}$ RB5 dye within the range of 25 to 125 mV of pulse amplitude, under the previous optimum parameters. Figure 7 shows that the I_p has sharply increased at the range of pulse amplitude from 25 to 75 mV and slowly decreased at higher values. The E_p has shifted towards less negative directions as the values of pulse amplitude increased.

The pulse amplitude of 75 mV was noted as the optimum condition due to the highest I_p observed which was 223 nA with E_p at -65.50 mV. By changing the pulse amplitude, the E_i was changed from +150 mV to +250 mV and the E_f was changed from -650 mV to -600 mV in order to observe the first reduction peak on the voltammograms.

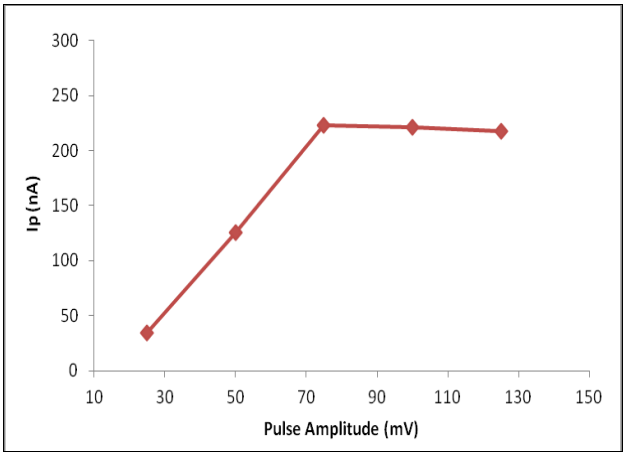

Figure 7. Effects of various pulse amplitudes on the I_p of 2 mg/L RB5 dye in BRB solution at pH 2.5. Initial instrumental parameters were E_i = +150 mV, E_f = -650 mV, v = 5 mV/s, t_{acc} = 80 s and E_{acc} = 0 mV

By applying these optimized parameters, the I_p was enhanced about 24 times, compared to the obtained I_p by using the unoptimized parameters which was 9 nA at E_p of -121 mV. Table 1 shows the optimum supporting electrolyte and instrumental parameters of the developed DPCSV technique of 2 x 10^{-6} $molL^{-1}$ RB5. These optimum parameters were then used to validate the developed method.

Table 1. Optimum supporting electrolyte and instrumental parameters of the developed DPSCV technique

Supporting Electrolyte and Instrumental Parameters	**Optimum Value**
Britton-Robinson Buffer (BRB)	pH 2.5
Initial Potential, E_i (mV)	+250
End Potential, E_f (mV)	-600
Scan Rate, v (mV/s)	5
Accumulation Time, t_{acc} (s)	80
Accumulation Potential, E_{acc} (mV)	0
Pulse Amplitude (mV)	+75

Validation of the developed method: Linearity, limit of detection, limit of quantification

The applicability of the developed DPCSV technique as an analytical method for the determination of RB5 dye standard solution was examined by measuring the obtained I_p as the function of concentration under the optimum operational and instrumental parameters as shown in Table 1.

Two linear regions were observed and the I_p of RB5 dye tended to maintain, starting at the concentration of 1.6 x 10^{-5} $molL^{-1}$. As suggested by Geremedhin et al. [42] and Radi et al. [43], this phenomenon may be due to the limited adsorption of RB5 dye at the mercury electrode, which resulted from the saturation of the electrode surface. As shown in Figure 8, the first linear region demonstrated its linearity from 2.5 x 10^{-7} $molL^{-1}$ to 2.0 x 10^{-6} $molL^{-1}$ at five different concentrations of RB5 dye standard solution. The constructed calibration graph was represented by the linear equation of I_p (nA) = 115.61 x – 10.31 with a correlation coefficient (R^2) of 0.9998. The second region was linear from 3.0 x 10^{-6} $molL^{-1}$ to 1.4 x 10^{-5} $molL^{-1}$ with the regression equation of I_p (nA) = 11.76 x + 211.56 and R^2 of 0.9987. The first linear region demonstrated a bigger slope than the second region, thus it was applied for RB5

dye determination since a higher sensitivity had been offered for analysis [44]. The calculated LOD for the standard solution was 1.3 x 10^{-8} molL^{-1} and the LOQ was found to be 4.3 x 10^{-8} mol L^{-1}.

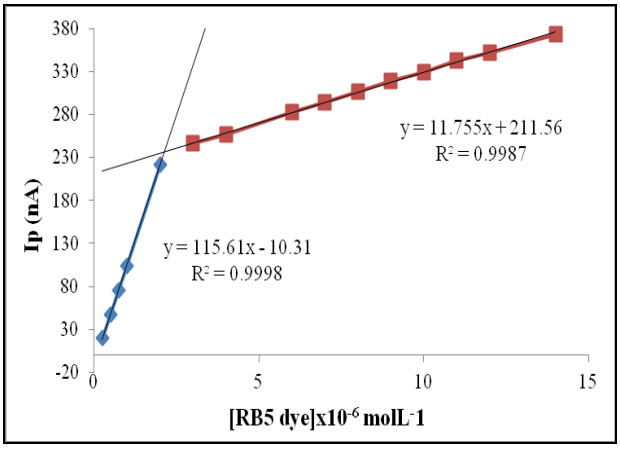

Figure 8. Two linear curves of RB5 dye in BRB solution at pH 2.5. (a) 2.5 x 10^{-7} to 2.0 x 10^{-6} molL^{-1} and (b) 3.0 x 10^{-6} to 1.4 x 10^{-5} molL^{-1}

Precision

The precision of the developed technique for RB5 dye determination was determined in five replicate measurements (n=5) at a concentration of 2.0 x 10^{-6} molL^{-1} [45]. The relative standard deviation (RSD) of 0.55% had been achieved for the measurements which indicated that the developed method was precise and confidence as the value was less than 2% [46]. The intra-day and inter-day repeatability studies were carried out by measuring 2.0 x 10^{-6} molL^{-1} RB5 dye for five replicates in three consecutive days using the developed technique. The RSD values for day 1, 2 and 3 were 0.55%, 0.24% and 0.40%, respectively which also indicated that the developed method was precise and confidence.

Accuracy

The accuracy of the developed technique was tested by spiking three known different concentrations of RB5 dye which were 5 x 10^{-7} molL^{-1}, 1.0 x 10^{-6} molL^{-1} and 2.0 x 10^{-6} molL^{-1} into a voltammetric cell containing BRB solution [47]. These spiked RB5 dye standard solutions were measured in three replicates (n=3) and the discovered amounts of the spiked solutions in the cell were calculated using the equation of I_p (nA) = 115.61 x – 10.31, where x is the found concentrations of RB5 dye in the voltammetric cell. The satisfactory recoveries of 99.94 ± 3.15%, 99.16 ± 1.80% and 100.61 ± 1.09% were respectively achieved for the spiked concentrations of 5 x 10^{-7} molL^{-1}, 1.0 x 10^{-6} molL^{-1} and 2.0 x 10^{-6} molL^{-1}.

Ruggedness

The RSD values were 0.49% and 0.38% for the first and second analyst, respectively for the measurements using the same voltammetry analyzer (VA 757). The RSD values were 0.49% and 0.20% for the analysis using the respective VA 757 and VA 797 (different voltammetry analyzers) by the first analyst. From the two-tailed *F* test, there were no significant differences between the obtained variances for RB5 dye when the measurements were performed by two different analysts with the same voltammetry analyzer and by the same analyst with two different voltammetry analyzers at the 5% significance level. Hence, the results indicated that the developed technique was considered rugged.

Robustness

By the two -tailed *F* test at 95% confidence level, none of small variations of the *v* (3 and 7 mV/s), t_{acc} (78 and 82 s), time interval analysis after the standard preparation (0, 30 and 60 minutes) and pH of BRB solution (pH 2.3 and 2.7)

had significantly influenced the obtained I_p of RB5 dye at the concentration of 2.0 x 10^{-6} molL^{-1} with five replicate (n=5) measurements [48, 49].

Determination of RB5 dye in wastewaters collected from the batik industry

To evaluate the application to a real samples analysis, the developed DPCSV technique was used to analyze RB5 dye in wastewater samples which were collected from the local batik factories. The wastewater samples were analyzed by the developed technique under optimum parameters without any sample pre-treatment. Table 2 shows the content of RB5 in the collected batik wastewater samples.

Table 2. The concentrations of RB5 dye in the batik wastewater samples from the first and second dyebath

Samples (First Dyebath)	Concentration of RB5 (x 10^{-6} mol/L)	Samples (Second Dyebath)	Concentration of RB5 (x 10^{-6} mol/L)
S1-A1	0.493	S1-B1	N.D
S2-A1	N.D	S2-B1	N.D
S3-A1	0.324	S3-B1	N.D
S4-A1	0.236	S4-B1	N.D
S5-A1	N.D	S5-B1	N.D
S6-A1	0.421	S6-B1	0.235
S7-A1	0.183	S7-B1	N.D
S8-A1	N.D	S8-B1	N.D
S9-A1	N.D	S9-B1	N.D

N.D: not detected

To verify these results, recovery experiments were carried out by spiking three different concentrations of RB5 standard solution with the concentrations of 0.5 x 10^{-6}, 1.0 x 10^{-6} and 2.0 x 10^{-6} molL^{-1} into the wastewaters collected from the batik factories that did not contain RB5 dye. The experiments were carried out using four wastewater samples (S1-B1, S2-B1, S5-B1 and S8-B1) with three replicate (n=3) measurements per each spiked concentration. The recoveries achieved for 0.5 x 10^{-6}, 1.0 x 10^{-6} and 2.0 x 10^{-6} molL^{-1} RB5 dye were from 83.97 ± 4.78 to 97.93 ± 5.45%, 95.91 ± 2.68 to 103.49 ± 1.32% and 99.17 ± 0.75 to 105.12 ± 0.28%, respectively. According to the *t*-test (two-tailed), there were no significant differences between the recovery and spiked value at the 95% confidence level with degree of freedom (n-1=2), since all the calculated *t* values in the experiment were lower than the theoretical *t* value, which was 4.303 [50, 51]. These good recovery values indicated that the matrixes did not affect the determination of RB5 dye in batik wastewater samples and it was suggested that the developed method can be applied for RB5 dye determination in the batik wastewater samples without any sample pre-treatment. The recovery results are listed in Table 3.

Comparison of the results by the developed DPCSV technique and spectrophotometry method

The performance of the developed DPCSV technique in determining the RB5 dye was then compared against UV-VIS spectrophotometry [52]. Spectrophotometry measurements of RB5 dye in the range of 300 to 700 nm had shown that the highest absorbance was obtained at 596 nm which was attributed to the diazo groups and responsible for the blue colour of the dye solution [53]. The calibration curve was constructed and a linear range was found from 1.0 x 10^{-6} to 1.5 x 10^{-4} molL^{-1} with the regression equation of $y = 0.0225 x + 0.0287$ ($R^2 = 0.9991$), as shown in Figure 9. The LOD and LOQ were 0.4 x 10^{-7} molL^{-1} and 1.3 x 10^{-7} molL^{-1}, respectively.

Table 3. Analytical results of RB5 dye in batik wastewater samples using the developed technique

Samples	Spiked[a] amount ($x10^{-6}$ $molL^{-1}$)	Found[a] amount ($x10^{-6}$ $molL^{-1}$)	Recovery ± SD (%)	RSD (%)
S1-B1	0.5	0.44	88.30 ± 7.69	8.71
	1.0	0.97	97.37 ± 1.42	1.46
	2.0	1.99	99.75 ± 0.66	0.66

[a]Average of three replicate measurements for each spiked concentration

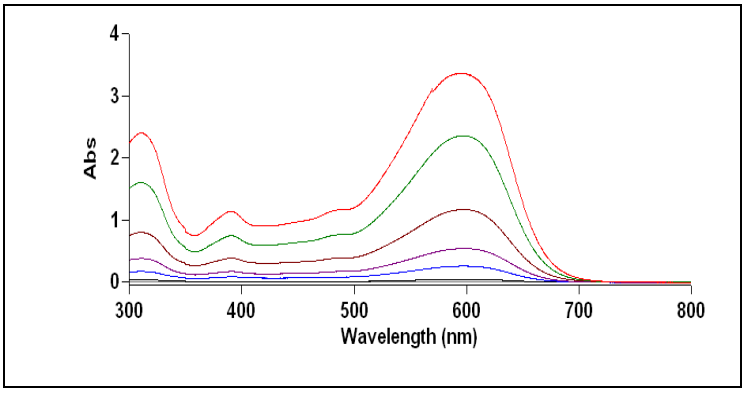

Figure 9. Spectra of RB5 dye with increasing concentration from 1.0 x 10^{-6} to 1.5 x 10^{-4} $molL^{-1}$

The results obtained by both developed DPCSV and spectrophotometry method in analyzing RB5 dye in the several wastewaters samples collected from the batik factories were then compared, as shown in Table 4. The developed DPCSV technique can be considered more sensitive as it had an ability to detect and determine the dye at a lower level compared to the UV-VIS Spectrophotometry method.

Table 4. The concentrations of RB5 dye in the batik wastewater samples using two different methods

Samples	Concentration of RB5 (x 10^{-6} mol/L)

Conclusion

The developed DPCSV technique had been succesfully applied to determine the RB5 dye in wastewaters from the batik industry. The present method had an advantage that no prior extractions or samples pre-treatment were required. It was also found to be practically rapid, convenient, sensitive, accurate, precise, rugged, robust and low in cost compared to the UV-VIS Spectrophotometry method. Therefore, it could be an excellent alternative method for the routine determination of RB5 dye in batik wastewaters samples.

Abstract

Protein Arginine Deiminase IV (PAD4) is a promising target for treating rheumatoid arthritis. Here, an *in-silico* screening was performed using PAD4 crystal structure against National Cancer Institute Diversity Set III compounds. Results obtained from the docking studies showed that the compounds have high affinity towards the protein. Visual inspections of the top compounds indicated that they preferred to bind at the front door of the catalytic pocket instead of the back door. The current results from this screening could provide a basis for the development of new PAD4 inhibitors.

Keywords: protein arginine deiminase IV, PAD4, virtual screening, NCI diversity set, structure-based

Abstrak

Protin arginina deiminase IV (PAD4) adalah sasaran yang berharapan untuk merawat artritis reumatoid. Di sini, satu saringan *in-silico* telah dilakukan menggunakan struktur kristal PAD4 terhadap molekul dari Set Beraneka Institut Kanser Nasional III. Keputusan dari pengdokan molekular menunjukkan molekul-molekul tersebut mempunyai daya tarikan yang tinggi terhadap protin. Pemeriksaan secara visual ke atas molekul teratas menunjukkan mereka mempunyai kecenderungan untuk terikat di pintu hadapan poket katalisis daripada di pintu belakang. Keputusan daripada pencarian ini boleh menjadi asas kepada penemuan perencat PAD4 yang baru.

Kata kunci: protin arginina deiminase IV, PAD4, pencarian maya, set beraneka NCI, struktur berasas

Introduction

Protein citrullination is a post-translational modification process, which converts peptidyl-bound arginine into peptidyl-bound citrulline (see Figure 1) [1]. This process is catalyzed by calcium-dependent enzyme called protein arginine deiminase (PAD) [2]. To date, there are five PAD isozymes reported, namely PAD1, PAD2, PAD3, PAD4 and PAD6, where each of them has specific expression place in human body [3]. Among all isozymes, PAD4 has

been linked to an inflammatory disease called rheumatoid arthritis [4]. Overexpression of PAD4 and citrullinated products was found to break the immune system tolerance and produce autoantibody responses against them, which consequently leads to the disease onset. Therefore, modulation of PAD4 activities is considered as an alternative therapeutic strategy against the disease.

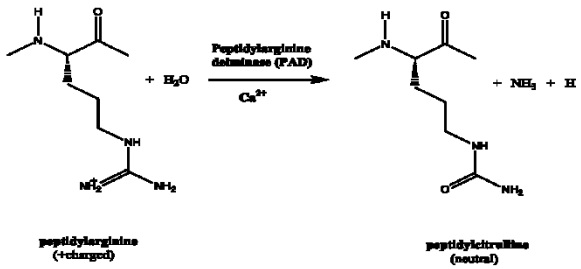

Figure 1. Citrullination process to convert peptidylarginine to peptidylcitrulline

Many researches have been conducted to design and discover PAD4 inhibitors. Based on the crystal structure of PAD4 in complex with small substrate, benzoyl-arginine amide [5], the citrullination process was catalyzed by four key residues, namely D350, H471, D473 and C645. These residues are arranged in a close proximity causing the overall shape of the pocket to be considerably narrow and deep. This significantly influenced PAD4 drug designs and studies were aimed at discovering an improved binding to one or more of the key residues [6-8]. Recent reports on PAD4 inhibitors [9] showed that the GSK199 and GSK147 compounds were binding the protein via another entrance of the catalytic pocket. The anchoring by residue N588 helps the GSK compounds to interact with H471 and distracts the protein activity. The knowledge about the entrance or the 'back door' has expanded the overall view of the pocket (see Figure 2).

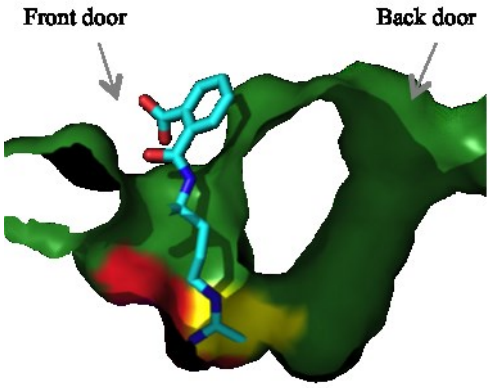

Figure 2. Two accessible doors of PAD4 catalytic pocket. Ligand such as *o*-F-amidine (rendered as blue stick) is bound at the front door. The main catalytic residue C645 is colored in yellow and H471 is colored in red.

Structure-based virtual screening (SBVS) has become an essential tool for drug pre-screening [10]. This approach is dependent on three-dimensional structures of target of interest i.e. protein, in which specific location on the protein can be aimed. The underlying concept in SBVS is the use of molecular docking algorithm to predict ligand poses corresponds to target of interest [11]. The method to evaluate the poses may include binding energies/affinities and reasonable binding interactions. SBVS has been applied in the previous PAD4 inhibitor screening [12]; however, the study was limited to exploring the PAD4 front door. Considering the potential of the PAD4 back door, it is

important that both doors should participate during the screening process. Here, we report SBVS performed using PAD4 crystal structure. The subjects of this study are from the National Cancer Institute Diversity Set 3 (NCIDS3), which is a compilation of pharmacophores with diverse skeleton and functional groups [13]. The poses of the compounds were predicted and evaluated computationally. It is hoped that the findings from this study can provide insight for searching and improvising PAD4 inhibitors.

Materials and Methods

Molecular docking

All molecular docking procedures were performed using AutoDock Vina program [14]. The crystal structure of PAD4 in complex with *o*-F-amidine inhibitors (PDB ID: 3B1U) [8] was used as receptor and control docking. Compounds from the previous PAD4 inhibitor screening report were used as reference compounds [15]. The NCIDS3 containing a total of 1880 ligands were downloaded in mol format from the ZINC database [16]. AutoDockTools version 1.5.6 [17] was used to add polar charges, assign Gasteiger charge [18] and prepare the input files.

Covalent docking protocol was applied exclusively for the control since the inhibitor was bound to PAD4 irreversibly [19-20]. This was achieved by docking a water molecule while setting the covalently bonded co-crystallized ligand, *o*-F-amidine to the thiol group of C645 as flexible residue. The volume of the grid box was 27 Å by 31 Å by 36 Å with a 1.0 Å spacing. The grid box was placed on the coordinate of -26.69, 14.74 and -28.8 centered on H640 to encompass both possible binding sites, namely the front door and the back door. The exhaustiveness was set to 8, while the number of run was set to 9. For the reference compounds and NCIDS3 ligands, conventional rigid protein and flexible ligand docking were performed while maintaining all the docking parameters.

In this work, the NCIDS3 ligands are referred to by their NCI index number (also known as the NSC number). For each ligand, the highest-affinity conformation of the docking result was selected as the docked pose for the ligand. The complexes were sorted by lowest binding affinity values. Complexes with predicted binding affinity equal to or less than -8.0 kcal/mol were filtered based on Lipinski's rule of 5 [21], here describes as: 1) molecular weight less than 500 g/mol, 2) number of hydrogen bond donor less than 5, 3) number of hydrogen bond acceptor less than 10 and 4) log P value less than 5. Only compounds that fulfilled all the criteria were further inspected. Analysis of the docking results was performed using AutoDock Vina shell script. The two-dimensional ligand structures were retrieved from chemicalize.org [22]. Analysis of binding interaction was performed using LigPlot^{+} [23]. Visualization and rendering routines for the docking complexes were done using Pymol version 1.4.1 [24].

Results and Discussion

Validation of docking parameters

The *o*-F-amidine ligand was redocked in consistent manner as seen in the crystal structure as shown in Figure 3. The all-atom RMSD of the predicted pose with respect to its crystallized pose was 1.06 Å. The main difference between the docked pose and the crystallized pose was observed at the benzene carboxylate group. The group was interacting with inconsistent hydrophobic contact. Autodock 4 [25] was also tested as alternative docking tool, however higher RMSD value was found as compared to the one obtained using Vina. The redocking was successful, indicating that dependability of AutoDock Vina in predicting ligand experimental pose.

In conventional virtual screening routine, the accuracy of any computational docking protocol is assessed using inhibitors with known activity against the target. It is a vital step in order to justify the current parameters used. Here in our case, we look forward to ensure that the protocol was suitable and reliable to distinguish and rank PAD4 inhibitors. To achieve the goal, a set of compounds with known PAD4 inhibitions (here labeled as S1 to S12) reported by Bozdag et al. was used [15].

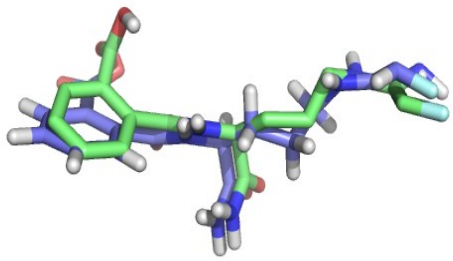

Figure 3. Redocking of *o*-F-amidine. The docked pose was rendered in green, while the crystallized structure was in purple

Table 1 showed the experimental inhibition, experimental rank, predicted binding affinity and predicted rank for compounds S1-S12. As can be seen from the table, it was obvious that Vina fairly predict the ranking of each compound. There was undoubted correlation between the compounds which having the high inhibition and its predicted binding affinity. Visual inspection of the docked poses showed that 11 out of 12 compounds have preference to bind at the front door; only compound S5 was seen to occupy the back door. Although the compounds with low inhibition were not in the exact rank, but it did pick the overall binding trend. Vina was able to distinguish between the high-ranked compounds (i.e. compound S11) and the low-ranked compounds (i.e. compound S4). These results suggested that predicted ranking reflect the experimental ranking with moderate degree of accuracy.

Table 1. Predicted binding affinity and ranks for compounds by Bozdag et al. [15]. The experimental inhibitions were listed for reference purposes.

Compound	% Inhibition at 10 µM	Experimental Rank	Predicted Binding affinity (kcal/mol)	Predicted Rank
S1	6	7	-5.7	7
S2	3	9	-6.0	6
S3	5	8	-6.2	5
S4	1	10	-5.2	8
S5	7	6	-6.0	6
S6	5	8	-4.8	9
S7	3	9	-6.2	5
S8	8	5	-6.8	4
S9	10	3	-6.9	3
S10	34	2	-7.3	2
S11	36	1	-7.4	1
S12	9	4	-5.5	8

Structure-based virtual screening of NCIDS3

It is interesting to observe that ligands from NCIDS3 are in similar predicted binding affinity window as the known PAD4 inhibitors [15]. The plot of number of ligands with respect to their binding affinity range as shown in Figure 4 followed a bell-shaped trend, with majority population lies within the range of -6.0 kcal/mol. In prior to this study, focus was given to compounds that were predicted to have binding affinity equal to or less than -8.0 kcal/mol. This cut-off criterion of -8.0 kcal/mol was imposed as the first filter to yield compounds with predicted binding affinity lower than the predicted binding affinity of the known PAD4 inhibitors (see Table 1) [15]. Even though this NCIDS3 screening have not yet been validated experimentally, the work here is promising, given that half of the shortlisted compounds were predicted to be binding the protein via similar interacting residues with that seen in the crystal structure [8]. All shortlisted compounds were observed to dock at the traditional front door area instead of the back door. The top 11 compounds together with their predicted binding affinity were listed in Table 2.

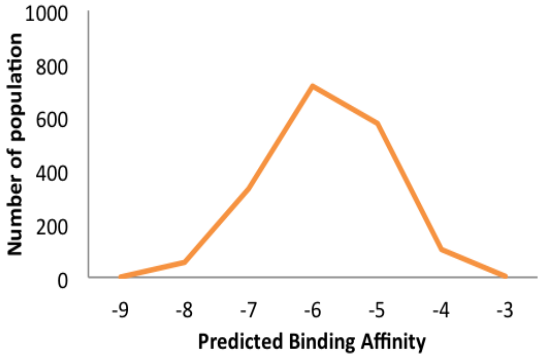

Figure 4. Binding affinities distribution of all NCIDS3 compounds towards PAD4 crystal structure (PDB ID: 3B1U)

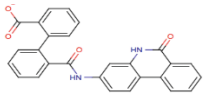
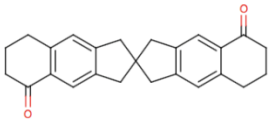
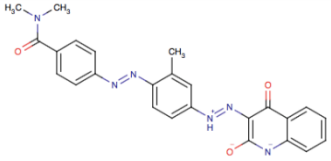
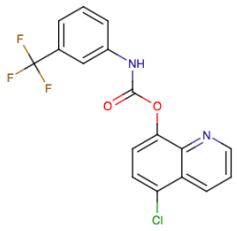
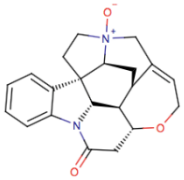
Table 2. List of potential PAD4 inhibitors

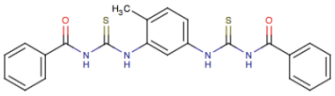


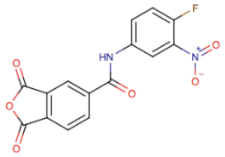


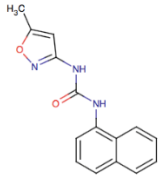


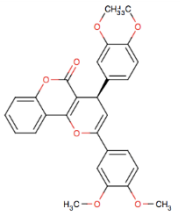


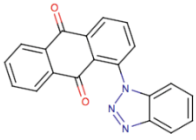


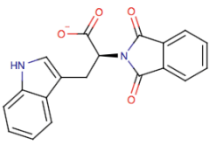












Number	NSC number	Structure	Predicted Binding Affinity (kcal/mol)
1	127133		-8.8
2	670283		-8.6
3	58052		-8.4

Table 2 (cont.). List of potential PAD4 inhibitors

Number	NSC number	Structure	Predicted Binding Affinity (kcal/mol)
4	377852		-8.4
5	24951		-8.3
6	5856		-8.2
7	215629		-8.2
8	203837		-8.1
9	211490		-8.1
10	80313		-8.0
11	401077		-8.0

The ligands were found to linger around the front door region. None of the compounds were able to approach the main catalytic residue C645, possibly because of ring skeleton possesses by each compound. An example of the docked poses was depicted in Figure 5a. There was no specific trend in the type of ligand; but it was observed that each of them contains carbonyl group to assist interactions. For example, Compound 6. As can be seen in Figure 5b, Compound 6 made four hydrogen bonds and six hydrophobic contacts at the front door region. The first two hydrogen bonds were formed between the indole nitrogen of W347 and guanidinium nitrogen of R374 with the carbonyl group of Compound 6. The third hydrogen bond was established between the carbonyl group of R639 backbone and nitrogen atom of Compound 6. Another hydrogen bond was formed between the hydroxyl group of S468 and nitrogen atom of Compound 6. The compound also formed non-hydrogen-bonding interactions with G403, S406, V469, L578 and H640.

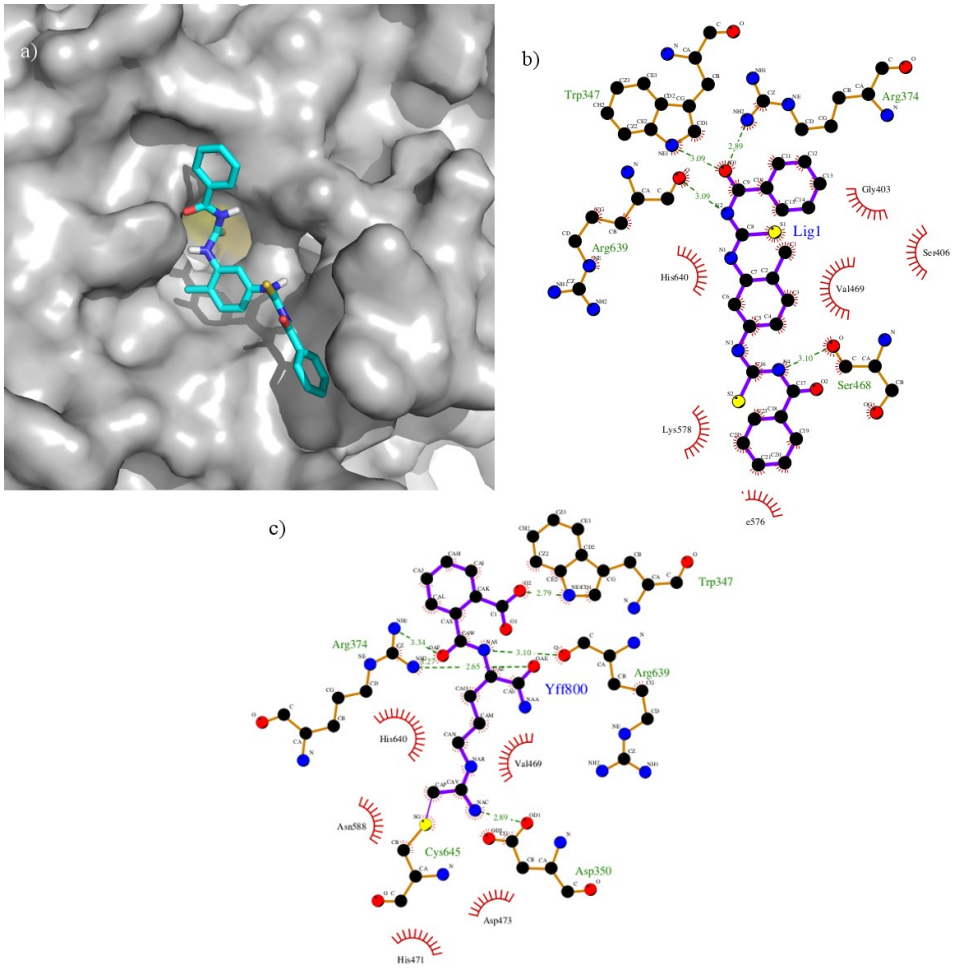


Figure 5. a) Docked pose of Compound 6 (rendered in cyan stick). PAD4 was shown as grey surface. C645 was colored in yellow. Other parts of the protein were discarded for visualization purpose, b) Interaction between PAD4 and Compound 6, c) Interaction of PAD in complex with *o*-F-amidine as reference [8].

Although Compound 6 did not interact with the main catalytic residue, C645, it interacted with important residues at the mouth of the pocket such as R374 and W347. Such interactions were also seen in PAD4-substrate/inhibitor complexes, as illustrated in Figure 5c. Arginine has high tendency to facilitate hydrogen bonds, since it is possible for the guanidinium side chain to donate five hydrogen bonds. Previous mutagenesis study revealed that the residue

R374 was important in PAD4 substrate recognition [26]. The role of W347 was also been studied [8,26]. Located at the line of the active site, the residue was observed to assist interaction via its indole nitrogen. Based on the above information, it is anticipated that the shortlisted compounds in theory would interfere with the binding of substrate to the catalytic residues. Undoubtedly, these compounds will need further optimization because of their current binding interaction. For improved binding, elongation of the compounds towards the active site tunnel may be required.

It is noticeable that the shortlisted compounds preferred to occupy the front door rather than the back door. This may be due to the use of bound front door protein structure. Since the back door did not contain any ligand, the shape of this entrance was not visibly made to occupy a ligand. To exclude the bias, it is suggested to use multiple protein structures to accommodate binding site dynamics in future screening.

Conclusion

SBVS has been successfully performed on PAD4 crystal structure using ligands from NCIDS3. This work indicates that NCIDS3 could serve as a good dataset for searching potential PAD4 inhibitors. All shortlisted compounds have preference to occupy the front door with good binding affinities. The compounds are ready to be tested experimentally. It may not be adequate to use only single protein structure in virtual screening, as binding site dynamics is unattainable. Future works suggested include flexible protein-flexible ligand docking and ensemble-based virtual screening.

Abstract

Cationic starch-based polymeric surfactant, 2-hydroxy-3-(N,N,N-trimethylammonium)propyloxy starch (S-ETAC) from *Dioscorea pyrifolia* tubers, was synthesized by etherification using 2,3-epoxytrimethylammonium chloride (ETAC) in the mass ratio of ETAC/starch (St) of 0.15:1, 0.25:1, 0.5:1, 1:1, 2:1 g/g and sodium hydroxide as a catalyst in aqueous medium. The degree of substitution (DS) and reaction efficiency (RE) were calculated using the percentage of nitrogen derived from the elemental analysis. The study found that the more the ETAC used, the higher the DS (0:11 to 0.76), but the RE decreased (69% to 35%). This S-ETAC was characterized by using the solubility and swelling power tests as well as attenuated total reflectance - Fourier transform infra-red (ATR - FTIR) spectroscopy, differential scanning calorimetry (DSC) and X-ray diffraction (XRD) to prove the reaction occurs at the starch structure.

Keywords: cationic starch, etherification, *Dioscorea pyrifolia*

Abstrak

Surfaktan polimer berasaskan kanji kationik, kanji 2-hidroksi-3-(N,N,N-trimetilammonium)propiloksi (S-ETAC) dari ubi *Dioscorea pyrifolia*, telah disintesis melalui tindak balas pengeteran menggunakan 2,3-epoksitrimetilammonium klorida (ETAC) dalam nisbah jisim ETAC/kanji (St) 0.15: 1, 0.25: 1, 0.5: 1, 1: 1, 2: 1 g/g dan natrium hidroksida sebagai pemangkin dalam medium akueus. Darjah penukargantian (DS) dan kecekapan tindak balas (RE) telah dikira menggunakan peratusan nitrogen yang diperolehi daripada penganalisis unsur. Kajian ini mendapati bahawa lebih banyak ETAC yang digunakan, semakin tinggi DS (0.11 kepada 0.76), tetapi RE menurun (69% kepada 35%). S-ETAC dicirikan dengan menggunakan ujian keterlarutan dan kuasa pembengkakkan serta spektroskopi transformasi Fourier inframerah - jumlah pantulan teratenuat (FTIR - ATR), kalorimetri pengimbas pembezaan (DSC) dan pembelauan sinar-X (XRD) untuk membuktikan bahawa tindak balas berlaku pada struktur kanji.

Kata kunci: kanji kationik, pengeteran, *Dioscorea pyrifolia*

Introduction

Starch modification is an alternative industry nowadays to meet the growing demand, reduce the cost of raw materials and reduce environmental pollution. The usage of native starch is usually limited due to its physicochemical properties that are not water-soluble and tend to form a non-stable emulsion. Thus, starch modification via physical, chemical or biological is used to increase the functionality that able to expand into to industrial use and has better features in terms of functional group and solubility [1]. Chemically modified starch

typically involves esterification, etherification or oxidation of hydroxyl groups on the α-D-glucopyranosyl of the starch structure. Most of the commercialized starches produced by adding reactants and organic solvents to the starch solution at control pH 7-9 for esterification [2] and pH 11-12 for etherification at temperatures above 60 °C [2, 3].

Cationic starches from sources such as corn, tapioca, wheat and potato have been widely used in the production of paper, textiles, cosmetics and treatment of waste water because they can improve the properties of surface, viscosity, retention performance and change the properties of colloids [2]. Cationic starches commonly used in most products which contained 0.1 – 0.4% nitrogen (< 0.05 DS) [2]. In previous studies, modified corn starch used quaternary ammonium group and dioxane-water-THF as the medium to produce cationic starch with DS 1.37 [3]. Reaction of corn starch with quaternary ammonium in the ionic liquid produced cationic starch with DS of 0.99 [1]. Homogenous reaction conditions using medium DMSO can increase the DS compared to heterogeneous reaction condition in ethanol/water medium [4]. Although there are several ways of obtaining cationic starches with high DS, the use of harmful solvents, difficult in purification process and high cost of solvents limits the production of the cationic starches. Conventional methods which use a lot of organic solvents are not only reduce the DS but also increase pollution to the environment [1].

Dioscorea pyrifolia is a monocot plants possess edible tubers, grown and sold in markets at east coast states of Malaysia [5]. The tubers are called "Ubi Itik" among the people in these states. Although cationic starches from sources as corn, tapioca, wheat and potato is an important product in the industry [2], the preparation and properties of cationic starch from *Dioscorea pyrifolia* tubers are not been reported yet. The information on the modified starch from this plant is still limited to the industry. In this study, a cationic starch-based surfactant from *Dioscorea pyrifolia* tubers is synthesized through etherification of ETAC and aqueous NaOH as a catalyst (Figure 1) using semi-dry method. The effect of the increasing ETAC in the NaOH/water medium was investigated with the calculation of the degree of substitution (DS) and reaction efficiency (RE) using percentage of nitrogen obtained from elemental analyzer. Then, the S-ETAC is characterized to ensure that the reaction occurs in the structure of the starch.

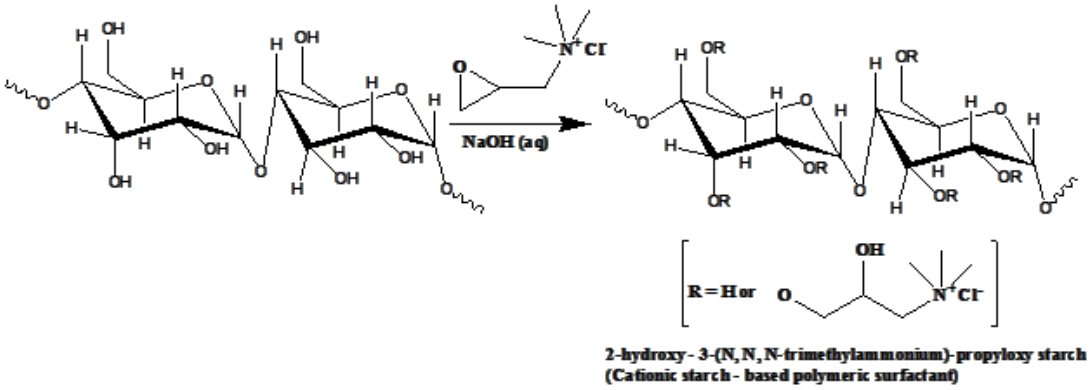

Figure 1. Synthesis of cationic starch-based polymeric surfactant

Materials and Methods

Materials

Starch was extracted from *Dioscorea pyrifolia* tubers taken in Kelantan, Malaysia. Chemicals used in this study are 2,3-epoxytrimethylammonium chloride (Sigma-Aldrich, >90%, technical grade), sodium hydroxide (R & M Chemical, 95%), ethanol (R & M Chemical, 95%, analytical grade) and acetone (EMSURE, 99.5%, analytical grade). Sodium hydroxide solution was prepared using deionized water.

Synthesis of cationic starch-based surfactant

The cationic starch-based polymeric surfactant was prepared by semi-dry process in a series of mass ratio ETAC:St starting with 0.15:1, and varying the masses of ETAC to 0.25, 0.5, 1 and 2 in 4 mL of 0.1 g/mL NaOH solution. The process was initiated by putting 1.5 g ETAC in a beaker containing the NaOH solution and stirred for 5 minutes. Then 10 g of starch incorporated into the solution and stirred, resulting in dough. It was heated in a water bath at 80 °C for 2 hours, and 4 mL water was added into the beaker to stop the reaction. Ethanol (5 mL) was added to the beaker and stirred to wash away the unreacted reagents. Next, acetone (10 mL) was added into the beaker so that the S-ETAC precipitates. The S-ETAC was rinsed three times with ethanol before dried in an oven at 50 ^{o}C. This S-ETAC was pulverized and sieved (600 µm pore size). This method has been reported by Lin et al. [6] with slight modifications.

Degree of substitution and reaction efficiency

The DS value is important to know the average number of ETAC replacement into the anhydrous glucose unit (AGU) of the starch structure. The actual and theoretical DS and RE (%) of the reaction were calculated by the percentage of nitrogen derived from the elemental analysis (Thermo-Finnigan, EA 1112 CHNS Analyzer series, Italy) using equations (1), (2), and (3), respectively:

$$\text{Actual DS} = \frac{(162.15 \text{ x N})}{(1401 - 151.64 \text{ x N})} \quad (1)$$

$$\text{Theoretical DS} = \frac{\text{W1}/151.64}{\text{W2}/162.15} \quad (2)$$

$$\text{RE (\%)} = \frac{\text{Actual DS}}{\text{Theoretical DS}} \text{ x } 100 \quad (3)$$

where N is the percentage of the nitrogen determined by elemental analysis, the 162.15 is the molar mass of anhydrous glucose units (AGU) in the starch, the molar mass of 151.64 is hydroxypropyltrimethylammonium chloride, 1401 is 100 times the mass of the nitrogen atom, W1 and W2 are the masses of ETAC and starch used [6, 7].

Solubility and swelling power

Native starch and S-ETAC incorporated into the different vials contained distilled water (1% w/v) and stirred for 30 minutes at room temperature before being cooled/heated at different temperatures (25, 35, 45, 55, 65, 75, 85 and 95 °C) for 1 hour. The starch slurry was cooled to room temperature, poured in a centrifuge tube and centrifuged at 3000 rpm for 15 minutes. The supernatant was gently put into a vial and dried in an oven at 110 ^{o}C. Wet starch in the centrifuge tube was weighed before dried. Different starch slurry was used for each different temperature and analysis carried out in triplicate [8]. Solubility and swelling power were calculated using equations (4) and (5), respectively.

$$\text{Solubility (\%)} = \frac{\text{mass of dry supernatant}}{\text{mass of dry starch}} \text{ x } 100 \quad (4)$$

$$\text{Swelling power (g/g)} = \frac{\text{mass of wet starch}}{\text{mass of dry starch} - \text{mass of dry supernatant}} \quad (5)$$

Fourier transform infrared analysis

S-ETAC and native starch (30 mg) were determined using a Fourier Transform Infra-Red – Attenuated Total Reflectance (FTIR-ATR Spectra 2000 Perkin Elmer) at 4000 to 650 cm^{-1} at spectral resolution of 4 cm^{-1} [6].

Differential scanning calorimetry

Differential Scanning Calorimetry (DSC 822 Mettler Toledo) was used to measure the gelatinization temperatures and enthalpies of the native starch and S-ETAC. DSC was calibrated with indium and empty aluminum pan was used as blank. Slurry of starch and water in a mass ratio of 1: 3 was placed in aluminum pan, sealed and let for 1

hour. Then the aluminum pan containing the sample was heated from 25 to 100 °C at a heating rate of 10 °C/min [9].

X-ray diffraction

The degree of crystallinity of starch and S-ETAC can be determined using X-ray diffraction (Bruker D8 Advance). The samples were put in special containers and diffraction patterns recorded in a reflection 5 – 80° (2θ) at room temperature, operating at 40 kV and 40 mA with Cu Kα radiation, k = 0.5406 nm [1, 10].

Results and Discussion

Degree of substitution and reaction efficiency

The actual DS (0.11, 0.16, 0.30, 0.48 and 0.76) in this study was increased as the mass ratio of ETAC:St increases (0.15:1, 0.25:1, 0.5:1, 1:1, 2:1), compared with theoretical DS (0.16, 0.27, 0.53, 1.07 and 2.14) (Figure 2 (a)). The percentage of RE decreases with the increasing amounts of ETAC by, 69, 59, 56, 45 and 35 % (Figure 2 (b)). The results show that the more the amounts ETAC added, the lower the RE (%) of the reactions. Kavaliauskaite et al. [11] produced a cationic starch having a DS of 0.2 to 0.85 using different ratios of reactant and different conditions at a temperature of 45°C for 24 to 48 hours. Wang et al. [3] also produced cationic starches with DS 0.27 to 1.37 using dioxane-tetrahydrofuran-water as the reaction medium at 60 °C for 4 – 8 hours. Wang and Xie [1] produced a cationic starch having a DS 0.19 to 0.99 using ionic liquid as the reaction medium at 70 °C for 24-72 hours. Lin et al. [6] also produced cationic starches with DS between 0.13 and 0.26 at 80 °C for 2 hours from waxy maize starch. All of the above studies using different starches, ETAC, NaOH ratios and different solvents. The findings of this study will give information about the reaction to produce a cationic starch using faster and more environmentally friendly method because it does not use organic solvents as well as the yield is easily purified.

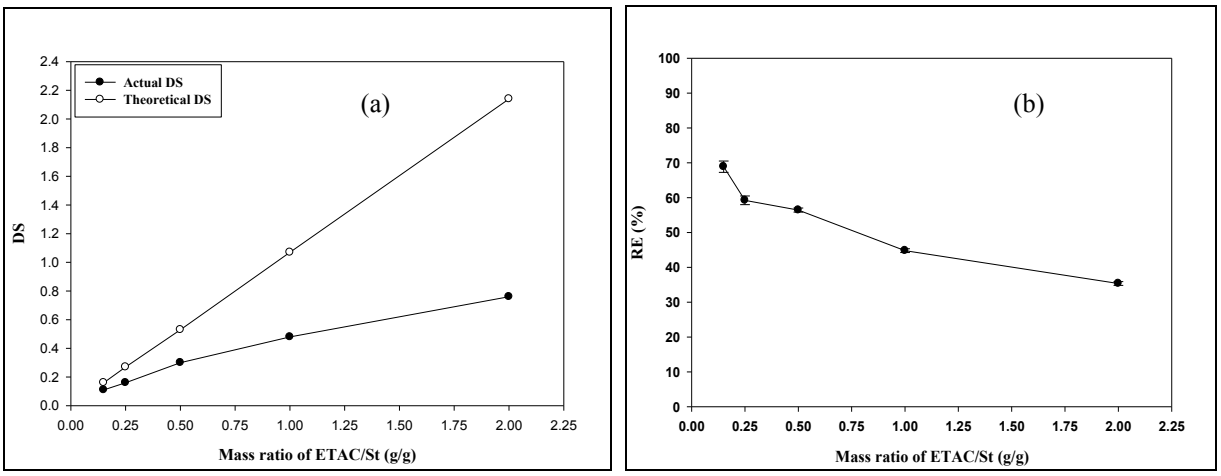

Figure 2. (a) Actual and theoretical DS and (b) RE (%) of S-ETAC at difference mass ratio of ETAC/St (g/g)

Solubility and swelling power

Solubility and swelling power of starch and S-ETAC are shown in Figure 3. Solubility of native starch and S-ETAC increased as temperature increased (Figure 3 (a)) but solubility S-ETAC increased dramatically at temperatures above 75 ^{o}C. This means that the reaction of starch and ETAC molecules produced will increase solubility of S-ETAC in water from 43.5 to 109.7% compared to the native starch. Modification of the structure of starch causes steric hindrance and repulsion between starch molecules, thereby facilitating the absorption of water in the crystalline regions in the starch granules [6]. Swelling power of native starch and S-ETAC also increase as the temperature increases (Figure 3 (b)). Swelling power increases because of the repulsion of the starch molecules cause water to penetrate into the S-ETAC molecules thus increased the swelling power between 124 and 548% compared to the native starch. Lin et al. [6] produces the cationic starch (using dry methods) that have higher

swelling power than the native starch but the solubility index is lower than the native starch. In this study, solubility and swelling power of the cationic starch are higher than the native starch. This may be caused by the gelatinization occurs during the reaction (using a semi-dry method) which causes the cationic starch produced is more soluble than the native starch.

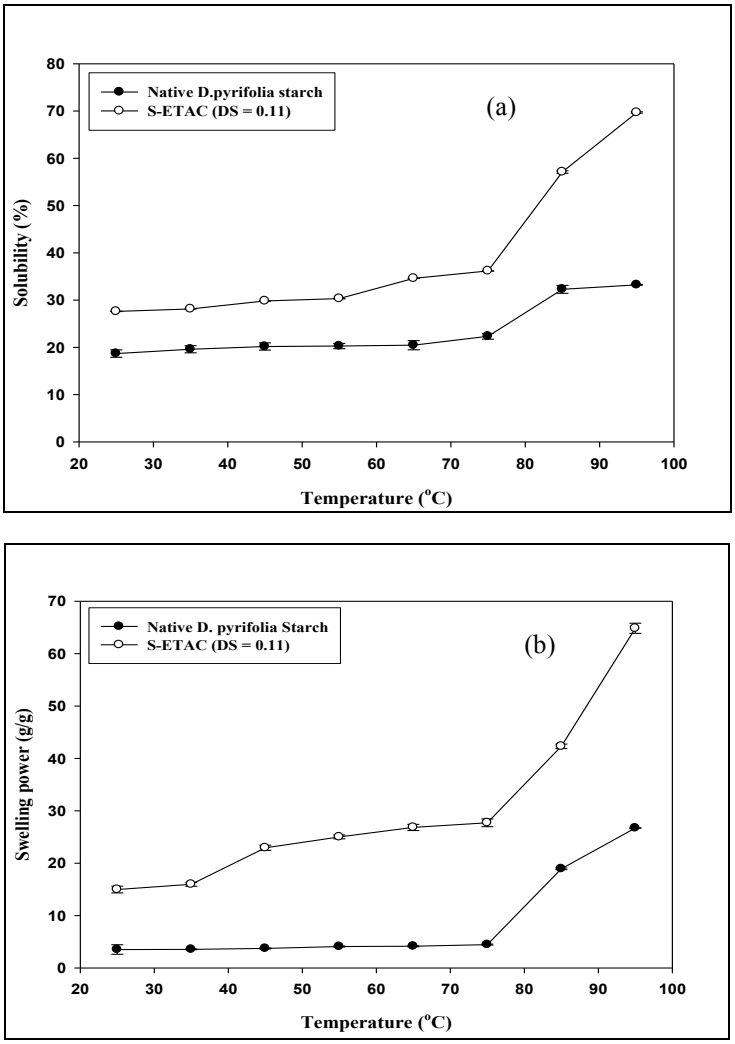

Figure 3. (a) Solubility (%) and (b) swelling power (g/g) of native starch and S-ETAC

Fourier transform infrared analysis (FTIR)

Figure 4 shows FTIR spectra of the native starch and S-ETAC. Infrared profile shows not much difference between the two spectra. Starch backbone shows at 3294 (-OH stretching), 2928 (-CH stretching), 1149, 1078, 996 (C-O stretching), 1363 (C-H deformation) and 1642 cm^{-1} (major peak of starch). The highlight of the S-ETAC at 855 cm^{-1} (-CN deformation) and 1483 cm^{-1} (C-N stretching) proved that the ETAC structure is bonded on the structure of starch. This finding is similar to findings reported by Wang and Xie [1], Wang et al. [3], and Lin et al. [6].

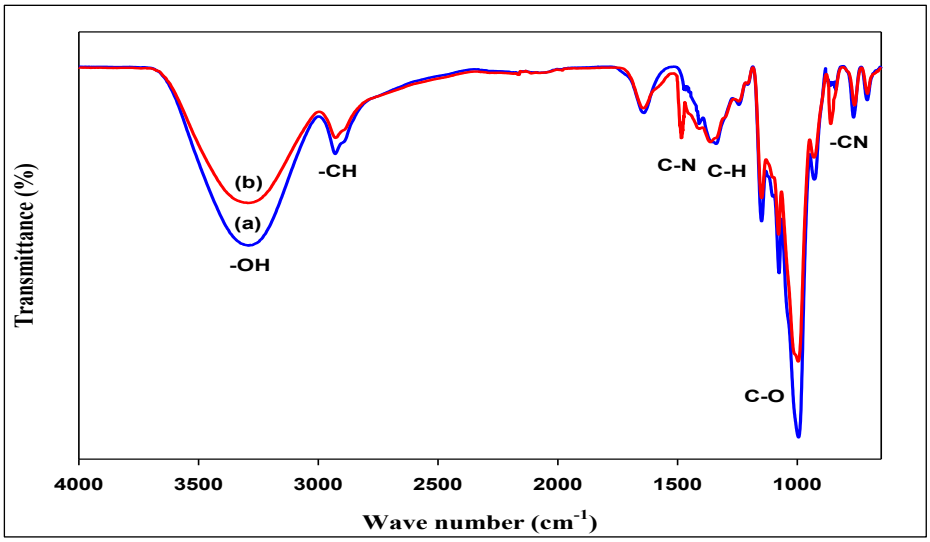

Figure 4. FTIR spectra of (a) native starch and (b) S-ETAC (DS = 0.11)

Differential scanning calorimetry (DSC)

Figure 5 shows the DSC termogram for the native starch and S-ETAC. Gelatinization temperature of native starch was at 71 ^{o}C (onset temperature), 75 ^{o}C (peak temperature) and 78 ^{o}C (conclusion temperature) (Figure 5 (a)), while gelatinization endotherm was not detected in the S-ETAC (Figure 5 (b)). The reaction between the starch and ETAC makes the gelatinization temperature of S-ETAC cannot be determined. This finding is similar to that previous study reported in Zhang et al. [12] using cationic acetylcholine groups as reagent for etherification of potato starch. The interaction between starch and ETAC will loosen starch structure causing starch molecules more easily absorb water during heating. The starch heating at high temperature of 80 °C caused the water to enter the starch granules so hydrogen bonds within and outside of the starch molecules are disrupted and swell. At high temperature, starch crystallites become unstable and disordered due to thermal motion and swelling force. Next, water will fully enter into starch crystallites region and breaks up the order of starch crystallites. The order of starch crystallites will destroy and turned into amorphous form. Thus, gelatinization temperature disappeared. These results confirmed by the X-ray diffraction analysis.

X-ray diffraction (XRD)

X-Ray diffraction patterns of the native starch (a) and S-ETAC (b) shown in Figure 6 are used to determine the changes of crystalline structure. Native starch showed crystallization of type-C pattern, while the diffraction pattern of S-ETAC changed to single broad peak with reduced intensity. This is due to starch crystallites region partly destroyed and converted into amorphous form after etherification of native starch with ETAC molecules. The amorphous properties from XRD pattern have been previously discussed by Wang et al. [3] and Zhang et al. [12]. The loss of crystallites region is caused by alkaline environment and water during etherification of starch. Therefore, these cationic starches have potential as flocculants because the presence of amorphous and solubility properties are important in practical point of view to improve its ability to form a colloidal or solution in cold water especially in waste water treatment plant [3]. It also has potential as additive to increase the viscosity of colloidal emulsion.

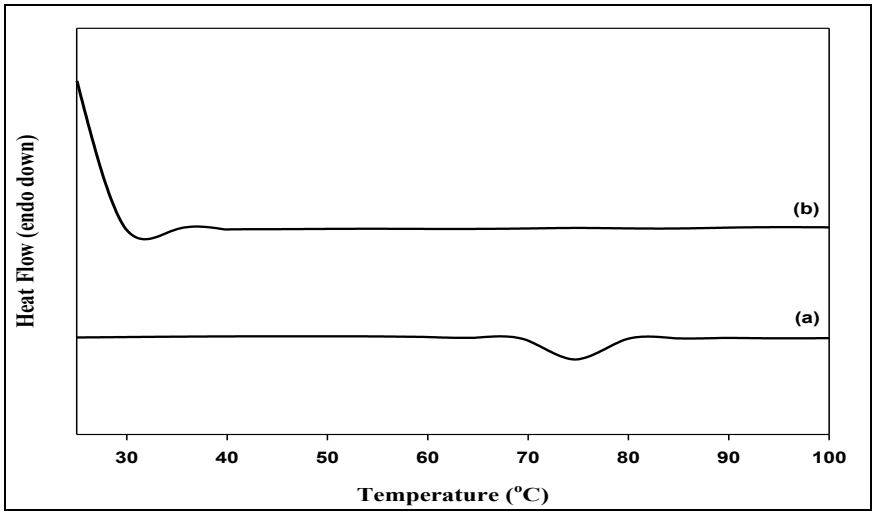

Figure 5. DSC termogram of (a) native starch and (b) S-ETAC (DS = 0.11)

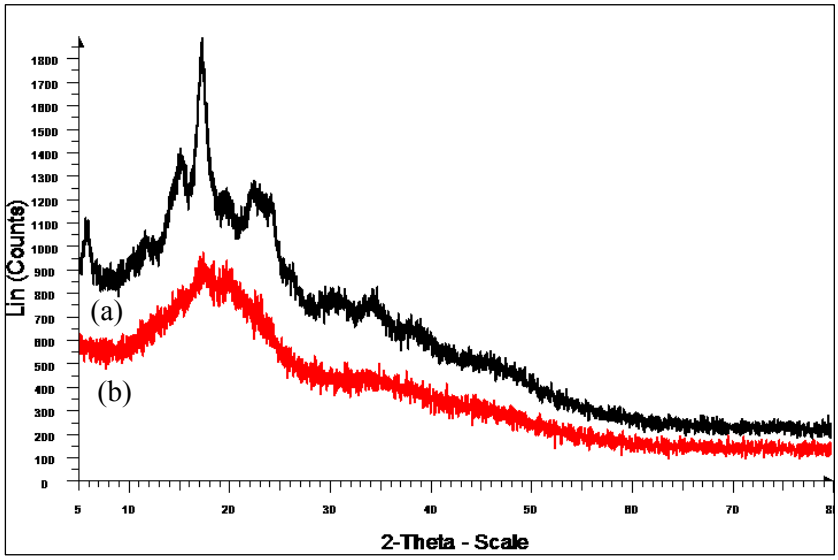

Figure 6. XRD patterns of (a) native starch and (b) S-ETAC (DS = 0.11).

Conclusion

Cationic starch-based polymeric surfactant (S-ETAC) from *Dioscorea pyrifolia* starch tubers has been successfully synthesized in a series of mass ratio ETAC:St at a temperature of 80 °C for 2 hours and the optimum reaction is in ratio of 0.15:1, which has a DS 0.11 and RE 68%. S-ETAC was characterized using the solubility and swelling power tests as well as analyses of ATR-FTIR, DSC and XRD. The results showed that the S-ETAC produced has a solubility and swelling power better than the native starch. The S-ETAC was high in solubility and swelling power in water. Preparation of S-ETAC is also more environmentally friendly, inexpensive and can be produced on a large scale. Further study is to characterize surface properties of S-ETAC to replace petroleum-based surfactant of similar character.

Abstract

Synthesized iron oxide, α-Fe_2O_3 used for CO_2 capturing was prepared by a simple mixing method and calcined at temperatures in a range of 350 – 850 °C. CO_2 adsorption isotherms at 25 °C and 1 atm found that the sample namely s450 that calcined at 450 °C gave the highest CO_2 adsorption activity with the adsorption capacity of 17.0 $mg_{CO2}/g_{adsorbent}$. Monodentate carbonate, bidentate carbonate and bicarbonates formation were observed on s450 through the IR spectra. The basicity of s450 was identified by chemisorption of CO-TPD which contains weak, medium and strong basic sites with CO total adsorbed amount of 1.99 cm^3/g. It was found that s450 calcined at 450 °C has certain crystallite peaks that abruptly increased through the XRD diffractogram. The texture properties of s450 generated high porosity and more uniform sphere shape particle size with high surface area (50.5 m^2/g). Furthermore, it is composed of trimodal distribution for pore size distribution curve desirable for CO_2 adsorption.

Keywords: CO_2 capture, adsorption, iron oxide, solid adsorbent, porosity

Abstrak

Penjerapan CO_2 terhadap ferum oksida, α-Fe_2O_3 yang disintesis melalui kaedah campuran ringkas dan dikalsin pada suhu 350-850 °C. Penjerapan isoterma CO_2 pada suhu bilik, 25 °C and 1 atm mendapati sampel s450 yang dikalsin pada suhu 450 °C menunjukkan aktiviti penjerapan CO_2 paling tinggi dengan keupayaan penjerapan sebanyak 17.0 $mg_{CO2}/g_{penjerap}$. Spektrum IR telah membuktikan pembentukan spesis monodentat karbonat, bidentat karbonat dan bikarbonat pada s450. Sifat bes s450 yang dikenalpasti menggunakan jerapan kimia CO-TPD dimana jumlah CO yang dijerap oleh tapak bes lemah, sederhana dan kuat adalah 1.99 cm^3/g. Difraktogram XRD pula menunjukkan terdapat beberapa puncak kekisi yang meningkat. Tekstur s450 pula mempunyai keporosan yang tinggi dan bentuk sfera yang lebih sekata serta luas permukaan yang tinggi (50.5 m^2/g). Tambahan lagi, graf taburan saiz liang s450 juga terdiri daripada taburan jenis trimodal yang menjadi salah satu faktor penting dalam penjerapan CO_2.

Kata kunci: penjerapan CO_2, penjerapan, ferum oksida, penjerapan pepejal, keporosan

Introduction

The main concern worldwide over the recent years is renewable energy which could generate for the rest of decades without worrying about the depletion of sources in the earth. Human population and consumption are directly proportional with the addition of technology provided and yet keep growth explosively which completed with extensive research and development in the industry and academic. This progressive situation made human realized with considerable attentions were paid to the green technology by using the anthropocentric environmental ethics which is people centered as an approach to reduce environmental pollutions and save the earth and future generation. It gave rise to anthropocentric individuals to feel the environment should be protected because of its value in maintaining or enhancing the quality of life for human [1].

Rapid growth development resulting in harmful air pollutants released into the atmosphere which became the major contribution in the global warming and several issues on urban smog, acid rain, and health problems contributed from emission of anthropogenic CO_2 [2]. The CO_2 in atmosphere, one of the major greenhouse gases, is now higher than the safety limit for the atmospheric CO_2 level of 350 ppm. According to the National Oceanic and Atmospheric Administration (NOAA) in U.S, the CO_2 level was higher than the safety limit since 80's and to date on September 2015 was approximately 397.63 ppm. Furthermore, the increased CO_2 growth rate about 2.0 ppm/year gives rise to the mitigating measure of capturing CO_2 [3].

According to Freund and Roberts [4], chemisorbed species is connected with the formation of $CO_2^{\delta-}$, the anionic molecule, which involves the charge transfer from the metal to the molecule. Consequently, the α-Fe_2O_3 decorated as the basic oxide where the CO_2 chemisorption involves the basic sites that act as electron donors and are associated with O_2^- ions localized on surface defects [5]. The physisorption is found in almost all cases whereas the chemisorbed species are only observed under very specific conditions: the surfaces have to be either atomically rough, containing a high defect: density in order to stabilize the chemisorbed species, or are alkali metal modified surfaces [4].

Metal oxides of calcium oxide (CaO) were among the earliest studies in the CO_2 capture that has promising properties of high adsorption capacity [6]. However, it consumed high energy during the desorption process up to 900 °C which is economically not favourable. Thus, the capability of the alternative adsorbents from the metal oxides was studied. The desorption process that required heat to dissociate formed carbonate can be explained by the interaction of CO_2 as adsorbate on the adsorbent which depends on its binding energy. In fact, others than alkali metal and alkali earth metal oxides, several metal oxides have been reported for a single crystal oxide that shows its capability in the CO_2 capture. Kwon et al. [7] reported the dissociation carbonate product on lanthanum sesquioxide (La_2O_3) using the IR frequencies at 500°C. Furthermore, the desorption temperature was increased to 700 °C when higher pressure was used during the CO_2 adsorption [8]. Silver oxide (AgO) exhibited desorption temperature at 247°C that was observed under the scanning tunnelling microscopy (STM) [9]. Meanwhile, Yoshikawa [10] discovered the order of dissociation of the different carbonate species (bicarbonate, monodentate, bidentate and polydentate carbonate) on cerium oxide (CeO_2) at the temperature range of 50 – 450 °C. Among the copper oxides (CuO and Cu_2O), it was found that copper (II) oxide (CuO) showed a higher adsorption capacity by physisorbed of 17.7 mg CO_2/g adsorbent and chemisorbed of 9.5 mmol/g with three times regeneration without significant loss of performance [11]. Our works reported that NiO exhibited adsorption capacity of 14.1 and 87.0 mg CO_2/g adsorbent by physio- and chemisorption respectively, with the desorption temperature range of 400 – 460 °C [12].

Previous studies of iron oxides, α-Fe_2O_3 as adsorbent showed evidence on the presence of various carbonate species formations such as monodentate, bidentate, and bicarbonate forms on the metal oxides adsorbent surface [13-17]. These studies described carbonates formation using the Fourier transfer infra red (FTIR) spectroscopy to analyze the configuration of C-O interaction with iron oxide surface. Ismail et al. [18] reported CO_2 adsorption by using the iron material from a steel-pickling waste (97 wt% $FeSO_4.7H_2O$). The original material was roasted at 700 °C for 5 hours in air, oxygen, and nitrogen prior to the adsorption process. However, none of these researches reported the basicity active site that contributes to CO_2.

In this study, α-Fe_2O_3 was synthesized by using a simple mixing method in order to obtain the preferable surfaces. The α-Fe_2O_3 was synthesized by using a low cost method to identify the optimum calcination temperature and quantify the basicity properties. Hence, the amount of CO_2 adsorbed physically at room temperature, 25°C and 1 atm was measured using the volumetric adsorption technique.

Materials and Methods

Sample preparation

The analytical grade iron (III) nitrate nonahydrate ($Fe(NO_3)_3 \cdot 9H_2O$, 98%) and ethanol (C_2H_5OH, 99.7%) were purchased from Sigma-Aldrich, USA and Systerm, Malaysia respectively. The bulk α-Fe_2O_3 obtained from BDH, United Kingdom was treated by calcined under nitrogen flow at 150 °C for 1 hour. The simple mixing method is very useful to produce α-Fe_2O_3 nanoparticles with low cost of starting materials. This method was modified from literature reported by Dong et al. [19]. The $Fe(NO_3)_3 \cdot 9H_2O$ was weighed to 16.16 g and dissolved in 20 ml distilled water to have concentration of 2 M. To this solution, ethanol was added with a volume percentage of 25% from the distilled water used and stirred for 1 hour at room temperature. The concentration of 2 M precursor was found to be the shortest time formation with a connection of large number of $Fe(OH)_3$ fine particles. Ethanol acts as a stabilizer for the colloidal particles avoid aggregation [19]. The solution was sonicated for 20 minutes to obtain better homogeneous condition and dried with vigorous stirring at the temperature of 80 – 100 °C. The dried solid was ground and kept in an oven for 24 hours at 110 °C. Finally, it was calcined under the air flow at the temperature ranging from 350 – 850 °C. The samples were labeled by the calcination temperatures namely: bulk, s350, s450, s550, s650, s750 and s850.

Characterization

These samples were characterized with Bruker AXS D8 Advance type with X-ray radiation source of Cu Kα (40 kV, 40 mA) to obtain the X-ray Diffraction (XRD) pattern. The crystal structures were verified by recording 2θ diffraction angle from 10° to 90° at wavelength (λ = 0.154 nm). The diffraction pattern obtained was matched with a standard diffraction data (JCPDS) file for identification of the crystalline phase composition.

The physical surface analysis of N_2 adsorption-desorption was conducted at 77 K in a Micromeritics ASAP 2020 instrument to determine the textural surface properties of the prepared samples. The catalysts were degassed at 200°C for 6 hours prior to analysis. The volumetric adsorption apparatus was used to determine the surface area and N_2 adsorption-desorption isotherm using the BET equation [20]. Pore volumes and pore size distribution were determined by Barret–Joyner–Halenda (BJH) method and applied based on the adsorption branch. The *t*-plot method was used to calculate the non-microporous (or external) surface area considerable as the mesoporous surface area [21-23]. The total pore volumes were estimated to be the liquid volume of adsorbate (N_2) at a relative pressure. All surface areas were calculated from the N_2 adsorption isotherms by assuming the area of a N_2 molecule to be 0.162 nm^2 [20]. The CO_2 adsorption behaviors of the sorbents were evaluated using the above mentioned instrument and evaluated at 25°C and 1 atm with circulated water bath and using 99.9% of purified CO_2 gas as adsorbate.

The particle sizes and morphology of the catalysts were measured by the transmission electron microscopy (TEM, CM12 Philips) which is equipped with an electron gun 200 kV. The synthesized of α-Fe_2O_3 before and after the exposure with CO_2 (5% and 15% of CO_2) as well as after temperature programmed desorption (TPD) at 650°C were examined using the Fourier transform infrared (FTIR) spectroscopy. The spectra of the samples were recorded between 4000 and 650 cm^{-1} in spectrum 400, FTIR Spectrometer (Perkin Elmer, UK) using the Attenuated Total Reflection (ATR) method for the sample preparation technique.

The basicity properties of catalysts were performed by the TPD from a conventional apparatus of Chemisorption Analyzer, Micrometrics 2920 Chemisorb. This instrument is equipped with a thermal conductivity detector (TCD). Approximately 50 mg of catalyst was preheated to 150°C to remove the moisture for 30 minutes before it was cooled down to 30°C under the pure He gas flow rate of 30 mL/min. The catalyst was exposed with a gas mixture of 5% CO in He in a constant temperature of 40°C under flow rate 30 mL/min for 60 minutes. The pure He gas again was introduced to the catalyst for the purpose of removing excess of the weak physically adsorbed CO at 50°C for 30 minutes. The TPD required ice to trap the moisture which was placed in the container of instrument prior to the

measurements and heated to 900°C with the heating rate of 10°C/min under pure He. The samples after the CO_2-TPD analysis by using 5% and 15% CO_2 were collected using above mentioned conditions and observed through FTIR.

Results and Discussion

XRD pattern

The X-ray diffractograms of bulk and synthesized α-Fe_2O_3 were determined and are represented in Figure 1. The peaks observed at d-values of 3.68, 2.70, 2.52, 2.20, 1.84, 1.69, 1.60, 1.49, 1.45, 1.34, 1.31, 1.26, 1.22, 1.19, 1.16, 1.14, 1.10 Å in all catalysts correspond to the rhombohedral phase of hematite, α-Fe_2O_3 with lattice parameters a=5.0356 and c=13.7489 (matched with JCPDS number 33-0664). The diffractograms show that the crystal formation of hematite phases can be seen at the calcination temperature of 350°C. Nevertheless, the crystallite peaks appear at this temperature had lower intensity compared to the bulk hematite especially on crystallites (018), (208), (10 10), (220), (306), (128), (02 10), (134) and (226). The s450 was found to have a better crystallinity of synthesized α-Fe_2O_3 among others. The crystallite peaks of (024), (116), (214) and (300) were abruptly increased for the calcined α-Fe_2O_3 at 450°C. The XRD pattern for the calcination temperatures ranging at 550 – 850 °C had similar intense of crystallinity.

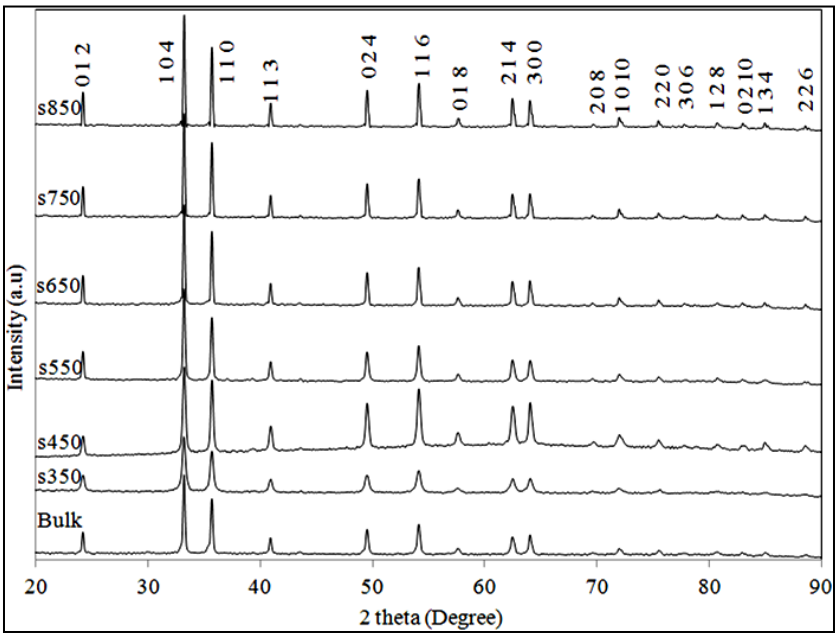

Figure 1. XRD patterns of α-Fe_2O_3 at different calcination temperatures

Textural properties

The N_2 adsorption-desorption isotherms, specific surface areas, and pore volumes for the bulk and synthesized α-Fe_2O_3 are presented in Figure 2 and Table 1, respectively. The isotherms for all samples are type III profile according to the IUPAC isotherms of classification with typical sloping adsorption and desorption branches covering a large range of relative pressure (P/P_o) where the adsorbent-adsorbate interaction is weak, but could be obtained with certain porous adsorbents [24]. It was proven from the H3 type hysteresis based on the isotherms ascribed from plate-like particles giving rise to slit-shaped pores from the adsorbent. The adsorbents showed large ranges of pore diameters which do not exhibit any limiting adsorption at high P/Po [20]. The adsorbents consist of mesoporous and macroporous structure in all samples based on the isotherms. It is interesting to note that s450 has the largest hysteresis area (Figure 2) compared to others which indicate the highest mesoporous and macroporous structure on the surface. The mesopore surface area with pore size ranging between 2 to 50 nm was evaluated by the

t-plot method. The macropore structure of bulk α-Fe_2O_3 was contributed more than mesopore since the mesopore surface area was smaller (3.9 m^2/g) than s650 (4.2 m^2/g) (Table 1). For s350, the temperature of 350 °C was not enough to create better pore structure. However, the sample s450 calcined at 450 °C created better pore structure which leads to a high surface area (50.5 m^2/g). Hence, the total pore volume was increased which is desirable for the adsorption behavior. This ascribed to the calcined α-Fe_2O_3 at a particular temperature provided the capability in generating well pore structure nor produced fine particles. At the temperature higher than 450 °C, it was found to be not efficient to obtain a high porosity α-Fe_2O_3. The constituent crystallites of the hematite grew and sintered resulting from the increased of thermal exposure, eventually generated smaller pores and also reduced the BET surface area. The low specific surface area indicative of less-defined porosity was observed for s550 and above. The bulk α-Fe_2O_3 exhibited better adsorption rather than s650 and above.

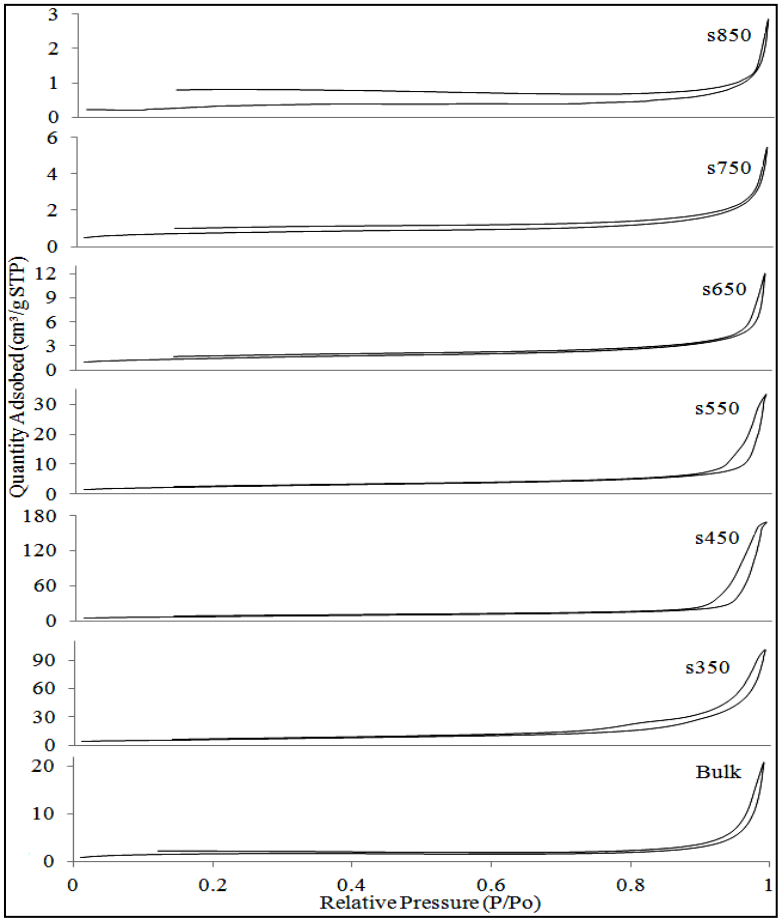

Figure 2. The effect of calcination temperature on α-Fe_2O_3 towards N_2 adsorption-desorption isotherms

Pore size distribution

The highest N_2 adsorption with the widest range of pore size can be seen from the pore size distribution curve illustrated in Figure 3. The distribution shows a wide range of pore sizes categorized under mesoporous and macroporous. A trimodal distribution was observed clearly for α-Fe_2O_3 calcined at 450 °C whereas the rest adsorbents established similar distribution and several multimodal distributions. The trimodal distribution has overcome the monomodal which appears to produce an enhancement in the surface area of the synthesized metal oxides [25]. It is interesting to note that s450 has three maximum pore diameter (652, 907 and 1271 Å) located in a

wide pore structure. These pores exhibited narrow pore size distribution compared to the others which are indicative of good porosity for gas adsorption retained based on the pore size distribution and BET surface area obtained.

Table 1. Textural parameters of the samples obtained from the N_2 adsorption-desorption and CO_2 adsorption isotherms

Calcination Temperature (°C)	BET Surface area (m^2/g)	Mesopore Surface area (m^2/g)	Total Pore volume (cm^3/g)	Pore diameter (Å)	CO_2 Adsorption at 25 °C (cm^3/g)	Adsorption Capacity at 25 °C ($mg_{CO2}/g_{adsorbent}$)
Bulk	5.7	3.9	0.022	154	1.53	3.0
s350	23.1	20.6	0.124	215	2.91	5.7
s450	50.5	27.0	0.227	371	8.66	17.0
s550	9.3	8.9	0.039	168	1.17	2.3

s750	2.6	1.7	0.006	91	0.94	1.8
s850	1.2	1.9	0.003	98	0.76	1.5

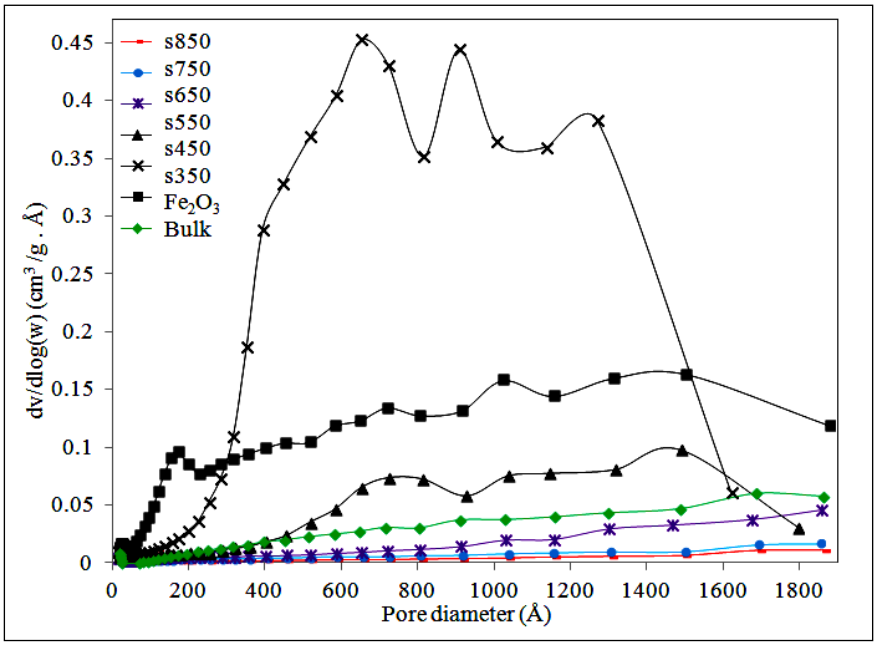

Figure 3. Pore size distribution of synthesized α-Fe_2O_3 by BJH method

Pore structure of the adsorbents

The bright field TEM micrographs of α-Fe_2O_3 prepared with increased calcination temperature are illustrated in Figure 4 to observe its crystallographic and morphological structure. The bulk α-Fe_2O_3 has larger crystallite size particles at 160.5 nm with aggregation and less pore structure which has agreement with the mesopore surface area based on N_2 adsorption-desorption isotherms. For s350, it did not show very good morphology and aggregation of

the particles with particle size range 12.6 to 57.0 nm. Nonetheless, small and uniform particle sizes of α-Fe_2O_3 particles with range of 24.5 to 56.0 nm were generated for s450. The pore structures well distributed on the particles surface are also easily seen from Figure 4. The one-hour calcination temperature of 550 °C was enough to make the particle size of s550 became larger (44.2 to 90.3 nm). At 650 °C, s650 exhibited more particles changing to ellipsoid with larger particle range of 73.0 to 119.2 nm and fine pore structure was observed. According to Dong et al. [19], particles changed at a higher temperature of 700 °C for longer calcination time of three hours. The porous images in Figure 4 for synthesized α-Fe_2O_3 by using simple mixing method could provide improvement in the porosity rather than bulk sample. The high porosity surfaces provide more active sites and space which are responsible in attracting CO_2.

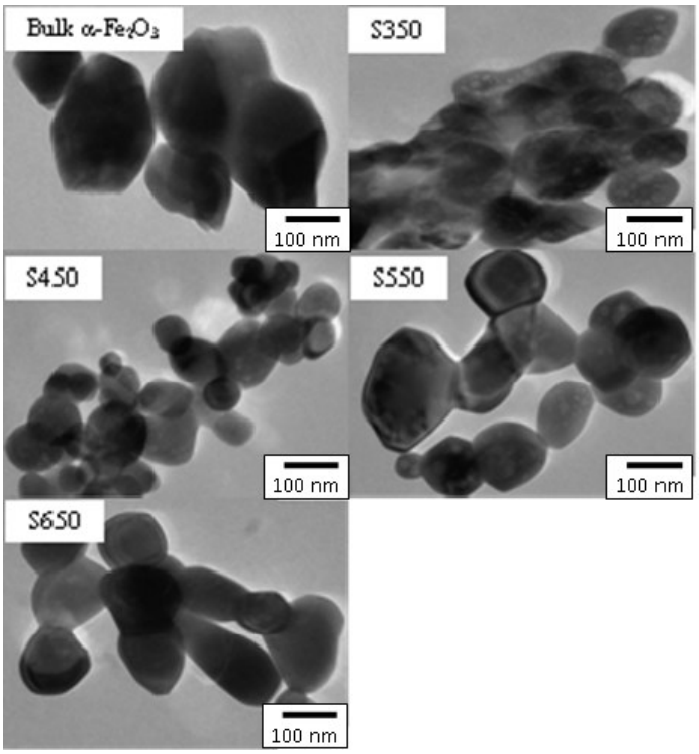

Figure 4. TEM view of synthesized α-Fe_2O_3 particles

Base strength distribution by CO-TPD analysis

The s450 was chosen based on the morphology studies, and used for the basicity measurement by TPD with CO as the probe molecule due to having the desirable properties in the CO_2 adsorption. Although CO_2 has been used worldwide for this purpose, somehow it could appear to be proper probe molecule because of its acidic in nature. The basic of adsorbent would attract the acidic gas easily to form various interaction modes. The CO-TPD profile in the literatures varies depending on the adsorption condition of CO. The broad desorption or high intensity peak indicative of CO has been adsorbed. The CO-TPD peaks represent the base strength distribution of the adsorbent are shown in Figure 5. The range of weak, medium and strong basic sites were estimated from the area under their TPD curve of 40 – 200, 200 – 400, >400 °C respectively. The temperature ranges chosen for the weak, medium and strong basic sites are CO-TPD observed from the most catalyst [26, 27]. The strengths of the basic sites are expressed in the temperature range wherein the CO_2 chemisorbed on the basic sites was desorbed. The CO-TPD curve showed maximum temperature of 170 °C (weak base), 314°C (medium base) and 641 °C (strong base) with the desorption quantity of 0.14, 0.42 and 1.43 cm^3/g respectively. This adsorbent had total amount of 1.99 cm^3/g resulting a potential adsorbent in CO_2 adsorption.

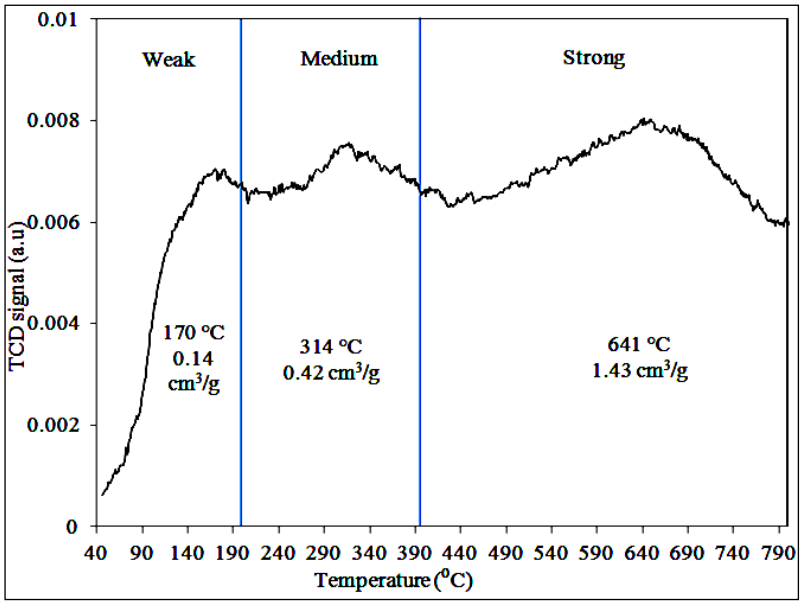

Figure 5. Base strength distribution from TPD profile of CO adsorption (CO-TPD) for s450

Formation of carbonate

The IR spectra for s450 obtained before and after being exposed to CO_2, and after desorption of CO_2 are shown in Figure 6 and vibrational frequencies assignments are tabulated in Table 2. The position of the bands at 1226 and 1630 cm^{-1} are indicative of the bicarbonate species for C-OH bending mode and asymmetry O-C-O vibrational modes of adsorbed bicarbonates respectively [15-17, 28]. The bicarbonate can be easily identified by its OH peak at 3639 cm^{-1} [15-17, 28]. Other peaks observed at 1038 and 1399 cm^{-1} were associated with the monodentate structures of carbonate from IR spectra with C-O stretches and symmetry O-C-O vibrational mode respectively [15-17]. The 1399 cm^{-1} peak only appeared for α-Fe_2O_3 with 5% CO_2 of exposure. The weak contributions around 1245 and 1554 cm^{-1} agreed with the formation of surface bidentate carbonate species with symmetry (O-C-O) and asymmetry (O-C-O) stretching respectively [15-17, 29] as a consequence of the adsorption of CO_2 on a metal oxide surface. In all spectra, the CO band from bridging CO_2 at 2035 cm^{-1} was more intense for α-Fe_2O_3 exposed with 15% CO_2 [30]. The intensity pattern of peak 2162 cm^{-1} was similar where C=O bonded with hydroxyl groups having weak acidic properties [31]. The broad IR absorption band at 3370 cm^{-1} was the characteristic of H-O-H bonding of the H_2O molecules which shows the presence of hydroxyl groups [32]. The intensities of hydroxyl group were found to be reduced and partially removed after CO_2-TPD at 650 °C due to the thermal exposure. Additionally, there was also a broad OH stretching region of 2700 to 3706 cm^{-1} for all spectra but more intense for those exposed with 5% and 15% CO_2 which was caused from moisture in the gas mixture. The adsorption band at 918 cm^{-1} was corresponded to the Fe-O-H deformation due to the source of gas containing traces amount of moisture that led to the hydroxide compound formation on metal oxide surface [33, 34].

CO_2 adsorption

CO_2 adsorption isotherms of the adsorbents at 25 °C and 1 atm are shown in Figure 7 and the adsorption capacity is tabulated in Table 1. The CO_2 adsorption branch began from the monolayer that was on the adsorbent surface and continued with the multilayer adsorptions that is known as physisorption. The bulk α-Fe_2O_3 shows the adsorption capacity was 1.53 cm^3/g. For the synthesized α-Fe_2O_3, the CO_2 adsorption capacity varies with the different calcination temperature parameters. s450 exhibited the highest BET surface area and total pore volume, showed the highest CO_2 adsorption capacity (17.0 mg_{CO2} / $g_{adsorbent}$) at 25 °C and 1 atm. The amounts of CO_2 adsorbed onto the synthesized α-Fe_2O_3 decreased progressively as the calcination temperature was increased which was influenced by poor surface area as a consequence of the sintering effect of the adsorbent. It also has a higher volume of narrower pores with trimodal distribution of the pore size as shown in Figure 3, that provides more spaces to capture CO_2. The adsorption capacity for s350 was rather higher than the rest of temperatures ascribed to crystallite grew and not exposed to the high thermal treatment that lead to sintering. The adsorption capacity for bulk α-Fe_2O_3 which was treated at 150 °C under N_2 recorded a higher value than s550 and above. In addition, the adsorbed weights (CO_2) of all the adsorbents are in the following order: 450 > 350 > bulk > 550 > 650 > 750 > 850. In fact, a linearly proportional relationship between the adsorptive capacity and surface area is suggested. Higher surface area provides more active sites to attract CO_2 which resulting in high adsorption capacity. Overall, the simple mixing method could save more energy on the calcination temperature compared to Ismail et al. [18] work which required 700°C for the CO_2 adsorption purpose.

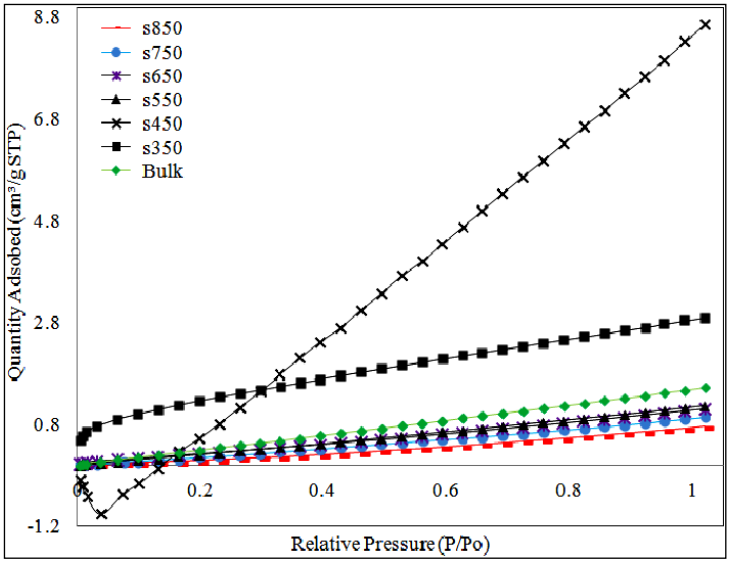

Figure 7. The effect of calcination temperatures on CO_2 adsorption isotherms at 25 °C and 1 atm

Conclusion

The calcination temperature of α-Fe_2O_3 at 450 °C by using a simple mixing method generated sphere particle size of fine particles with high BET surface area, mesopore surface area, and total pore volumes. These features provide an enhancement in CO_2 adsorption at 25 °C and 1 atm with the highest adsorption capacity among all adsorbents was 17.0 $mg_{CO2}/g_{adsorbent}$. Furthermore, the total basic site presence for all three weak, medium and strong basic site was 1.99 cm^3/g. The striking peak was observed at strong base site with amount of 1.43 cm^3/g. The IR spectra described various configurations of CO_2 interacted with α-Fe_2O_3 surface by monodentate, bidentate and bicarbonate forms although exposed with low concentration of 5% of CO_2.

Abstract

A series of magnesium-doped MoVTeNbOx (MVTN-Mg) catalysts, as well as undoped sample (MVTN) was prepared by microwave-assisted slurry method followed by calcination in nitrogen at 873 K for 2 hours. The catalysts were further post-treated in aqueous hydrogen peroxide. The physicochemical properties of the catalysts were investigated using X-ray diffraction (XRD), surface area measurement using Brunauer-Emmett-Teller (BET) method, Fourier Transform Infrared (FTIR) and Field Emission Scanning Electron Microscopy (FESEM) which showed the formation of orthorhombic M1 phase, $Te_2M_{20}O_{57}$ (M = Mo, V or Nb) when doped with Mg at a molar ratio of Mg/Mo of 0.06. Temperature Programmed Reduction in hydrogen (H_2-TPR) results indicated the enhanced reducibility of the Mg doped catalysts as opposed to the undoped ones, signifying the apparent high activity of the catalyst.

Keywords: magnesium, dopant, microwave-assisted slurry method, reducibility, propane oxidation

Abstrak

Mangkin MoVTeNbOx (MVTN) dan mangkin MoVTeNbOx yang didopkan magnesium (MVTN-Mg) telah dihasilkan melalui kaedah buburan berbantukan oleh penyinaran gelombang mikro. Prekursor telah dikalsinkan dalam nitrogen pada suhu 873 K and seterusnya dirawat dengan hidrogen peroksida. Sifat fisikokimia mangkin yang dikaji dengan menggunakan pembelauan sinar-X (XRD), pengukuran luas permukaan dengan kaedah Brunauer-Emmett-Teller (BET), spektroskopi inframerah transformasi Fourier (FTIR) dan medan elektron-mikroskopi imbasan elektron (FESEM) menunjukkan pembentukan fasa ortorombik M1, $Te_2M_{20}O_{57}$ (M = Mo, V atau Nb) apabila mangkin didopkan magnesium dengan nisbah molar Mg/Mo adalah 0.06. Keputusan penurunan terprogram suhu dengan hidrogen (H_2-TPR) mendedahkan penambahbaikan kebolehturunan mangkin Mg-MoVTeNbOx berbanding dengan mangkin tanpa dopan dan dengan demikian ini menandakan aktiviti mangkin yang tinggi.

Kata kunci: magnesium, dopan, kaedah buburan dibantu oleh penyinaran gelombang mikro, kebolehturunan, pengoksidaan propana

Introduction

Multicomponents MoVTeNbOx catalysts have been recognized as the most promising catalyst in giving high activity and selectivity in propane partial oxidation to acrylic acid [1]. Typically, MoVTeNbOx catalysts present as main crystalline phases of orthorhombic M1 phase $Te_2M_{20}O_{57}$ (M = Mo, V or Nb) [2-11] and hexagonal M2 phase

$Te_{0.33}MO_{3.33}$ (M = Mo, V or Nb) [4-10]. Each of the individual elements in the mixed oxide catalysts has its own role in converting propane to acrylic acid. It was proposed that propane adsorbed on the V^{5+} site of the catalyst surface through the formation of resonance structure with V^{4+}, hence the catalyst must be in a reduced state. Te^{4+} strategically positioned with the bonding distance of its surface, abstract the α-hydrogen of propane to form propylene [12]. Further process is followed by the insertion of oxygen at Mo^{6+} site, thus forming acrolein and followed by another oxygen insertion at the same site to form acrylic acid [13]. Nb^{5+} site is needed to stabilize the product (acrylic acid) from further oxidation into CO and CO_2 [14]. The ability of MoVTeNbOx to be reduced is a prime condition for a successful catalyst as this will activate it into reacting with the incoming reactant (propane). The reducibility of the catalyst is determined by subjecting it into reducing environment such as CO and hydrogen followed by the quantification of the amount of oxygen removed. The onset of reduction process and the peak maxima for the reduction give an indication of the extent of reduction of the metal oxides.

The catalyst properties may also be further improved by the introduction of metal ions into the lattice [15-21]. Promoter such as cobalt has been reported successful in modifying the properties of $(VO)_2P_2O_7$ through the formation of crystalline form of V^{4+} (vanadyl pyrophosphate, $(VO)_2P_2O_7$), $CoPO_4$ phase and a small amount of V^{5+} (β-$VOPO_4$ phase). It also plays a role in having an effect on the reducibility of the catalyst through oxygen diffusion within the lattice of the $(VO)_2P_2O_7$ catalyst that have dramatically increased the specific rate of butane oxidation into forming maleic anhydride three times as compared to the undoped ones [22]. There is also a study done on incorporating potassium into the MoVSb mixed oxide catalysts to affect the catalytic ability. It was found that the conversion of propane was slightly decreases. However, with an appropriate amount of this alkaline metal, it drastically increases the selectivity of acrylic acid about 2 to 3 times as compared to undoped catalysts. In addition, a decrease in the selectivity of undesired products (acetic acid, carbon monoxide and carbon dioxide) could be seen [23-26].

Pure M1 phase MoVTeNbOx can be obtained directly by hydrothermal synthesis [27,28] in an autoclave heated at 448 K in a nitrogen atmosphere with a synthesis time of 72 h. The synthesis method is mainly characterized by its high solvent effect and equilibrium conditions which lead to the formation of the favoured crystalline phase. Another approach is by using a slurry method [29,30] on the basis of a non-solution precursor. This condition inevitably contributes to the multiphase MoVTeNbOx system in which the species is always present in different valence states due to its non-equilibrium state.

In the present work, a microwave-assisted slurry method has been developed for the synthesis of MoVTeNbOx catalysts, promoted and undoped ones. The method allows intimate mixing of the metal species in a homogeneous state under atmospheric pressure in a very short time. This method is derived from the patented method developed by this research group [31].

Materials and Methods

Catalysts preparation

The undoped (MVTN) and magnesium-promoted MoVTeNbOx (MVTN-Mg) catalysts with a Mo/V/Te/Nb/Mg molar ratio of 1/0.3/0.23/0.12/x (x = 0.02, 0.04, 0.06, 0.08, 0.10) were prepared via microwave assisted slurry method. Ammonium heptamolybdate tetrahydrate, $(NH_4)_6Mo_7O_{24}.4H_2O$ (Merck), ammonium metavanadate, $(NH_4)VO_3$ (Merck), telluric acid, $Te(OH)_6$ (Sigma-Aldrich), ammonium niobium oxalate, $(NH_4)_2Nb_2(C_2O_4)_5$ (Sigma-Aldrich), and magnesium nitrate hexahydrate, $Mg(NO_3)_2.6H_2O$ (Bendosen Laboratory Chemicals) were used as metal sources for each of the elements. Appropriate amount of different metal salts was added in sequence into deionized water beginning ammonium heptamolybdate tetrahydrate and followed by ammonium metavanadate, telluric acid and magnesium nitrate hexahydrate to give solution A. Each time after the metal salt was added, the solution was subjected to microwave irradiation for 1.5 minutes. While solution B was obtained by dissolving ammonium niobium oxalate in deionized water and was also subjected to 1.5 minutes microwave irradiation. After that, the two solutions were mixed and the resulting orange slurry was aged for overnight to homogenise the particle distribution. The slurry was then dried by using a rotary evaporator at 353 K to give a sample precursor. Calcination was then carried out to the precursor where it was heated at 553 K for 1 h in air and at 873 K for 2 h under nitrogen flow. Post treatment process was done by washing the solid with 30% hydrogen peroxide. The peroxide was

removed through centrifugation, and the solid was dried in an oven at 373 K for overnight. The Mg containing catalysts are designated as MVTN-Mg(x), x being the Mg/Mo molar ratio.

Catalysts characterization

The BET surface area of the catalysts was determined by using a Thermo Finnigan Sorptomatic Instrument model 1990 series with adsorption of nitrogen at 77 K.

Powder X-ray diffraction (XRD) patterns were collected by employing a Shimadzu 6000 X-ray diffractometer using Ni filtered CuK_{α} radiation with wavelength λ=1.542Å. The catalysts were ground and put on a horizontal sample holder. The XRD patterns were recorded in the 2° to 60° 2Θ range at a scanning rate of 2.0° min^{-1}.

Fourier-Transform Infrared (FT-IR) analysis was carried out at room temperature in the 280 – 4000 cm^{-1} region with a Perkin Elmer 1725X spectrophotometer. The pellets were prepared with mixing a catalyst sample with 200 mg of dry KBr and pressed into disks.

The morphology of the catalysts was obtained by using a Nova 200 Nanolab Field Electron Scanning Electron Microscope (FE-SEM). The surface catalyst images were recorded at an accelerating voltage of 15 kV and magnification of 100,000.

Reducibility study

Temperature programmed reduction in hydrogen (H_2-TPR) was performed by using a Thermo Finnigan TPDRO 1100 apparatus, utilizing a thermal conductivity detector (TCD). Before subjecting the catalysts to the reducing gas, the samples were first treated by flowing nitrogen at room temperature for half an hour to remove any weak species that might present on the surface. After which the nitrogen gas flow was switched to 5.1% H_2 in argon gas with a flow rate of 25 ml min^{-1} at a heating rate of 10 K min^{-1} from room temperature up to 1223 K. The mass spectrometer records the evolution of water continuously during the course of the reaction.

Results and Discussion

Characterisation of as-synthesised samples

XRD patterns of the as-synthesised samples (before calcination) are displayed in Figure 1. The reflections are found in the 2θ = 5 – 15° and 25 – 30° range. These reflections are typical of Anderson-type structure $(NH_4)_6TeMo_6O_{24}.7H_2O$ as reported by Evans et al. [32] and $(NH_4)_7TeMo_5VO_{24}.8H_2O$ reported by Sun et al. [33] which indicates the presence of heteropoly compounds (HPCs). The narrow diffractions observed in undoped sample becomes broad bands when Mg was added signifying that the HPCs slowly turns into pseudo-crystallines with increasing amount of Mg.

Figure 2 shows the FTIR spectra of as-synthesised samples taken in the range of wavenumber 280 – 4000 cm^{-1}. All samples give FTIR spectra with practically identical bands. The bands at 576 cm^{-1} are assigned to a V=O group and/or V-O-*M* bonds (*M* = V, Nb). Whereas the absorption bands at 483, 630, 678, and 883 cm^{-1} could be assigned to heteropoly-telluromolybdates, $(NH_4)_6TeMo_6O_{24}.7H_2O$ [34,35] in accordance with the XRD results. The bands at 3400 – 3550 cm^{-1} are associated to the symmetric and anti-symmetric O-H bending modes of lattice water, while the bands at 1650 cm^{-1} could be related to H-O-H bending modes [36,37]. Additionally, the asymmetric and symmetric stretching vibration of ammonium cation ($\nu(NH_4^+)$) are determined by the band at 1425 cm^{-1}, and at 3000 and 3200 cm^{-1} respectively [34-36].

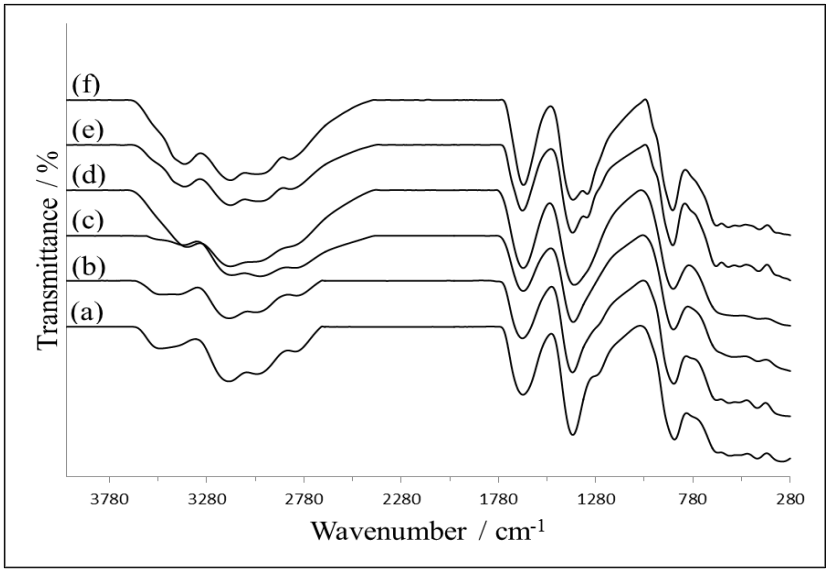

Figure 2. FTIR spectra of magnesium free and magnesium containing catalyst precursors: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10).

Characterization of calcined catalysts

The XRD patterns of the calcined catalysts are shown in Figure 3. All of the samples show a similar diffraction peaks with five prominent peaks at 2θ = 22.1°, 28.2°, 36.2°, 45.0° and 50.0°. Termed as the "famous five", however, it was reported that the MoVTeNbOx catalysts containing these peaks did not work effectively [38],

suggesting they are not the key drivers of a successful MoVTeNb mixed oxide catalysts. These five peaks associated with the presence of hexagonal M2, $Te_{0.33}MO_{3.33}$ (*M* = Mo, V and Nb) phase [39-41] which is isomorphous to that of $Sb_4M_{10}O_{31}$ phase [10], and hexagonal tungsten bronze (HTB)-type phase [42]. The formation of M2 phase is common since it is usually started to form at 723 K [43]. It is also noted the development of new peaks in the range of 2θ = 6.7 – 10.0°. These peaks are assigned to orthorhombic M1, $Te_2M_{20}O_{57}$ (*M* = Mo, V and Nb) phase [43,44].

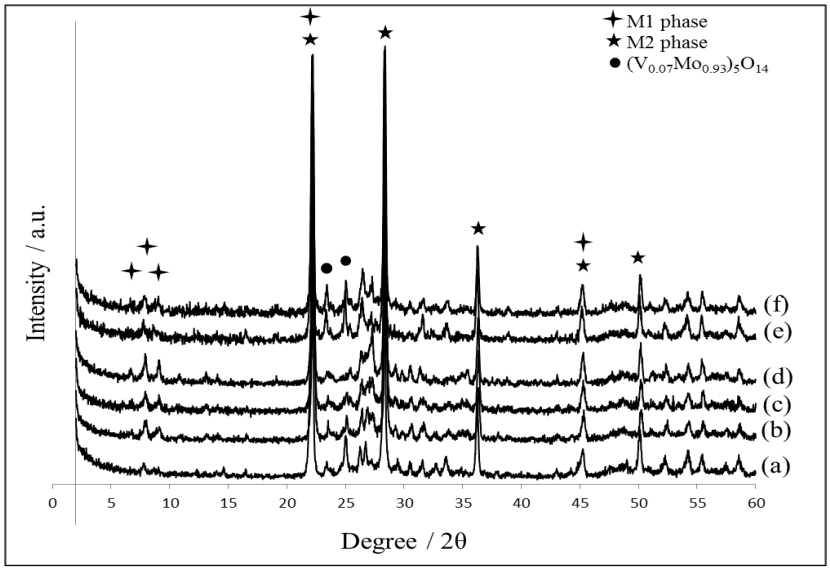

Figure 3. XRD patterns of magnesium free and magnesium containing calcined catalysts: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10).

In the case of post-treated catalysts, $Te_2M_{20}O_{57}$ (*M* = Mo, V and Nb) orthorhombic M1 was the crystalline phase mainly observed (Figure 4) which can be identified with the peaks at 2θ = 6.7°, 7.8°, 9.0°, 22.1°, 26.2°, 26.8°, 27.2°, 29.2° and 35.4° [7]. Thus it can be concluded that the post treatment with an aqueous solution of hydrogen peroxide leads to the selective removal of the hexagonal M2 phase from the Mg-doped and undoped MoVTeNbOx catalysts containing M1 and M2 phase mixtures [45]. However, additional phase of tetragonal $(V_{0.07}Mo_{0.93})_5O_{14}$ (JCPDS File No. 31-1473) can be found. Comparison of the XRD patterns of the Mg-promoted with undoped catalysts revealed that the appearance of phase reflections at 2θ = 23.3, 24.6 and 31.5° in undoped catalysts corresponds to the rich tetragonal $(V_{0.07}Mo_{0.93})_5O_{14}$ phase. This phase was slightly diminished when Mg was added until the molar ratio of Mg/Mo was 0.06, suggesting the incorporation of Mg in catalyst lattice is responsible for the suppression of the tetragonal crystallization step. However, beyond that amount (molar ratio = 0.06) the crystallization of tetragonal phase was started to taken over. The XRD patterns of the formed structural material of MVTN-Mg(0.06) catalyst is quite similar to the one observed in the case of monophasic MoVTeNbOx orthorhombic M1 phase which were hydrothermally synthesized [27,28].

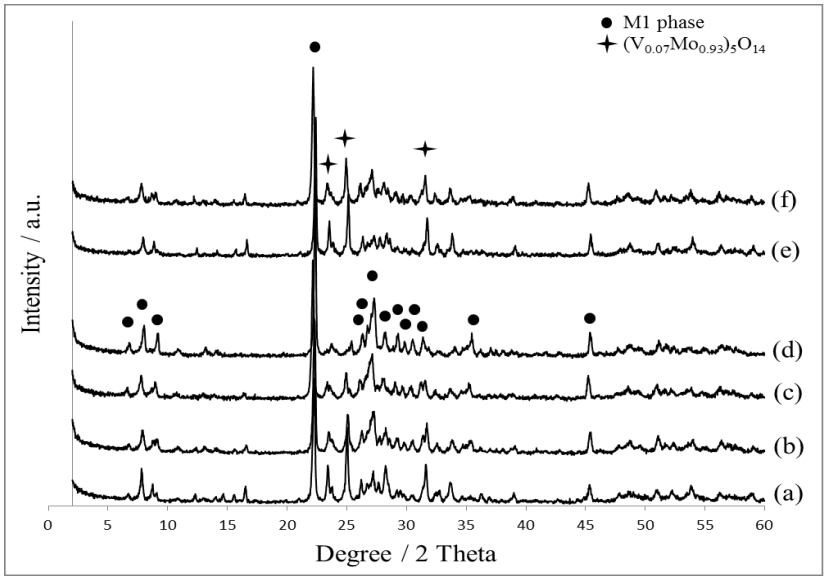

Figure 4. XRD patterns of magnesium free and magnesium containing post-treated catalysts: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10)

FTIR spectra of post-treated catalysts are shown in Figure 5. The FTIR spectra of bulk MVTN and MVTN-Mg samples composed of M1 and tetragonal phases show absorption bands at 357 cm^{-1} indicates the existence of Mo-O-Mo bridge with symmetric stretching vibration [34]. Meanwhile, the band that is related to the anti-symmetric vibration of Mo-O-*M* (*M* = V, Nb, Te) bridging bonds which appear around 700 – 900 cm^{-1} is observed at 745 cm^{-1}. The bands at 560 cm^{-1} may probably presents a V=O group and/or V-O-*M* (*M* = Mo, Nb, Te) bonds. The symmetric stretching vibration of Mo=O group that is around 900 – 1000 cm^{-1} is identified by the absorption band at 910 cm^{-1} [46,47]. The most highlighted difference among IR spectra is an intensity of the bands for the catalysts containing tetragonal phase due to the improved crystallization of this phase. The broad bands at higher region (at around 3000 cm^{-1} – 3400 cm^{-1}) could be attributed as symmetric and anti-symmetric O-H bending modes of lattice water. The absorption bands at about 1650 cm^{-1} could be assigned to the presence of H-O-H bending modes [36,37]. This is due to the incomplete drying of post-treated catalysts after washing with hydrogen peroxide. The deviation caused by the containing water was eliminated as pre-treatment was carried out before catalysts were characterised.

The morphology of post-treated catalyst was investigated by FESEM analysis. In general, all of the catalysts were found to have a similar morphology of small rod shaped crystallites as shown in Fig. 6. Such kind of morphology was already been reported by López Nieto and his research team, and are commonly observed for M1 phase crystals [48]. The particle size is rather homogeneous with apparent edges and pointed corners that agreed well with the sharp peaks observed in XRD results. There is no clear effect of the addition of promoter to the catalyst morphology.

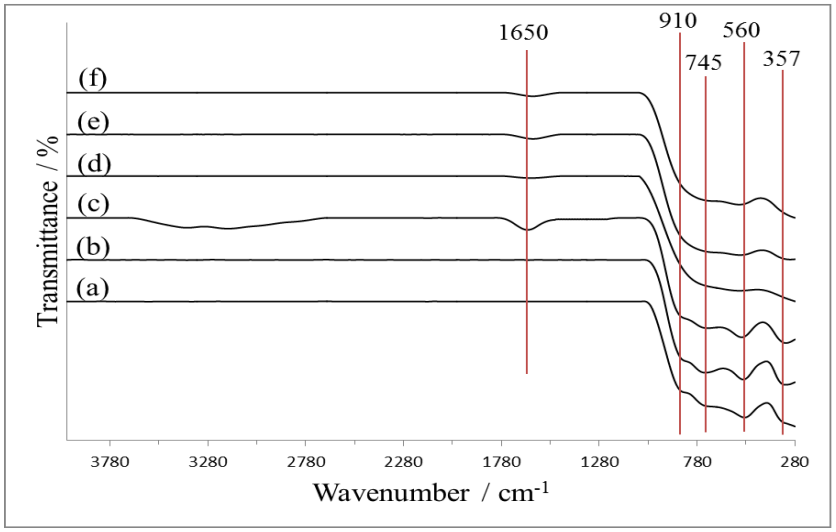

Figure 5. FTIR spectra of magnesium free and magnesium containing post-treated catalysts: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10)

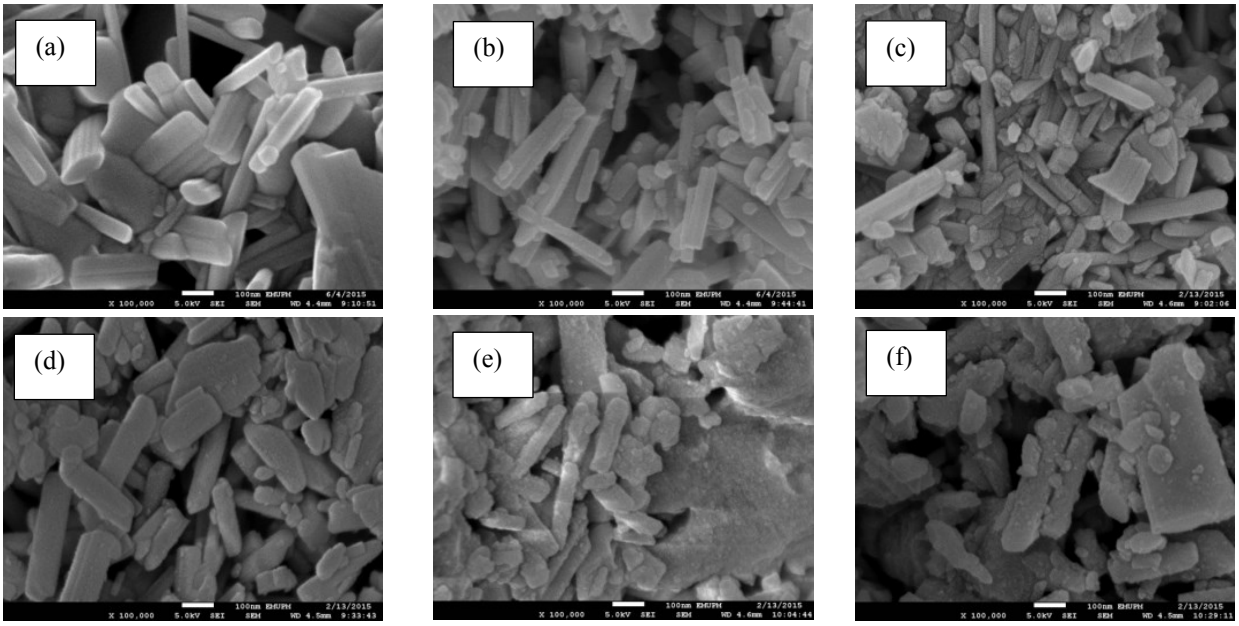

Figure 6. FESEM images of magnesium free and magnesium containing post-treated catalysts: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10)

BET surface area of MVTN and MVTN-Mg catalysts are shown in Table 1. Low surface area (3.3 – 4.2 m^2 g^{-1}) is observed in all calcined samples. Therefore, there is no significant effect of magnesium addition to the catalyst crystal structure. However, when the catalysts were post-treated with hydrogen peroxide, the surface area value

significantly improved (13.4 – 20.4 m^2 g^{-1}). This could be related to the selective removal of M2 phase during the post treatment that contributed to the smaller particle size.

Table 1. General characteristics of heat-treated and post-treated catalysts

Catalysts	BET Surface Area (m^2 g^{-1})		TPR Results[a]

[a] TPR results of post-treated catalysts

Catalyst reducibility study

The TPR profiles of MVTN and MVTN-Mg catalysts are shown in Figure 7. The analysis was done by flowing hydrogen over the catalyst while temperature was increased at a heating rate of 10 K/min from room temperature to 1223 K. The hydrogen upon interacts with surface oxygen will reacts to form water as the product. The evolution of water was recorded continuously during the course of reaction.

The interaction between the gas phase hydrogen with the surface oxygen can be represented as follows:

$$H_2(g) + O(s) \rightarrow H_2O(g) + \square$$

where (g), (s), and □ denotes gas, surface and vacancy.

Comparison of the peak profiles show that the undoped catalyst (MVTN) has a broad peak with maximum temperature (T_m) occurs at 930 K. The catalyst is less reducible as stipulated by the slow climbing of the reduction peak. On the other hand, all of the promoted catalysts (MVTN-Mg) show a different reduction profile with the peak climbing start immediately after the catalyst started to reduced. The T_m can be found as low as 825 K (for sample MVTN-Mg (0.02)). There is also a presence of other peak maxima in these Mg-promoted catalysts which signify the kinetically different of oxygen species present in the catalysts. The onset of reduction for Mg-promoted catalysts was at 650 K which is coincidence with the reaction temperature for propane oxidation. Meanwhile, the undoped catalyst showed the onset of reduction at about 770 K which indicated the less reducible of this sample.

For the undoped MVTN catalyst, the reduction of pure *M*On (*M* = Mo, V) was at 948 K and 995 K [49]. Both Mo and V species undergo stepwise reduction from $Mo^{6+} \rightarrow Mo^{4+}$ and $Mo^{4+} \rightarrow Mo^0$, and $V^{5+} \rightarrow V^{4+}$ and $V^{4+} \rightarrow V^0$,

respectively. Therefore, the reduction peak observed in this catalyst at 930 K could be attributed to the reduction of both species. Additionally, Nb^{5+} might also be reduced to Nb^{4+} at higher reduction temperature of more than 1000 K as indicated by Pereira et al. [50] in their work on Nb_2O_5.

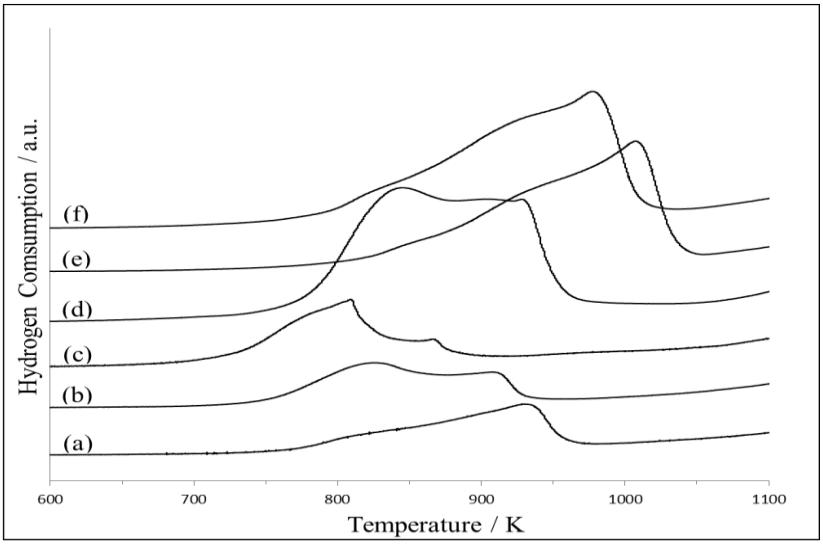

Figure 7. TPR profiles of magnesium free and magnesium containing post-treated catalysts: (a) MVTN, (b) MVTN-Mg (0.02), (c) MVTN-Mg (0.04), (d) MVTN-Mg (0.06), (e) MVTN-Mg (0.08) and (f) MVTN-Mg (0.10)

Meanwhile, the lower peak maximum given by the Mg-promoted MoVTeNbOx catalysts indicated the positive contribution of promoter. The Mg metals might be well dispersed on the catalyst's surface and formed weaker bonds with oxygen species that promote the reducibility of the catalysts. The reduction profiles of MVTN-Mg catalysts are due to the reduction of MoO_n, VO_n, NbO_n and also from $MgO \rightarrow Mg^0$. For MoO_n, the species reduced from $Mo^{6+} \rightarrow Mo^{4+}$ and $Mo^{4+} \rightarrow Mo^0$, for VO_n, the reduction occurs from $V^{5+} \rightarrow V^{4+}$ and $V^{4+} \rightarrow V^0$, and NbO_n reduces from $Nb^{5+} \rightarrow Nb^0$ [49,50].

The amount of removable oxygen can be quantified by calculating the area under the peak and the value of the reduction activation energy, E_r, can be obtained from the modified version of the Redhead equation 1:

$$\frac{E_r}{RT_m^2} = \left(\frac{A_r}{\beta}\right)[H_2]_m exp\left(\frac{E_r}{RT_m}\right) \quad (1)$$

where T_m is the peak maximum temperature (K) in the rate of reaction of H_2, E_r is the reduction activation energy (kJ mol^{-1}), R is the gas constant (J K^{-1} mol^{-1}), β is the heating rate (K s^{-1}), A_r is the reduction pre-exponential term (cm^3 mol^{-1} s^{-1}) which is given the value of a standard collision number of 10^{13} cm^3 mol^{-1} s^{-1} and $[H_2]_m$ is the gas phase concentration of hydrogen (mol cm^{-3}) at the peak maximum.

The values obtained are listed in Table 1. The total number of oxygen atoms released by the undoped and Mg-promoted MoVTeNbOx catalysts are found similar (~2.56 x 10^{21} atom g^{-1}). Close inspection revealed that the Mg-promoted catalysts are more reducible as indicated by the ability of the catalyst to be reduced at lower temperature. Hence, the oxygen species in these promoted catalysts are more labile signifying the higher activity of the promoted catalysts. It is also important to note that the MVTN-Mg (0.06) sample have the highest total amount of oxygen removed. The oxygen species in this catalyst is more reducible at lower temperature as compared to others due to the existence of orthorhombic M1 phase in this sample that facilitates the oxygen removable.

The reduction activation energy, E_r value > 100 kJ mol^{-1} is high for all samples suggesting that the oxygen being removed are surface and lattice oxygen species. The circumstance that the reduction study was done in an anaerobic condition contributed to these findings. There is no weakly bonded oxygen present in these catalysts as shown by no peak evolution at lower temperature (less than 650 K). Therefore, the surface and lattice oxygen removed in this works are the strongly bonded ones that could be playing an important role in the catalytic activity of the catalysts. It has been reported that the oxidation of propane to acrylic acid requires surface and lattice oxygen to be selectively inserted into the intermediate to form final product. The present of weakly bonded oxygen will somehow assist in the C-C bond breakage that might lead to the formation of unwanted products such as acetic acid, CO and CO_2 [51].

Conclusion

Magnesium doped MoVTeNb mixed oxides were successfully synthesized by microwave-assisted slurry method, calcined in nitrogen at 875 K for 2 h and followed by post treatment with hydrogen peroxide. It was found that the incorporation of magnesium into the catalyst lattice were greatly affected the catalyst properties as can be clearly seen in the formation of crystalline phases as observed in the XRD. A highly pure orthorhombic M1 phase that is reported important in the catalyst activity for propane oxidation have successfully derived when the loading of Mg/Mo was in the molar ratio of 0.06. Adding less or more that will give mixture of phases with the present of tetragonal phase became more dominant. The Mg-doped catalysts show a high reducibility property when subjected to reducing agent which is an important property for an oxidation catalyst. The oxygen in the doped catalysts are more labile to be removed at lower temperature with high amount of oxygen removable as the consequence of the weak interaction of the oxygen with the Mg species over the surface of the catalyst.

Abstract

Three new 4-methoxybenzoylthiourea derivatives namely *N*-phenyl-*N'*-4-methoxybenzoylthiourea (A), *N*-(2-methoxy-phenyl)-*N'*-4-methoxybenzoylthiourea (B) and *N*-(2-nitrophenyl)-*N'*-4-methoxybenzoylthiourea (C) has successfully synthesized and characterized by elemental analysis, Fourier Transform Infrared (FTIR), proton (^{1}H) and carbon (^{13}C) Nuclear Magnetic Resonance (NMR) spectroscopy. Result obtained for IR showed the presence of important bands of the compounds such as ν(N-H), ν(C=O), ν(C-N) and ν(C=S) which were observed at 3200 cm^{-1}, 1670 cm^{-1}, 1200 cm^{-1} and 700 cm^{-1}, respectively. The ^{1}H chemical shifts for CONH and CSNH had been observed around 9 ppm and 12 ppm, respectively. For the ^{13}C resonance, the signal of C=O and C=S had been observed at 180 ppm and 200 ppm, respectively. The efficiency of the synthesized compounds was investigated as corrosion inhibitor of mild steel in 1.0 M H_2SO_4 by using linear polarization resistance (LPR) technique.

Keywords: 4-methoxybenzoylthiourea, spectroscopy, corrosion inhibitor

Abstrak

Tiga terbitan 4-metoksibenzoiltiourea iaitu *N*-fenil-*N'*-4-metoksibenzoiltiourea (A), *N*-(2-metoksifenil)-*N'*-4-metoksi benzoiltiourea (B) and *N*-(2-nitrofenil)-*N'*-4- metoksibenzoiltiourea (C) telah berjaya disintesis dan dicirikan dengan penganalisis unsur, spektroskopi infra merah (IR), proton (^{1}H) dan karbon (^{13}C) resonans magnet nuklear (RMN). Hasil daripada IR menunjukkan kumpulan penting dalam sebatian seperti ν(N-H), ν(C=O), ν(C-N) and ν(C=S) yang terdapat pada 3200 cm^{-1}, 1670 cm^{-1}, 1200 cm^{-1} and 700 cm^{-1}. Anjakan kimia ^{1}H untuk CONH dan CSNH telah dilihat pada 9 ppm dan 12 ppm. Bagi resonans ^{13}C, C=O dan C=S dapat dilihat pada 180 ppm dan 200 ppm. Keberkesanan sebatian yang disintesis telah dikaji sebagai perencat kakisan keluli lembut dalam 1.0 M H_2SO_4 dengan menggunakan teknik rintangan polarisasi linear.

Kata kunci: 4-metoksibenzoiltiourea, spektroskopi, perencat kakisan

Introduction

Corrosion prevention by using organic inhibitors is one the most practical ways to protect metal in acidic medium [1] The studies on it had attracted many attentions of researchers [2,3]. Corrosion inhibitors are substances that may retard or slow down the corrosion rate when added in small concentration to the system. Organic inhibitors containing nitrogen (N), sulphur (S) and oxygen (O) atoms are considered to be the effective and potential corrosion inhibitors [3-6]. The inhibitors that have these atoms in their structure may induce greater adsorption of the

compounds onto the metal surfaces which leads to the formation of a corrosion protecting film. In addition, the stability of the adsorbed inhibitor film on the metal surface also depends on functional groups [9,11,12].

Thiourea and its derivatives were reported to be the potential corrosion inhibitors as compared with other organic compounds because thiourea molecules contain one S atom and two N atoms [6-8]. These atoms act as centre of adsorption that forms a protective layer on the metal surface from the corrosive attack [9-10]. The corrosion inhibition of thiourea is greater in acidic media because this inhibitor acts simultaneously in both anodic and cathodic areas. Thiourea molecules are very effective inhibitors for steel in acidic conditions because S atom is easily protonated in acidic solution and a stronger electron donor than nitrogen [16].

In this study, a series of 4-methoxybenzoylthiourea derivatives with different substituent groups were synthesized and tested as potential corrosion inhibitor in 1.0 M H_2SO_4 to achieve inhibition efficiency more than 90%. The effect of different substituent group on the inhibition efficiency at different inhibitors' concentrations were also has been studied.

Materials and Methods

Physical measurement

All reactions were performed under an ambient atmosphere and no special precautions were taken to exclude air or moisture. The chemicals (4-methoxybenzoyl chloride, ammonium thiocyanate, aniline, *o*-Anisidine, 2-nitroaniline) and solvents (acetone and acetonitrile) were purchased from Sigma Aldrich and were used without further purification. Melting points were measured using BÜCHI Melting Point B-545. Infrared spectra were recorded using FTIR Perkin Elmer 100 Spectrophotometer in the spectral range of 4000 to 400 cm^{-1} by using KBr pellet. ^{1}H and ^{13}C NMR spectra were obtained from Bruker Advance III 300 Spectrometer at room temperature. The elemental analyses of compound were performed by CHNS Analyzer FLASH 2000 series.

Synthesis of *N*-phenyl-*N'*-4-methoxybenzoylthiourea (A)

Freshly prepared 5mmol (0.85 g) of 4-methoxybenzoyl chloride in 15 ml acetone was added to equal molar of ammonium thiocyanate (0.38 g). The solution was stirred about 20 min. The precipitate formed was discarded and the solution was kept. An amount of 5 mmol (0.46 ml) of aniline was mixed with the previous solution and undergo refluxed for 3 hours. The solution was poured into a beaker containing ice cubes. The resulting precipitate was collected by filtration, washed ethanol and purified by recrystallization with acetonitrile. Figure 1 show the chemical structure of *N*-phenyl-*N'*-4-methoxybenzoyl thiourea (A).

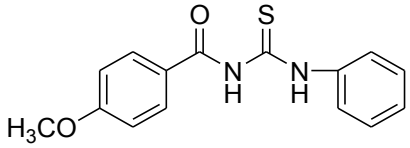

Figure 1. Chemical structure of *N*-phenyl-*N'*-4-methoxybenzoyl thiourea (A)

Synthesis of *N*-(2-methoxyphenyl)-*N'*-4-methoxybenzoylthiourea (B)

Similar procedure as the above, this compound was synthesized by reacting 4-methoxybenzoyl chloride (5 mmol, 0.85 g), ammonium thiocyanate (5 mmol, 0.38 g) and *o*-Anisidine (5 mmol, 0.62 g). Figure 2 show the chemical structure of N-(2-methoxyphenyl)-N'-4-methoxybenzoyl thiourea (B).

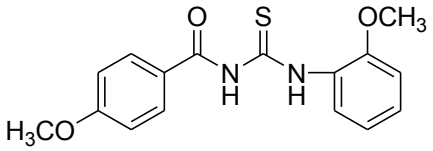

Figure 2. Chemical structure of *N*-(2-methoxyphenyl)-*N'*-4-methoxybenzoyl thiourea (B)

Synthesis of *N*-(2-nitrophenyl)-*N*'-4-methoxybenzoylthiourea (C)
This compound was prepared by similar procedure as above with 4-methoxybenzoyl chloride (5 mmol, 0.85 g), ammonium thiocyanate (5 mmol, 0.38 g) and 2-nitroaniline (5 mmol, 0.69 g). Figure 3 show the chemical structure of N-(2-nitrophenyl)-N'-4-methoxybenzoyl thiourea (C)

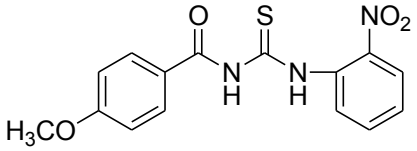

Figure 3. Chemical structure of *N*-(2-nitrophenyl)-*N*'-4-methoxybenzoyl thiourea (C)

Linear polarization resistance (LPR) technique
This method was carried out in a three-electrode cells consist of Silver-silver chloride (Ag/AgCl) as a reference electrode, platinum as a counter electrode and the mild steel sample as working electrode. The working electrode was prepared by embedding a rod with a mild steel sample in epoxy resin. The exposed surface area of the sample was 0.065 cm^2. The measurements by AUTOLAB potentiostat/galvanostat instrument equipped with NOVA software. The polarization curves were recorded at a rate of 0.5 mV s^{-1}. Prior to analysis, the working electrode was polished with emery paper, washed with distilled water, dried and finally immersed in the tested solution for an hour to achieve steady state. The tested solution used was sulphuric acid (H_2SO_4) with or without compound A, B and C.

Results and Discussion

Physical measurement
Table 1 shows the percentage yield, colour, melting point and elemental percentage of compound A, B and C. The composition values of the calculated and experimental for elemental analysis are in good agreement. Meanwhile, Table 2 shows the important FTIR adsorption bands, ^1H and ^{13}C NMR chemical shifts for the three compounds.

Table 1. Percentage yield, colour, melting point and elemental analysis for compound A, B and C

Compound	Percentage yield (%)	Colour	Melting point (°C)	Elemental analysis (Experimental) (%) C	H	N	S
A	52.9	White	140	62.94 (61.00)	4.90 (4.92)	9.79 (9.06)	11.19 (10.42)
B	63.1	White	138	60.76 (60.84)	5.06 (4.95)	8.86 (8.56)	10.12 (9.29)
C	58.7	White	142	54.38 (59.46)	5.06 (4.31)	12.69 (10.87)	9.67 (8.50)

Table 2. FTIR absorption bands, NMR proton (^{1}H) and carbon (^{13}C) shifts for compound A, B and C

Compound	FTIR				NMR ^{1}H		^{13}C

Linear polarization resistance

The polarization curves of mild steel in 1.0 M H_2SO_4 in the absence and presence of 4-methoxybenzoyl thiourea derivatives are shown in Figures 4 – 6. The corrosion parameters such as corrosion potential (E_{corr}), corrosion current density (i_{corr}), anodic Tafel slope (b_a), cathodic Tafel slope (b_c) and inhibition efficiency (IE%) are listed in Table 3. As compared with the H_2SO_4 without the presence of any inhibitor or also known as blank, it can be observed that i_{corr} decrease in the presence of the inhibitors and decrease as the concentration of the inhibitors increases. The decrease of these values with the presence of inhibitor and increasing inhibitors concentration indicates that there are inhibiting natures of the thiourea derivatives [13,14].

Table 3. LPR parameters of mild steel in 1.0 M H_2SO_4 containing different concentrations of A, B and C

Compound	Concentration (M)	b_a (V/dec)	b_c (V/dec)	E_{corr} (V)	i_{corr} (A/cm^2)	Corrosion rate (mm/year)	IE %
Blank	-	0.1339	0.0380	-0.4287	2.02E-04	2.3425	-
A	1 x 10^{-5}	0.0308	0.0214	-0.4119	5.83E-05	0.6767	71.1
	1 x 10^{-4}	0.1138	0.0256	-0.3941	5.39E-05	0.6258	73.3
	1 x 10^{-3}	0.0618	0.0208	-0.3693	4.13E-05	0.47919	79.6
B	1 x 10^{-5}	0.1042	0.0349	-0.4045	6.53E-05	0.7581	67.7
	1 x 10^{-4}	0.0697	0.0258	-0.3944	3.48E-05	0.4036	82.8
	1 x 10^{-3}	0.0570	0.0199	-0.3744	2.60E-05	0.3017	87.1
C	1 x 10^{-5}	0.1282	0.0406	-0.4226	0.00012	1.3890	40.6
	1 x 10^{-4}	0.0665	0.0340	-0.4110	6.43E-05	0.7460	68.2
	1 x 10^{-3}	0.1225	0.0460	-0.3900	6.36E-05	0.7386	77.6

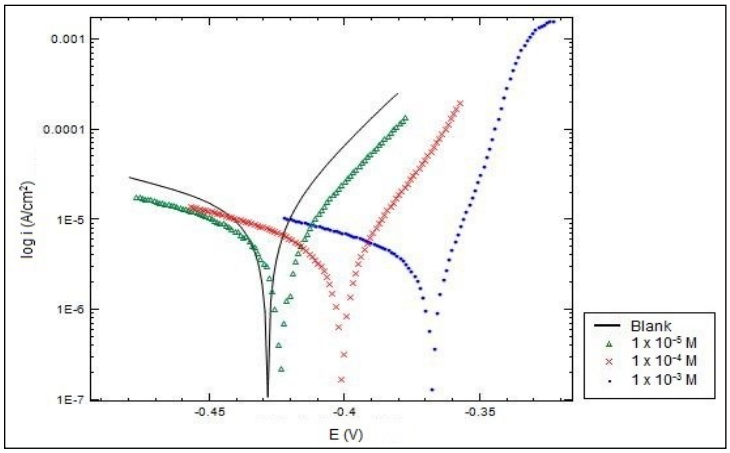

Figure 4. Polarization curves of various concentration of compound A in 1.0 M H_2SO_4

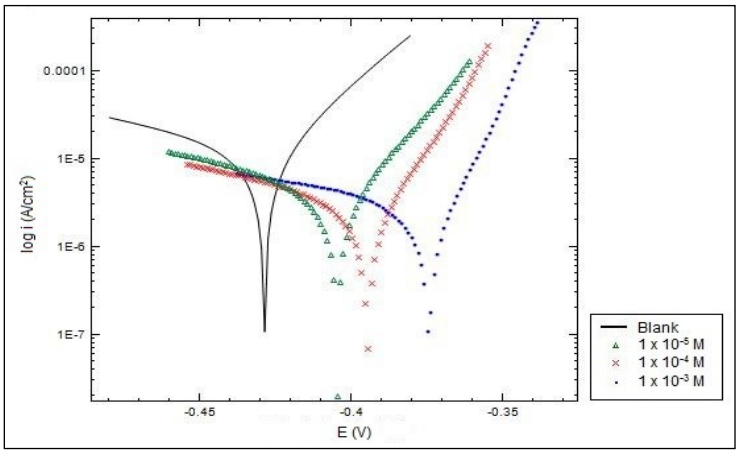

Figure 5. Polarization curves of various concentration of compound B in 1.0 M H_2SO_4

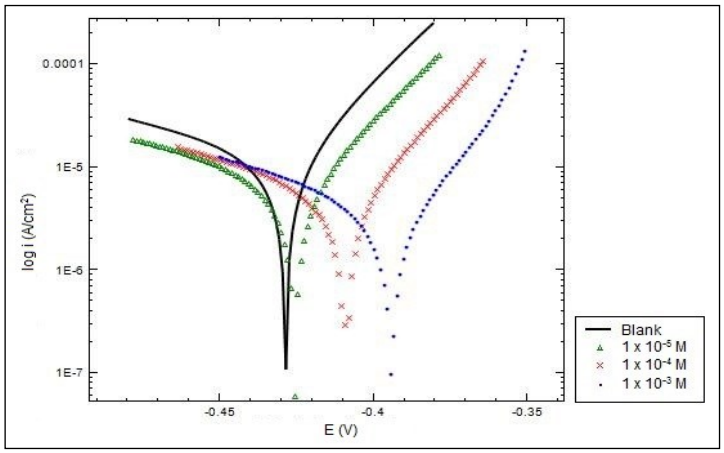

Figure 6. Polarization curves of various concentration of compound C in 1.0 M H_2SO_4

From Table 3, the E_{corr} values shown slight changes in the presence of the inhibitors. This means that the thiourea derivatives are mixed-type inhibitor in 1.0 M H_2SO_4. In addition, the average displacement of E_{corr} is not more than 85 mV, which suggest that these compounds are mixed-type inhibitors [13] even though the polarization curves shift toward the positive side with respect to blank. It also can be observed that the values of b_c did not change drastically with the addition of the compounds showing that thiourea derivatives did not affect the hydrogen evolution reaction [9]. The changes in b_a values with the inhibitors concentration shows that may alter the metal dissolution process. Results from this technique shows that the efficiency of these compounds increased as the concentration of corrosion inhibitor increased. The IE% of the inhibitor was calculated based on the i_{corr} values obtained from the measurement using the following formula equation 1 [15]:

$$\text{IE } \% = \frac{I'_{corr} - I_{corr}}{I'_{corr}} \quad (1)$$

where I'_{corr} and I_{corr} are the corrosion current densities in the absence and presence of an inhibitor, respectively.

Among these three compounds, compound B has the highest IE% which is 87.1%. The presence of different substituent in each compounds affect the IE%. Since compound B has methoxy substituent which is classified as electron donating group, it donates electrons to the system and make it electron rich. This enables the compound to form a protective layer on the metal surface. Unlike compound C which posses electron withdrawing group substituent (NO_2), the substituent will withdraw electrons from the system and make it unstable. Thus, forming a less effective layer. The order of the effectiveness of the compounds as corrosion inhibitors are B > A > C.

Conclusion

N-phenyl-*N'*-4-methoxybenzoylthiourea (A), *N*-(2-methoxyphenyl)-*N'*-4-methoxybenzoylthiourea (B) and *N*-(2-nitrophenyl)-*N'*-4-methoxybenzoylthiourea (C) has been successfully synthesized and characterized. Compound B with methoxy substituent has the highest IE% which is 87.1%. This compound has the potential as an effective corrosion inhibitor that can be used in acid pickling process in chemical or petroleum industries.

Abstract

The concentration of total organic carbon (TOC) and mean size sediment in a total of 24 samples of surficial sediment were determined. From the results of study, the concentration of TOC (5.33%) was found high nearby the housing area at Sungai Pinang. At the downstream of the river tend to have higher concentration of TOC (1.05% - 5.33 %) while at the upstream tend to have low degree of TOC in surficial sediments (0.36% - 0.78%). The major contribution in TOC contamination at the bottom part of the river maybe due to anthropogenic activities such as waste effluent from urban runoff, industrial activities and boat activities. Apart from that, the mean grain size was probably an important factor that influences the TOC content in surficial sediment at Sungai Pinang. This is because the distribution of the mean grain size that had similar trend to TOC. In addition, the high correlation relationship between TOC and mean grain size were observed and it had accounted for $r = 0.67$ owing to fine particles of sediment which had provided a large binding capacity for the sorption of organic carbon. Moreover, fine sediment probably indicates slow hydrodynamic energy at the downstream. It might affect the chemical sorption process and allow the particulate organic carbon to accumulate at the bottom of the water column. Thus, fine sediment maybe playing dominant role in the content of TOC in surficial sediment at Sungai Pinang.

Keywords: total organic carbon, mean size sediment, surficial sediments, Sungai Pinang

Abstrak

Kandungan jumlah karbon organik (TOC) dan purata saiz sedimen di dalam 24 sampel sedimen permukaan telah ditentukan. Dari hasil kajian ini, kepekatan TOC (5.33%) didapati tinggi berhampiran dengan kawasan perumahan di Sungai Pinang. Di kawasan hilir sungai tersebut mempunyai kepekatan TOC yang lebih tinggi (1.05% - 5.33%) manakala di kawasan hulu sungai mempunyai kepekatan yang rendah dalam permukaan sedimen (0.36% - 0.78%). Kemungkinan punca utama untuk pencemaran TOC di bahagian hilir sungai adalah dari aktiviti antropogenik seperti sisa buangan daripada bandar, aktiviti perindustrian dan aktiviti bot. Selain itu, purata saiz partikel kemungkinan adalah faktor penting menpergaruhi kandungan TOC dalam sedimen permukaan di Sungai Pinang. Ini kerana taburan purata saiz partikel mempunyai corak yang sama dengan TOC. Tambahan pula, hubungan korelasi antara TOC dan purata saiz partikel didapati tinggi dalam sedimen permukaan, iaitu $r = 0.67$ disebabkan saiz partikel yang halus memperolehi kapasiti pengikatan yang luas untuk penyerapan karbon organik. Selain itu, sedimen yang halus berkemungkinan menunjukkan tenaga hidrodinamik yang perlahan di bahagian hiliran. Hal ini berkemungkinan mempengaruhi proses penyerapan dan pengumpulan zarah karbon organik di bahagian bawah turus air. Oleh itu, sedimen yang halus berkemungkinan besar memainkan peranan yang paling dominan kepada kandungan TOC yang dalam sedimen permukaan di Sungai Pinang.

Kata kunci: jumlah karbon organik, purata saiz sedimen, sedimen permukaan, Sungai Pinang

Introduction

In general, total organic carbon (TOC) includes all of organic carbon compounds contain in sediment [1,2]. The amount of organic matter that can be stored in river sediment is influenced by several factors, for instances, the types and sources of organic compounds introduced, sediment texture, grain particle size and sedimentation [3,4]. In previous sediment geochemical-related research studies, TOC has been proved to be playing a dominant controlling factor as it manipulates the distribution of other components, including chemical component and biological component in aquatic environment [1,5]. The quantity of organic and inorganic chemical contaminants in sediments such as hydrophobic organic compounds and total mercury respectively were reported to have high correlation with TOC [6,7,8,]. This is because the organic matter is regulating the mobility of those pollutants in sediment [6,7,8]. In addition, some researchers are calculating the fraction of TOC with total sulfur while some other researchers determine the relationship between TOC and total nitrogen for the purpose of evaluation of the type of sedimentary environment and elucidate the dynamic of organic matter in sediment [2,3,9]. Hence, TOC is one of the important chemical sediment quality measurements that has been widely used in environmental evaluation analysis [1,8].

Surficial sediment was used as environment indicator in this present study. Surficial sediment is acting as the sink of TOC and other chemical pollutants as it is able to accumulate all the substances that have settled down on the bottom of water column, including particulate organic carbon and sediment particles which is attached with organic carbon substance [3,5,9]. Thus, surficial sediment is capable of reflecting the latest deposited pollution history [2,10]. On one hand, the strength of preservation of chemical components in surficial sediment is much greater and consistence [10]. However, some contaminants in sediment may return into water system if there is an environmental alteration [10]. Therefore, surficial sediment has been widely used as environmental tool by researchers.

It is important to determine the TOC content at Sungai Pinang because it is one of seven most contaminated river basins in Malaysia according to the Department of Environment (DOE) [11,12]. Based on National Water Quality Standards for Malaysia (NWQS), the water quality of Sungai Pinang basin was classified under IV which is very polluted in year 1999 [13]. In addition, previous study by Saad et al. [13] had concluded that the water quality of Sungai Pinang had degraded and was classified under V showing a very high level of chemical oxygen demand (COD) which was 1219.33 mg/L, very low in dissolved oxygen (DO) which account for < 1.0 mg/L and the temperature ($^{\circ}$C) of water was not categorized in normal range. Apart of that Sungai Pinang is surrounded by heavy industrial and urban areas, the river mouth is an important channel in the distribution of carbon matters [9,14]. Thus, the surficial sediment of Sungai Pinang is exposure to various chemical compound contamination which is contained in the bottom of the water.

In the recent years, Malaysia Environment Quality report (2012) showed that the water quality in Sungai Pinang estuary had improved to class ÏII [15]. However, chemical pollutants that is adsorbed onto the surface sediment, both inorganic and organic pollutants might be released back into water column if there is a sudden change in water quality [2,5]. The increment of toxicity level of pollutants eventually will give adverse impacts on the entire food web in the aquatic ecosystem [3,5]. Therefore, determination of TOC content (%) in the surface sediment is a vital piece of information to Department of Environment (DOE) or policy maker to take further actions in minimizing the anthropogenic discharge.

In the light of these reasons, the aim of the present study is to determine the concentration of TOC (%) in surface sediments at Sungai Pinang. Those results can be established as a baseline assessment of sediment quality. In addition, particle size of sediment is playing an important role in controlling the concentration of chemical components in sediment [5,16]. Therefore, the second objective is to reveal the relationship between TOC (%) and mean size sediments (Ø).

Materials and Methods

Study area

The sampling location is at Sungai Pinang (5° 24' N; l00^{o} 19' E) located in Penang Island, which situated in the northeast of Peninsular Malaysia (Figure 1). This research study was carried out on 20th of July in year 2013. In

order not to miss any hotspot that might contain extreme level of TOC, a total of 24 sampling stations was deployed along Sungai Pinang that is about 100 m apart from each other (Figure 2). The distance between P1 and P21 are about 2.47 km. The total area of Sungai Pinang basin is about 50.97 km^2 [13,17,18]. According to Malaysian Meteorological Department (MMD), Malaysia was having dry weather condition with low rainfall distribution that had accounted for less than 200 mm of precipitation in July of year 2013. Sungai Pinang was surrounded by 70% of wet markets with warehouses, small industrial facilities, residential areas, slaughter houses, and working areas which have a potential to release high amount of waste and toxic chemicals [13,17].

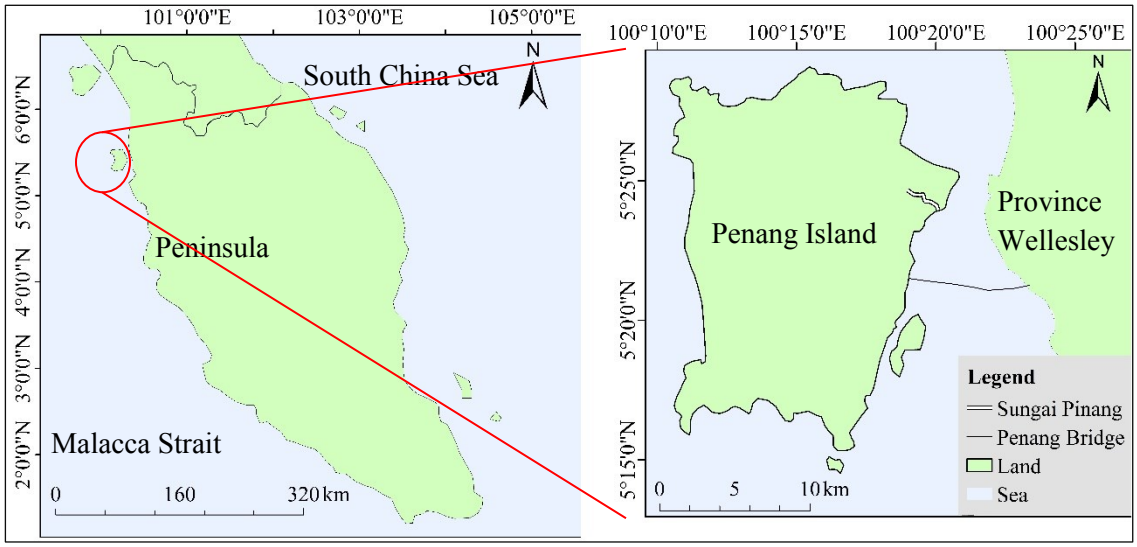

Figure 1. Sampling activity was conducted at Penang Island which is located at Northeast of Peninsular Malaysia

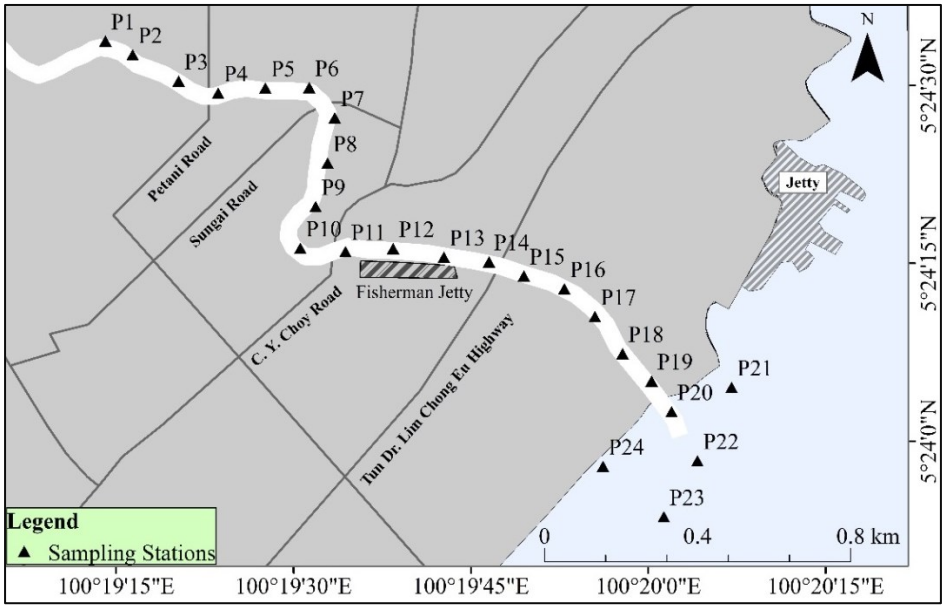

Figure 2. A total of 24 sampling locations was deployed along Sungai Pinang and its river mouth in Penang Island, Penang, Malaysia

For preparation of sampling activity, all apparatus including plastic spoon and polythene bag were cleaned with 10% of nitric acid and rinsed with distilled water. About 5 cm depth of the surface sediment samples were collected by Ponar grab. Precaution was taken to make sure the grab is firmly closed to ensure the maximum preservation of fine sediments samples, so that the reading for the size fractions of sediment is accurate [19]. The actual coordinate of sampling stations is recorded by using Global Positioning System (GPS). In order to minimize the chemical and biological reaction, sediments samples were kept at low temperature (< 4 ^{o}C) in an ice-box during sampling and is stored in a freezer after it is transferred back to the laboratory [19,20]. The sediment samples were dried using oven at 60 ^{o}C and weighed using electronic balance until consistency of samples weight was achieved [20]. The dried sediment samples were proceeded into two separate analyses.

Extraction method for total organic carbon

Wet oxidation method by means of titration was used to determine the TOC content in surficial sediment as it is simple, low in costing, and less equipment is needed for titration [21]. A total of 10 mL of 1 N potassium dichromates ($K_2Cr_2O_7$) was added into 0.5 g of sediments samples, standard solution (0.03 g of glucose) and blank solution (cleaned boiling tube) separately. Next, 20 mL of concentrated sulphuric acid (H_2SO_4) was added into the mixture. If the mixture sediments samples had changed into green color, 5 mL of $K_2Cr_2O_7$ will be added subsequently to ensure the mixture turn brown. The total volume of $K_2Cr_2O_7$ was recorded.

The mixtures were then heated to complete the digestion process for 30 minutes by using boiling bath water on a laboratory hot plate. Once 30 minutes is up, all the boiling tubes were set aside for cooling to allow the exothermic reaction to take place. The mixtures were rinsed with 200.0 mL of distilled water and transferred into Erlenmeyer flask (Standard solution and Blank solution should go through titration first before the titration of sediments sample solution). A volumes of 10.0 mL phosphoric acid (H_3PO_4) and 1 mL of indicator diphenylamine ($C_6H_5.2H_2O$) were added into the Erlenmeyer flask. A dark blue solution was observed.

The initial reading of the volume of Ferrous Sulfate ($Fe_2SO_4.7H_2O$) in the burette was recorded. The mixtures were then titrated with $Fe_2SO_4.7H_2O$ and mixed well with Orbital shaker. End point was reached when the solution turn into a light green in color [6]. The final reading for the volume of $Fe_2SO_4.7H_2O$ in burette was recorded. Percentage of carbon for glucose solution (Standard solution) was approximately 36 ± 5%. The calculation formula was applied to obtain percentage (%) of organic carbon, as shown in equation 1 below:

$$\text{Organic Carbon (\%)} = \frac{(V1-V2)\text{ x } 0.003\text{ x } 100}{\text{Weight of sample (g)}} \quad (1)$$

Where V1 is define as Volume of Potassium dichromate used (mL), V2 is define as Volume of Ferrous sulfate titrated (mL) and 10 mL of dichromate and 3 mg of carbon = 0.003 g carbon

Sediment characteristic analysis method for coarse sediment

Dry sieve method was used to determine the mean size of coarse sediment. A total of 200 g of dried sediment was sieved by using Sieves and Shaker for 10 minutes. A total of 14 different mesh size sieves was arranged consecutively downward from larger mesh size to fine size as follows: 4000 µm, 2800 µm, 2000 µm, 1400 µm, 1000 µm, 710 µm, 500 µm, 355 µm, 250 µm, 18 µm, 125 µm, 90 µm, 63 µm and < 63µm. Sediment samples retained in each layer of sieve were weighted by using an electronic balance. The reading of weight in each sieve was recorded [22]. Mean value can be computed by a moment method, as shown in equation 2 below:

$$\text{Mean } (\emptyset) = \frac{\sum \text{fm}}{n} \quad (2)$$

where f is defined as percentage weight of each grade of particle size (%), m is median of each particle in size in Ø and *n* is defined as total number of sample in 100 when f = %

Sediment characteristic analysis method for fine sediment

Laser diffraction method was used for the determination of the mean size of fine sediment. A total of 1.5 g of sediment samples was transferred into a centrifuge tube and 5 mL of 10% of Calgon solution was added. The

Calgon solution was used to disperse the bonded particle sediments [23]. The mixture was then topped up with distilled water to 50 mL and the grain size sediments were analyzed by using Particle Size Analyzer (PSA) [24].

Results and Discussion

Figure 3 shows the distribution of TOC (%) in surficial sediments of Sungai Pinang. According to the figure, the range was from 0.36% at P4 to 5.33% at P10 with the mean of 2.16%. The trend of TOC (%) remained steady at the upstream zone (from P1 to P9) and followed by a sharp rise at P10. The content of TOC remained constant and followed by a gradual decreased after P20. Housing area was observed at nearby P10 which had the highest TOC concentration at the studied river which is 5.33%. Additionally, there were a high number of fishing boats nearby P12 during sampling activities. In overall, the downstream zone of the river (from P13 to P24) showed that it was having high mean value of TOC concentration which accounted for 3.04% in comparison with upstream zone of the river, 1.28% (from P1 to P12).

TOC concentration is one of the measurements to estimate the amount of organic matters preserved in sediment [1,25]. The contribution of high in TOC concentration at Sungai Pinang might possibly be coming from the continuous deposit of organic matter from terrestrial, dead organisms, urban runoff, untreated waste effluent from industrial factories [1,25,26]. Additionally, variety of chemical wastes, for instance, fuel oil from boat activities which is shown at P12 was probably a major contributor of TOC concentration in surficial sediment [27,28]. This phenomenon can be seen at the Cape Town harbor which had an intense vessel traffic. It had suggested that the wastes discharges from shipping activities might be cause the elevated level of TOC concentration in surficial sediments [28]. In addition, it has been reported that high correlation relationship between total petroleum hydrocarbon and TOC concentration in surficial sediment was observed [27]. According to the research done by Ali et al. [27], it had mentioned that the possible sources of elevation in total petroleum hydrocarbon was closely related to shipping activities and it promotes the deposition of TOC content in surficial sediments.

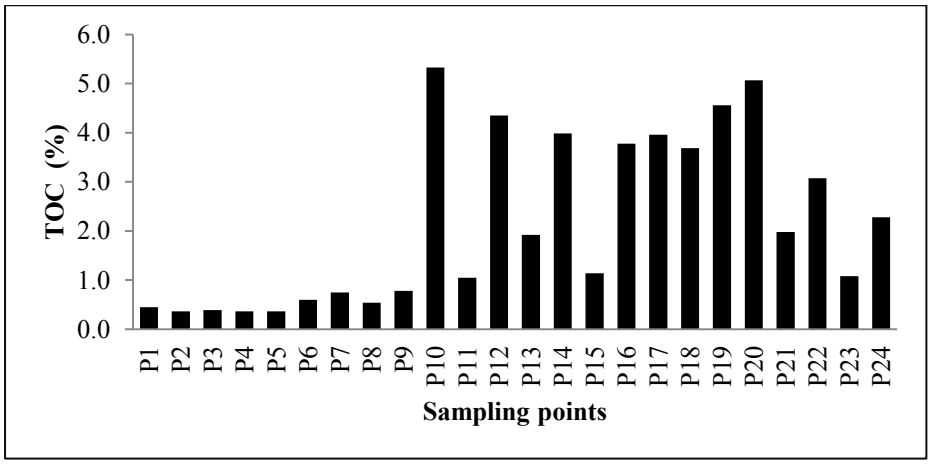

Figure 3. Distribution of TOC (%) in surficial sediments of Sungai Pinang, Penang

Apart from that, grain size sediment would be playing an important role which affects the organic matter bound to surface sediments [25,29]. The fine sediments have been known to be a preference for sorption of chemical compound [4,25,30]. Hence, it is indicated that sediment at lower catchment might possibly have wider surface area to volume ratio of binding site for organic compounds absorption [20,30]. In addition, fine particle sediment may denote slow hydrodynamic energy and particulate OC in water column have enough time to be absorbed on surficial sediment [20,30].

After P20 which is located at the river mouth, it tends to have a lower concentration of TOC and this phenomenon is similar to the estuary of Mahi River, India. Dinakaran and Krishnayya [14] had suggested that the sediment in the estuary might be affected by backwater system. In addition, the other physical components including tidal alteration might influence the level of TOC in sediments at river mouth [2].

The effect of high content of OC in surficial sediment might have contributed to the depletion of DO at the bottom of water column at the downstream of Sungai Pinang [1]. This is because high number of organic matter is promoting the growth of anaerobic bacteria which needs the DO to carry out their microbial activities [1,7].

Although high content of organic matter in aquatic environment may not contribute to a significant threat to human health, it will enhance the synergic effects when it is associated with other chemical compounds and nutrient availability [3,5,7]. It has been reported that TOC concentration is one of the important chemical factors that regulates the behavior of other chemical components in sediments [1,2,5]. Thus, determination of TOC concentration in surficial sediment is taken into the account of environment characteristic analysis [1, 2].

The comparison concentration of TOC (%) in surficial sediment of Sungai Pinang and other regions are shown in Table 1. From the table compassion, Sungai Pinang recorded higher TOC level compared to other rivers such as Sungai Klang basin [31], Sungai Langat [32], Yangtze Estuary [33], Changhua River Estuary [34], Pearl River Estuary [35], Danube River [36] and Beijiang River [37] except Port Klang in Malaysia [20]. Different environmental condition of each study location might probably give different results on TOC content in the surficial sediment. Port Klang, Malaysia has the highest concentration of TOC compared to present study as it reported that the source of TOC concentration probably caused by the discharge of chemical contaminants from shipping area and industrial wastes, weak water current as well as high portion of fine-sized grains sediments [20]. Thus, the fine grain size might be acting as synergic effects in concentration of TOC.

Table 1. Comparison of concentration TOC in surface sediments of Sungai Pinang to published data from similar habitat environments

Beijing River, China	1.29 ± 0.82	[37]

Figure 4 shows the sediments mean size (Ø) in surficial sediments of Sungai Pinang. The mean grain size was classified according to Wentworth size class [38]. From the grain size sediments analysis, the largest particle size of sediments was recorded at P2 in which is under the coarse grain size category (-0.67Ø), while the finest particle size of sediments was located at P23 (5.46Ø) which was classified as medium silt. The average of mean size of sediments of the 24 sampling stations at Sungai Pinang was 2.63Ø. The trend showed the particle size of sediments decreases gradually from upstream of river towards river mouth.

The upper river catchment had higher composition of coarse sediments compared to downstream. According to [2,20], the environmental changes of river such as transportation and process of sedimentary as well as distribution of material input would affect the grain size of sediments. Additionally, upstream zone tends to have coarser grain size sediments which have a higher possibility of strong hydraulic energy which causes the fine sediment particles to have a shorter residence time which reduces the deposits at the bottom of water column [4, 33,39]. Moreover, silt and clay have more loose fabric with higher degree of porosity and permeability, which is easier to be transported to downstream and leave coarser sediments on the river bed [25,40].

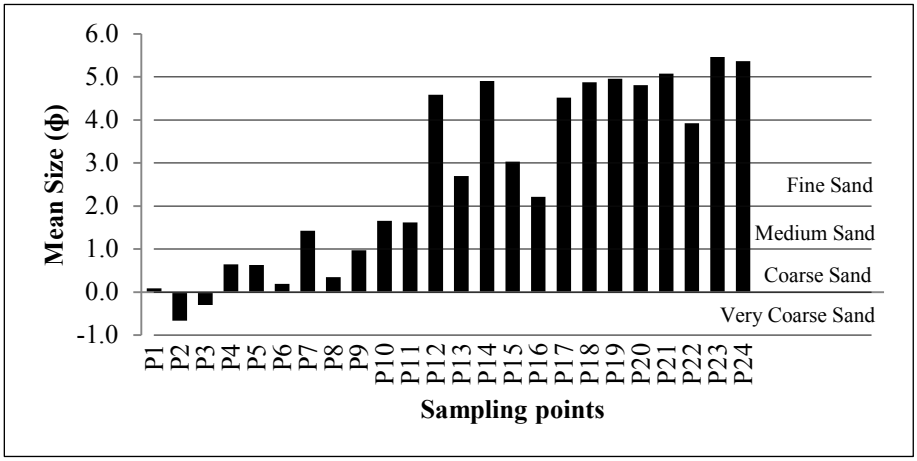

Figure 4. Variation of mean sediment size (Ø) in surficial sediments of Sungai Pinang, Penang

The type of surface sediments at Sungai Pinang varies from coarse sand to medium silt. Figure 5 shows the average sediments texture percentage (%) in surficial sediments of Sungai Pinang. The trend of sand grain size (63 – 2000 µm) decreases towards the river mouth while for the trend of silt and clay grain size is shown to be vice versa. From the result of sediments texture percentage (%), it was shown that the highest proportion for the category of silt grain size (4 – 63 µm) was found at P23 which was accounted for 81.39% whereas for the category of clay grain size (< 4 µm) was found in P21, 4.72% was observed.

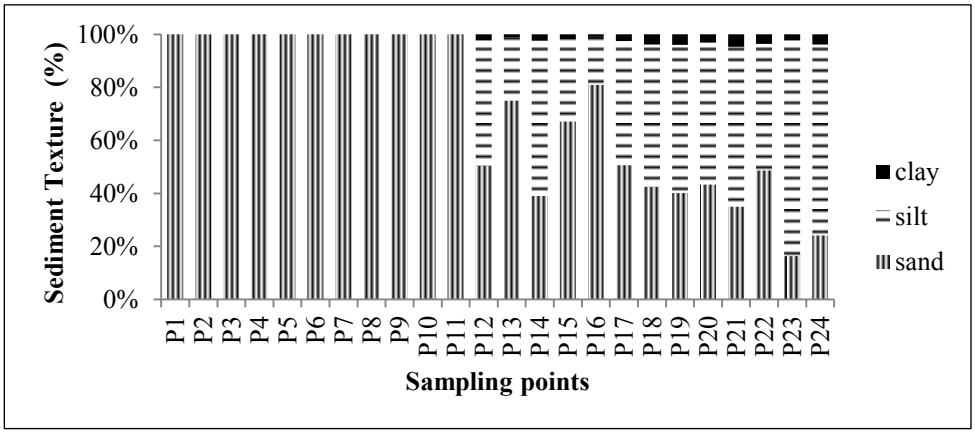

Figure 5. An average percentage sediments texture (%) in surficial sediments of Sungai Pinang, Penang

Downstream tend to have high proportion of slit and clay grain size sediments. It indicates that it might have a low hydrodynamic condition at the estuary [20,30]. The low water flow condition leads to sediments being suspended in water column to have more time to sink and redeposited at the bottom [20]. The consequences of river transportation were found in many rivers such as Klang River [20], Juru River, Malaysia [41] and Keelung River drainage basin, Taiwan [42] Furthermore, estuary has been well known as a settlement for sedimentation during tidal period and tends to have higher sedimentation rate [20, 41].

Generally, fine particle sediments are well known as dominant controlling factors to regulate the TOC concentration in surficial sediment [14,20,33]. Figure 6 shows the correlation relationship of high percentage of TOC concentration is directly proportional to fine sediments size and it is accounted for $r = 0.67$. It was suggesting that the finer grain size sediments might be a significant factor in controlling the TOC content in surficial sediments at Sungai Pinang [14,20,34]. This is because the fine sediments are providing a larger specific surface area and binding sites for organic carbon absorption [4,33,40]. This phenomenon also can be seen at Port Klang, Malaysia as it is reported that the fine grain size sediment had a significant positive correlation with TOC concentration [20].

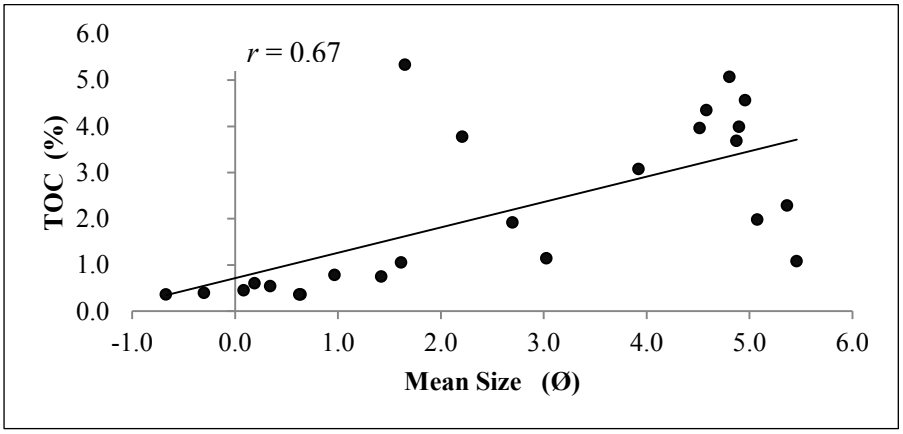

Figure 6. Correlation between TOC (%) and mean sediments size (Ø) in surficial sediments of Sungai Penang

Conclusion

In conclusion, the highest concentration of TOC (5.33%) at Sungai Pinang was found nearby housing area. At the downstream of Sungai Pinang tend to have a high concentration of TOC (1.05% - 5.33%). This is because the fine particle of sediments had provided larger binding sites to organic carbon for absorption. Apart from that, the fine sediments were probably denoted slow hydrodynamic energy at the downstream. It might strengthen the absorption process and lead to accumulation of TOC at the bottom of water column. Thus, the grain size sediment might be playing an important role as controlling factor of concentration of TOC in surficial sediments at Sungai Pinang. The results of present study are a necessity in making assessment of sediment quality and ecological risk. This is because the TOC is one of the controlling factors in regulating the chemical and biological compounds in surficial sediments. The chemical organic and inorganic pollutants such as polycyclic aromatic hydrocarbons (PAHs) and heavy metals respectively in surficial sediments can be the secondary source of water pollution if there is an environmental change. Consequently, it will give a deleterious health effects on living organisms in aquatic environment.

Acknowledgement

This research was conducted with funding from the Ministry of Higher Education Malaysia (MOHE), under the Niche Area Research Grant Scheme (NRGS) project number 53131 and Fundamental Research Grant Scheme (FRGS) 59299. The authors wish to express their gratitude to Oceanography and Biodiversity Laboratory, School of Marine and Environmental Sciences teams for their invaluable assistance and providing the facilities to carry out

the research. We are grateful to our editors and referees for their invaluable comments that helped improve this manuscript.

Abstract

Neopenthyl glycol dioleate (NPGDO) is a biolubricant base that was formed via esterification process with oleic acid. The presence of oleic acid leads to poor oxidative stability. In this study, epoxidation reaction between NPGDO, formic acid and hydrogen peroxide has been carried out to produce epoxidized NPG dioleate (ENPGDO) which acts as the intermediate of biolubricant. Epoxidized oil can be further modified for better properties. The temperature for this reaction was 40 °C and the molar ratio of NPGDO:formic acid:hydrogen peroxide was 1:3:4. The reaction had taken place for 3 hours. The presence of the epoxy in the product was confirmed through Fourier Transform Infrared (FTIR). The structure of ENPGDO was confirmed using both proton and carbon Nuclear Magnetic Resonance (^{1}H-NMR and ^{13}C-NMR) analysis. The product was found to have 218 (viscosity indeks), 205 °C (flash point), −18 °C (pour point) and 197 °C (oxidative stability). The relative conversion of oxirane (RCO) for ENPGDO was 97.5%.

Keywords: biolubricant, neopenthyl glycol, oleic acid, epoxidized NPG diolete

Abstrak

Dioleat neopentil glikol (DONPG) merupakan bahan asas biopelincir yang dihasilkan melalui tindak balas pengesteran dengan asid oleik. Kehadiran asid oleik menjadikan kestabilan oksidatifnya rendah. Di dalam penyelidikan ini, pengepoksidaan antara DONPG, asid formik dan hidrogen peroksida dilakukan bagi menghasilkan epoksida dioleat NPG (EDONPG) yang bertindak sebagai bahan perantara biopelincir. Modifikasi kimia dilakukan ke atas EDONPG menghasilkan sifat yang lebih baik. Suhu bagi tindak balas ini adalah 40 °C dan nisbah molar DONPG: asid formik: hidrogen peroksida adalah 1:3:4. Masa tindak balas adalah 3 jam. Kehadiran epoksi di dalam produk ditentukan melalui spektroskopi Fourier transformasi inframerah (FTIR). Struktur EDONPG pula ditentukan melalui proton dan karbon spektroskopi resonan magnetik nuklear (^{1}H-NMR and ^{13}C-NMR). Pencirian fizikal produk dimana indeks kelikatan produk adalah (218), takat kilat (205 °C), takat tuang (−18 °C) dan kestabilan oksidatif (197 °C). Relatif pertukaran oksirana (RCO) produk ialah 97.5%.

Kata kunci: biopelincir, neopentil glikol, asid oleik, epoksida dioleat NPG

Introduction

Biolubricant is a perfect substitute of mineral-based lubricants. The utilization of renewable feedstock to produce biolubricants has overcome the depletion of source problem faced by mineral-based lubricants. The biodegradable feedstock reduces environment pollution issues [1]. Biolubricants also have high viscosity index, high flash points,

good lubricity and less toxic properties. Hence, the subject of biolubricant has become the key interest by researchers and highly favourable by consumers. Although, biolubricants may have poor low temperature properties, as well as low oxidative and thermal stability [2] which require improvements through chemical modifications such as epoxidation and oxirane ring opening.

The highly reactive epoxide is a three-membered cyclic ether that suits the characteristic of an excellent raw material for further chemical modification. This chemical modification such as oxirane ring opening could improvise the properties of a product to make it more practical for industrial uses [3]. Epoxide products have extensively been used as a plasticizer and additive in biolubricant [4]. It is rather crucial for biolubricants to have a good oxidative stability as it reflects the quality and shelf life of the oil. Therefore, epoxidation could be performed to produce oil with better oxidative stability.

Recently, a growing body of literature has established the relavence of vegetable oil or unsaturated fatty acids epoxidation. The epoxidized carbon double bond provides a space for further reactions. Epoxidation on mustard oil was carried out which resulted in better oxidative sability [5]. The improvement on oxidative stability was achieved by converting the double bond in oil into oxirane ring. Epoxidation process can be carried out with and without the presence of catalyst. A catayst is used to produce higher yield and percentage of RCO.

In this study, the main purpose was to develop a biolubricant intermediate from NPGDO via epoxidation. Epoxidation was conducted without catalyst. Optimization of epoxidation was carried out to produce ENPGDO with higher yield and maximum percentage of RCO at mild condition. Epoxidized NPGDO act as an intermediate of biolubricant.

Materials and Methods

Materials

The NPGDO used was synthesized in the laboratory. It was prepared via esterification between NPG and oleic acid in ratio 1:2 at 130 °C for 4 hours with 2% of sulphuric acid as a catalyst. The NPGDO was purified. Hydrogen peroxide, formic acid and sodium chloride used in this experiment were purchased from Systerm. The sodium hydrogen bicarbonate and sodium sulphate were purchased from R&M Chemicals.

Epoxidation procedure

The NPGDO was added into a 250 ml three-necked round bottom flask which was equipped with thermometer, magnetic stirer and a stopper. Formic acid was added according to mole ratio ranging from 1:1 up to 1:5 of NPGDO:formic acid. The round bottom flask was attached to a condenser with heating mantle. Temperature and reaction time were tested at 20 °C to 60 °C and 2 hours up to 6 hours respectively. Peroxide acid was then added drop wise into the flask for 60 minutes. Mole ratio of NPGDO to peroxide acid used in this experiment was 1:1 to 1:5. At the end of the reaction, the mixture was washed with 100 mL of 5% of sodium bicarbonate, 100 mL of 5% sodium chloride and 100 mL of distilled water to remove the acidity. It was then dried overnight with magnesium sulphate. The ethyl acetate solvent used in the mixture to extract oil was removed using a rotary evaporator [6].

Epoxidized NPG dioleate analysis

The oxirane oxygen content (%OOC) were calculated according to AOCS recommended practices. The relative conversion to oxirane was calculated using the following expression (equation 1) as reported by Michelle [3]:
Relative conversion to oxirane content:

$$\mathrm{RCO} = OOc/OOt \tag{1}$$

where, OOc is define as experimental oxygen oxirane and OOt is define as theoretical maximum oxirane oxygen from the expression (equation 2);

$$OO_{\mathrm{t}} = \left(\frac{IV_{\mathrm{O}}/2Ai}{100+(IV_{\mathrm{O}}/2Ai)A_{\mathrm{O}}}\right) Ao \times 100 \tag{2}$$

where, A_i (126.9) and A_0 (16) are atomic weight of iodine and oxygen respectively. Meanwhile, IV_0 is the initial iodine value of sample.

Formation of epoxy was confirmed by using Perkin Elmer GX FTIR in the range of 400 cm^{-1} to 4000 cm^{-1}. Subsequently, the ENPGDO was analysed with ^{1}H NMR and ^{13}C NMR using Bruker ARX-600 for structure conformation. Tetramethyl Silen (TMS) were used as internal standard with deuterochloroform as solvent.

Epoxidized NPG dioleate physicochemical analysis

The improvement in the characteristics of NPGDO and ENPGDO were analysed. For the pour point and oxidative stability, Differential Scanning Calorimetri (DSC) was used. The flash point was determined using ASTM D92 method (ASTM1965). The viscosity of the sample was analysed using Rhemometer Anton Paar at 40 ºC and 100 ºC. For the calculation of viscosity index (VI), ASTM 2270 method (ASTM 1964), the equation 3 or 4 was used as below:

For oils of 0 to 100 VI:

$$VI = [(L- U) / (L-H)] \times 100 \quad (3)$$

where, U is define as kinematic viscocity of oil in centistokes at 40 °C, L and H is value from Table L and H based on kinematic viscocity (cSt) at 100 °C.

For oils of 100 VI and greater:

$$VI = [((\text{antilog } N) - 1) / 0.00715] = 100 \quad (4)$$

where, U is define as kinematic viscocity of oil in centistokes at 40 °C, Y is define as kinematic viscocity of oil in centistokes at 100 °C, and L and H is the value from Table L and H based on kinematic viscocity (cSt) at 100 °C.

Results and Discussion

Neopentyl glycol (NPG) is a polyhydic alcohol. It does not contain hydrogen in β position as glycerol. β hydrogen atom can lead to partial defragmentation into unsaturated compound at high temperature. This compound will later undergo polymerization and form precipitates [7]. In this study, NPG was esterified with oleic acid to form NPGDO. Unsaturation leads to poor oxidative and thermal stability. Meanwhile saturated fatty acid will cause poor low temperature properties. Monounsaturated oleic acid gives moderate oxidative stability and better low temperature properties. It also provides space for chemical modification to improve the properties of NPGDO [7].

Epoxidation of olefin is an important reaction for further chemical modification on NPGDO. The double bond of oleic acid in NPGDO causes the poor oxidative stability. The oxidative and thermal stability have been improved via epoxidation. Epoxidized oil acts as antirust in biolubricant. The biodegradability of oil remains the same [8]. Figure 1 shows the reaction scheme of epoxidized NPG dioleat. Epoxide is a compound with a cyclic ether with three-ring atom which is highly strained. Due to this, it is very reactive and treated as an intermediate for further reaction [3].

The optimization for this reaction was done to obtain ENPGDO in high yield with high oxygen oxirane content (OOC) and high percentage of RCO. OOC value describes the weight percent of oxirane oxygen in a molecule. It shows the conversion of unsaturation to epoxy groups [9]. Figure 2 shows the effect of different mol ratio of NPGDO:formic acid on percentage of RCO. From Figure 2, the highest percentage of RCO is at mol ratio 1:3.

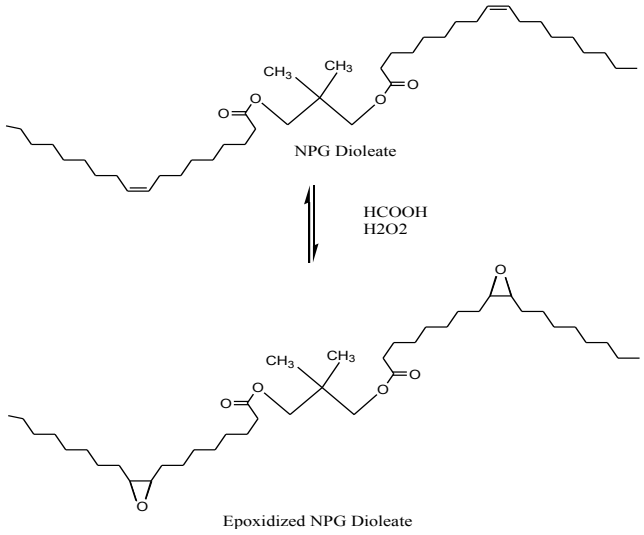

Figure 1. Reaction scheme for the epoxidized NPG dioleate

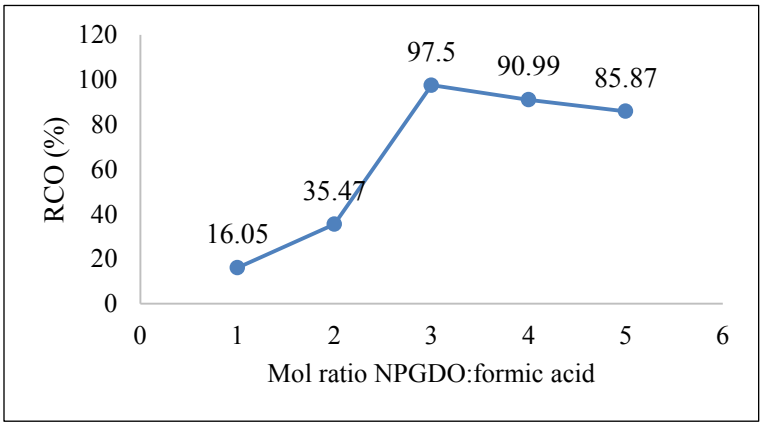

Figure 2. Effect of mol ratio NPGDO:formic acid on percentage of RCO

Figure 3 shows the percentage of RCO in accordance to mol ratio of NPGDO:hydrogen peroxide. The highest percentage of RCO can be seen at mol ratio 1:4. Figure 4 shows the effect of temperature towards the percentage of RCO. At 40 ºC, highest percentage of RCO was obtained. Figure 5 shows the correlation between time of rection on percentage of RCO which remarks 97% as the highest percentage of RCO, obtained after 3 hours of reaction.

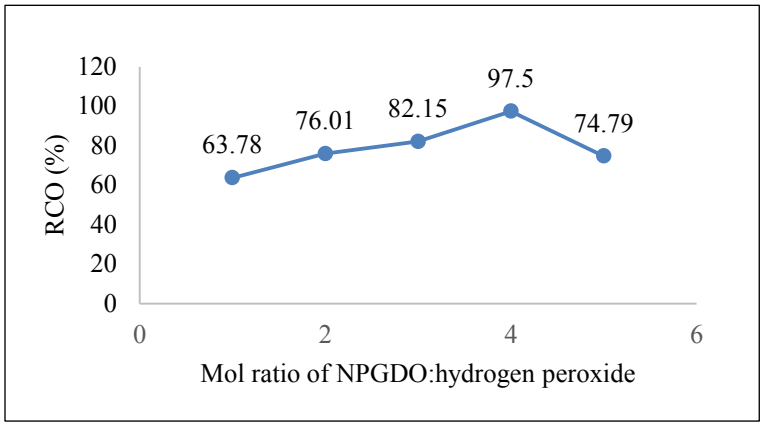

Figure 3. Effect of mol ratio NPGDO: hydrogen peroxide on percentage of RCO

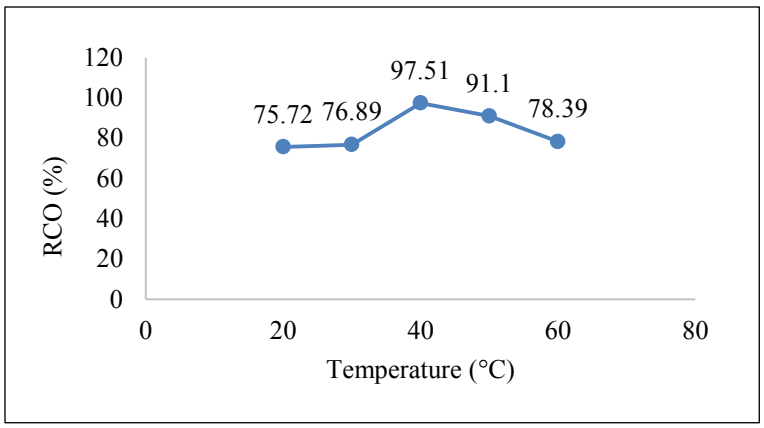

Figure 4. Effect of temperature on percentage of RCO

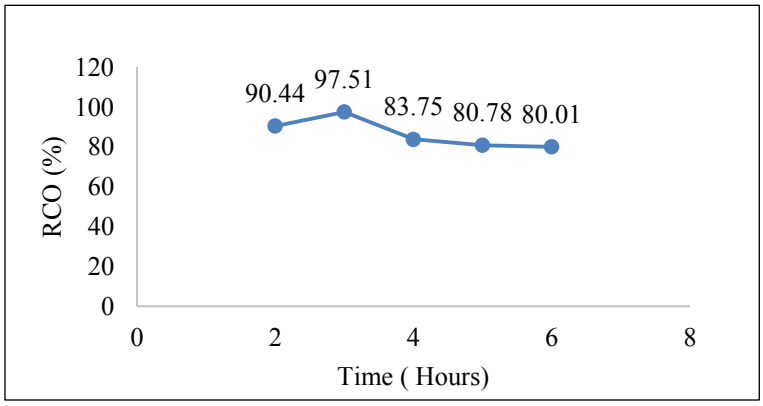

Figure 5. Effect of time of reaction on percentage of RCO

From the optimization graph, it can be concluded that the best condition for the formation of ENPGDO was obtained at 40 ºC for 3 hours. The mol ratio of NPGDO:formic acid:hydrogen peroxide was 1:3:4. The yield obtained was at average 83%. The percentage of OOC was high at 4.3% and the percentage of conversion of double bond in NPG dioelate to epoxy ring was 97%. The formation of ENPGDO was confirmed with Fourier Transform Infrared (FTIR) analysis. Figure 6 shows the comparison of FTIR spectrum before and after epoxidation of NPGDO. Peaks at 821.25 cm^{-1} and 933.33 cm^{-1} represent the C–O–C stretching of epoxide. There is no peak in the range of 3000 cm^{-1} to 3100 cm^{-1} which indicates that all the double bond in NPGDO has been converted into epoxide. The O–H stretching band that should have been appeared between 3200 cm^{-1} to 3400 cm^{-1} is also absent. This proves that ring opening did not occur.

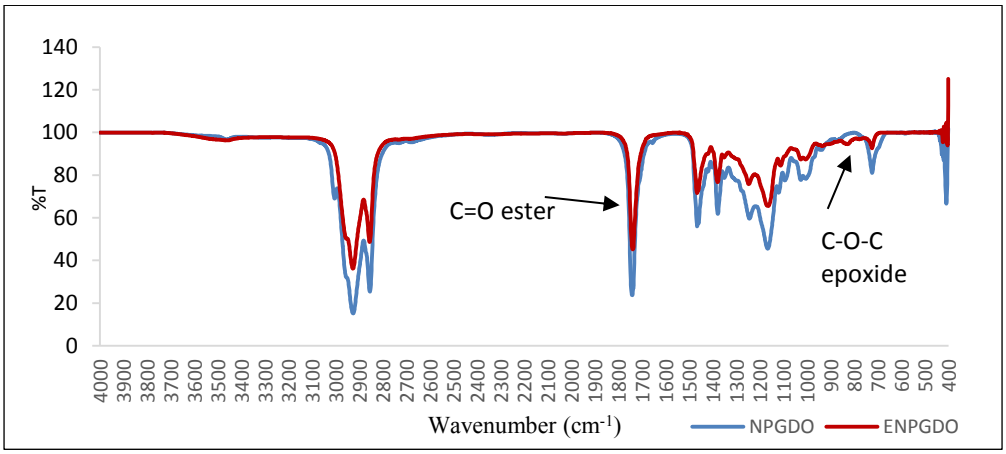

Figure 6. Comparison of FTIR spectrum between NPGDO and ENPGDO

The structural conformation was validated with Nuclear Magnetic Resonance (NMR). Figure 7 shows the ^{1}H NMR spectra.

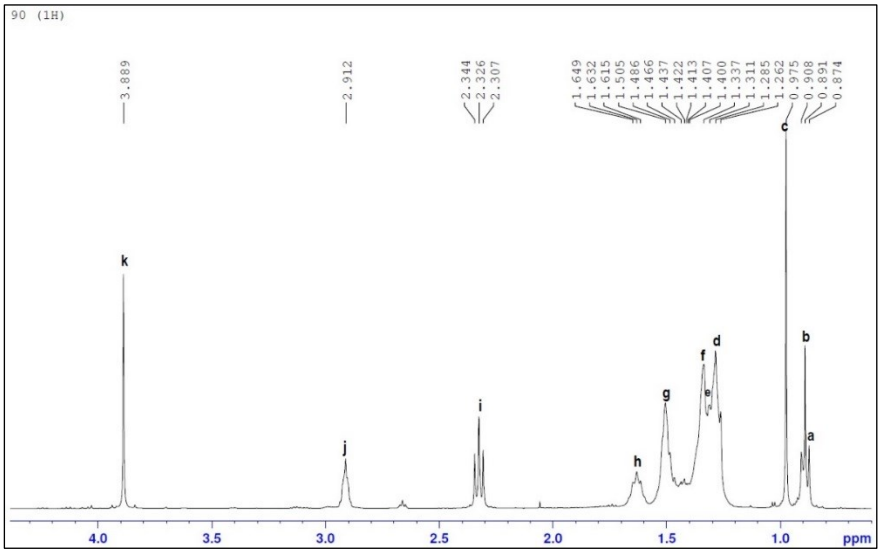

Figure 7. ^{1}H NMR spectra for epoxidized NPG dioleate

Label on Figure 8 represents respective signals on ^{1}H NMR spectra. The peak at 2.9 ppm corresponds the the proton attached to the epoxide group. The absence of peak at 5.381 ppm proves that all double bond has been converted to epoxides. Figure 9 shows the ^{13}C NMR spectra and label on Figure 10 represents respective signals on the ^{13}C NMR spectra. The absence of peak at 120 ppm to 140 ppm prove the absence of double bond in the product. Meanwhile the peak at chemical shift 57 ppm proves the formation of epoxide in the product.

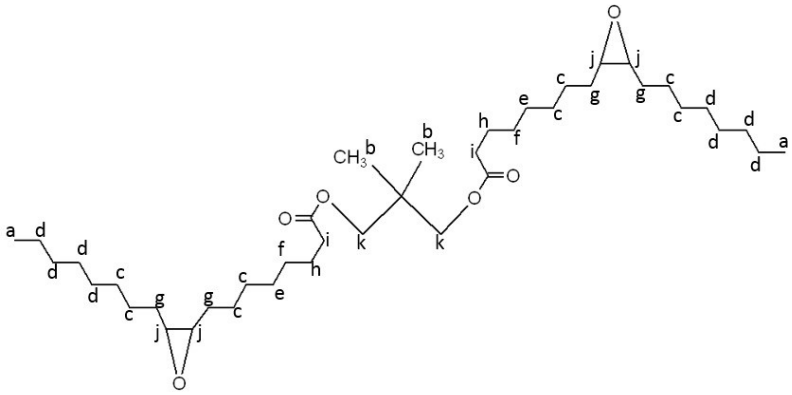

Figure 8. Structure representing signals on ^{1}H NMR spectra

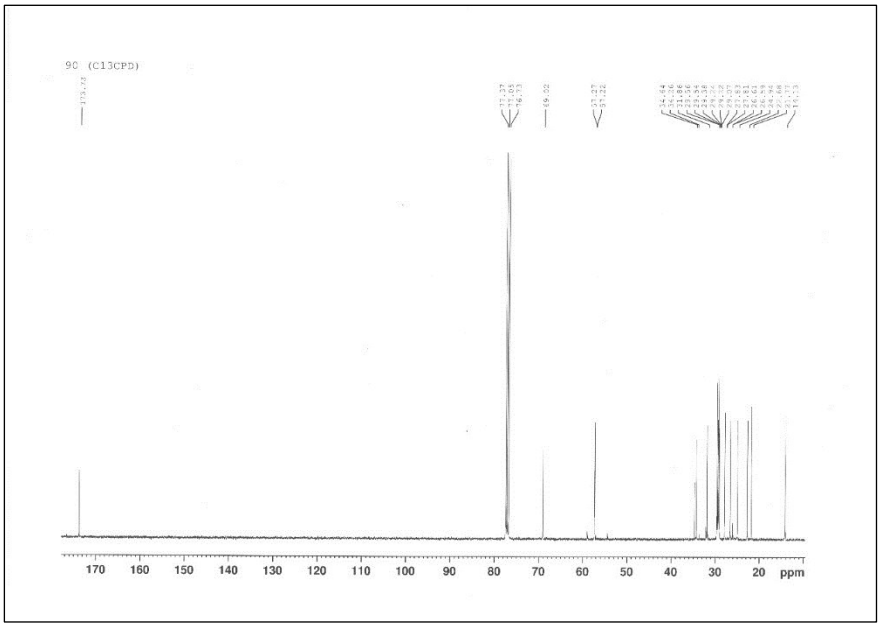

Figure 9. ^{13}C NMR Spectra for epoxidized NPG dioleate

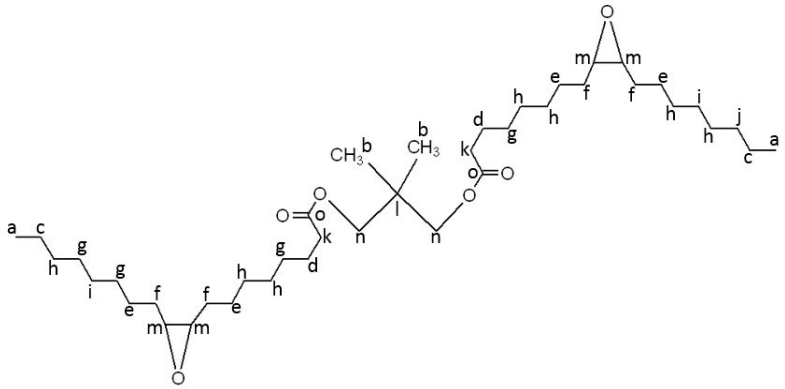

Figure 10. Structure representing signals on ^{1}H NMR spectra

The oxidative stability measures oil resistance towards oxidation. It is important as it reflects the shelf life of the oil [10]. The oxidative stability of ENPGDO has been increased from 177 ºC to 197 ºC. Oxidative stability increased as the number of hydroxyl group decreased by forming free radicals. This have resulted in oxidative degradation [11]. The absence of double bond in the product have led to better oxidative stability. The flash point of epoxide is 205 °C, which is significantly high to ensure safety during use. The ENPGDO possess a pour point of −18 °C, which is higher than NPGDO which is −44 ºC. The pour point is a very important low temperature flow property where it indicates the lowest temperature at which the sample can be poured from a tilted jar [12]. The pour point tends to improve with the attachement of ester. The presence of this large branching group in the middle or end of the chain will have a steric hindrance effect, hence inhibit the formation of crystals [11]. The viscosity index of the epoxidized NPG dioleate is 218. The viscocity index increased as the molecular weight of product increased [13]. Through epoxidation, the oxidative stability and flash point have been improved compared to NPGDO. The viscocity index and pour point properties had decreased compared to NPGDO. These properties can be further improved by chemical modification of ENPGDO which acts as a biolubricant intermediate. The oxirane ring provides the site for further modification to obtain better properties.

Conclusion

The ENPGDO was succesully produced in high yield which was 83% with high percentage of OOC (4.3%). The RCO of epoxide was also high, that was 97%. The optimized condition for epoxidation process was at 40 ºC for 3 hours, and the ratio of NPG dioleate to formic acid to hydrogen peroxide was 1:3:4. The oxidative stability of epoxide increased to 197 ºC. The ENPGDO has −18 ºC of pour point and 205 ºC of flash point. The viscosity index of the epoxide was achieved as 218. The physicochemical properties of epoxide can be further modified through ring opening and other processes for better properties.

Acknowledgement

Authors thanked Universiti Kebangsaan Malaysia for providing the fund IP-2014-070, FRGS/2/2014/ST01/UKM/01/2 and all the staff from the Faculty of Science and Technology, Universiti Kebangsaan Malaysia for giving full support in completing this research.

Abstract

Bismuth vanadate ($BiVO_4$) and a series of Cu-loaded $BiVO_4$ (CuO-$BiVO_4$) photocatalysts were prepared via precipitation and wet impregnation methods respectively. The samples were characterized by X-ray diffractometry (XRD), transmission electron microscopy (TEM) and the band gap energy was elucidated via UV-visible diffuse reflectance spectroscopy (DRS). Spherically-shaped particles of the photocatalysts were obtained which contained mixtures of monoclinic and tetragonal $BiVO_4$ phases. The particle sizes of the photocatalysts ranged from 20 to 100 nm and band gap energies varied from 2.47 to 2.53 eV. The photodegradation efficiency of the photocatalysts was evaluated by degrading methylene blue (MB) dye under visible-light irradiation. The optimum conditions for the photocatalytic degradation were determined based on wt% Cu loaded, mass loading, initial dye concentration and pH. 1 wt% CuO-$BiVO_4$ exhibited the highest photocatalytic activity where the complete removal of 10 mgL^{-1} of MB was obtained at pH 10 when 0.8 g of the catalyst was used under 4 hours of 18W fluorescent light irradiation.

Keywords: copper oxide-bismuth vanadate, visible light photocatalyst, semiconductor, methylene blue

Abstrak

Bismut vanadat ($BiVO_4$) dan satu siri fotomangkin CuO-$BiVO_4$ masing – masing telah disediakan melalui kaedah pemendakan dan impregnasi basah. Pencirian sampel menggunakan pembelauan Sinar-X (XRD), transmisi elektron mikroskopi (TEM) dan tenaga jurang jalurnya melalui spektroskopi UV-Vis pantulan resap (DRS). Fotomangkin yang berbentuk sfera mengandungi campuran fasa monoklinik dan tetragonal $BiVO_4$ telah dihasilkan. Saiz zarah fotomangkin adalah antara julat 20 – 100 nm dan tenaga jurang jalurnya adalah 2.47 – 2.53 eV. Keberkesanan fotodegradasi pemangkin telah dinilai dengan menyingkirkan pewarna metilena biru (MB) di bawah sinaran cahaya nampak. Keadaan optimum bagi degradasi fotopemangkinan adalah berdasarkan % berat Cu yang dimuatkan, muatan jisim, kepekatan awal pewarna dan pH. 1% berat CuO-$BiVO_4$ menunjukkan aktiviti fotopemangkinan adalah paling tinggi di mana penyingkiran peratusan MB menghampiri 100% 10 mgL^{-1} of MB di bawah keadaan optimum iaitu pH 10 dengan 0.8 g pemangkin digunakan yang didedahkan di bawah sinaran 18W cahaya pendarfluor selama 4 jam.

Kata kunci: kuprum oksida- bismut vanadat, fotomangkin cahaya nampak, semikonduktor, metilena biru

Introduction

Photocatalytic degradation is a promising method for the treatment of wastewater containing organic and inorganic pollutants. The process begins with the activation of the photocatalyst by light irradiation followed by the

degradation of the pollutants to harmless products. The use of titanium dioxide (TiO_2) as a photocatalyst in this process has been extensively studied [1]. However, TiO_2 is only effective under UV light. Thus, with the intention to utilize solar radiation to degrade wastewater pollutants, the search for efficient visible-light driven photocatalysts has attracted many researchers. Two approaches have been employed; doping of TiO_2 and synthesizing non-TiO_2 based photocatalysts. Several reports have shown that although the band gap of TiO_2 reduced after doping, the quantum efficiency of TiO_2 also reduced due to the formation of recombination centers [2, 3]. Hence there has been renewed interest in producing non–TiO_2 based visible-light photocatalysts with better properties.

Several complexes such as Fe_2O_3, WO_3, $BiVO_4$, Bi_2WO_6 and Ag_3PO_4 [4-8] have been tested as visible light photocatalysts. Among these complexes, monoclinic scheelite $BiVO_4$ with a band gap energy of 2.4 eV has been reported to be an effective photocatalyst thus attracting considerable attention [9]. This photocatalyst has been synthesized via several methods including polyol, sol-gel, hydrothermal and polymer assisted co-precipitation methods [10-14]. However, the photocatalytic activity of pure $BiVO_4$ has been reported to be comparatively low. Several researchers have observed enhanced photocatalytic activity of $BiVO_4$ when metals such as iron and thallium [15-16], and metal oxides such as Ag_2O, Bi_2WO_6, CuO, Cu_2O and WO_3 [11, 17-20] were doped on the $BiVO_4$ surface. The enhancement in activity was reported to be due to the suppression of photogenerated electrons and holes recombination at the photocatalyst/co-catalyst interfaces.

In this study, a series of CuO-$BiVO_4$ photocatalysts were prepared via impregnation to evaluate the effect of CuO loading on the photocatalytic efficiency of the photocatalysts in degrading methylene blue dye (MB) under low-wattage visible-light irradiation. The optimal conditions for the photocatalytic degradation of MB were also determined.

Materials and Methods

Preparation of the photocatalysts

An amount of 0.1 M of bismuth (III) nitrate pentahydrate solution was prepared by dissolving 10 mmol of bismuth (III) nitrate pentahydrate (Acros) in 10 mL of concentrated nitric acid (65%, Fischer Scientific)) and 90 mL of deionized water. Separately, 0.1 M of ammonium metavanadate was prepared by dissolving 10 mmol of ammonium metavanadate (Aldrich) in 100 mL of deionized water at 80 °C. Upon cooling to room temperature, the solutions were mixed and continuously stirred for 30 minutes and left overnight for precipitation to occur. The yellow precipitate that formed was washed with deionized water, collected via centrifugation and oven-dried at 70 °C overnight. The dried sample was ground and calcined in air at 550°C for 1 hour.

The CuO-$BiVO_4$ catalysts were prepared by suspending 3.962g of $BiVO_4$ in an ethanolic solution (3:1 ethanol: water) containing copper (II) nitrate trihydrate (Acros) that would yield 0.25 – 1.25 wt % of Cu. The suspension was magnetically stirred until almost all the ethanol evaporated. The slurry obtained was then oven-dried at 70 °C overnight and the resulting powder was calcined at 300 °C for 4 hours.

Characterization of the photocatalysts

X-Ray Diffraction (XRD) analyses of the prepared photocatalysts were performed on a Shimadzu XRD-6000 Diffractometer with Nickel-filtered Cu Kα radiation (λ = 1.5406 Å), over a 2θ range of 10-60º. The diffuse reflectance spectra (DRS) of the photocatalysts were recorded using a UV-Vis spectrophotometer (Lambda 35, Perkin Elmer, USA) equipped with an integration sphere. The microstructure of the photocatalysts was recorded using a transmission electron microscope (Hitachi H-7100). The amount of Cu incorporated into the $BiVO_4$ catalysts was analyzed using the Thermo Scientific S Series Atomic Absorption Spectrometer.

Photocatalytic activity

The photocatalytic activity of the synthesized photocatalysts was evaluated by analyzing the degradation of methylene blue (MB, BDH) under visible-light irradiation (18-watt Cool Day fluorescent light-bulb, Philips) at room temperature. A desired amount of the photocatalyst was suspended in 1 L of 10 mg/L MB solution. Prior to the visible-light illumination, the suspension was magnetically stirred for 30 min ($BiVO_4$) or 45 min (CuO-$BiVO_4$) in the dark, for adsorption-desorption equilibrium. Air was bubbled continuously into the suspension by an aquarium air pump to maintain constant oxygen saturation in the solution throughout the 4 hours reaction period. At

specific time intervals, 5 mL of the suspension was drawn and filtered through cellulose nitrate membrane filters (0.45 µm) to separate the photocatalyst from the solution. The concentration of MB was determined at λ_{max} = 664 nm during the photocatalytic degradation process by a Perkin Elmer Lambda 35 UV-Vis spectrophotometer. The percentage of photodegradation of MB was calculated using equation 1:

$$\text{Photodegradation (\%)} = (C_0\text{-}C)/C_0 \times 100\% \quad (1)$$

where C_0 was the initial concentration of MB and C was the concentration of MB at time t.

Results and Discussion

Characteristics of the photocatalysts

Figure 1 shows the XRD patterns of pure $BiVO_4$ and Cu–$BiVO_4$ with different Cu contents. Characteristic peaks of the monoclinic scheelite $BiVO_4$ phase were observed at 2θ = 28.8º, 30.5º, 39.8º and 53.5º with clear splitting peaks at 2θ = 18.8º, 35º, 47º, 58.4º (JCPDS No. 00-014-0688). Weak peaks corresponding to the tetragonal $BiVO_4$ phase were also observed at 24.4º and 32.7º (JCPDS No. 00-014-0133). This indicated the presence of both $BiVO_4$ phases with monoclinic scheelite as the dominant phase. No diffractive peaks corresponding to CuO were found for any of the CuO-$BiVO_4$ photocatalysts in this work due to the low amount of copper used in the synthesis. To ensure the presence of Cu, the CuO-$BiVO_4$ photocatalysts were digested in aqua regia and analysed by AAS. As listed in Table 1, the Cu content obtained matched well with the calculated values.

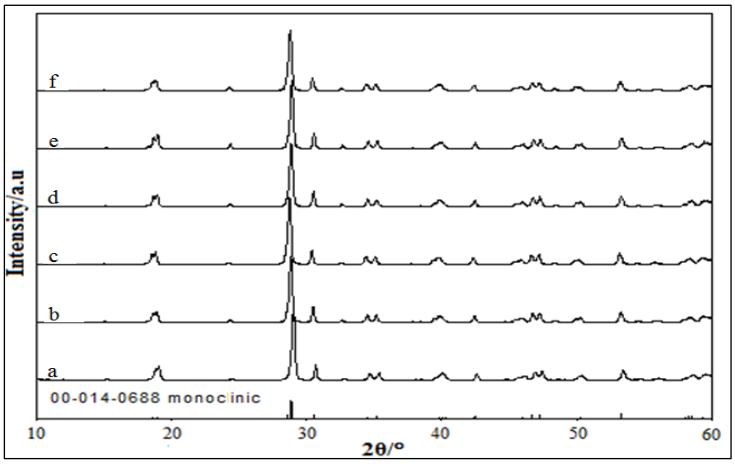

Figure 1. XRD patterns of (a) pure $BiVO_4$ and CuO-$BiVO_4$ at different Cu loading; (b) 0.25, (c) 0.50, (d) 0.75, (e) 1 and (f) 1.25 wt %.

Table 1. Physical properties of the synthesized $BiVO_4$ and CuO-$BiVO_4$ photocatalysts

Samples	Cu content (% wt)	Average Particle Size (nm)	Band Gap Energy (eV)
$BiVO_4$		40.2	2.47
0.25 wt% CuO-$BiVO_4$	0.247	60.6	2.47
0.50 wt% CuO-$BiVO_4$	0.522	40.2	2.52
0.75 w% CuO-$BiVO_4$	0.808	36.3	2.52
1 wt% CuO-$BiVO_4$	1.066	34.1	2.52
1.25 wt% CuO-$BiVO_4$	1.381	37.0	2.53

Photocatalytic degradation of methylene blue

The photocatalytic performance of $BiVO_4$ and CuO-$BiVO_4$ photocatalysts in the degradation of MB and their kinetics study are shown in Figure 4. In the absence of a photocatalyst (Figure 4a), 5% of the MB dye was photolysed under visible-light irradiation while in dark conditions; only approximately 5% of the MB dye was adsorbed on the surface of the photocatalysts. The photocatalytic degradation efficiency of MB steadily increased from 40% to 92% when $BiVO_4$ was doped with increasing amounts of CuO up to 1 wt%. As illustrated in Figure 4b, the photodegradation of MB followed a pseudo first-order reaction. The UV-Vis spectra that displays the progressive degradation of MB by the 1wt% CuO-$BiVO_4$ photocatalyst, as a function of time are shown in Fig 5. The enhancement in the photoactivity of CuO-$BiVO_4$ was attributed to efficient separation of the photogenerated electrons and holes. The band gap energy of CuO and BiVO4 has been reported as 1.70 eV and 2.45 eV, respectively. Since the calculated energy level of the conduction band of CuO (0.46 eV) was higher than that of $BiVO_4$ (0.34 eV), the photoexcited electrons on the conduction band of $BiVO_4$ were not transferred to the conduction band of CuO. Instead the holes were transferred to the valence band of CuO, resulting in a separation of the electron-hole pairs, thereby subsequently increasing the photocatalytic activity [21]. However, at CuO loading higher than 1 wt%, lower photocatalytic activity was observed because CuO acts as a recombination center of photoinduced electron-hole pairs leading to a reduction in photocatalytic activity [21-22]. Thus, 1 wt% CuO-$BiVO_4$ was used as the model photocatalyst for the remainder of this study.

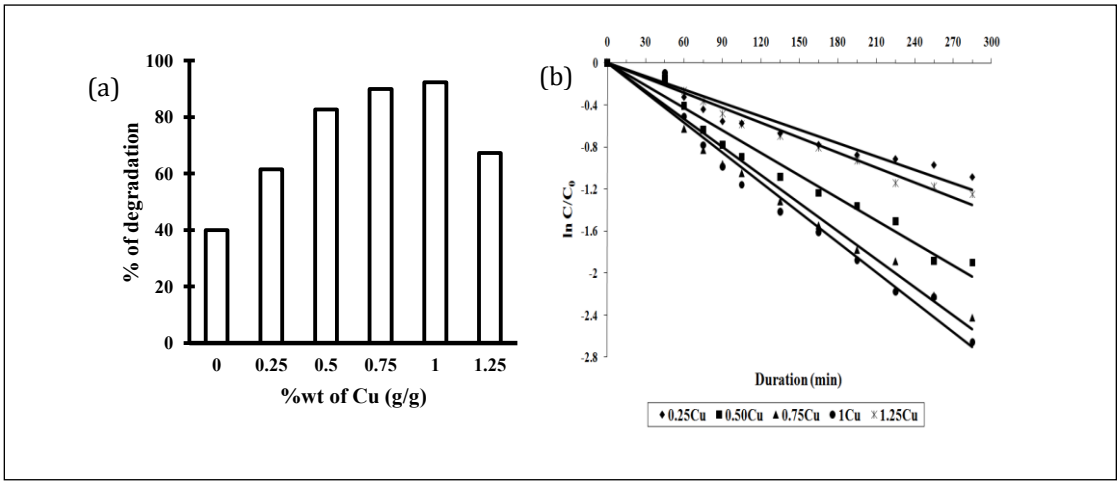

Figure 4. (a) Photocatalytic degradation efficiency and (b) kinetics of pure $BiVO_4$ and Cu-loaded $BiVO_4$ in the degradation of MB (catalyst dosage = 600 mg, initial MB concentration = 10 mg/L and natural pH)

The effect of mass of the 1 wt% CuO-$BiVO_4$ photocatalyst, initial concentration and pH of the MB solution on the degradation efficiency of MB is illustrated in Figure 6. Figure 6a showed that the photodegradation of MB increased proportionally with the amount of photocatalyst loading until 800 mg, after which the photodegradation decreased (1000 mg). The increase in the photocatalytic degradation efficiency of MB was due to the increase in the effective surface area of the photocatalyst, consequently enhancing light absorption and generating more surface active sites for the degradation reaction. The decrease in the efficiency beyond the optimum photocatalyst loading (800 mg) might be attributed to the light scattering effect and agglomeration of the photocatalyst particles in the solution [23].

The photocatalytic degradation of MB at various initial concentrations (10 – 30 mg/L) was studied using 800 mg of 1 wt% CuO-$BiVO_4$. Figure 6b showed that the percentage of degradation decreased with increasing MB concentration. It was also found that the rate of the MB photodegradation was unaffected by change in MB concentration, thus the amount of MB degraded did not change significantly. The maximum amount of MB that could be degraded by 1 wt% CuO-$BiVO_4$ was 10.5 mg/g at any MB concentration.

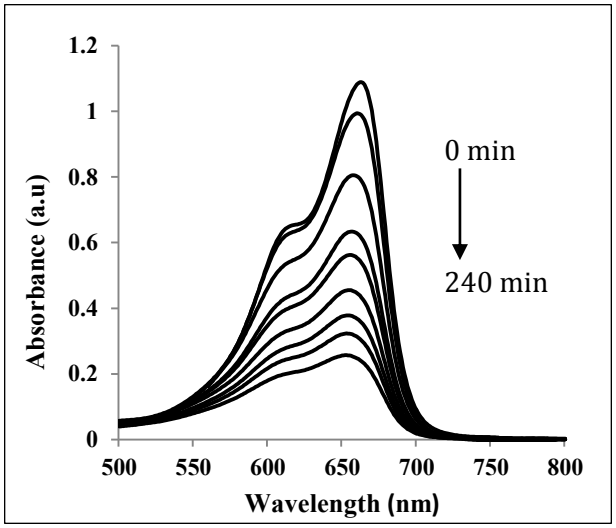

Figure 5. UV-Vis spectra of MB recorded at 30 min intervals during the photodegradation using 1 wt% CuO-$BiVO_4$ photocatalyst. (Catalyst dosage = 600 mg, initial MB concentration = 10 mg/L and natural pH)

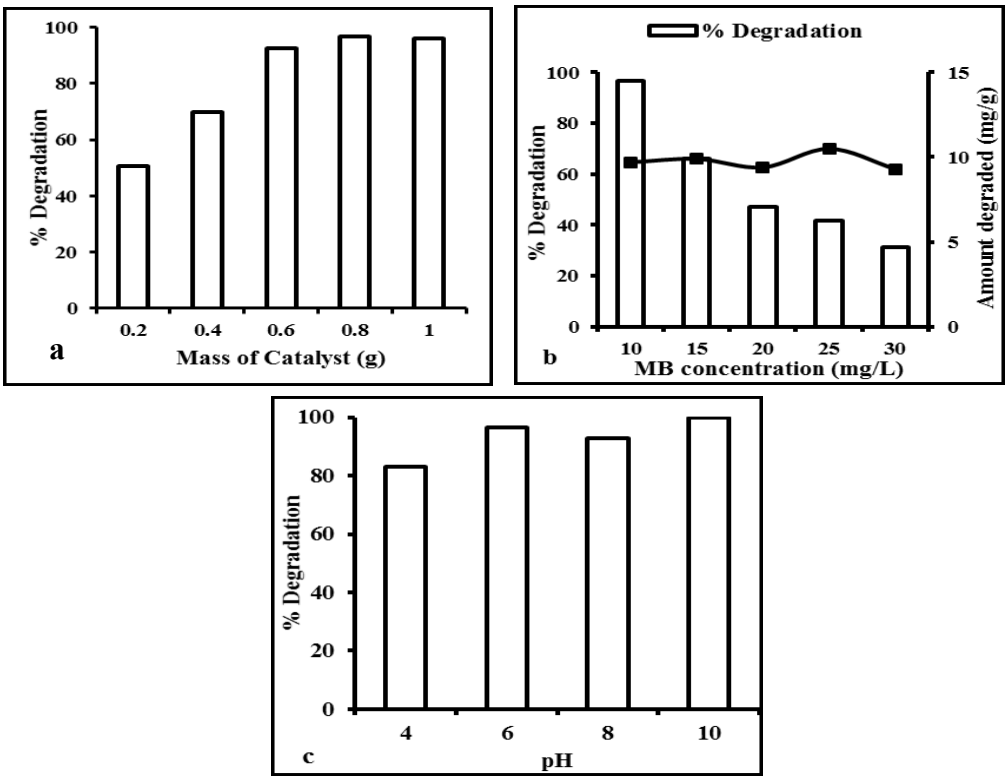

Figure 6. Photocatalytic degradation of methylene blue under different (a) mass of catalyst used, (b) concentrations and (c) pH of the methylene blue solution while keeping the other parameters constant. (Catalyst dosage = 800 mg, initial MB concentration = 10 mg/L and natural pH)

Figure 6c shows the photocatalytic efficiency of the CuO-$BiVO_4$ photocatalyst in the degradation of 10 mg/L MB solution at different initial pH levels. The photocatalytic degradation of MB increased from 83% to 96% when the pH was increased from 4 to 6 but did not show any significant difference after that till a pH of 10. In the photocatalytic mechanism, the holes can react with the added OH^-, in alkaline conditions, to produce hydroxyl radicals (Equation 2) which subsequently can degrade the pollutant. At the same time the holes themselves can also degrade the pollutant (Equation 4).

$$h^+ + HO^- \rightarrow \bullet OH \quad (2)$$

$$\bullet OH + \text{organic pollutant} \rightarrow \text{product of degradation} \quad (3)$$

$$h^+ + \text{organic pollutant} \rightarrow \text{product of degradation} \quad (4)$$

It was hence expected that the rate constant at pH 10 would be higher than that of pH 6 as more hydroxyl radicals were produced to degrade the MB dye. For confirmation, the rate constant of the reaction, k_{app}, at pH 6 – 10 was determined. It was found that although the degradation of MB reached 100% at pH 10, the calculated rate constant, k_{app}, remained almost constant, with value of $0.011 min^{-1}$ at pH 6 and $0.012\ min^{-1}$ at pH 10. This indicated that the photodegradation of the 10 mgL^{-1} MB was mainly due to the reaction between the holes and the MB molecules.

Conclusion

A series of CuO-$BiVO_4$ photocatalysts were successfully prepared via impregnation of nanocrystalline $BiVO_4$. Structural studies indicated that the synthesized photocatalysts were spherical with a particle size range of 20 to 100 nm and were dominated by the monoclinic scheelite crystalline phase. The photocatalytic activity of the pure $BiVO_4$ photocatalyst, prepared by a simple precipitation method, was enhanced with CuO loading and the highest photodegradation efficiency of MB was obtained at 1 wt% CuO content. The optimized conditions for the photodegradation of MB were catalyst dosage = 800 mg, initial concentration and pH of the MB solution = 10 mg/L and 10, respectively.

Abstract

Soil contamination is one of the sensitive issue in agricultural region of Cameron Highlands, Malaysia, which is a largest vegetable producer. Organochlorine pesticides (OCPs), organophosphorus pesticides (OPPs) and pyrethroids pesticides (PYRs) concentrations were measured in 35 soil samples of selected crops. Among OCPs, the average concentration in the soil of these crops grown was in the order of cauliflowers > cabbage > broccoli > lettuce > celery > spinach > mustard, while for OPPs; spinach > broccoli > cabbage > cauliflower > celery > lettuce > mustard > and for PYRs it was broccoli > cabbage > cauliflower > spinach > mustard > celery > lettuce. For risk assessment life time average daily dose (LADD) of ΣOCPs, ΣOPPs and ΣPYRs for adults were calculated at 2.1 x 10^{-7} – 1 x 10^{-6} mg kg^{-1} d^{-1}, 1.46 x 10^{-11} – 3.6 x 10^{-10} mg kg^{-1} d^{-1} and 1.28 x 10^{-12} – 3.42 x 10^{-12} mg kg^{-1} d^{-1} meanwhile for children 5.3 x 10^{-8} – 2.7 x 10^{-7} mg kg^{-1} d^{-1}, 3.8 x 10^{-11} – 9.4 x 10^{-10} mg kg^{-1} d^{-1} and 8.8 x 10^{-12} – 1.6 x 10^{-10} mg kg^{-1} d^{-1}. The hazard quotient (HQ) was ≤ 1 indicating less health risks for humans. Principal Component Analysis (PCA) indicates a strong correlation of high pesticides residual concentration of the soil of crops (cauliflower, cabbage and broccoli) with soil properties (pH and organic content) thus influencing its mobility and persistence whereas for other crops soil the decrease residual concentration might be related to crop type, rotation, roots exude, rhizosphere effect, or a rapid disappearance of pesticides after application.

Keywords: organochlorine, organophosphorus, pyrethroids, gas chromatography, multivariate analysis

Abstrak

Pencemaran tanah merupakan salah satu daripada isu yang sensitif dalam kawasan pertanian di Cameron Highlands, Malaysia, di mana ianya merupakan kawasan pengeluar sayur yang terbesar di Malaysia. Kepekatan racun serangga organoklorin (OCPs), organofosforus (OPPs) dan piretroid (PYRs) telah diukur dalam 35 sampel tanah dari tanaman yang terpilih. Berikut merupakan tertib kepekatan OCPs dalam tanah dari tanaman kubis bunga > kubis > brokoli > salad > sederi > bayam > sawi, manakala untuk OPPs adalah bayam > brokoli > kubis > kubis bunga > saderi > salad > sawi dan untuk PYRs adalah brokoli > kubis > kubis bunga > bayam > sawi > saderi > salad. Bagi penilaian risiko purata jangka hayat dos harian (LADD) untuk ΣOCPs, ΣOPPs dan ΣPYRs untuk dewasa adalah 2.1 x 10^{-7} – 1 x 10^{-6} mg kg^{-1} d^{-1}, 1.46 x 10^{-11} – 3.6 x 10^{-10} mg kg^{-1} d^{-1} dan 1.28 x 10^{-12} – 3.42 x 10^{-12} mg kg^{-1} d^{-1}, manakala kanak – kanak 5.3 x 10^{-8} – 2.7 x 10^{-7} mg kg^{-1} d^{-1}, 3.8 x 10^{-11} – 9.4 x 10^{-10} mg kg^{-1} d^{-1} dan 8.8 x 10^{-12} – 1.6 x 10^{-10} mg kg^{-1} d^{-1}. Darjah bahaya (HQ) adalah ≤ 1 iaitu menjelaskan bahawa ianya kurang berisiko terhadap kesihatan manusia.

Analisis komponen utama (PCA) menunjukkan terdapat korelasi yang kuat untuk kepekatan residu racun serangga yang tinggi daripada tanah untuk tanaman (kubis bunga, kubis, dan brokoli) dengan ciri – ciri tanah (pH dan kandungan organik) sekali gus mempengaruhi mobiliti dan pengekalannya manakala untuk tanah tanaman lain kepekatan residu berkurangan mungkin disebabkan oleh faktor yang berkaitan jenis tanaman, kitaran, rembesan akar – akar, kesan rezosfera, atau kehilangan racun yang cepat selepas penggunaannya.

Introduction

Pesticides pollution is extensively contaminating the environment due to its uncontrolled usage that degrades soil functions by degrading its biological activity and ability to remove pollutants that result in reduction of crop yield. Soil is regarded as a reservoir of xenobiotic that may be adsorbed to organic matter in soil and retained for decades or might be transported or degraded. Literature already proved that decomposition of these pesticides is less from soil to aquatic environment; therefore, it is even more threatening for future generations. Europe has already discussed the persistence behavior of pesticides in the Frame of Directive 91/414/EEC [1]. Soil system is relatively static and beyond human controls [1]. WHO/FAO [2] estimated 3 million cases of acute and severe pesticides poisoning with some 220,000 deaths and also reveals that largest human acute toxicity is caused by OPPs. One of the major soil contaminants are organophosphorus pesticides (OPPs), organochlorine pesticides (OCPs) and pyrethroids (PYRs). It can move in environment by volatilization, infiltration, runoff and transport along food chain [3,4].

Organophosphorus pesticides are highly toxic; it has the ability to penetrate the cells of living organism. They are moderately polar and are mobile to leach and can be retained on vegetation that can affect the environment and food chain [5]. It not only effects the pests but also other microorganisms like fungi and bacteria that brings nutrients to the roots of plants so effecting the healthy interaction and replacing it with chemicals [6]. In contrast to OCPs, OPPs are less persistent but this behavior varies from few days to month and sometimes years depending upon the texture and organic content of soil [7]. Sorption, volatilization, solubility in water, hydrolysis or oxidation, photo-degradation and biodegradation are some of the important factors dealing with the fate of OPPs in the environment [8].

PYRs are basically used for paralyzing insects and are less toxic and persistent than OCPs and OPPs. It is often used in combination with OPPs to enhance their insecticidal activity. It is considered to be the most widely used insecticide for vegetables farming in Malaysia and about 60% of farmers in use permethrin to control pests in the Cameron Highlands Malaysia [9].

Organochlorine pesticides are used worldwide due to its extensive insecticidal property and its use is prohibited due to high persistence (>10 years) and lipophilicity like DDT and β-HCH having higher stability and bio-accumulative property [10]. To understand the fate of OCPs globally it is necessary to know its fate in the tropical regions since they are considered as “net emissions” of OCPs to their “net sinks” Polar Regions. DDTs breakdown very slowly into its metabolites DDD and DDE. Among HCHs, the β-isomer is the most stable and persistent while α-isomer is more volatile and dissipates quickly [11].

However, the use of these pesticides might cause alteration in local environment including death of farm animals, and also risks to human health [12]. Due to their properties of having hydrophobic, strong sorption to soil organic matter, and resistant to degradation such as DDT and HCH they might persist for longer period of time in environment. The human exposure might occur due to occupational exposure or direct consumption of these vegetables and in this case the inhalation, ingestion can be one of the main reason for exposure since agriculture is becoming the occupation and norm of the people in this region and this exposure might cause several toxicological health effects [13,14].

The objective of this study is to identify and quantify the multi-residue of OCPs, OPPs and PYRs pesticides in soils of selected vegetables on the basis of its wide distribution and economic importance in agricultural region of Malaysia, Cameron Highlands and also to evaluate its correlation with physiochemical properties since the

degradation of pesticides depends upon the microbiological, physical and chemical properties while the sorption depends upon the organic content of soil and its pH because of its effect on soil properties such as electric charge and ionic strength [15]. The third objective is to access human health risks associated with soil contamination.

Materials and Methods

Chemicals

Pesticides standards were obtained from Dr. Ehrenstorfer (Augsberg, Germany) with highest purity certificate. Individual pesticides stock solution of 1000 ppm was prepared in acetone and stored in glass bottles at < –16 °C. Working pesticides mixture solution was prepared from stock solution and stored at 4 °C. Acetone, Hexane, ethyl acetate and anhydrous sodium sulphate of analytical grade were from Merck (Darmstadt, Germany and Friendmann Schmidt Chemical). Combo SPE Florisil (500 mg 6 mL^{-1}) packed was obtained from Restek (USA). The rotary evaporator (model A 1000s, Eyela), Soxhlet apparatus (Acott Lab Supplies Sdn. Bhd., Malaysia), Cellulose extraction thimbles with dimension 30 mm x 80 mm (Whatmann, England) and laboratory test sieve (Endecotts Limited, England) were used in the present study.

Sample collection and preparation

Cameron Highlands is the second largest producer of vegetables to Malaysia. Thus, it remarkably very important agricultural and environmentally sensitive area for Malaysia. It is situated in Pahang state having an estimated area of 712 km^2. Its location lies between 04° 20' N – 4° 37' N and 101° 20' – 101° 36' E and its altitude is between 1280 – 1830 m above sea level. Average daily temperature and annual rainfall is between 14 - 21 ˚C and 2800 mm.

In this study, seven different sampling sites were chosen as shown in Figure 1. The distance between station to station is 5 km Kg Raja – Tanah Rata, 13 km (Tanah Rata – Telom), 19.3 km (Telom – Brinchang), 4 km Brinchang – Telom), 8 km (Tanah Rata – Habu) and 3 km (Habu – Ringlet). The spraying pattern varies at each sampling points during both wet and dry seasons. About 64% of farmers spray more frequently every 7 - 9 days. However, during the wet seasons, the spraying pattern is even more frequent of about 4 – 6 days between each spraying. The highest being of 1 – 3 days' interval recorded at upper part of the valley. High humidity and continuous cultivation caused the contamination of river in highland by OCPs and OPPs due to enormous use in plant protection [16,17].

A total of 35 soil samples (0 – 10 cm) soil layer, consisting of three soil samples of approximately 1 – 2 kg for each corresponding vegetable were taken randomly from the cultivated horizon of seven different sites of agricultural region (Figure 1) by a stainless steel scoop wrapped in aluminum foil and placed in polyethylene bags stored in dark and transported to laboratory as soon as possible. These soil samples differed in terms of soil properties and land usage. Each soil sample was divided into two parts, one for pesticide analysis and other for soil geochemical properties. Samples were registered with sample location and site description. Soil samples were placed in amber glass bottles and stored at -18 ˚C until extraction. Soil samples were frozen, oven dried and homogenized by 80-mesh steel sieve.

Soil samples were frozen, oven dried and homogenized by 80-mesh steel sieve. A 15 g of dried weight sample was spiked by 1 mL of mixture of pesticides solution and was placed in thimble along with 6 – 7 g of anhydrous sodium sulphate and extracted with 150 mL of acetone: hexane (1:1) in soxhlet apparatus for 4 hours. The extract was concentrated to 3 mL by rotary evaporator (40 °C). The cleanup was done by Florisil (500 mg 6 mL^{-1}) priory conditioned by 5 mL of methanol and the sorbent were not allowed to dry during conditioning and loading steps. Sample loading was performed at 5 mL min^{-1} column and eluted with ethylacetate: hexane (1:1) and the final extract was concentrated by nitrogen gas up to 1 mL and analyzed by gas chromatography – electron capture detector (GC-ECD).

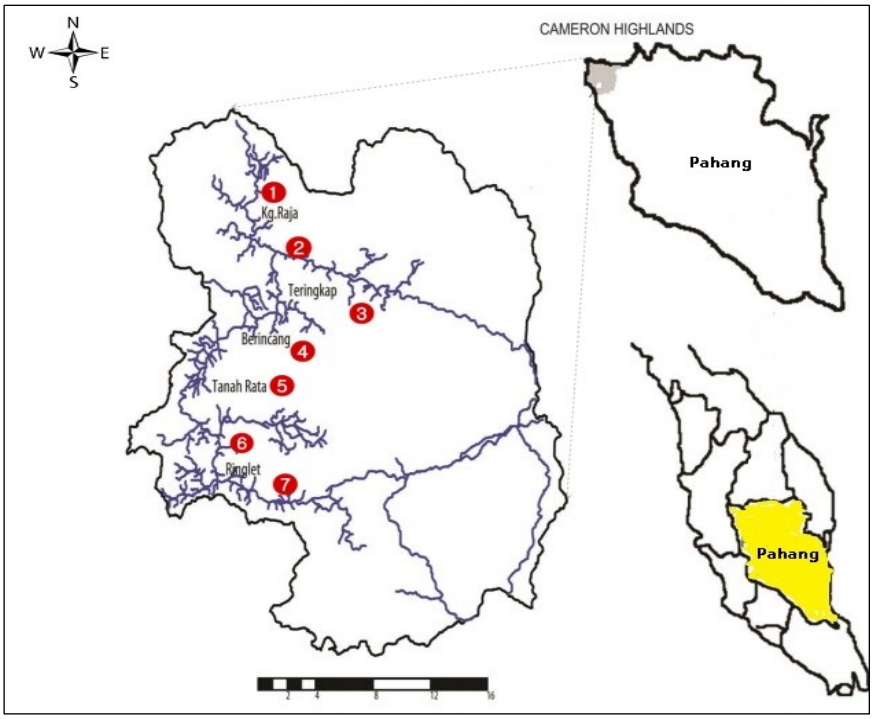

Figure 1. Map showing study area and sampling location (label in red)

Human exposure to pesticides and the consequent health risks associated with it was estimated by the equation given by USEPA. In this study the life time average daily dose (LADD) of pesticides and hazard quotient (HQ) were calculated through soil ingestion according to US Environmental Protection Agency and Agency for Toxic Substances and Disease Registry [13,18,19]. The following equations 1 and 2 were used for estimating the LADD and HQ:

$$\text{LADD (mg kg}^{-1}\text{ day}^{-1}\text{)} = (\text{Cs x IRF X EF x ED})/\text{BW x AT}) \quad (1)$$

$$\text{Hazard Quotient (HQ)} = \text{LADD/RFD} \quad (2)$$

where Cs is the pollutant concentration in soil (mg kg^{-1}), IR is soil ingestion rate (100 mg d^{-1} for adults) [18], F is the conversion factor unit, EF is the exposure frequency (365 days/year), ED is the lifetime exposure duration (adults, 70 years; children, 12 years), BW is a body weight (adults, 70 kg; children, 27 kg) [18] and AT is the averaging time for carcinogens (EF x ED). RFD is the reference dose for particular compound in mg/kg day^{-1} [13].

Soil pH was determined from water: soil (5:1) slurry by using soil pH meter. The organic matter content was determined by loss on ignition in which soil sample were first dried in oven at 104 °C for 24 hours and then the organic matter was combusted to ash and CO_2 at temperature between 500 – 550 °C and the loss on ignition (LOI) was calculated by the following equation 3 [20].

$$LOI_{550} = [(DW_{105} - DW_{550})/DW_{105}] \text{ x } 100 \quad (3)$$

Particle size was used to evaluate the soil texture. USDA classification scheme was used as reference in particle size analysis. The dry method of sieve analysis was performed by weighing 500 g of oven dried sample and separated

through three size of fractions (< 0.05 mm, 0.05 mm -2 mm and 2mm). The empty sieve and pan was weighed to 0.1 g and the mass of soil size of each fraction was weighed and mass fraction was calculated.

Analytical quality control

Pesticides concentrations were determined by external standard method using the peak areas of samples and five levels calibration curves of the standards. The peak was identified by their respective retention times of each standard. Cross contamination of all solvents and chemicals was checked by running a procedural blank. Linearity was estimated by an external calibration curve which was constructed at 5 calibration points by triplicate analysis ranging from 0.5 – 3 mg L^{-1}. These calibration curves were linear with r^2 value ranging from 0.990 – 0.995. The precision was established by triplicate analysis and extraction during accuracy studies. Acceptable precision was a value less than 20 %.

The recovery was calculated at two fortification levels with addition of known quantity of standard. For this purpose, pesticide free samples were collected from the remote areas for spiked samples. Samples were spiked at concentration of 1 mg kg^{-1} and 0.5 mg kg^{-1} with a pesticide mixture. The spiked and non-spiked samples were processed separately as real samples in triplicate. The average recoveries of OCPs were within a range 68% – 98%, (±2.37% - 16.5%), OPPs ranges between 75% – 103%, (±1.1% – 10.7%) and SPY ranges between 68% – 95%, (± 1% – 7%), respectively. The limit of detection and limit of quantification were calculated according to the IUPAC recommendation, three times the standard deviation of seven soil samples spiked at lowest concentration. The limit of detection (LOD) for analytes ranges between 0.04 ng g^{-1} – 0.4 ng g^{-1}, 0.8 ng g^{-1} – 1.8 ng g^{-1} and from 3.8 ng g^{-1} – 5 ng g^{-1} for OCPs, OPPs and PYRs, respectively. Multivariate statistical analysis namely principle component analysis was used for interpretation of data (Minitab Inc., State college, USA).

Instrumentation

Varian chrome pack CP-3800 gas chromatography was used to analyze pesticides residue content. The instrument equipped with ^{63}Ni electron capture detector and a 30 m x 0.32 mm i.d (0.25 µm film thickness), HP-MS 5ms fused silica capillary column. Nitrogen gas (99.99%) was used as a carrier at a flow rate of 1.5 mL min^{-1}. Oven temperature was kept at 90 °C for 1 min than increased to 170 °C at a rate of 3.5 °C min^{-1} and finally to 280 °C at rate of 5 °C/min. The injector and the detector temperature were adjusted to 250 °C and 300 °C. An amount of 2 µL of each sample was injected to GC-ECD for separation and quantitative analysis.

Results and Discussion

Concentration of organochlorine pesticides

The sum of ΣOCPs concentration were 44.1±19.3 µg kg^{-1}, 49.1±19.0 µg kg^{-1}, 25.8±18.3 µg kg^{-1}, 28.4±19.4 µg kg^{-1}, 28.1±18.5 µg kg^{-1}, 37.2±18.4 µg kg^{-1}, 13.7±16.3 µg kg^{-1} in soils of crops cabbage, cauliflower, spinach, celery, lettuce, broccoli and mustard (Table 1). The total concentration of OCPs (sum of α-HCH, β-HCH γ-HCH, DDE, DDD, DDT, endosulfan) in the soil of these crops ranges as ND – 13.3 µg kg^{-1} in cabbage, cauliflower (ND – 13.3 µg kg^{-1}), spinach (ND – 55.3 µg kg^{-1}, celery (ND – 6.6 µg kg^{-1}), lettuce (ND – 8 µg kg^{-1}), broccoli (ND – 4 µg kg^{-1}), and mustard (ND – 3.3 µg kg^{-1}). The observed trend of concentration of studied OCPs in these studies were γ-HCH (23.9%) > endosulfan (21.7%) > DDE (18.1%) > DDD (11.7%) > α-HCH (11.5%) > β-HCH (7.7%) > DDT (4.5%). The OCPs concentration in the soils of these crops decreases in the following order cauliflowers > cabbage > broccoli > celery > lettuce > mustard. Among HCHs the concentration decreases in the following order γ-HCH > α-HCH > β-HCH. This might be due to some new inputs for HCHs or its slow degradation rate. DDTs ranges as DDE > DDD > DDT showing its degradation and historical inputs. This high concentration of DDE shows the aerobic environment in surface soil [21] and this also shows that the degradation of the DDT is related to the physical property like pH in this case found to be higher (8.5) as an average for the soil of brassica leafy vegetables. Thus, its enhancing the degradation factor in soil of these crops. The ΣOCPs concentration observed in these studies were compared with other agriculture sites such as Mexico (36.91 – 389.31 µg kg^{-1}) and (5.2 – 316.4 µg kg^{-1}) [10, 21], China (7.82 – 765 µg kg^{-1}) [11] and India (1231 – 1734 ng g^{-1}) [2].

Table 1. Concentration of OCPs in agricultural soil of Cameron Highlands

Compounds	Concentration in Soil Sample of Vegetables (μg kg^{-1})						
	Cabbage	Cauliflower	Spinach	Celery	Lettuce	Broccoli	Mustard
α-HCH	2.6±0.4	13.3±0.8	4.66±0.4	ND	ND	4.6±0.5	1.3±2.2
β-HCH	3.3±5.2	4.0±7.4	2.6±1.2	ND	ND	4.0±5.8	4.0±1.9
γ-HCH	6.0±1.8	6.6±1.5	6.6±1.9	10.6±7.5	6.6±2.4	12.6±1.8	6±6.42
DDE	10.6±5.5	10.6±1.9	0.6±2.9	8.6±2.4	6.6±1.4	2.0±2.4	1.8±4.5
DDD	9.3±0.7	2.6±1.6	2.0±0.1	0.6±4.1	6.6±1.2	5.13±2.8	0.6±1.2
DDT	2.0±4.9	2.0±5.1.0	2.0±10.9	0.6±3.4	1.3±8.7	2.3±2.4	ND
Endosulfan	10±0.7	10±1.0	7.3±0.8	8.0±2.5	7.0±4.8	6.6±2.7	ND
Σ OCPs	44±19.3	49.1±19	25.76±18.3	28.4±19.9	28.1±18.5	37.23±18.4	13.7±16.3

β-HCH is the most stable, symmetrical structure and does not degrade easily in soil so in degradation process other HCH isomers will convert back to β-isomer and in soil its concentration will keep on increasing during degradation process that is why in many studies the ratio of β/α+γ is used to identify the historical pollution sources. If β/α+γ-HCH is higher than 0.5 would mean that it is due to historical pollution and if less than 0.5 would mean new sources has been introduced [3]. In current studies the majority of soil samples of their respective vegetables showed negative values indicating that the new sources accounted more for HCH pollution. This indicates the importance of pesticides spraying method, wind dispersion, leaching, wash out and volatilization that accounts for 80 – 90% of HCH from other farms to natural farms which is enhanced at high temperature, humidity, and intense solar radiation in tropical regions [11,22,23].

In the case of DDTs, DDE/DDT the ratio was higher than 1. The value for DDT > 1 indicating its historical inputs or its degradation by microbial activity or by enzymes secreted by root exudates or it can be due to high temperature [24]. The spatial distribution analysis of OCPs was investigated. The DDTs values were higher at Kuala Terla station ranging from 11 – 40 μg kg^{-1}. The maximum value at Kuala Terla station arises due to aerobic metabolites DDE of DDT. This results might be because of past usage of DDT in the agricultural area. The spatial distribution of HCHs and DDTs were not same at all sites. At seven sampling sites the sequence pattern for DDTs family were DDE> DDD> DDT. For HCH concentrations, the highest HCHs were found at Brinchang ranging from 1.3 – 26.6 μg kg^{-1}. This maximum value arises due to the presence of β-HCH the most stable isomer of HCHs indicating the past usage of HCH at this site. The highest endosulfan concentration was found at Kuala Terla of about 5 μg kg^{-1}. Among all sites, the Kuala Terla site seems to be most polluted by the OCPs indicating an extensive agricultural activity in this region and the illiteracy of the farmers also contributing to it. The lowest OCPs concentration was found at Habu station.

Human health risk assessment of OCPs

Health assessment was based on the assumption that human beings might be exposed to pesticides contaminated soil through ingestion, dermal contact or inhalation. The study area is an agricultural area so the farmers might be at great risk and since the compounds are persistent and hydrophobic so they would have higher affinity with soil particles. Therefore, the LADD of pesticides and HQ were calculated through soil ingestion [13,18,19] (Table 2). In this study we included adults of 70-year-old and children of 12 years of age exposed for all the days in a year during their life span. The estimated LADD of total OCPs for adults and children through soil ranged between 2.1×10^{-8} – 1×10^{-7} mg kg^{-1} d^{-1} and 5.3×10^{-8} – 2.7×10^{-7} mg kg^{-1} d^{-1} with the mean values as 5.2×10^{-7} mg kg^{-1} d^{-1} and 1.3×10^{-7} mg kg^{-1} d^{-1} (Table 2). HQ for human adults for sum of OCPs are 6.7×10^{-5}, 8×10^{-6}, 1.6×10^{-5} and for children was 3×10^{-5}, 4×10^{-6}, 8.6×10^{-6} (Table 3) which were lower than the acceptable risk levels. Thus, it indicated that the daily dose is below the proposed guidelines of USEPA 2012 [13].

Table 2. Concentration of OCPs and its life time average daily dose for humans through soil ingestion

Compounds	Concentration (μg kg^{-1})		(LADD mg kg^{-1} d^{-1})			
			Adults		Children	
	Range	Mean	Range	Mean	Range	Mean
α-HCH	2.6 – 13.3	3.8	3.7 x 10^{-9} – 1.9 x10^{-8}	5.4 x 10^{-8}	1.9 x 10^{-8} – 9.8 x10^{-8}	2.8 x 10^{-8}
β-HCH	0.6 – 4	2.5	8.5x 10^{-10} – 5.7 x 10^{-9}	3.6 x 10^{-8}	4.4 x 10^{-9} – 2.9 x 10^{-8}	1.9 x 10^{-8}
γ-HCH	3.3 – 12.6	7.8	4.7 x 10^{-9} – 1.8 x 10^{-7}	1 x 10^{-7}	2.4 x 10^{-8} – 9.3 x 10^{-8}	5.7 x 10^{-8}
DDE	2 – 17.3	6.0	2.8 x 10^{-9} – 2.5 x 10^{-8}	8.5 x 10^{-8}	1.4 x 10^{-8} – 4.8 x 10^{-8}	4.4 x 10^{-8}
DDD	0.6 – 9.3	3.8	8.6 x 10^{-10} – 1.3 x 10^{-8}	5.5 x 10^{-8}	4.4 x 10^{-9} – 6.8 x 10^{-8}	2.8 x 10^{-8}
DDT	2 – 6.6	1.5	2.8 x 10^{-9} – 9.4 x 10^{-9}	2 x 10^{-8}	1.5 x 10^{-8} – 1.2 x 10^{-7}	1.0 x 10^{-8}
Endosulfan	3.3 – 10	7.0	4.7x 10^{-9} – 1.4 x 10^{-8}	1 x 10^{-8}	4.4 x 10^{-9} – 1.2 x 10^{-7}	5.0 x 10^{-8}
Total OCPs	14.4 – 73.1	32.4	2.1 x 10^{-8} – 1.0 x 10^{-7}	4.6 x 10^{-7}	5.3 x 10^{-8} – 2.7 x 10^{-7}	2.4 x 10^{-7}

Table 3. Hazard quotients to humans due to OCPs

Pesticide	Reference dose (mg kg^{-1})	LADD (mg kg^{-1} d^{-1})		Hazard Quotient		Health risk
		Adults	Children	Adults	Children	
Σ HCHs	3 x 10^{-3}	2.4 x 10^{-7}	1 x 10^{-7}	6.7 x 10^{-5}	3 x 10^{-5}	No
Σ DDTs	2 x 10^{-2}	1.6 x 10^{-7}	8.3 x 10^{-8}	8 x 10^{-6}	4 x 10^{-6}	No
Endosulfan	6 x 10^{-3}	1.0 x 10^{-8}	5 x 10^{-8}	1.6 x 10^{-5}	8.6 x 10^{-6}	No

Concentration of organophosphorus and pyrethroids

The sum of ΣOPPs concentration were 45.1±7.2 μgkg^{-1}, 34.9±10.3 μgkg^{-1}, 65.8 ±2.3 μgkg^{-1}, 22.7 ±19.8 μg kg^{-1}, 15.5±16.4 μg kg^{-1}, 15.5±57.6 μg kg^{-1}, 14.7±18.9 μg kg^{-1}in the soil of crops cabbage, cauliflower, spinach, celery, lettuce, broccoli and mustard (Table 4). The sum of total concentration of OPPs (dimethoate, diazinon, chlorpyriphos, malathion, parathion methyl, parathion ethyl) in the soil of these crops ranges as ND-20 μg kg^{-1} in cabbage, ND – 26 μg kg^{-1} in brocolli, 0.2 – 8 μg kg^{-1}in celery, ND – 20 μg kg^{-1} in spinach, ND – 8 μg kg^{-1} in lettuce, and ND – 3.3 μg kg^{-1} in mustard. The OPPs concentration in these soil crops decreases in the following order spinach > broccoli > cabbage > cauliflower > celery > lettuce > mustard. This shows the same trend as that of OCPs except the spinach soil indicating that loose structure of soil of these vegetables might decrease the concentration of pesticides due to leaching or via exposure of these plots to the rainfall and since this part has a tropical climate so the decrease in concentration might be due to high temperature, moisture and intense microbial activity [17]. The observation of pesticides residue for spinach soil is highly contaminated by OPPs and mustard soils the least which might be due to the cultivation process of these crops or the type of irrigation system. The observed trend of concentration of studied OPPs in these studies were parathion ethyl (25.3%) > dimethoate (23.8%) > diazinon (21%) > malathion (14.3%) > chlorpyriphos (13.3 %) > parathion methyl (2.2 %). The slight high concentration of OPPs as compared to OCPs in the soil of these crops might be because these vegetables are more susceptible towards the insects or due to easily degradation of OPPs that's is why these are applied frequently and there can be a possibility that insects have developed a low level of resistance towards these pesticides. These OPPs concentration was higher than other studies in Cameron Highland (< 0.01 – 0.06 mg kg^{-1}) [17], 16.68 ng g^{-1} for dimethoate [25]. The spatial distribution of OPPs were not same at all sites. Among stations the highest concentration for OPPs were found at Kuala Terla ranging from 4.6 – 15 μg kg^{-1} where dimethoate accounted the most indicating its extensive use over the vegetables. The lowest concentration of OPPs were found at Telom region ranging from ND – 0.02 μg kg^{-1}.

The sum of ΣPYRs concentration were 7.9±12.7 μg kg^{-1}, 7.9 ±15.1 μg kg^{-1}, 3.6 ±14.2 μg kg^{-1}, 1.3 ±2.7 μg kg^{-1}, 1.3±1.6 μg kg^{-1}, 10.8±1.1 μg kg^{-1} and 2.7±12.4 μg kg^{-1} in the soil of crops cabbage, cauliflower, spinach, celery, lettuce, broccoli and mustard showing that the sum of residual concentration is same in cabbage and cauliflower soil and in celery and lettuce (Table 4). The total concentration of PYRs (sum of permethrin and fenvelerate) for soil ranges between ND – 1.3 μg kg^{-1} in cabbage, ND – 1.3 μg kg^{-1} in celery, ND – 0.6 μg kg^{-1} in lettuce, ND – 6.6 μg kg^{-1} in cauliflower, ND – 5.3 μg kg^{-1} in broccoli, ND – 6.6 μg kg^{-1} in spinach and ND –1.3 μg kg^{-1} in mustard. The observed trend of concentration studied for PYRs were fenvelerate (62.2%) > permethrin (37.7%). This does indicate the usage of pyrethroids pesticides in Cameron Highlands as already been reported [8]. PYRs seemed to be the least detected pesticides among all sites indicating its less use in study area. However, the highest concentration was found at Kuala Terla of which fenvelerate accounted the most (10 μg kg^{-1}).

Human health risk assessment for OPPs and PYRs

In this study we included adults of 70 years old and children of 12 years of age exposed for all the days in a year during their life span. The estimated LADD of total OPPs for adults and children through soil ranged between 6.9 x 10^{-9} – 3.6 x 10^{-7} mg kg^{-1} d^{-1} and 3.6 x 10^{-8} – 1.8 x 10^{-6} mg kg^{-1} d^{-1} (Table 5). HQ of OPPs for human adults was 5.7 x 10^{-6}, 1.6 x 10^{-5}, 3.8 x 10^{-7}, 3.3 x 10^{-6}, 2.5 x 10^{-8}, 6.9 x 10^{-7}, while for children was 3 x 10^{-5}, 8 x 10^{-5}, 1.9 x 10^{-6}, 1.7 x 10^{-5}, 1.3 x 10^{-7}, 3.5 x 10^{-6} (Table 5) which were lower than the acceptable risk levels indicating that the daily dose is below the proposed guide lines of USEPA 2012 [12]. For PYRs the LADD adults ranges as 3.7 x 10^{-9} – 3.4 x 10^{-8} mg kg^{-1} d^{-1} and for children as 6 x 10^{-9} – 1.7 x 10^{-8} mg kg^{-1} d^{-1} with the mean values as 7 x 10^{-9} mg kg^{-1} d^{-1} and 1.7 x 10^{-8} mg kg^{-1} d^{-1}. The HQ by fenvelerate and permethrin for adults is 2.2 x 10^{-7}, 5.4 x 10^{-8} and for children is 1 x 10^{-6}, 2.8 x 10^{-7} (Table 6).

Table 5. Concentration of OPPs and PYRs and its life time average daily dose for humans through soil ingestion

Compound	Concentration (μg kg^{-1})		(LADD mg kg^{-1} d^{-1})			
			Adults		Children	
	Range	Mean	Range	Mean	Range	Mean
Dimethoate	0.06 – 200	8.0	$8.6 \times 10^{-11} – 2.9 \times 10^{-7}$	1.1×10^{-8}	$4.4 \times 10^{-10} – 1.5 \times 10^{-6}$	5.9×10^{-8}
Diazinon	0.6 – 23	7.7	$8.5 \times 10^{-10} – 3.3 \times 10^{-8}$	1.1×10^{-8}	$4.4 \times 10^{-9} – 1.7 \times 10^{-7}$	5.7×10^{-8}
ParathionMethyl	0.2 – 12	0.8	$2.8 \times 10^{-13} – 1.7 \times 10^{-8}$	1.1×10^{-9}	$1.5 \times 10^{-9} – 8.9 \times 10^{-8}$	6.0×10^{-9}
Parathion Ethyl	0.2 – 10	9.3	$3.0 \times 10^{-10} – 1.4 \times 10^{-8}$	1.3×10^{-8}	$1.5 \times 10^{-9} – 7.4 \times 10^{-8}$	6.9×10^{-8}
Malathion	2 - 3	5.2	$2.9 \times 10^{-9} – 4.2 \times 10^{-9}$	7.4×10^{-9}	$1.5 \times 10^{-8} – 2.2 \times 10^{-8}$	3.8×10^{-8}
Chlorpyriphos	1.8 – 5.3	4.8	$2.6 \times 10^{-9} – 7.6 \times 10^{-9}$	6.8×10^{-9}	$1.3 \times 10^{-8} – 3.9 \times 10^{-8}$	3.5×10^{-8}
Total OPPs	4.9 – 253.3	35.8	$6.9 \times 10^{-9} – 3.6 \times 10^{-7}$	5.1×10^{-8}	$3.6 \times 10^{-8} – 1.8 \times 10^{-6}$	2.7×10^{-7}

Relationship of soil properties with pesticides residue

The soil samples were analyzed for three physico-chemical properties including texture, pH, and organic carbon content (Table 7). These parameters are important in order to study the mobility and degradation behavior of pesticides. Soil properties influence the fate of the pesticides in soil e.g. the organic content of soil, clay content and the soil pH. As increase in organic content increases the binding forces by bonding with the hydrophobic compounds in the soil thus reducing their mobility. This correlation among the residue of pesticides and soil properties is shown by a biplot (Figure 2) by using the PCA, which is a powerful tool for pattern recognition, classification and modeling and other aspects of data evaluation. It was performed on data of pesticides in soil under study showing the relationship among 17 variables.

Table 7. Physico-chemical properties of soil

Textures (%)			pH	Organic Carbon (%)
Coarse Sand	Fine sand	Clay and Silt		
68	17	12	7 – 8	17.6

Four principal components with Eigen value >1 accounts for 98% of total variance sets show a high residual concentration of pesticides in soil of brassica vegetables like cabbage, cauliflower, broccoli as compared to other leafy vegetable. Secondly TOC and pH are not separated by larger distance and are more correlated with DDT, DDD, DDE, endosulfan, ∝-HCH, permethrin, diazinon, chloripyrphos and diazinon in the soils of brassica vegetables like cabbage, cauliflower and broccoli and it also shows that the organic content and pH of the soil is more correlated with the soils of these crops as compared to other leafy vegetables (mustard, celery and lettuce) thus reducing pesticides mobility due to strong hydrophobic interactions [26]. This shows that the amount of pesticides usage depends upon crop type; the soil of brassica leafy vegetables is more contaminated and it might be possible that these vegetables has the ability to accumulate more OCPs because of the roots of these vegetables exudes organic compounds consisting of 20-30% of photosynthetic compounds which supports pesticides movement [27] while the decrease in the soil concentration of other leafy vegetables is due to in situ biomass burning during harvesting time of crop cultivation that favors the volatilization of these OCPs [10].

There can be several factors contributing in these observations of these high residual content in brassica vegetables which can be due to a close cultivation of these vegetables in the small field or the procedures used by the farmers for crop protection would be similar for these plants in case of other leafy vegetables the less association of soil with pesticides residues might be because rapid disappearance of pesticides after application or the high rotation frequency of unproductive culture before completely grown [1]. There can also be a possibility that the roots of these vegetables release dehydrohalogenase enzymes that dechlorinate the organohalogenated compounds or there can be enhance degradation due to rhizosphere effect which is the influence of the root system on uptake of contaminants via soil [27]. Biplot also shows a strong correlation between pH 7 – 8, and organic content (14%) with the OCPs like DDT, endosulfan and HCHs showing a hydrophobic interaction between the soil particles and pesticides. This indicates a strong pesticide-soil organic interaction masking the acidity and alkalinity of soil [28].

There is not a significant correlation between most of the OPPs with pH and organic content of soil except diazinon indicating that adsorption of polar OPPs decreases with increase pH (7 – 8). However, endosulfan showed a significant correlation indicating that higher pH is favoured for adsorption of neutral pesticides in soil. These results are similar to the studies reported by Krishna and Philip [29] that pesticides adsorption is maximum between pH 2-8. In this case the persistence of these OPPs in the soil of these crops might be due to its adsorption on the clay fraction of soil because of its polar nature as clay particles has a small size and its combination with the organic content is useful because both of these are associated of their mutual interaction of molecular attraction and surface charges [30]. It might also be possible that inhibition of microbial degradation is responsible for holding these pollutants in soil rather than the organic content. It is also had been proved by other studies that in case if polar pesticides are not correlated with the organic content of soil than it has the ability to relate with other factors of soil such as inorganic matter, calcium concentration cation exchange capacity [30,31]. There is also a possibility that under the influence of roots of the brassica vegetables has the ability to facilitate the movements of these chemicals from soil towards the rhizosphere soil from where they are taken up by the roots [32], that is why these vegetables have high concentration of pesticides.

Biplot also indicates that mixture of pesticides has been used on crops and that might also influence the persistence of these pesticides [25]. Diazinon is an exceptional to other OPPs as it seemed to be more correlated with the organic content and pH of soil showing that at high pH diazinon is more persistent than other OPPs and it has also more association with organic content that's why cannot be broken easily by water thus cannot be removed by leaching [30,33]. This is in agreement reported previously by Chapman and Cole [28] that maximum correlation of diazinon and chlorpyriphos at high pH. This high correlation of diazinon and chlorpyriphos as compared to other OPPs might also be because of increased difficulty to access the adsorption sites of soil by other pesticides due to increased concentration [34], this increased sorption correlates with the sorption studies [35], suggesting the high sorption based on organic content and the k_{ow} of these pesticides. In the case of pyrethroids, permethrin is more correlated with the organic content in these vegetable soils as compared to fenvelerate showing its adsorption with the organic content this correlate with the studies of other researchers [9]. Biplot also indicates that pesticides are originating from different sources as farmers use mixture of pesticides to have more residual effect.

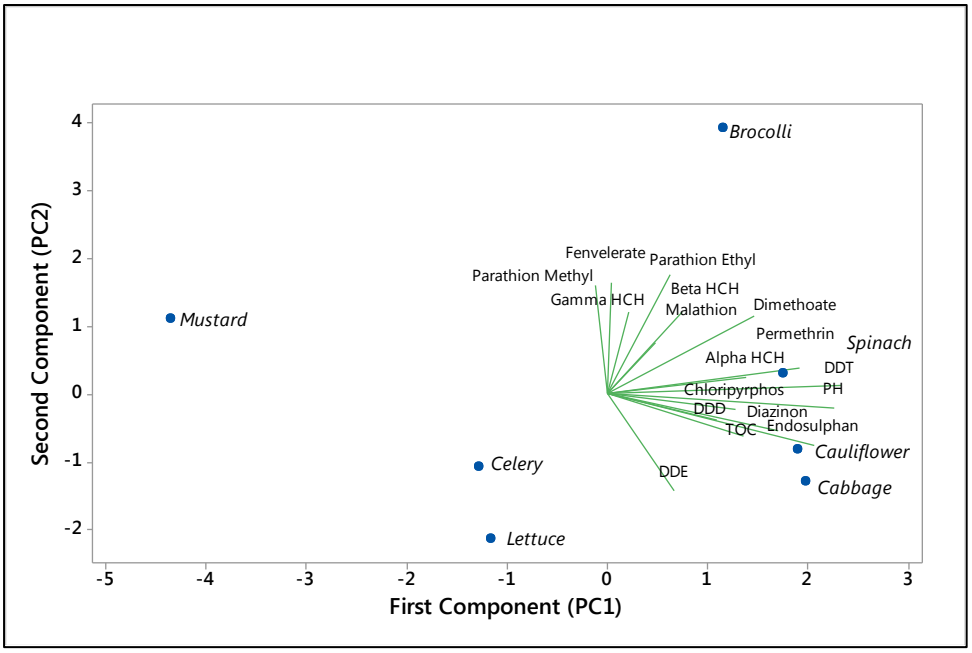

Figure 2. Biplot of two component loading (PC1 x PC2)

Conclusion

Despite restriction on OCPs, the residues of these pesticides were found in the agricultural soil of Cameron Highlands. The average highest concentration of DDT and γ-HCH indicates the presence of both new and historical input sources for HCHs while historical inputs for DDTs contamination or its slow degradation. The highest concentration for OCPs in soil of these crops were seen as cauliflowers > cabbage > broccoli > celery > lettuce > mustard. The OPPs concentration were higher indicating its continuous use in soil of these crops following order as spinach > cabbage > broccoli > cauliflower > celery > lettuce > mustard. Among PYRs, permethrin was used in high concentration and in soil crops its concentration follows as following order broccoli > cabbage > cauliflower > spinach > celery > lettuce > mustard. These results also show that the farmers prefer to use mixture of these pesticides as they believe it is more effective than using a single kind. PCA shows high residual concentration in soil of brassica vegetables and indicated that the presence of these pesticides in the soil is more correlated with type of crop, its cycle or crop protection and it also shows that most of OCPs and permethrin was more correlated with the total organic content and pH of soil. Meanwhile in some cases OPPs and fenvelerate were not as correlated with the pH and organic content indicating its less adsorption on the organic content of soil. The health risk assessment showed that though residues of these contaminants were found in these soil during both less and high frequent spraying by farmers but it poses no health risks to humans working in this agricultural region as the HQs were less than one (≤1).In conclusion it is noteworthy to remark that soil total organic content has reduced the mobility for most of the pesticides in the soil of brassica vegetables (cabbage, cauliflower, broccoli) as it has effect on the leachability, biodegradability, volatility, persistence and bioactivity of these pesticides.

Abstract

Zinc layered hydroxide (ZLH) intercalated with curcumin was successfully prepared by ion exchange method. The synthesised nanocomposite was characterised by Powder X-ray diffraction (PXRD) and Fourier transform infrared spectroscopy (FTIR). The obtained intercalation compound, ZLH-curcumin nanocomposite (ZiCUR), showed a basal spacing of 10.0 Å when 0.01M of curcumin solution was used in the synthesis. The shifting in the stretching frequency of the curcumin anion provides strong evidence that the anion is bonded to the ZLH through electrostatic force. In FTIR, after intercalation, there is a noticeable shift of the O-H stretching vibrational bands. This is due to the formation of strong hydrogen bonds between curcumin and –OH groups in ZLH. Thus, this indicates that curcumin anions are present in the sample and were intercalated between positively charged ZLH layers, as indicated by the characteristics of PXRD pattern.

Keywords: zinc layered hydroxide, curcumin, ion exchange method

Abstrak

Zink hidroksida berlapis (ZHB) disisip bersama kurkumin telah berjaya disediakan menggunakan kaedah pertukaran ion. Komposit nano yang telah di sintesis dicirikan menggunakan X-ray Serbuk Pembelauan dan Spektroskopi Infra Merah Transformasi Fourier. Sebatian interkalasi yang diperoleh iaitu komposit nano zink hidrosida berlapis-kurkumin, menunjukkan jarak basal sebanyak 10.0 Å apabila kepekatan 0.01M larutan kurkumin digunakan semasa proses sintesis. Perubahan pada frekuensi anion kurkumin menunjukkan bukti yang kukuh di mana anion telah dilekatkan kepada ZHB menggunakan daya elektrostatik. Melalui Spektroskopi Infra Merah Transformasi Fourier, selepas interkalasi, perubahan yang ketara pada O-H regangan jalur getaran dapat di lihat. Hal ini kerana, pembentukan ikatan hidrogen yang kuat antara kurkumin dan kumpulan -OH di dalam ZHB. Maka, ia menunjukkan bahawa anion kurkumin hadir di dalam sampel dan telah disisipkan antara lapisan ZHB yang bercas positif, seperti mana yang ditunjukkan oleh ciri – ciri corak Spektroskopi Infra Merah Transformasi Fourier.

Kata kunci: zink hidroksida berlapis, kurkumin, kaedah pertukaran ion

Introduction

According to the World Health Organization, open injuries have the potential for serious bacterial wound infections, including gas gangrene and tetanus, and these, in turn, may lead to long term disabilities, chronic wound or bone infection, and death [1]. Wound infection is particularly of concern when injured patients are presented late for definitive care. Problems, such as lack of knowledge about how to diagnose and treat wounds and lack of funding to

proper therapies, medical technologies and trained wound-care professionals, will lead to millions of untreated and mistreated patients each year.

Turmeric, (*Curcuma longa* L.), has been used in traditional medical applications since ancient times. The principal curcuminoid in turmeric is curcumin [2], which was extensively studied as antibacterial compound. The wound healing ability of curcumin, involving the mechanisms of reduced inflammation, granulation, and remodelling of the tissue, was intensively examined in rats and guinea pigs. The recent studies have highlighted that punch wounds in curcumin-treated animals healed much faster than curcumin untreated animals [3] [4]. However, the curcumin molecule is unstable and therefore, demonstrates limited biological activity and practical applications. In this study, in order to stabilize the curcumin, attempts were made by intercalating curcumin into layered metal hydroxide.

Layered metal hydroxide can be classified as layered double hydroxide (LDH) and layered hydroxide salt (LHS). Layered double hydroxide (LDH) nanocomposite is a class of inorganic material with a chemical composition represented by the general formula, $[M^{2+}_{1-x}\ M^{3+}_{x}\ (OH)_2]^{x+}\ [A^{n-}_{x/n}.mH_2O]$, where M^{2+} and M^{3+} are divalent and trivalent metal cations, respectively [5]. Previous studies have shown that curcumin intercalated into Mg/Al LDH exhibited excellent wound healing properties [6]. However, to the best of our knowledge, the application of a Zinc layered hydroxide salt (LHS) as a host has yet to be explored.

Zinc layered hydroxide (ZLH) is represented by the general formula of $M^{2+}(OH)_{2-x}(A^{m-})_{x/m}.nH_2O$, where M^{2+} in this case is the metal cation Zn^{2+} and A^{m-} is the counter ion [7]. The ZLH structure consists of positively charged layers that can expand or contract depending on the nature of the interlayer anions. In this current investigation, we study the intercalation of curcumin into interlayer galleries of ZLH via ion exchange method, as well as properties of the resulting ZLH-curcumin intercalation compound. This direct method involved a direct reaction between the curcumin solution and the zinc oxide (ZnO) precursor. Compared with other LHS synthesis methods, like urea hydrolysis [8], structural memory effects [9], co-precipitation [10] and solid state reactions [11], ion exchange method was chosen as the best method because it is simple, environmentally friendly, and economical as it involves fewer chemicals and fewer steps.

Materials and Methods

Materials

Zinc oxide, 99%, curcumin ($C_{21}H_{20}O_6$ molecular weight 368.3799 g/mol), 98%, and sodium hydroxide, 99% purity, were purchased from Acros Organics (Geel, Belgium) and Merck (Darmstadt, Germany), respectively. Chemicals were used without further purification. Deionized water was used throughout the experiment.

Synthesis of zinc layered hydroxide intercalated with curcumin

The curcumin-intercalated ZLH was prepared using the ion-exchange method [12,13,14]. An amount of 100 mL of Curcumin at 0.01 M was added to the aqueous solution containing 1.0 g ZnO. The mixture was stirred vigorously for 2 hours at room temperature. The reaction mixture was aged at 70 °C for 18 hours before the resulting slurry was centrifuged, washed with water, dried in an oven at 70 °C, and kept for further characterisation.

Characterisation

Powder X-ray diffraction (PXRD) patterns were recorded with a XRD-6000 (Shimazdu, Kyoto, Japan) using CuKα radiation (λ = 1.5418 Å) at 30 kV and 30mA. Fourier transform infrared (FTIR) spectra were recorded over the range of 400 – 4000 cm^{-1} on a Perkin-Elmer Spectrum 100 (Perkin-Elmer, Waltham, Massachusetts, USA) equipped with a universal attenuated total reflectance (ATR) accessory.

Results and Discussion

Powder X-ray diffraction analysis

Figure 1 shows the PXRD patterns of ZnO and ZLH-curcumin nanocomposite (ZiCUR). The PXRD pattern of ZnO showed characteristics of high crystallinity peaks. However, in ZiCUR, the peak of ZnO phase still dominated the PXRD pattern, which is due to an incomplete reaction. The intercalation occurred when the ZnO was transformed to ZLH and the curcumin anion was intercalated between the layers. This can be observed by the presence of peaks at a lower 2θ value, as shown in the diffraction patterns of ZiCUR. The expansion of the basal spacing recorded at

10.0 Å was caused by a larger molecular size of curcumin, as well as the spatial arrangement of the anion in the interlayer space. From previous studies, it was proposed that the formation of ZiCUR from ZnO occurred in three steps through a dissociation-deposition mechanism [15,16,17]. The first step described in Eq. 1 involves hydrolysis of ZnO in water. When ZnO particles are immersed in the water, the surface of ZnO hydrolyses to form a layer of $Zn(OH)_2$. The layer of $Zn(OH)_2$ that is formed then becomes more soluble than ZnO in the presence of acid to become Zn^{2+} and OH^- (Eq. 2). Finally, the Zn^{2+} species, hydroxyls, H_2O, and curcumin anions (CA^-) in the solution react to generate the layered intercalation compound (Eq. 3). The process is repeated until all the ZnO phase and the $Zn(OH)_2$ phase has completely converted to the layered compound. ZiCUR is formed from the host-guest interactions, namely electrostatic attraction, hydrogen bonding, and van der Walls forces [18]. The mechanism of dissociation-deposition is described in the equations below:

$$ZnO + H_2O \rightarrow Zn(OH)_2 \quad (1)$$

$$Zn(OH)_2 \rightarrow Zn^{2+} + 2OH^- \quad (2)$$

$$Zn^{2+} + 2OH^- + CA^- + H_2O \rightarrow Zn^{2+}(OH)_{2-x}(CA^-)_x nH_2O \quad (3)$$

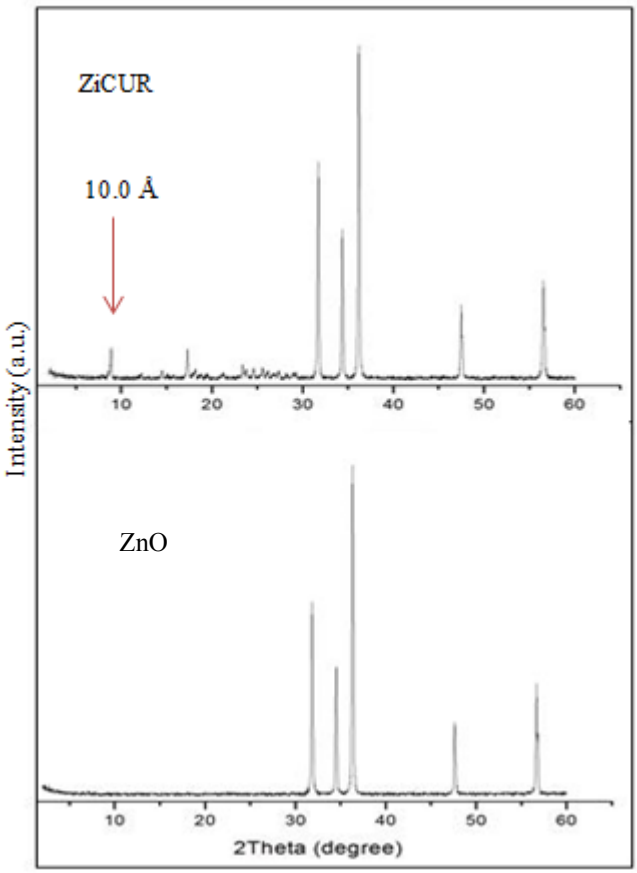

Figure 1. PXRD patterns of ZnO and ZiCUR compounds

Fourier transform infrared analysis

The presence of the curcumin in the ZLH interlayers was also elucidated by FTIR spectroscopy, which supported the PXRD results [19]. Figure 2 exhibited the FTIR spectrum of pure ZnO, curcumin, and ZiCUR. The sharp and

intense peak of ZnO at the lower wavenumber range, 400 cm^{-1} is due to the Zn-O sublattice stretching vibration [20]. Similar absorption bands could also be observed for the ZiCUR, as it possesses the same functional group. The FTIR spectra of curcumin showed strong characteristic vibrations at 1592 cm^{-1} attributed to C=C bending and 1270 cm^{-1} to C-O stretching. Trans-C-H out-of-plane bend for curcumin was detected at 960 cm^{-1}. The C-H monosubstitution band for phenyl group could be detected at 720 cm^{-1}, 809 cm^{-1}, and 856 cm^{-1}.

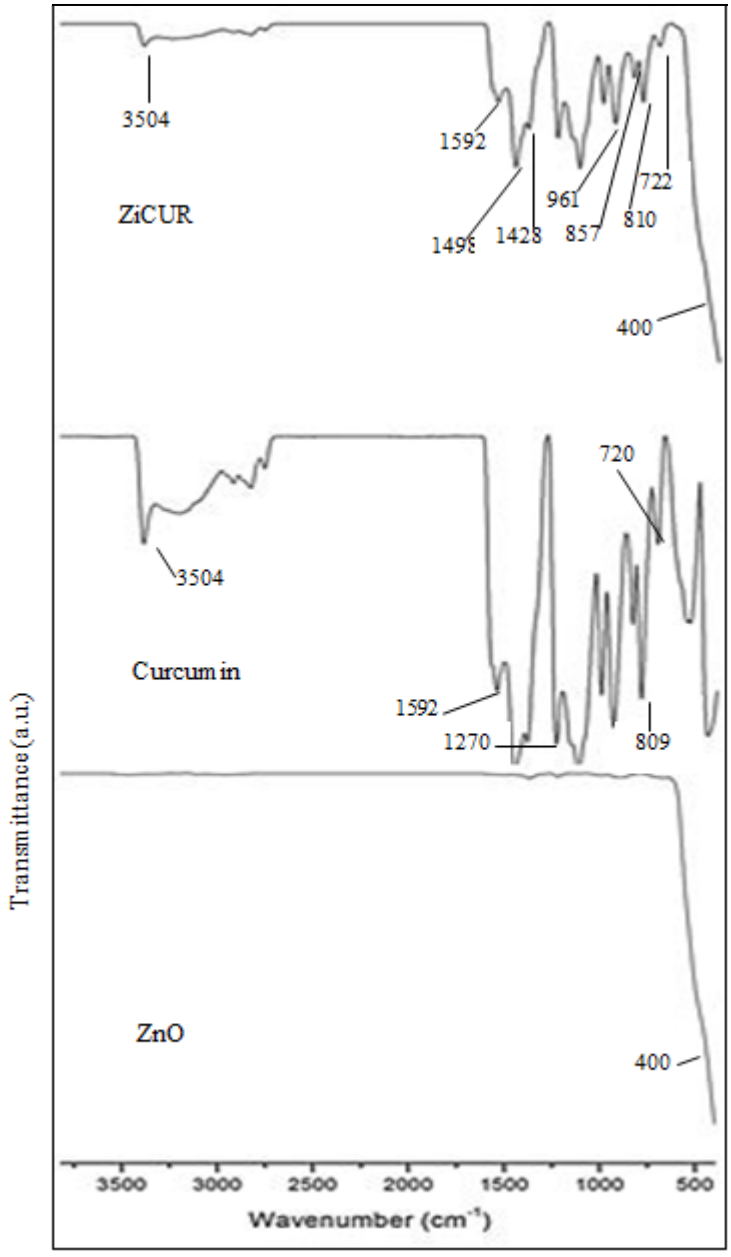

Figure 2. FTIR spectra of ZnO, Curcumin and ZiCUR compounds

On the other hand, the intercalation compound exhibited most of the vibrations assigned of curcumin, although several vibrations shifted due to the interaction between the curcumin anion and the interlayer. In particular, vibrations were due to trans-C-H out of plane bend at 961 cm^{-1} and C-H monosubstitution band at 722 cm^{-1}, 810 cm^{-1} and 857 cm^{-1}. COO^- stretching of intercalated curcumin anion overlapped and appeared at 1498 cm^{-1} and 1428 cm^{-1}. The C=C stretch in intercalated ZLH also overlapped at 1592 cm^{-1}. The broad band at 3504 cm^{-1} was assigned to the O-H stretching of vibration of interlayer water molecules. These results indicate that both curcumin and ZnO functional groups were present in the compound and further confirmed the intercalation of curcumin between positively charged ZLH layers, as indicated by the characteristics of PXRD pattern.

Conclusion

The curcumin anion was successfully intercalated into the Zn layered hydroxide by the ion exchange method. The interlayer spacing of ZiCUR obtained by PXRD characterization suggests the successful intercalation reactions between ZLH nanolayers and curcumin. The FTIR spectra further confirmed the presence of curcumin in the ZLH. The product, therefore, is hoped to demonstrate future potential as wound dressings for human skin.

ENZYMATIC GLYCEROLYSIS OF METHYL LAURATE UTILIZING *Candida antarctica* Lipase b

(Gliserolisis Berenzim oleh Metil Laurat Menggunakan Lipase b *Candida antarctica*)

Abstract

Enzymatic glycerolysis using *Candida antarctica* lipase b (CALB) as catalyst was studied. Production of monolaurin was optimized based on two selected types of CALB, varying enzyme concentrations and reaction time. Novozyme-435 (N-435) and *Aspergillus oryzae* were used in this study. About 47.6% of monolaurin was synthesized using N-435 at a 5% enzyme concentration within 24 hours of reaction time. Characterizations were performed using different techniques namely gas chromatography-flame ionization detector (GC-FID), thin layer chromatography (TLC) and Fourier transform infrared spectroscopy (FTIR) analysis.

Keywords: methyl laurate, enzymatic glycerolysis, monolaurin, Novozyme-435, *Aspergillus oryzae*

Abstrak

Tindak balas gliserolisis berenzim menggunakan lipase b *Candida antarctica* (CALB) telah dikaji. Penghasilan monolaurin dioptimumkan berasaskan dua jenis CALB, kepekatan enzim dan masa tindak balas. Novozym-435 (N-435) dan *Aspergillus oryzae* digunakan dalam kajian ini. Sebanyak 47.6% monolaurin telah berjaya disintesis menggunakan N-435 pada kepekatan enzim 5% dalam tempoh 24 jam masa tindak balas. Pencirian dijalankan menggunakan teknik analisis berbeza seperti kromatografi gas (GC), kromatografi lapisan nipis (TLC) dan spektroskopi inframerah transfomasi Fourier (FTIR).

Kata kunci: metil laurat, gliserolisis berenzim, monolaurin, Novozym-435, *Aspergillus oryzae*

Introduction

Enzymatic glycerolysis reactions were reported to be carried out in a mild reaction condition, low temperature with solvents that are not harmful towards the environment. With the proliferated interest in green and moderate chemical reaction, enzymatic reaction is attractively favored in researches that produce edible products such as monoacylglycerol (MAG) and diacylglycerol (DAG) [1].

MAG which is the glycerol monoester of fatty acids exhibits surfactant and emulsifying properties that advocates mixing of hydrophilic and lipophilic substances. MAG is extensively used in food, detergent, cosmetics, pharmaceutical formulations and plasticizer. Monolaurin (ML) is a medium-chain monoacylglycerol (MAG) with 12 carbons. The industry highly anticipates MAG of various fatty acids due to its unique feature that prevents microbial activity among diverse microorganisms including gram-positive, gram-negative bacteria, spore-forming bacteria, yeasts, filamentous fungi and developed viruses. In particular, ML compounds are able to dissolve and

penetrate into the phospholipid layer of bacterial cell and disintegrate the membrane layer. Thus, ML compounds inhibit bacterial cell reproduction by hindering cell replications [2]. A natural occurring ML exists as an active ingredient in breast milk, which acts as a booster to the infant's immune system [3].

So far, search on literature revealed studies which were focused on the synthesis reaction. MAG could be synthesized by promoting methyl oleate upon a strongly basic MgO via glycerolysis. The catalyst activity decreased with calcination temperature following a trend similar to the site density of the strong base [4]. Furthermore, 2-MAG can be produced from *Echium plantagineum* seed oil and marinol with three purification methods, silica gel column chromatography, liquids-liquids extraction and low temperature crystallization [5]. In addition, it can also be produced from canarium oil by enzymatic reaction using immobilized lipase from *Mucor miehei*, of which has a specific activity towards triacylglycerol (TAG)[6]. Besides that, 2-MAG was produced by enzymatic glycerolysis of omega-3-polyunsaturated fatty acid using short path distillation (SPD) of an acylglycerols mixture [7]. Additionally, the production of 2-MAG done via glycerol esterification of functionalized SBA-15 mesoporous catalyst has been carried out [8].

Lipases are stable enzyme and the general classes of enzymes that break down fat molecules. Lipases are often obtained from animals, plants and recombinant microorganisms. The physiological role of lipases (water-soluble triacylglycerol acylhydrolases) is the catalytic conversion of tri-glycerides into di- or mono-glycerides, fatty acids and glycerol [9]. Extracellular lipases from *Candida sp., Pseudomonas sp., Thermomyces lanuginosus and Rhizomucor miehei* have been investigated by a considerable number of studies to be employed in the biodiesel synthesis [10]. Lipases are hydrolases that catalyze the hydrolysis of fatty acid esters found in living organisms [11].

Candida Antarctica lipase b (CALB) is one of the most effective lipases in the synthesis of ester [12]. The structure as shown in Figure 1. It is an enzyme extracted from yeast. Compared to bacteria, yeasts are easier to handle and grow. This enzyme is commonly used in organic synthesis reactions and as a biocatalyst that is associated to its stereoselectivity and thermal stability. CALB does not show interfacial activation compared to other lipases. This enzyme is optimized at pH 7. CALB generally convert straight-chain acid, which prefers 5 to 12 carbon atoms. This is because bulky acyl groups restrict the size of the binding pocket. CALB is an effective biocatalyst for promoting high FAME production yield [13].

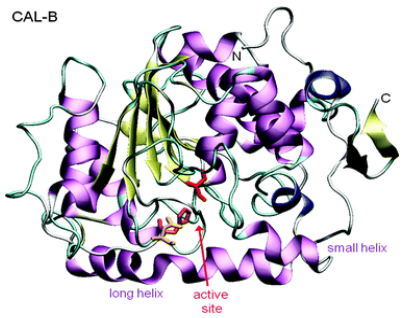

Figure 1. Crystal structure of the lipase CAL-B [17]

Novozyme-435 (N-435) is a heterogeneous biocatalyst system that consists of lipase b from CALB immobilized on a hydrophobic carrier. During esterification and transesterification of sugars, nucleosides and steroids, N-435 has an extraordinary ability to provide high regioselectivity [14]. Previously, a research found that the enzyme showed low activity in the presence of water and proposed a reaction to be done in an anhydrous medium for efficient catalyst activity. N-435 can be used ten times without loss of significant activity [11].

Aspergillus oryzae is a filamentous fungus that has ability to secrete large amounts of hydrolytic enzymes [15]. It is used as a host because it has high protein productivity in the expression of heterogeneous gene using improved

promoters [16]. In this research, we aimed to produce ML with the highest composition through enzymatic glycerolysis of methyl laurate with two selected *Candida antarctica* lipase b *(CALB),* Novozyme-435 (N-435) and *Aspergillus oryzae* with differences concentration of enzyme and reaction time.

Materials and Methods

Raw materials

Glycerol 99%, methyl laurate $C_{13}H_6O_2$, Novozyme-435, CALB *Aspergillus oryzae*, sodium chloride, sodium hydroxide, sodium bicarbonate, chloroform, diethyl ether and ethyl-ethanol were purchased from Sigma Aldrich.

Enzymatic glycerolysis of methyl laurate

Reaction ratio between glycerol and methyl laurate was ratio 1:1 (mol/mol). About 5 g of glycerol reacted with 11.64 g of methyl laurate. Concentrations of enzyme were tested at 3%, 5% and 10% based on the weight of glycerol. Mixtures were heated at 50 °C for 6, 12, 18, 24 and 30 hours in oven shaker with a speed of 250 rpm. Once the reaction ended, the sample was post-treated with 60 mL of sodium bicarbonate solution, 60 mL of sodium chloride solution, 60 mL of sodium hydroxide solution, 60 mL of distilled water, 80 mL of chloroform and 40 mL of ethanol. Unreacted glycerol and water as by-products were dissolved in ethanol, while the desired product was dissolved in chloroform. Products were separated using separating funnel and sample was further purified to isolate monolaurin from by-products (dilaurin and trilaurin) using solid phase extraction (SPE) method. Schematic reaction for enzymatic glycerolysis of methyl laurate was illustrated in Figure 2.

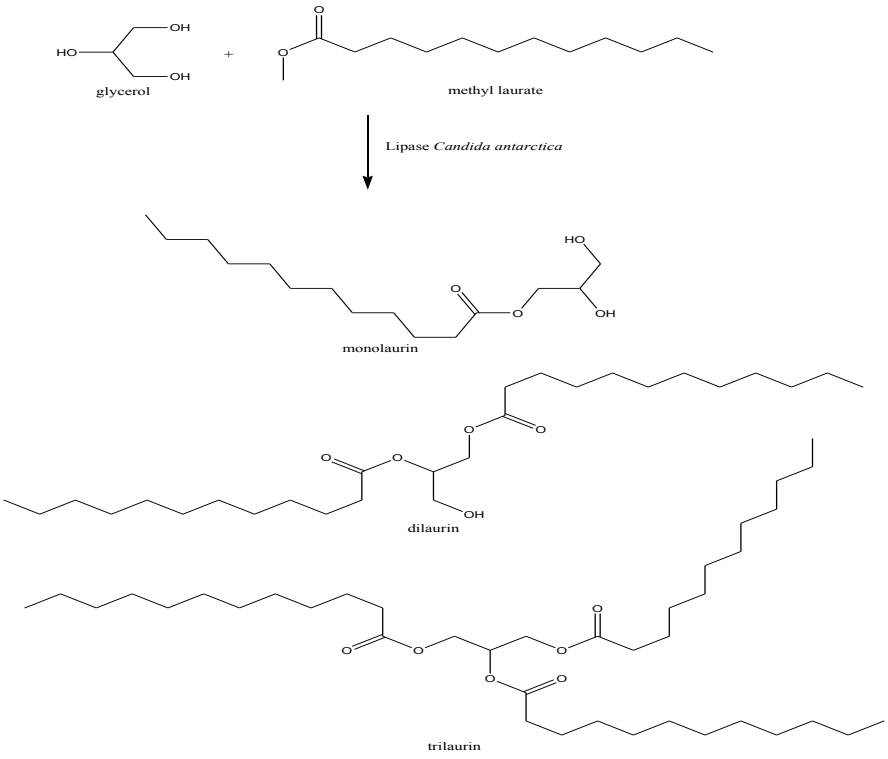

Figure 2. Enzymatic glycerolysis of methyl laurate

Characterization

A series characterization was performed using three different techniques namely thin layer chromatography (TLC), gas chromatography-flame ionization detector (GC-FID) and Fourier transform infrared spectroscopy analysis. A total of 100 mL of TLC mobile phase used toluene: chloroform: acetone with the ratio 70:20:10 (v/v) [18]. GC-FID

analysis is carried out using a capillary column DB-5HT column (30 m × 0.25 mm × 0:10 m). The operator setting GC-FID as follow; the temperature of the injector 250 °C, a temperature of detector 400 °C, initial temperature of 100 °C (1 minute), the final temperature of 380 °C (25 minutes) with a rate of increase of 5 °C/minutes and the carrier gas is nitrogen gas. The sample was prepared by adding 0.03 mL of reaction sample with 1.0 mL ethyl acetate.

Results and Discussion

Figure 3 and 4 represents the production of ML at different enzyme concentration (3%, 5% and 10% by weight) using N-435 and CALB *Aspergillus oryzae*. It is apparent that reaction using N-435 5%wt exhibits higher ML production with 47.6% of conversion in 24 hours of enzymatic glycerolysis. The lowest composition of ML production was 14.4% using CALB from *Aspergillus oryzae*. Hence, it could conceivably be inferred that N-435 is more effective for the synthesis of ML than *Aspergillus oryzae*. It is relevant to hypothesize that N-435 was immobilized on an acrylic resin. In general, acrylic resin is a robust support material for the enzyme which increased thermo stability [14]. Robust material was required to prevent the enzyme from entering the organic media. The lipase hydrolyzed not only produce ML but also dilaurin (DL) and trilaurin (TL). N-435 has higher specificity production toward ML and DL while *Aspergillus oryzae* specificity toward TL.

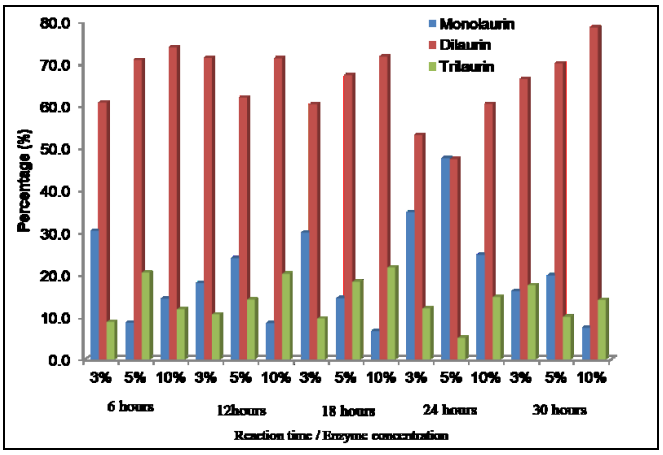

Figure 3. Product composition against concentration of Novozyme-435 and reaction time

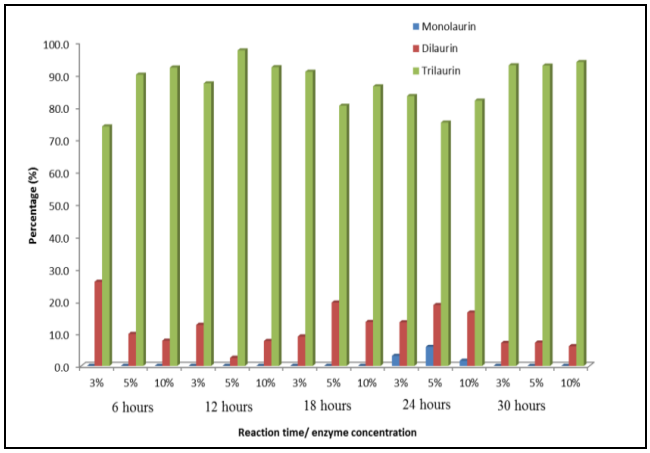

Figure 4. Product composition against concentration of *Candida Antarctica* lipase b from *Aspergillus oryzae* and reaction time

Thin layer chromatography

Separation using TLC was explained by the differences in affinity degree on the plates among the occurring components (Figure 5). Therefore, adsorption depended on the interaction of certain components with the stationary phase [19]. Sample dripped on TLC plates was known as the substrate. Substrates with higher polarity were adsorbed first because the interaction between the substrate and the stationary phase was very strong. This study chemically produced ML, DL and TL from enzymatic glycerolysis. Theoretically, ML has two OH groups and was higher in polarity than DL and TL. Both DL and TL moved slower than ML during elution process due to the hydrogen bonds that formed with the stationary phase. Sample chromatogram was compared with the reference [20].

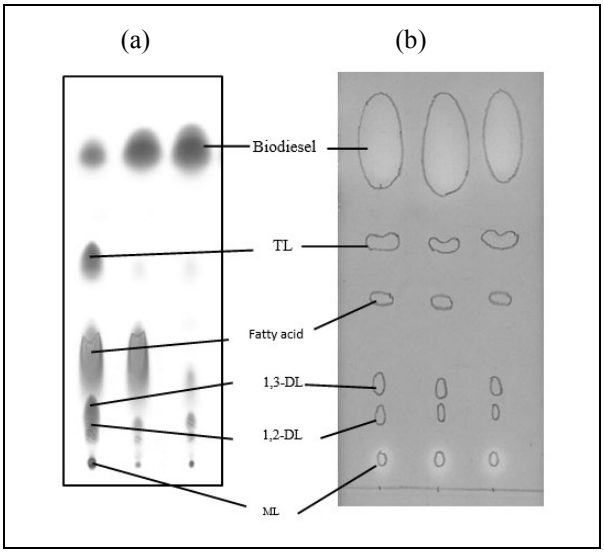

Figure 5. TLC Plate of glycerolysis reaction (a) reference TLC on lipid separation [20] and (b) TLC of sample

Gas chromatography analysis

Synthesized ML was directly compared with the standard mixtures of ML, DL and TL chromatogram (Figure 6). The percentage of ML composition was determined based on the total area of the chromatogram [21]. A relevant idea from a previous study mentioned that fatty acids of methyl esters with similar carbon chain have the same response factor and volatility. Therefore, the sample can be directly compared with the peak area to determine the composition [18]. While, Figure 7 shows a single peak GC chromatogram of purified ML after solid phase extraction (SPE) was performed. Thus, the synthesized ML has been successfully separated and purified from the side products (dilaurin and trilaurin).

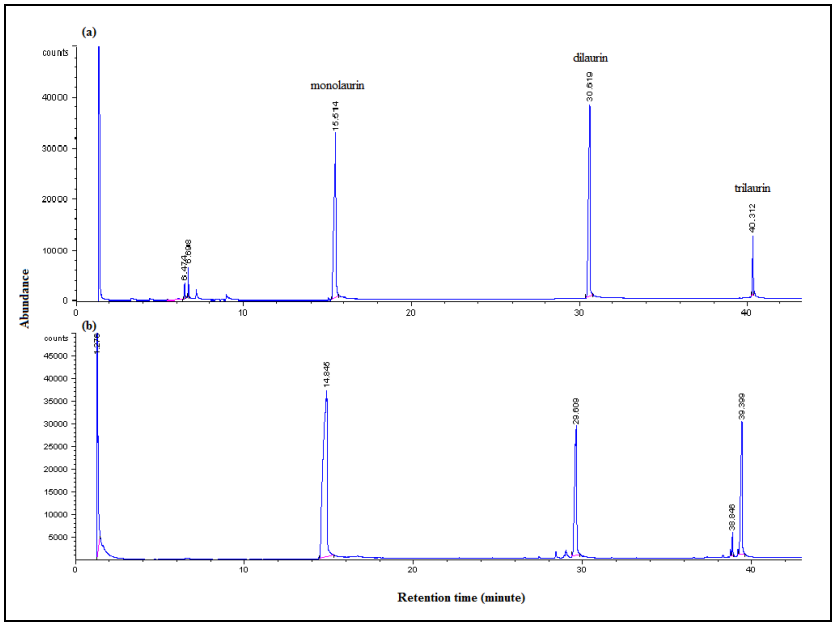

Figure 6. Comparison of GC-FID chromatogram (a) synthesized ML (b) standard mixtures of ML, DL, TL

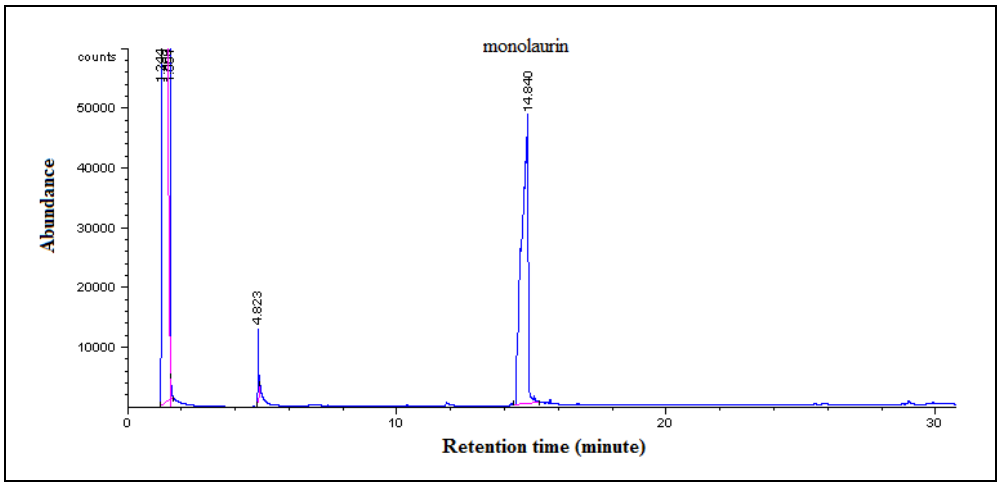

Figure 7. GC chromatogram of purified monolaurin

Infrared spectra

Figure 8 shows comparison of methyl laurate and purified monolaurin infrared spectra. Based on the figure, the present of hydroxyl group can be confirmed by looking at the O-H stretching broad band spectrum at wavenumber 3205 cm^{-1}. It proves the glycerolysis reaction has been successfully performed.

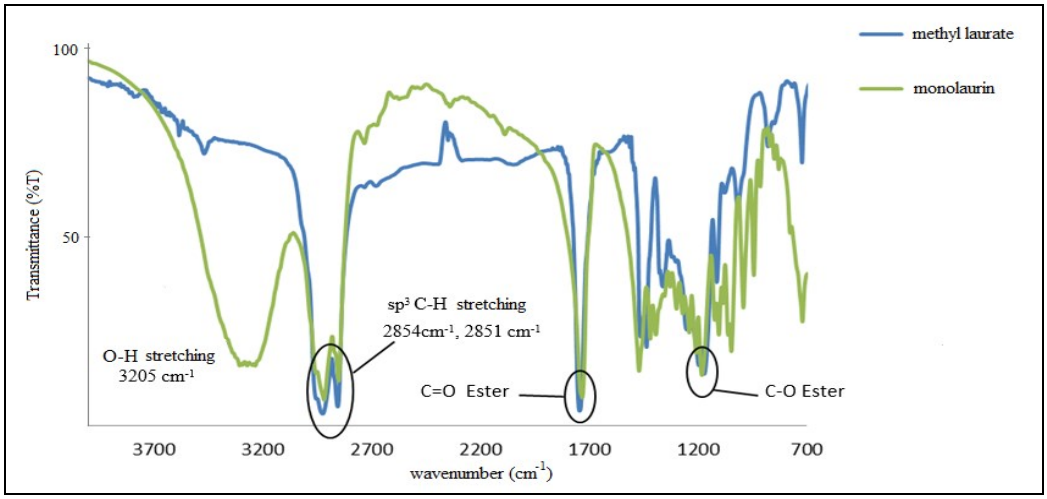

Figure 8. Comparison of infrared spectra between monolaurin and methyl laurate

Conclusion

Monolaurin was successfully synthesized (47.6% yield) and purified by enzymatic glycerolysis of methyl laurate which catalyzed by *Candida antarctica* lipase b. The optimum glycerolysis reaction conditions was using CALB (N-435) 5%wt at 24 hours of reaction time. Monolaurin was successfully characterized using TLC, GC-FID and FTIR analysis techniques. Acrylic resin that bonded onto CALB (N-435) was a robust support material because it restrained the enzyme from getting into the organic media.

Abstract

This paper presents the impact of heat treatments on the yield and quality of the palm oil using solvent extraction techniques. Heating temperature range from 70 to 90 °C and heating time range from 30 to 90 min were studied. The quality parameters measured were free fatty acids (FFA), deterioration of bleaching index (DOBI), carotene content, oxidative stability and fatty acid composition of the oil. These parameters were used to determine CPO quality which has been stored for 3 months. It was found that the yield significantly increased with the increasing of heating temperature and time. The optimum parameter was achieved with heating temperature of 90 °C and heating time of 60 min via wet heating. Optimum oil yield obtained was 24% with 0.93% FFA content, 6.10 DOBI, 938.42 ppm carotene content and oxidative stability of 26.87 hours. Fatty acid composition (FAC) of oil extracted showed a reduction in unsaturated fatty acids as the heating duration increased. After 3 months of storage, 60 min of heating time via wet heating process was recorded the lowest increment of FFA (1.32%) and low reduction of DOBI value (0.41). However, carotene content gave the highest loss with 113.54 ppm towards the end of the storage.

Keywords: crude palm oil, heat treatments, oil yield, oil quality, storage stability

Abstrak

Kajian ini bertujuan untuk menganalisis kesan rawatan haba semasa pensterilan ke atas peratus pengekstrakan minyak dan kualiti minyak sawit mentah (MSM) dengan menggunakan pelarut bagi mengekstrak MSM. Suhu dan masa pensterilan yang berlainan telah digunakan bagi mengekstrak MSM iaitu suhu pensterilan dari 70 hingga 90 °C manakala masa pensterilan dari 30 hingga 90 min. Kesan rawatan haba ke atas peratus pengekstrakan minyak telah dijalankan. Kualiti MSM yang diekstrak iaitu asid lemak bebas (ALB), indeks pemerosotan terhadap pelunturan (DOBI), kandungan karotena, kestabilan oksidatif dan komposisi asid lemak telah dicirikan. Parameter ini digunakan untuk menentukan kualiti MSM yang telah disimpan selama 3 bulan. Hasil kajian mendapati peratus pengekstrakan minyak meningkat secara signifikan dengan kenaikkan suhu dan masa. Hasil optimum pada tahap maksimum iaitu sebanyak 24% telah dicapai pada suhu pensterilan 90 °C dan masa pensterilan 60 min dengan menggunakan pemanasan basah. Kualiti minyak pula menunjukkan kandungan ALB sebanyak 0.93%, DOBI sebanyak 6.10, kandungan karotena sebanyak 938.42 ppm dan kestabilan oksidatif selama 26.87 jam. Selepas 3 bulan penyimpanan, masa pemanasan selama 60 min menggunakan pemanasan basah telah menunjukkan peningkatan kandungan ALB dan penurunan bacaan DOBI yang paling rendah iaitu masing-masing 1.32% dan 0.41. Namun, kandungan karotena didapati merosot paling tinggi iaitu sebanyak 113.54 ppm.

Kata kunci: minyak sawit mentah, rawatan haba, peratus pengekstrakan minyak, kualiti minyak, kestabilan minyak

Introduction

Palm oil fruitlets are usually subjected to sterilization as a first step of the milling process. This process is carried out by steam sterilization of the bunches in sterilizers which are steam pressurized to as high as 40 psi at a temperature of 140°C. The objectives of the sterilization process are to prevent free fatty acids (FFA) build up in the oil, soften the palm fruitlets and loosen the fruit on the bunch to facilitate stripping. It also helps to break up the oil bearing cells of the fruit mesocarp to release maximum oil during the digestion process [1]. After sterilization, the bunches are threshed in rotating threshers to detach the individual fruits. The detached fruits are then further soften and mashed in digesters, where the oil is extracted by screw pressing [2]. The crude palm oil is then clarified, purified and go through the oil vacuum dryer to be dried before it is stored in purified oil storage tank [3]. The conventional palm oil milling process as afore described does not involve solvent extraction. Instead, it is a combination of physical and mechanical approaches.

Strict quality control is practiced in the mill to ensure the least amount of deterioration of oil quality during the milling process. Fats and oils are graded by their acid and free fatty acid (FFA) contents, which are as an index to determine their quality. Palm oil contains about 45% of saturated palmitic acid and 39% of mono-unsaturated oleic acid [4]. Fatty acids play a very important role in fats and oils because of their health implications in the human diet and properties in industrial processes. The type of fatty acid determines the nutritional status and storability of the oil. Oil with higher levels of monounsaturated fatty acids such as oleic acid or polyunsaturated fatty acids such as linoleic or linolenic are more desirable for human consumption than saturated fatty acids. However, from the processing perspective, higher levels of polyunsaturated fatty acids contribute to oil oxidative instability, short shelf life, and rancidity.

The conventional sterilization process also involves with high temperature, wet treatment and mechanical screw pressing which creating an environment favorable to the chemical and enzymatic reaction of hydrolysis including oxidation. Thus, researches have been done to look into the possibility of utilization of dry heating coupled with solvent extraction process. The influenced of heating time [2, 5 – 8] also has been investigated on the quality of crude palm oil (CPO). Solvent extraction and lower heating time was able to gives higher oil yield as well as good quality than conventional screw press. However, variations of time entail biochemical modifications of fat, which are explained by the variation of the free fatty acid and the degree of oxidation [6].

The aim of this research are to determine the effect of heating parameters of dry and wet heating process coupled with solvent extraction to increase oil yield as well as minimize the production of FFA and the oxidation of the fat. Stability of palm oil stored at room temperature after three months periods were also analyzed. Quality parameters measured were FFA, DOBI and carotene content to determined degradation by oxidation under these heating time conditions.

Material and Methods

All solvents and chemical used were analytical and chromatographic grades. Palm fruits were obtained from Palm Oil Milling Technology Centre (POMTEC) of Malaysian Palm Oil Board (MPOB) in Negeri Sembilan, Malaysia.

Processing palm fruitlets: Experimental design

Sterilization of oil palm fruits were carried out by studying the effects of heating temperature and time. In this study, oil palm fruits obtained from the mill were cleaned to remove any dirt on the surface followed by heated at required temperature and time under dry and wet condition using electrical oven (Memmert, UM 400, 1400 watt, 50/60 Hz) and heating bath (Buchi B-490, 1400 watt, 50/60 Hz) respectively.

Sterilization of oil palm fruits at different heating temperature and time

Oil palm fruits were heated at 70, 80 and 90°C for fix heating time at 90 min. Meanwhile, oil palm fruit were heated at 90°C at different heating time of 30, 45, 60 and 90 min.

Oil yield
The mesocarp of the fruits was peeled and the nuts were removed. The peel mesocarp were soaked in the hexane for 24 h at a solvent to fruit ratio of 1:1 (v/w) and latter pressed using fruit press expeller. The extraction solution was filtered through a whatman filter paper No. 1. Solvent of the filtrate was then removed from the oil at 60°C via vacuum rotary evaporator. The yield of palm oil extract was determined using equation (1) below.

$$\% \text{ oil yield} = \frac{x}{y} \times 100 \quad (1)$$

where, *x* is define as mass of oil extracted (g) and y is defined as mass of oil palm fruits (g).

Physicochemical analyses of extracted oil: Chemical analysis
Free fatty acid (FFA) content of the extracted oil was determined by using MPOB test method p2.5:2004 [9]. Sodium hydroxide solution (0.1M) was prepared and standardized with potassium hydrogen phthalate. A known mass of the oil sample was dissolved in neutralised iso-propanol and the free acids were neutralised with sodium hydroxide. FFA values were expressed as palmitic acid (%). A mean value of duplicate samples was calculated.

Deterioration of Bleachability Index (DOBI) was also determined according to MPOB test method p2.9:2004 [9]. DOBI is defines as the ratio of the spectrometric absorbance at 446 nm to that 269 nm. A known mass of the oil was dissolved in n-hexane in 25 ml volumetric flask and dilute to the mark. The absorbance reading of the solution at 446 nm and 269 nm was taken using Hitachi U-2000 Spectrophotometer (Japan). A mean value of duplicate samples was calculated.

Carotene contents were carried using MPOB test method p2.6:2004 [9]. A known mass of the oil was dissolved in n-hexane in a 25 ml volumetric flask and dilute to the mark. The absorbance reading of the solution at 446 nm was taken using Hitachi U-2000 Spectrophotometer (Japan). A mean value of duplicate samples was calculated. The carotene content is expressed as ppm β – carotene and is calculated as equation (2) below.

$$\beta\text{-carotene (ppm)} = 25 \times \frac{383}{100\,\mathrm{W}}(\mathrm{a_s} - \mathrm{a_b}) \quad (2)$$

where, a_s is define as absorbance of the sample a_b is define as cuvette error and w is define as weight of the sample in gram.

Oxidative stability
The rancimat method was used to determine oxidative stability by using a Metrohm 743 Rancimat. An amount 3.0 g of oil sample was prepared in a reaction vessel and placed in a heating block. The block temperature and air flow were set at 110 °C and 10 L/h respectively. A mean value of duplicate samples was calculated.

Fatty acid composition
Fatty acid composition (FAC) was measured by conversion of the oil sample to their fatty acid methyl esters (FAME) according to the method described in MPOB test method (2004) with a minor modification. FAME was prepared by adding 50 mg of oil into 6 ml methanolic sodium hydroxide (0.5 M). The mixture was heated on the steam bath for 10 minutes. 7 ml of boron trifluoride methanol (20%) was added and further heated for 2 min followed by 5 ml of hexane and heated for 1 min. The solution was removed from heat and 15 ml of saturated sodium chloride solution was added to the solution. FAME was collected and dried over anhydrous sodium sulphate for 1 to 2 hours.

Storage of palm oil extract
Samples of oil extract from different heating time via wet heating were stored at room temperature with a temperature range of 28 °C to 32 °C for 3 months. Stability of oil was observed by measuring the changes in FFA, DOBI and carotene content. A mean value of duplicate samples was calculated.

Results and Discussion

Oil Yield

Effect of temperature

The dependence of oil yield on temperature was determined at 70, 80, and 90 °C for fix heating time at 90 min. Figure 1 shows the effect of temperature on the oil yield. As expected, the oil yield was low at lower temperature. In this study, heating temperature of 90 °C is found to be adequate for optimum oil yield. Significant result is in agreement as reported by [10]. According to Baryeh [10] higher temperatures led to greater oil yield for both dry and wet heating process. Furthermore, results obtained suggested that the heating temperature should not be above 100°C for optimum yield. This is due to the increasing in yield was very small and also involving extra cost.

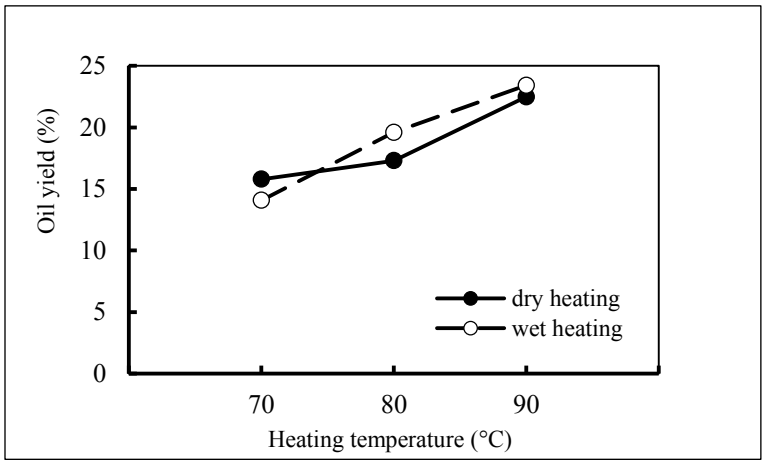

Figure 1. Effect of temperature on oil yield at heating time of 90 min

Effect of time

Heat penetration is the key factor in sterilization of palm fruitlets. Inefficient penetration of heat supply leads to lower oil production. In addition, heating duration also played a crucial part in ensuring the heated fruit remained in good condition for subsequent oil extraction. The oil yield showed the efficiency of solvent extraction process and the effect of different heating duration on the oil content (Fig. 2). The results show that the oil yield increases with increasing duration time for dry (18.86% – 20.99%) and wet (21.64% - 24.55%) heating process. Higher oil yield was obtained when longer heating duration was used as more cell walls of the palm fruits had been ruptured due to heat generated. The results obtained were in good agreement with previous findings [5,6]. According to Malaysian Oil Palm Statistic in 2009, the average oil extraction rate from conventional sterilization and screw pressing in commercial palm oil mill was recorded as 20.21% [11].

Long heating duration caused the palm fruits to be overcooked and increment yield of burnt mesocarp. In contrast, moderate heating period giving a competent time to loosen the nuts from its mesocarp while keeping the yield high to reach the required standard as recommended by MPOB. Maximum oil yield of 24.55% was achieved at 90 min of heating time via the wet heating. However of all trials made, it was found that optimum range period of heating time was between 45 to 60 min via wet heating. Above 45 min heating time, the rise in yield nearly insignificant.

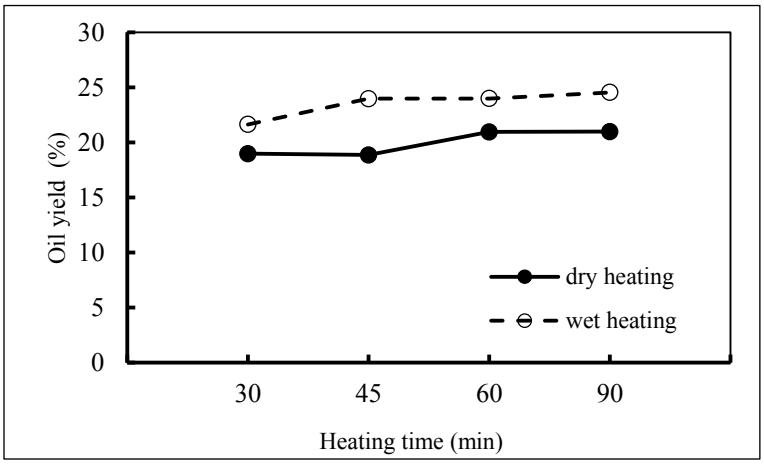

Figure 2. Effect of time on oil yield at heating temperature of 90 °C

Physicochemical analyses of extracted oil

Chemical analysis

Oil extracted from various heating time were selected to be further characterized. The quality of extracted oil using dry and wet heating are shown in Table 1. It is noted that oil extracted using the wet heating approach gave better quality compared to the dry heating. The results obtained from this study proposed the techniques used was able to produce better quality extracted oil set against the commercial CPO for all heating time used.

Table 1. Effect of heating time on oil quality

Heating Time (min)	Quality of Oil					
	FFA (%)		DOBI		Carotene Content (ppm)	
	Dry	Wet	Dry	Wet	Dry	Wet
30	4.97	1.20	4.52	6.25	595.31	806.78
45	2.45	1.15	5.21	5.57	588.98	791.76
60	2.37	0.93	6.06	6.10	846.09	938.42
90	1.42	0.99	6.09	5.42	930.01	763.10
Commercial CPO	< 5.0[a]		> 2.8[b]		500 – 700[c]	

[a] [19]; [b] [20]; [c] [21]

FFA value was gradually decreased as the duration of the heating time was increased for all the heating time. This is due to termination of hydrolysis enzyme in fruits. The lowering of FFA content hence contributed to higher DOBI value. Unfortunately, this situation not helping in increasing the carotene content. Therefore, both FFA and DOBI values gave no effect on the carotene content.

Unsaturated fatty acids contents

The TAG in palm oil partially defines most of the physical characteristics of the palm oil such as melting point and crystallization behavior [12]. Figure 3 shows the unsaturated fatty acid composition for both dry and wet heating process. Unsaturated fatty acid content slightly drops with the time after 60 min exposure, due to long term heating

duration. The composition of fatty acid obtained was within the reported range for all heating duration used. The ranges for unsaturated fatty acid in commercial crude palm oil (CPO) is between 47.5% - 51.8% [4].

Lower unsaturated fatty acid was obtained when longer heating duration was applied as more cell walls of the palm fruits had been ruptured due to heat generated. Similar observation was also observed by Macaire et al. in their study of kernel oil [13]. Owolarafe et al. [14] reported similar results when they studied the micro-structural characterization of palm fruit.

The oil extracted show narrow range in unsaturated fatty composition for dry and wet heating processes (with different only 0.11% – 2.33%). Oil extracted from wet heating show lower unsaturated fatty acid content compared with dry heating process. Wet heating process possesses water to facilitate rupturing of oil cells and destruction of the cell wall [14]. Thus their unsaturated fatty acids fix oxygen and oxidize easily.

The slightly higher content of fatty acid for dry heating compared to wet heating was due to this fatty acid remains trapped in cells. Heat penetration of dry heating was not efficiently penetrated into the fruit but only the outer surface of the fruit. Increases in heating time thus hardened the mesocarp and reduce the chances of the disintegration of the cell content, consequently blocking site from exposing to oxygen and the enzymes to attack double bond.

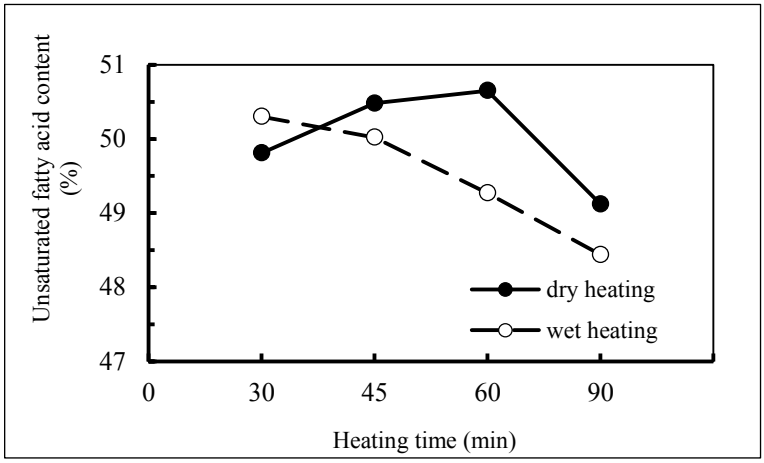

Figure 3. Content of unsaturated fatty acids at various heating time

Oxidative stability

Rancimat test is usually carried out to determine the oxidative stability by considering the Rancimat induction period (RIP). The RIP values represent the stability of the sample. The greater the RIP value, the sample is less susceptible towards oxidation [15]. Figure 4 shows the oxidative stability for both dry and wet heating process varied between 20.56 – 26.87 h. Oxidative stability (RIP) in CPO is >25 hours [15].

In this study, heating duration less than 45 min did not achieve comparable RIP to that of commercial CPO. Higher RIP (25.51 – 26.87 hours) was obtained after 45 and 60 min of heating duration. This result showed that oxidative stability increased with increasing heating duration. At 60 min of heating, the oil extracted from dry and wet heating recorded the highest oxidative stability.

During the heating time, oxidative stability increases due to heating assistance to break the cellular membrane of the fruit mesocarp. In this study, results shows the wet heating has higher oxidative stability compared to dry heating

process. The findings relatively significant to the results obtained from unsaturated fatty acid and FFA content respectively (Figure 3 and Table 1).

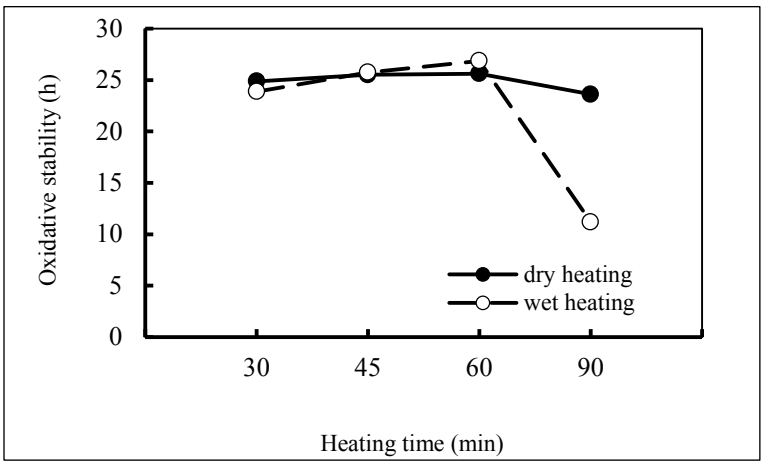

Figure 4. Oxidative stability of oil extracted at various heating time

Storage stability

It is essential to any palm oil mill to extract CPO with excellent quality and stability. The oil stabilities during storage are vital parameter for ensuring that oil appears the good performance at elevated temperature. Table 2 shows the initial value of FFA, DOBI and carotene content for dry and wet heating process before storage at room temperature. For all heating time used, dry heating process gives higher value of FFA compared to wet heating process therefore higher deterioration. Thus, oil sample from wet heating process will produce better quality storage oil in terms of lower FFA content.

Table 2. Initial value of FFA, DOBI and carotene content in palm oil extract at different heating time

Heating Time (min)	Quality of Oil					
	FFA (%)		DOBI		Carotene Content (ppm)	
	Dry	Wet	Dry	Wet	Dry	Wet
30	2.49	2.36	3.17	3.79	754.13	746.09
45	2.64	2.24	2.40	3.64	762.09	779.65
60	2.17	1.95	3.03	3.65	762.80	880.60
90	2.03	1.44	3.23	3.49	717.87	710.20

Figure 5 shows the changes in quality of palm oil extracted at different heating time via wet heating. The quality of extracted oil was determined before and after 3 months storage at room temperature. After 3 months storage, 60 min of heating time recorded the lowest increment of FFA, 1.32 as well as lowest reduction of DOBI value, 0.41. This finding was due to higher initial carotene content that helps to decrease the rate of oxidation or prolong the induction period by interrupting the oxidation reaction. However, it suffers the highest loss of carotene content,

113.54 ppm towards the end of storage. Similar findings of carotene content loss have been reported by Noor Akhmazilla et al. [8].

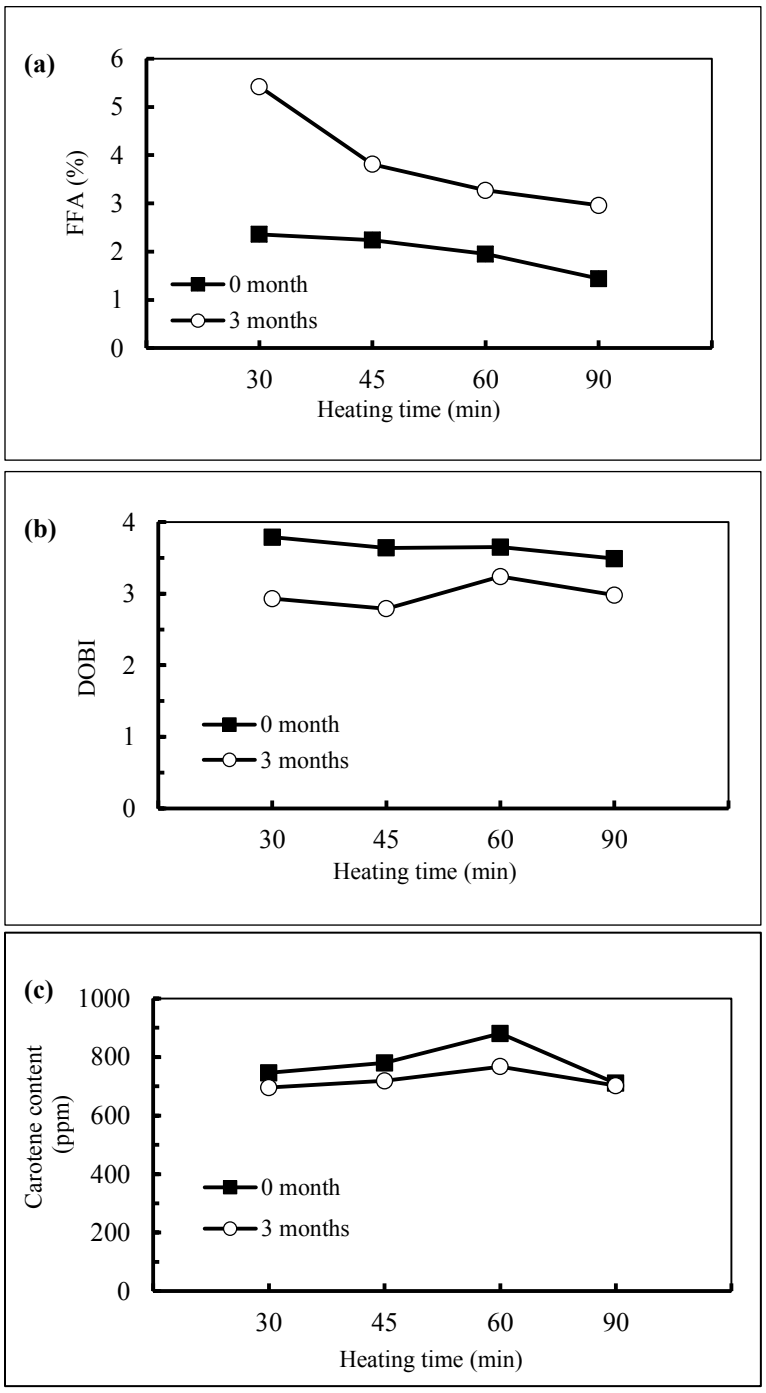

Figure 5. (a) FFA (b) DOBI and (c) Carotene content of extracted oil via wet heating before and after 3 months storage

Conclusion

Heat treatments during sterilization process are an important factor in determining oil yield and quality of extracted oil. This study showed that the temperature and time gave effect on the yield of extracted oil. Wet heating gives higher oil yield than dry heating process. However, dry heating and wet heating process had little effect on quality of extracted oil. This study has revealed that heating temperature at 90 °C and heating time at 60 min via wet heating extract higher oil yield, better CPO quality and good storage stability. The oil extraction yield can be further increased by optimizing other extraction technique. Other quality parameters could also be measured to support the efficiency of the heat treatment used during sterilization.

Abstract

Nanotechnology has been utilized in medicine for therapeutic drug delivery and the development of treatments for a variety of diseases and disorders. Mesoporous silica nanoparticles (MSN), which combine both unique properties of nanomaterials and mesostructured substances, have aroused special attention in biomedical research field due to its great advantages in many aspects such as well biocompatible, unique properties of tunable pore size and structure, large surface areas and pore volumes, controllable morphology and modifiable surfaces, high chemical and thermal stabilities. In this study, the microwave was utilized to synthesize MSN under 100 W, 300 W and 450 W heating powers. All MSNs was tested for adsorption and release of an anti-inflammatory and anti-cancer drug, ibuprofen. The characterization revealed that the MSN prepared under 450 W (MSN450) produced the most ordered and prominent mesoporous structure compared to lower power applied. MSN450 exhibited the highest ibuprofen adsorption, followed by MSN300 and MSN100, confirming that more ordered MSN demonstrated higher adsorptivity toward ibuprofen. For the release study, MSN450 showed the slowest release rate of ibuprofen, followed by MSN300 and MSN100. All MSNs was found to exhibit good activity for the ibuprofen adsorption and release.

Keywords: microwave, mesoporous silica, ibuprofen, adsorption, drug delivery

Abstrak

Teknologi nano telah digunakan dalam bidang perubatan untuk penyampaian ubat terapeutik dan pembangunan rawatan untuk pelbagai penyakit dan gangguan. Partikel nano silika mesoliang, yang menggabungkan kedua-dua ciri-ciri yang unik bahan nano dan bahan struktur meso, telah membangkitkan perhatian khusus dalam bidang penyelidikan bioperubatan kerana kelebihan yang besar dalam banyak aspek seperti bioserasi, ciri-ciri unik bolehubah saiz liang dan struktur, kawasan permukaan dan isipadu liang yang besar, morfologi bolehkawal dan permukaan boleh ubahsuai, serta tinggi kestabilan kimia dan haba. Dalam kajian ini, gelombang mikro telah digunakan untuk mensintesis partikel nano silika mesoliang (MSN) dibawah kuasa pemanasan 100 W, 300 W dan 450 W. Semua MSN telah diuji untuk penjerapan dan pembebasan ubat anti-radang dan anti-kanser, ibuprofen. Pencirian mendedahkan bahawa MSN yang disediakan di bawah 450 W (MSN_{450}) menghasilkan struktur paling tersusun dan terbaik dibandingkan dengan kuasa lebih rendah. MSN_{450} telah mencapai penjerapan ibuprofen tertinggi, diikuti dengan MSN_{300} dan MSN_{100}, mengesahkan bahawa MSN yang lebih tersusun menunjukkan penjerapan ibuprofen lebih tinggi. Untuk kajian

pembebasan, MSN_{450} menunjukkan kadar pembebasan ibuprofen paling rendah, diikuti dengan MSN_{300} dan MSN_{100}. Semua MSN ditemui mencapai keaktifan yang baik untuk penjerapan dan pembebasan ibuprofen.

Kata kunci: gelombang mikro, silica berliang meso, ibuprofen, penjerapan, penyampaian ubat

Introduction

In recent years, mesoporous silica nanoparticles (MSNs) have been well developed as effective drug storage vehicles in drug delivery systems due to their large pore volume (~1cm^3/g), high surface area (> 1000 m^2/g), ease of functionalization, low toxicity and biodegradability [1-3]. Exclusively in drug delivery, mesoporous silica is often used with modification to suit treatment needs. The study of the loading and release of drugs into/from mesoporous silica is in high demand for the development of tissue regeneration, transdermal therapy, and cell regulation due to the biocompatibility of this material.

The traditional synthesis method of mesoporous materials is the hydrothermal route, which uses a certain number of surfactants, as well as acid or alkali to compose a mixed aqueous preparation. Next, inorganic sources are added and heated to crystallize, followed by filtration, drying, and calcination or extraction to remove the template. Although finely ordered mesoporous materials are obtained, the process is time and energy consuming [4]. Heating solids in the conventional system leads to an uneven temperature distribution due to poor heat transfer into the bulk of the material. The outer temperature may be substantially higher than the inner one, because the material itself acts as an insulator. In these modern days where scientific findings and technology go hand in hand, any improvement to a synthesis technique that saves time in the synthesis of new materials or improves the properties of materials would be extremely beneficial. It is known that hydrothermal synthesis of inorganic materials using microwave (MW) heating promotes nucleation and can reduce the synthesis time and particle size significantly in comparison with the conventional convection heating method [5-6]. Besides, with faster polymerization under MW irradiation, it was also found that the swelling rate of the material was much higher compared to a material prepared by conventional heating.

In this study, we synthesized the MSN by co-condensation methods, and the physicochemical properties of the MSNs were characterized using X-ray powder diffractometer (XRD), Transmission Electron Microscopy (TEM), and Field Emission Scanning Electron Microscopy (FESEM). The performances of the three MSNs were then examined on the adsorption and release of ibuprofen, a non-steroidal anti-inflammatory drug widely used in the treatment of pain and inflammation in rheumatic disease and other musculoskeletal disorders. Millions of kilograms of ibuprofen are produced and consumed annually by humans; thus, the application of MSN to ibuprofen delivery is crucial and ever continuing research [7]. The influences of structure and morphologies of the MSNs towards the model drug delivery system were discussed in brief.

Materials and Methods

Cetyltrimethylammonium bromide (CTAB), ethylene glycol (EG), and tetraethyl orthosilicate (TEOS) were purchased from Merck Sdn Bhd, Malaysia. Ammonium hydroxide (NH_4OH) was obtained from QRec, Malaysia. The synthesis procedure was as follows. CTAB, EG, and NH_4OH were dissolved in 700 mL of water. After vigorous heating, TEOS were added to the mixture to give a white micelle solution. After stirring for 2 hours, the white solution was moved into a beaker and deposited in the microwave oven under heating power settings of 100, 300, and 450 W in 8, 4 and 1 hour, respectively. The variation of time was decided according to the complete evaporation of the solvent mixture for the purpose of shorten the drying time before preceded to calcination. The mixture was kept under continuous stirring and the sample was collected by centrifugation. The obtained gel was heated at 110 °C for 24 hours followed by calcination at 550 °C.

The crystallinity of catalysts was measured with a Bruker Advance D8 X-ray powder diffractometer with Cu Kα (λ = 1.5418 Á) radiation as the diffracted monochromatic beam at 40 kV and 40 mA. Transmission electron microscopy (TEM) was carried out using a JEOL JEM-2100F micro-scope. The samples were ultrasonically dispersed in acetone and deposited on an amorphous, porous carbon grid. The surface morphology and surface

elemental analysis of the samples were performed using FESEM-EDX (JEOL JSM-6701F) with an accelerating voltage of 15 kV. The samples were coated with platinum by electro-deposition under vacuum prior to analyses.

Powdered mesoporous samples were loaded with ibuprofen by soaking them into an ethanol solution of ibuprofen followed by continuous stirring for 24 hours at 310 K. Ibuprofen loaded samples were recovered by filtration, washed with ethanol and dried for 24 hours at 313 K. During the process, aliquots of 2 mL were withdrawn at pre-determined time intervals and centrifuged in a Hettich Zentrifugen Micro 120 before being analyzed by UV–Vis spectrophotometer (Agilent Technologies) to determine the residual concentration of ibuprofen. Each set of experiments was performed three times. The adsorption band of ibuprofen was taken at a maximum wavelength (λ_{max}) of 264 nm. The ibuprofen release profile was obtained by adding the drug-impregnated powders in a simulated body fluid (SBF) at 37 °C under continuous stirring. The drug concentration in the release fluid for the different release time was determined using UV/VIS spectrophotometer.

Results and Discussion

Figure 1 shows FESEM and TEM images of the MSNs at different microwave power levels, respectively. Comparing the three MSNs in Fig. 1 (a, b, c) FESEM analysis revealed spherical particles with smooth surface for the MSN prepared at microwave power of 450 W; however, irregular particles with a rough surface were formed at a microwave power of 100 W. Moreover, the TEM images in Fig 1 (d, e, f) shows clusters of hexagonally-ordered silica nanoparticles approximately 30–45 nm in size. The average particle sizes and ordering of the hexagonal silica were increased with increasing microwave power, since MSN_{450} exhibited more visible long-range silica arrangement. This may be due to the enhanced assembly of parallel CTAB chains upon increasing the microwave power, which resulted in an increased of silica hydrolysis; thus, a more ordered silica arrangement was formed compared to the MSN prepared at a low microwave power [8].

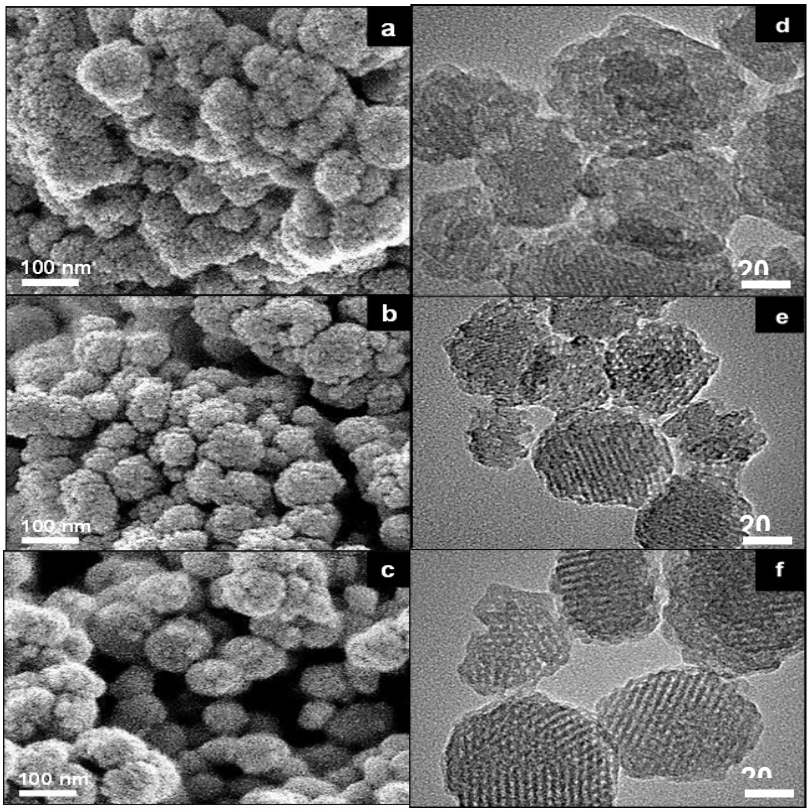

Figure 1. FESEM images of (a)MSN_{100}; (b)MSN_{300}; (c)MSN_{450}; and TEM image of (d)MSN_{100}; (e)MSN_{300}; (f)MSN_{450}

Hence, it can be stated that the crystal growth of MSN was greatly influenced by the microwave power, which resulted in different morphology and particle sizes. It is presumed that these properties will affect MSN behavior regarding ibuprofen adsorption [9]. Indeed, the microwave synthesis of MCM-41 has been reported earlier [10]. In the report, the MCM-41 was synthesized by the composition of synthesis materials of CTAB, TMAOH, TEOS and H_2O, while MSN was synthesized using CTAB, ethylene glycol, NH_4OH, TEOS and H_2O. Different particle size was obtained, which is 100 nm for the former, and 30–45 nm for the latter. This may be due to the difference in the composition led to the different crystal growth for both materials.

Figure 2 demonstrates the difference in the hexagonal density of all MSNs in the low *2θ* region. The pattern illustrates the reflection of a typical MCM-41 type material, which consists of an ordered hexagonal array of parallel silica tubes and can be indexed assuming a hexagonal unit cell as (100), (110), and (200) [11]. Since the materials were not crystalline at the atomic level, no reflections were observed at higher angles.

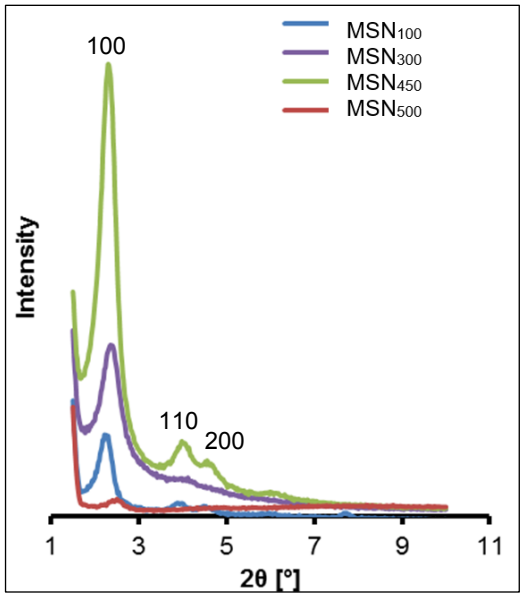

Figure 2. X-ray diffraction patterns of all MSNs

A substantial increment of the diffraction peak intensity corresponding to the (100) reflection was observed upon increasing the microwave power from 100 to 450 W, indicating the alteration of the long-range ordering of the mesoporous structure, while the MSN structure was unchanged. Although the appropriate synthesis time was given to all of the MSN for well crystal growth, the MSN prepared under 450 W exhibited higher crystallinity and silica order as compared to 300 W and 100 W. This may be related to the higher instantaneous microwave power delivery and consequently higher microwave electric field at 450 W during synthesis. While the microwave power was also further increased up to 500 W but disordered structure was obtained, this may be due to the fast drying (30 min) led to the incomplete condensation of TEOS and molecular assembly.

A similar observation was reported for the synthesis of iron-platinum nanoparticles using variable microwave power, in which the XRD data revealed an increase in the peak intensity upon increasing the microwave power from 120 to 420 W [12]. After increasing microwave power, the degree of hydration of the CTAB chains may also increase and their interaction with silica species in the solution becomes stronger, in combination with the increasing rate of hydrolysis and polymerization of the TEOS source that led to the formation of more ordered silica. This may also be related to the effect of synthesis temperature, wherein the temperature rapidly rose when the

microwaves coupled directly with the molecules of the entire reaction mixture, which led to the instantaneous localized superheating of the substance [13]. A less ordered structure of SBA-16 prepared at a lower temperature was reported due to the low degree of Pluronic F127 chain hydration, which resulted in weaker interactions with the silica species [14].

Based on the characterization results, the mechanism for the formation of MSNs using microwaves is proposed. The use of microwave power of 100 W seemed inadequate since it formed poorly crystalline, irregular mesoporous MSN structures with a small surface area. Since to the electromagnetic field generated by microwaves affects the enhancement of crystal growth, a low microwave power with a short irradiation time was probably insufficient to provide the homogeneous heating required for optimal crystal growth [15]. The irregularities in the structure were presumed to be a consequence of the formation of ''hot spots'' at certain locations in the microwave reactor.

A similar result was reported regarding the disruption of the ferrite structure due to ''hot spots'' or areas that induce a localized enhancement in the reaction rate [9]. On the contrary, the use of a microwave power of 450 W generated a more homogeneous and uniform silica order. Although the ''hot spots'' phenomenon also occurred at 450 W, it is presumed that the strong thermal supply directed the micelles to accumulate faster than at 100 W of microwave power. As a result, the MSN formed at 450 W displayed a more highly ordered structure (Figure 3). These differences in MSN characteristics were presumed to affect the adsorption and release pattern of ibuprofen.

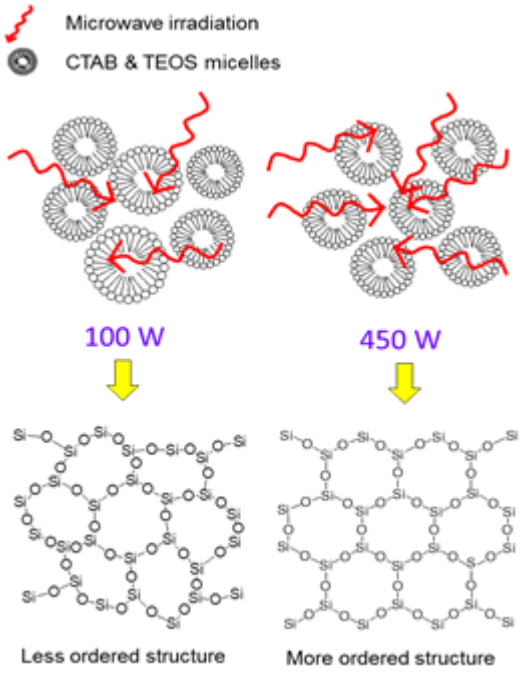

Figure 3. Formation of hexagonal order of MSN_{100} and MSN_{450}

Ibuprofen was used as a model drug to evaluate the adsorptivity and drug storage ability of the synthesized MSNs (Figure 4a). MSN_{450} displayed the highest adsorption rate at the first 6 hours and almost complete adsorption was achieved with 98.3% adsorption after 7 hours. The MSN_{300} and MSN_{100} demonstrated almost similar pattern of adsorption with 81.3% and 74.1%, respectively. Although the MSNs had almost the same chemical structure, ibuprofen adsorption increased with an increase in the microwave power used during MSN synthesis. This result implies that the differences in the material properties resulted in variable ibuprofen adsorption behavior.

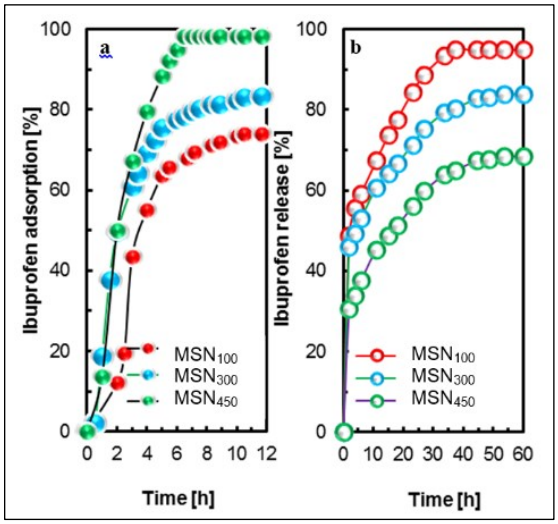

Figure 4. Adsorption (a) and release (b) of ibuprofen by all MSNs

Based on the characterization by TEM and FESEM, the variation in microwave power led to dissimilar patterns in the material's structure. In parallel with the crystallinity, increasing the microwave power also resulted in the enhancement of hexagonal order and the range of the silica. The complete adsorption of ibuprofen by MSN_{450} was probably caused by the higher surface area and fewer irregularities in the morphology that resulted in a more accessible surface as compared to MSN_{300} and MSN_{150}.

It is of great importance to comprehensively understand the drug delivery profiles using in vitro simulated body fluid (SBF) before creating a suitable controlled formulation of mesoporous silica materials for use in vivo. The concentration of ibuprofen released in SBF as a function of time was determined by monitoring changes in the absorbance by UV–Vis spectroscopy at a wavelength of 264 nm. The release rates are shown in Figure 4b. The ibuprofen released fastest from MSN_{100}, followed by MSN_{300} and MSN_{450}. MSN_{450} displayed the slowest release rate of ibuprofen with only 65% of the release percentage of MSN_{300} and MSN_{100} within the same contact time. The ibuprofen release of MSN_{300} and MSN_{100} were 81% and 95% release, respectively. MSN_{100}, with a less ordered silica arrangement, showed the highest release percentage and the fastest drug release rate before equilibrium was reached.

Since the pore surface chemistry of the mesoporous silica was quite similar, it is presumed that the difference in drug delivery behavior may be reasonably attributed to the pore structure of the MSN structure. In fact, a similar pore diameter and drug molecule size allows for sustained release owing to the size confinement effect; thus, the loaded drug can be released at a relatively high rate when the pore size of the MSN is much larger than the size of the drug molecule [16].

On the contrary, MSN-MW_{450}, which is presumed to have the largest and similar average pore distribution due to its most ordered structure did not exhibit the fastest release rate. This observation demonstrated the presence of diffusion process constraints during the release process, probably influenced by the pathway (the channel length of silica) of mesoporous silica, as discussed in the XRD characterization. The long ordered channels of MSN_{450} retained ibuprofen molecules, rendering the rapid release of drug molecules from the surface unfavorable. In a similar report, fast ibuprofen release was observed with MCM-41, which was characterized by a short channel length [17]. Hence, the length of the pathway is one of the most important factors when investigating drug delivery behavior, in addition to other factors such as the pore size, surface chemistry, and pore geometry of mesoporous silica.

The phenomenon of the adsorption and release of ibuprofen molecules is proposed according to the XRD, FESEM, and TEM results. Increasing the microwave power was found to form enhanced hexagonal order and range of silica, which led to a greater surface area, pore width and pore volume. The fewer irregularities in the morphology and a better silica arrangement were found to improve ibuprofen adsorption.

Conclusion

The enhancement of crystal growth was observed in the formation of mesoporous silica nanoparticles synthesized with variable microwave power in the range of 100 – 450 W. The use of low heating power (100 W) resulted in low crystallinity, an irregular mesoporous structure and a low surface area of MSN_{100}, which on the contrary, highest heating power produced more crystallized and better silica arrangement. In relation to the adsorption properties, MSN_{450} demonstrated the highest ibuprofen adsorption (98.3%), followed by MSN_{300} (81.3%) and MSN_{100} (74.1%), confirming that the difference in the material properties was a contributing factor in ibuprofen adsorption. By exhibiting the most crystallized structure, complete adsorption of ibuprofen by MSN_{450} was probably caused by fewer irregularities in its morphology that resulted in a more accessible surface compared to MSN_{300} and MSN_{150}. In accordance, MSN_{450} showed the slowest release rate of adsorption due to its wide pore diameter and long range of silica order.

Abstract

A study was conducted to prepare activated carbon from $ZnCl_2$-treated oil palm kernel shell using the sequential combination of carbon dioxide and steam (CO_2 + steam) as activated agent. The development of pores of activated carbon and methane adsorption on the prepared activated carbon were investigated. The results show that the sequential combination of CO_2 and steam was a good combination producing activated carbon with high total pore volume of 1.0 cm^3/g and BET surface area of 1548.0 m^2/g. The resultant activated carbon contained microporous and mesoporous structure with a nearly balance volume percentage. The highest methane uptake in this study was 145.89 V/V at 10 bar and ambient temperature.

Keywords: activated carbon, palm kernel shell, methane adsorption, porosity development

Abstrak

Satu kajian telah dijalankan bagi menyediakan karbon teraktif daripada isirong kelapa sawit yang dirawat bersama $ZnCl_2$ dengan menggunakan agen pengaktifan karbon dioksida dan stim secara berturutan. Dalam kajian ini, pembangunan liang pada karbon teraktif dan penjerapan gas metana telah dikaji. Hasil dari kajian ini menunjukkan bahawa kombinasi secara urutan bagi gas karbon dioksida dan stim merupakan kombinasi agen pengakifan yang baik dan menghasilkan karbon teraktif yang mempunyai jumlah isipadu liang yang tinggi iaitu 1.0 cm^3/g dan luas kawasan BET sebanyak 1548.0 m^2/g. Karbon teraktif yang terhasil juga mempunyai kandungan liang mikro dan liang meso yang hampir seimbang. Hasil kajian ini, penjerapan gas metana yang tertinggi adalah 145.89 V/V pada 10 bar dan suhu ambien.

Introduction

A sustainable energy supply and environmental protection are the challenges faced by the world presently. Conserving the sustainable energy is vital in order to ensure the security and the consistency of supply and the diversification of the various energy resources. The search for alternative fuel for vehicles has been actively pursued nowadays due to the issue of sustainability, energy and oil market crisis, and the increased awareness of environmental protection

Methane gas is a promising alternative fuel. It is a clean gas and can be found through various resources such as lake, swamp, landfill and also from fossil fuel. However because of its very low energy density, storing large amounts of methane in a limited volume is very challenging for its application like gas-powered vehicles. A new revolution of natural gas storage technology has been developed through adsorption in porous materials

(activated carbon) which known as adsorbed natural gas (ANG). By using this technique, methane gas can be stored in the same amount as conventional tank but at a lower pressure. The activated carbon provides "extra room" for storing methane gas. The force exerted by the carbon atom inside the pores attract a lot of methane gas molecules into the pores, thus the amount of the bulk of gas will reduce. As a result, the pressure of tank can be kept as low as possible while maintaining high density of methane in the pores.

Extensive studies have been performed to enhance the ability of adsorbing methane gas through activated carbon produced from low cost agriculture waste precursors [1-3]. Production of the most suitable activated carbon for the gas adsorption application usually requires consideration of various factors such as chemical agent, impregnation ratio, activation temperature, and activation time [4]. One of the crucial factor contributing to the pore development of activated carbon is activation agents [5]. Different agents may influence differently in the properties, the activation rate and the yield of carbon material.

There are two main steps in producing activated carbon: i) the carbonisation of raw precursors in the absence of oxidising gas and ii) the activation of carbonisation product (char) using activation agent (physical, chemical or combination of both). Physical activation is widely used and can be applied to all raw materials. Generally, the precursors will undergo carbonisation process in the presence of inert gas at 500 – 800 °C followed by the activation by oxidising gas such as steam, CO_2 or their mixture at 800 – 1100 °C. During carbonisation, the precursors undergo three main stages: i) the elimination of water, ii) the primary pyrolysis (i.e. thermal decomposition of carbonaceous materials to form basic char structure, light gases and tar) and iii) the consolidation of char structure [6]. In the activation step, some carbons are eliminated by the activation agent to form gases via reactions (1) or (2), thus develop the porosity in the carbonised materials

CO_2 activation

$$C + CO_2 = 2CO \quad (1)$$

Steam activation

$$C + H_2O = CO + H_2 \quad (2)$$

Although large amount of researches have been conducted with steam, CO_2 or their simultaneous combination (i.e. mixture) as activating agent for different types of carbonaceous material [5, 7, 8], very few of the previous works has addressed the effect of CO_2-steam activation sequences on the pore development for methane adsorption application. This study is therefore aimed in investigating the methane adsorption performance from palm kernel shell derived activated carbon using the sequential combination (as opposed to the usual simultaneous combination) of CO_2 + steam activation. Our findings provide additional insight into developing an efficient activation procedure for producing high quality activated carbon for methane adsorption.

Materials and Methods

Raw material preparation

Oil palm kernel shells (PKS) were used as activated carbon precursors in this study. PKS were obtained from Sime Darby Research and Development Centre (R&D) in Carey Island, Malaysia. PKS samples were washed with distilled water to remove dust and impurities. The washed PKS were sundried for 48 hours and further dried in an oven at 110 °C overnight to remove moisture and to preserve from biological degradation. The dried PKS were crushed and sieved to obtain particles sizes in the range of 0.5 to 1.0 mm.

Preparation of activated carbon

Dried PKS with the mass of 110 (±0.1) g were mixed into 220 mL solution (98% purity from Acros Organics) of 55% (w/w) zinc chloride. The mixture was stirred by a magnetic stirrer in a beaker at 80 °C for 3 hours. The mixture was then dried in an oven at 110 °C until the PKS achieved complete dryness. Figure 1 shows the experimental setup for carbonisation and activation processes. The setup consists of a double layer stainless steel reactor. The treated-PKS was carbonised under nitrogen flow of 192 cm^3/min until the temperature reached 900 ^oC. N_2 gas was then switched to CO_2 and followed by steam sequentially for 2 hours. The activated carbon obtained was washed under stirring with 0.1M of hydrochloric acid for one hour and further washed with hot distilled water six times (30 minutes each) to remove the remaining chemicals.

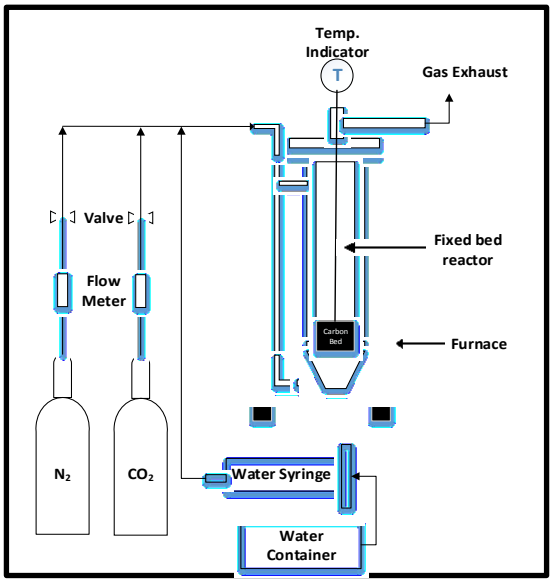

Figure 1. Schematic diagram of the preparation of activated carbon

Methane adsorption by volumetric method

An amount 20 (±0.1) g of activated carbon sample was weighed and placed into high pressure stainless steel adsorbent cell and degassed for several hours to remove any impurity at room temperature. Schematic diagram of experimental set-up is shown in Figure 2. Two pressure transmitters model TPS20-G27F8-00 (range 0 – 20 kg/cm^3 with accuracy ± 0.001) manufactured by Murr Electronic were used to measure the pressure. The temperature condition of the experiment was within the range of 300 (±0.1)K up to 303 (±0.1)K. Methane gas was injected using needle valve up to 10(± 0.001) bar continuously. The number of mol of methane uptake was determined from the mass balance by the application of ideal gas equation of states (3).

$$n_{ads} = \frac{1}{M_w}\left[\left(\frac{P_{r1}}{Z_{r1}} - \frac{P_{r2}}{Z_{r2}}\right)\frac{V_{gl}}{RT} - \left(\frac{P_{ad2}}{Z_{ad2}} - \frac{P_{ad1}}{Z_{ad1}}\right)\frac{V_{ad}}{RT}\right] \quad (3)$$

where M_w is molecular weight of methane gas, V_r is volume of reference cell and V_{ad} is volume of adsorption cell.

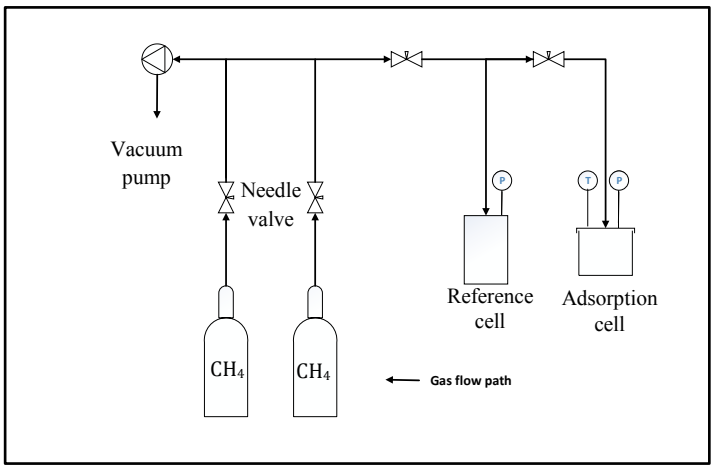

Figure 2. Schematic diagram of methane adsorption unit

Results and Discussion

Proximate and ultimate analysis

Based on the proximate and ultimate analyses the volatile matter of the PKS is 62% and the carbon content of 48%. Sufficient amount of volatile content is important, since the evolution of volatiles during carbonisation and activation processes results in making more porous structures in activated carbon [9]. The high carbon content contributes to structural strength of activated carbon [10]. After activation process (using steam + CO_2 agents), the volatile content of PKS (activated carbon) decreased drastically from 62.15% to 13.8% whilst the fixed carbon increased from 34.85 % to 69.59%. This is because at high degree of activation the volatile were removed through thermal decomposition aided by activation agent (CO_2 + Steam) leaving the residual elementary carbon atom (fixed carbon). Thus, it can be seen in Table 1 that the percentage of carbon (C) was also increased which subsequently caused in decrease to the other elements.

Table 1. Proximate and ultimate analysis of raw PKS and activated carbon PKS

Sample	Proximate Analysis (wt. %)				Ultimate analysis (wt. %)			
	Moisture	Volatile Matter	Fixed carbon	Ash	C	H	N	O
Raw PKS	1.60	62.15	34.85	1.4	47.9	7.2	1.0	43.9

Characteristics of prepared activated carbon

The activated carbon was characterised by N_2 adsorption/ desorption, BET surface and pore size distribution analyses. Figure 3 shows the adsorption/desorption isotherm of nitrogen at 77K. It can be ascertained from the graph that the isotherm of activated carbon belongs to the Type IV of IUPAC classification [11] representing adsorption isotherm with hysteresis. The Type IV shape follows the same path as Type II at lower relative pressure. The sharp "knee" suggests that a considerable amount of micropores are present, and the slop of the plateau at high relative pressure is due to multilayer adsorption on non-microporous, i.e. mesoporous [12]. This indicates that the porous structures of the activated carbon are mainly microporous and mesoporous. According to Kundu et al. [13], intensive activation would increase the elimination of low molecular weight volatiles that causes development in pore. The use of CO_2 changes the structure (especially the outer one) of char, leaving more active site to be used for steam to generate microporous structure at a faster rate. In addition, at high temperature (900°C) the microporous structure was collapsed to result in the formation of mesoporous activated carbon.

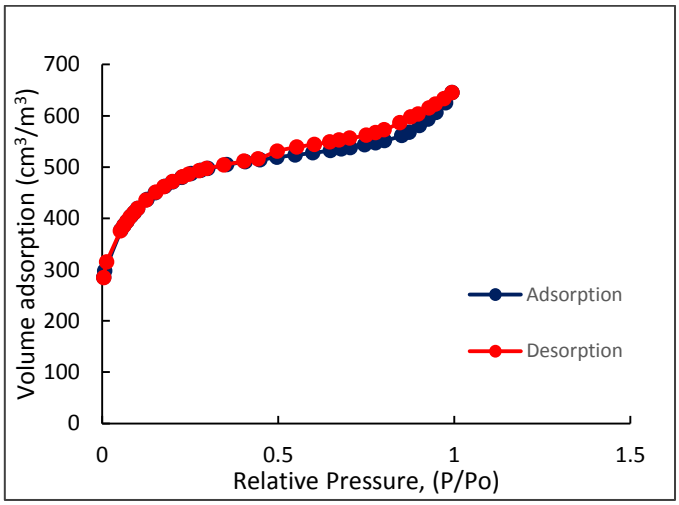

Figure 3. N_2 adsorption on activated carbons produced at the optimum conditions

From the nitrogen adsorption isotherm analysis, the BET surface area and total pore volume of the activated carbon were 1551 m^2/g and 1.00 cm^3/g, respectively. According to Rodriguez-Reinoso et al., steam activation aids enhancement and continuously develops microporosity which would produce more selective attack on the carbon structure, while CO_2 activation tends to enhance the size of micropores to produce more mesoporous and macroporous volume. Therefore, the combination using CO_2 as the first agent and steam as the second agent is a good combination to improve the porosity since CO_2 enlarges the existing pores allowing steam to penetrate deep into or inside porous structure and creates more new pores in the carbon, resulting in a higher surface area and pore volume. Furthermore, with $ZnCl_2$ impregnation, the removal of the volatiles through the pore passage was not hindered since $ZnCl_2$ acts as a dehydrating agent during activation that inhibit tar formation and other liquid clogging, thus increasing number of porosity [14].

Figure 4 illustrates the distribution of pore development by DFT analysis of nitrogen isotherm. Based on the graph, the observed peaks are in the range of 1 to 3 nm, indicating that majority of pores are located within microporous and initial mesoporous range, thus it can be concluded that the result obtained is consistent with the N_2 isotherm trend discussed above. The proportion of micropores (58%) and mesopores (42%) of the activated carbon in this study are nearly balance. It can be inferred that, at low degree of activation, the microporous structure was initially developed and it was progressively widens with increase in degree of activation.

Methane adsorption

The activated carbon prepared using combination of CO_2 + steam underwent further analysis of methane adsorption. The activated carbons prepared from single activation of steam and CO_2 were also prepared at the same conditions for comparative study. Figure 5 shows the methane uptake (mol/kg) of all the three activated carbons. The methane gas were charged continuously until the pressure reached 10 bar and measured at 293.15K. It can be seen clearly, methane uptake increases linearly with the pressure. The results agree well with a previous study by Arami-Niya et al. [15]. High amount of methane adsorption is expected when the adsorption has large surface area and high total pore volume. In this study, it is suggested that the porosity of activated carbon prepared using combination of CO_2 + steam is well developed compared to other set of conditions. It is clearly shown in Table 2, the BET surface area and total pore volume are double the amount of other activated carbons. However higher percentage of microporous structure can be observed when using single activation agent.

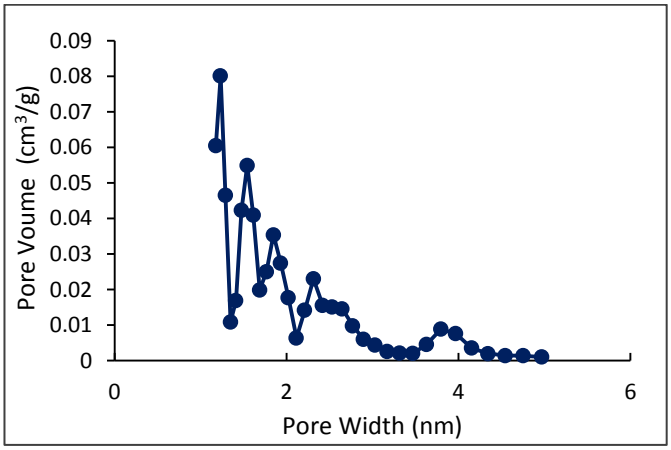

Figure 4. DFT pore size distribution of activated carbon at optimum conditions

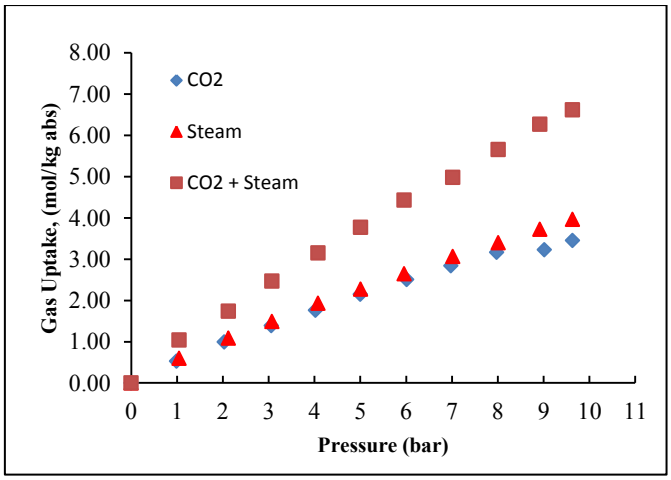

Figure 5. Methane uptake of activated carbons prepared at different conditions.

Table 2. Characteristics of porosity of activated carbons

Sample	SBET (m^2/g)	V_{total} (cm^3/g)	$V_{Microporous}$ (cm^3/g)	Microporous (%)	$V_{Mesoporous}$ (cm^3/g)	Mesoporous (%)
CO_2 + Steam	1548.0	1.000	0.580	58.00	0.420	42.00
Steam	798.2	0.459	0.449	97.99	0.009	2.01
CO_2	787.0	0.435	0.359	82.46	0.076	17.54

It is widely known that steam is more reactive than CO_2. According to thermochemical dissociation of water and carbon dioxide, the hydrogen-oxygen bond of water molecule is relatively easier to break compared to the carbon-oxygen bond, explaining the higher reactivity of steam than CO_2 [11,16]. Nevertheless, with suitable total pore size distribution, the pore wall of the activated carbon provides relatively strong attractive forces to the surrounding gas molecules. The energy of gas molecules slowly lowered as it passes through narrow space. As a result, gas molecules are packed densely within pore networks of the carbon [17]. Since the diameter size of methane gas is about 0.4nm [18], thus to obtain the highest gas adsorption, the pore size of activated carbon must be bigger than the size of two molecules of methane (0.8nm) [19]. Less methane adsorption capacity is expected when activated carbon has low surface area, low volume and has very large pore size diameter.

Thus, in this study, the average pore size diameter, total pore volume and surface area can be regarded as suitable dimension for methane gas adsorption. Therefore, high capacity of methane gas is favourably adsorbed into activated carbon. Similar results were reported by Daud et al. [20], and Azevedo et al. [21], on the porosity development.

Simultaneously, the methane uptake was analysed in term of volume basis. The volume of activated carbon is determined by compressing a known amount of activated carbon at 200 bar. The highest methane uptake of the three activated carbons are shown in Figure 6. The methane storage was measured at 293.15K and 10 bar. As can be seen in the Figure 5, the activated carbon prepared using combination of CO_2 + steam activation agent recorded the highest storage of 145.89 V/V compared to other mode of activation. According US Department of Energy, the practical storage capacity for gas-powered vehicles is 180 V/V at 35 bar [21]. Thus it can be concluded that, the methane uptake of activated carbon prepared under sequential combination of CO_2 + steam activation agent nearly achieved the desired storage capacity for vehicle application.

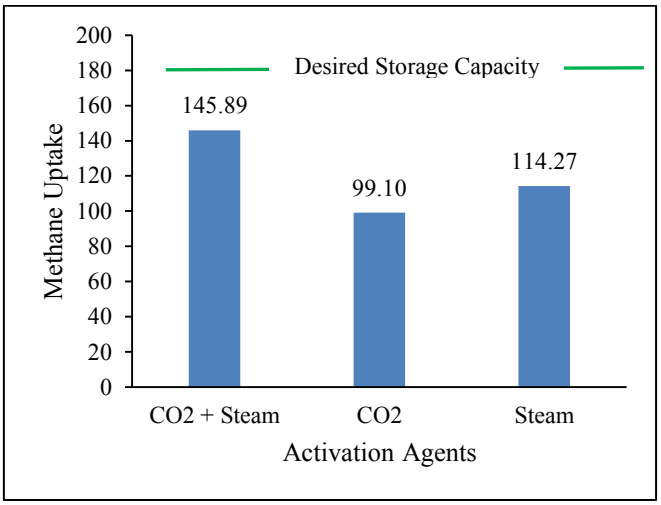

Figure 6. Methane Uptake in volumetric based

Conclusion

Palm kernel shell is regarded as suitable precursors for production of activated carbon. The activation with $ZnCl_2$ under combination in sequence of CO_2 and followed by physical activation proved to be an efficient method in production of activated carbon for methane adsorption. This preparation method leads to high BET surface area (1548.00 m^2/g) and high pore volume (1.00 cm^3/g) with proper dimension of pore size distribution (1 – 3 nm). The sequential combination of CO_2 and steam is a good combination since CO_2 tends to open the outer structure of activated carbon allowing steam with higher rate of reaction strike deep inside activated carbon to develop more pore volume. Methane adsorption capacities of various activated carbons prepared at combination of activation agent and single activation agent were determined at 293.15K and 10 bar on mass basis as well as on the volume basis. Among the three different activated carbons, the higher methane uptake on the mass and volume basis was found in activated carbon prepared under combination of activation agent owing to its high surface area, and large total pore volume.

Abstract

Membrane separation technology is gaining importance nowadays in reducing the emission of carbon dioxide (CO_2) as greenhouse gas due to the global climate change. Gas permeation studies play significant role in reflecting the potential of the membranes in separating the gas mixtures. In this study, Ba-SAPO-34 zeolite membrane was formed by membrane synthesis process using microwave (MW) heating and followed by membrane ion-exchange process with Ba^{2+} cation. The Ba-SAPO-34 zeolite membrane was investigated for its performance in the CO_2 and N_2 gases permeation studies. The effects of permeation temperature (30 – 180 ^oC) and pressure difference (100 – 500 kPa) across the membrane on the gas permeation performance of the Ba-SAPO-34 membrane were studied. CO_2 single permeance of ~9.4-19.5 x 10^{-8} mol/m^2.s.Pa and N_2 single permeance of ~0.635-0.694 x 10^{-8} mol/m^2.s.Pa were obtained for gases permeation through Ba-SAPO-34 membrane performed under the range of permeation temperature and pressure difference across the membrane studied. Maximum CO_2/N_2 ideal selectivity of 29.6 was obtained for gases permeation through Ba-SAPO-34 membrane at 30 ^oC and 100 kPa pressure difference.

Keywords: Ba-SAPO-34, membrane, gas permeation

Abstrak

Teknologi membran pemisahan adalah semakin penting pada masa kini dalam mengurangkan pelepasan karbon dioksida (CO_2) sebagai gas rumah hijau disebabkan oleh perubahan iklim sejagat. Kajian resapan gas memainkan peranan yang penting dalam mencerminkan potensi membran dalam pemisahan campuran gas. Dalam kajian ini, membrane zeolit Ba-SAPO-34 telah dibentuk melalui proses sintesis membran dengan menggunakan pemanasan gelombang mikro dan diikuti oleh proses pertukaran ion membran dengan kation Ba^{2+}. Membran zeolit Ba-SAPO-34 tersebut telah dikaji untuk prestasinya dalam kajian resapan gas CO_2 dan N_2. Kesan suhu resapan (30 – 180 ^oC) dan perbezaan tekanan (100 – 500 kPa) merentasi membrane terhadap prestasi resapan gas membrane Ba-SAPO-34 telah dikaji. Ketelapan tunggal CO_2 sebanyak ~9.4-19.5 x 10^{-8} mol/m^2.s.Pa dan ketelapan tunggal N_2 sebanyak ~0.635-0.694 x 10^{-8} mol/m^2.s.Pa telah diperolehi bagi resapan gas melalui membran Ba-SAPO-34 di bawah julat suhu resapan dan perbezaan tekanan merentasi membran yang dikaji. Kememilihan CO_2/N_2 sebanyak 29.6 (maksimum) telah diperolehi bagi resapan gas melalui membran Ba-SAPO-34 pada 30 ^oC dan perbezaaan suhu sebanyak 100 kPa.

Kata kunci: Ba-SAPO-34, membran, resapan gas

Introduction

Reduction in emissions of greenhouse gases is becoming one of the major environmental issues due to the increase in global temperature, which is likely to bring several drawbacks such as disturbance in ecosystems and rise in sea

levels. The increasing concentration of greenhouse gas, in particular carbon dioxide (CO_2), in the atmosphere in recent years has drawn attention of many researchers around the globe. The CO_2 separation from nitrogen (N_2) is among the worldwide concern nowadays in restricting the emission of CO_2 from large emission sources, i.e. flue gas from power plants. In the industrial post-combustion capture for fossil fuel combustion process, CO_2/N_2 separation remains an engineering challenge in removing the CO_2 from the flue gas emitted. In view of this issue, there are increasing number of articles published by the researchers with the aim to explore potential processes for separation and recovery of CO_2 from different sources [1-5]. Conventional technologies used for CO_2 separation from gas mixtures includes absorption using amine based solvents and pressure swing adsorption [6, 7]. However, the drawbacks of these conventional technologies are complexity of the system, high energy consumption for solvent regeneration, equipment corrosion and flow problems caused by viscosity of solvent [8, 9].

Membrane processes appear to be a promising alternative for gas permeation and separation. Polymer membranes, which have been widely investigated for gas permeation and separation, offer advantages such as low cost and ease of preparation. However, the disadvantages of polymer membranes, such as possible occurrence of plasticization due to high CO_2 partial pressure, poor chemical, thermal and mechanical strength, limit their performance in the application [10–12]. Zeolite membranes are gaining increasing interest for gas permeation and separation, in view of their uniform pore structure, high chemical, thermal and mechanical stability [13,14].

There have been extensive studies on different zeolite membranes for gas permeation and separation [12,15 – 19]. Silicoaluminophosphate, SAPO-34 membrane has been studied extensively for gas permeation and separation due to its small pore structure [6,17, 20,21]. Conventionally, the SAPO-34 membranes were prepared by hydrothermal synthesis method. Microwave (MW) heating emerged as a potential technology offering number of advantages against conventional hydrothermal heating such as shorter synthesis time, rapid heating rate and production of small zeolite crystals with narrow size distribution [22–24]. To our best knowledge, our group has been the first to report synthesis of SAPO-34 zeolite membrane using MW heating [25].

In the present study, Ba-SAPO-34 membrane was prepared using MW heating followed by ion-exchange process. In our previous work reported [26], the CO_2/CH_4 gas separation of Ba-SAPO-34 membrane was investigated. In the present study, the Ba-SAPO-34 membrane was tested for single gas permeation of CO_2 and N_2. The effects of permeation temperature and pressure difference across the membrane on the CO_2 and N_2 single gas permeation performance of the Ba-SAPO-34 membrane were studied.

Materials and Methods

Ba-SAPO-34 membrane preparation

α-alumina disc with thickness of 3 mm and diameter of 25 mm was used as the support where the membrane was deposited on. The Ba-SAPO-34 membrane was prepared according to the procedures described in our previous work [26].

Gas permeation studies

Figure 1 show the setup diagram of the gas permeation studies. The disc-shaped Ba-SAPO-34 membrane was placed in a stainless steel module and the module was sealed using silicone gaskets in order to avoid any gas leakage from the module during gas permeation studies. Total feed flow of 60 ml/min was applied for single gas permeation of CO_2 and N_2 through Ba-SAPO-34 membrane. Pure CO_2 or N_2 gas was fed to the membrane using a mass flow controller. By closing the end of the retentate side of the membrane module, the feed pressure was controlled while the permeate pressure was kept at atmospheric pressure in order to vary the pressure difference between 100 and 500 kPa across the membrane. The temperature of the gas permeation was controlled between 30 and 180 ^oC by using an oven where the stainless steel module was placed.

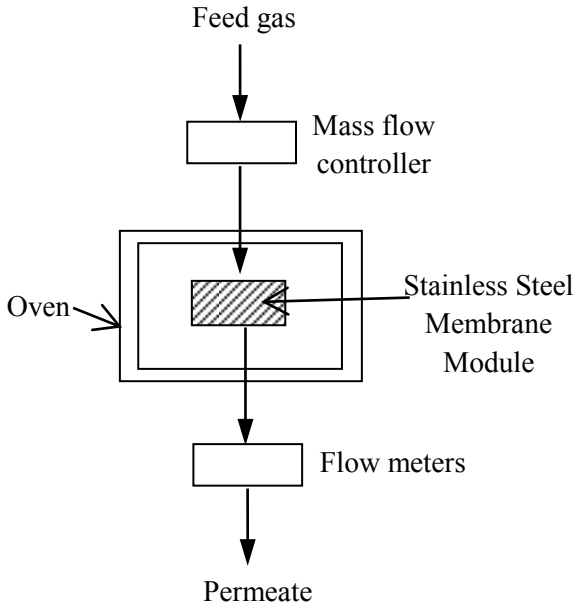

Figure 1. Setup diagram of the gas permeation studies

Flux, J_i (mol/m^2.s) of component gas *i* was calculated as shown in Equation (1).

$$J_i = \frac{n_i}{A \cdot t} \tag{1}$$

where $\frac{n_i}{t}$ is the molar flow rate of component *i* (mol/s), A is the effective permeation area of the membrane (m^2), the component *i* may refer to CO_2 or N_2.

Permeance, P_i (mol/m^2.s.Pa) of component gas *i* was calculated as shown in Equation (2).

$$P_i = \frac{J_i}{\Delta p_i} \tag{2}$$

where Δp_i is the pressure difference of component *i* across the membrane (Pa).

The ideal selectivity of the membranes, $\alpha_{CO_2/N_2}^{ideal}$ was calculated from the ratio of single gas permeance as shown in Equation (3).

$$\alpha_{CO_2/N_2}^{ideal} = \frac{P_{CO_2}}{P_{N_2}} \tag{3}$$

Results and Discussion

Gas permeation studies

Figure 2 presents the effect of pressure difference on the single gas fluxes through Ba-SAPO-34 membrane. The single gas flux of CO_2 and N_2 increased linearly with increase in pressure difference across the membrane. In the range of temperature (30 – 180 ^oC) and pressure difference (100 – 500 kPa) studied in current study, CO_2 displayed higher single gas fluxes even though CO_2 possess higher molecular weight than N_2. The gas flux is the sum of micropore diffusion and surface diffusion [27]. It was relatively easier for CO_2 diffusion through the micropore

framework of Ba-SAPO-34 due to smaller kinetic diameter of CO_2 compared to N_2. In addition, Li et al. [28] reported that the strength of adsorption of CO_2 gas molecules on SAPO-34 framework was higher than those of N_2 gas molecules. Owing to larger quadruple moment of CO_2, CO_2 was more strongly adsorbed on Ba-SAPO-34 pore framework and followed by stronger surface diffusion through the pore framework compared to N_2. The combination effect of micropore diffusion and surface diffusion explains the higher CO_2 single gas flux compared to N_2 in the present study.

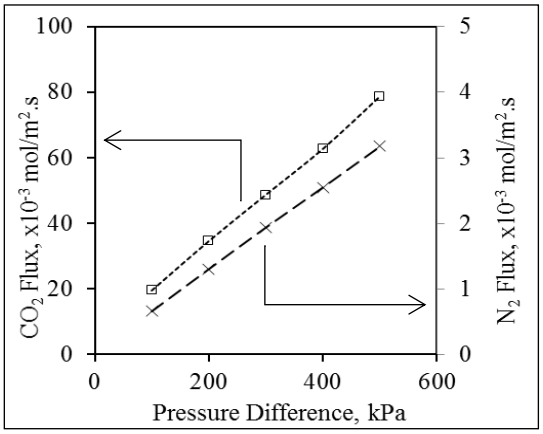

Figure 2. Single gas fluxes of CO_2 and N_2 through Ba-SAPO-34 membrane as a function of pressure difference at 30 ^oC.

Figure 3 shows the effect of pressure difference on the single gas permeances through Ba-SAPO-34 membrane at 30 ^oC. Gas permeance was calculated by dividing the gas flow with pressure difference of that respective gas. The CO_2 single gas permeance decreased from ~19.5 to ~15.7×10^{-8} mol/m^2.s.Pa and the N_2 single gas permeance decreased from ~0.659 to ~0.635×10^{-8} mol/m^2.s.Pa when the pressure difference increased from 100 to 500 kPa at 30 ^oC. The drop in CO_2 gas permeance was a result of adsorption-controlled permeation mechanism reported by Bernal et al. [29]. Owing to high adsorption strength of CO_2 on Ba-SAPO-34 pore framework, feeding pure CO_2 to the membrane at temperature as low as 30 ^oC brought the surface coverage of CO_2 on the retentate side of the membrane close to saturated level. Further increase in the CO_2 pressure difference increased the CO_2 single gas flux, but the increase was not adequate to compensate for the higher increase of pressure difference, which resulted in decrease in CO_2 single gas permeance (flux per pressure difference).

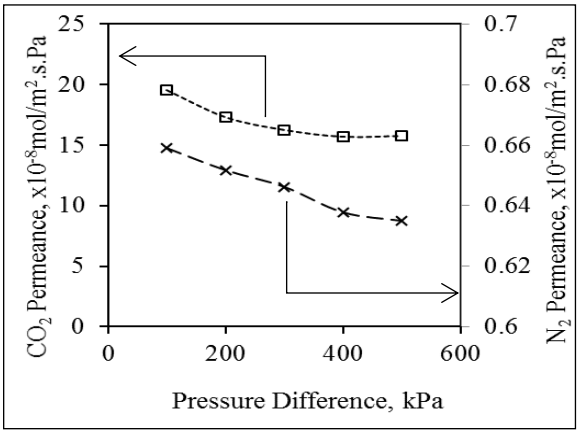

Figure 3. Single gas permeances of CO_2 and N_2 through Ba-SAPO-34 membrane as a function of pressure difference at 30 ^oC

Figures 4 and 5 shows the effect of temperature on the single gas fluxes and single gas permeances, respectively through Ba-SAPO-34 membrane at 100 kPa pressure difference. Generally, surface diffusion decreases but micropore diffusion increases with increase in temperature. In present study, the CO_2 single gas flux and permeance dropped with increase in permeation temperature from 30 to 180 ^oC due to reduction of surface coverage of CO_2 on the Ba-SAPO-34 pore framework with increase in temperature [6]. N_2 exhibited trend of rise in single gas flux and permeance with increase in temperature. This indicated that the micropore diffusion dominated the diffusion of N_2 through Ba-SAPO-34 pore framework instead of surface diffusion.

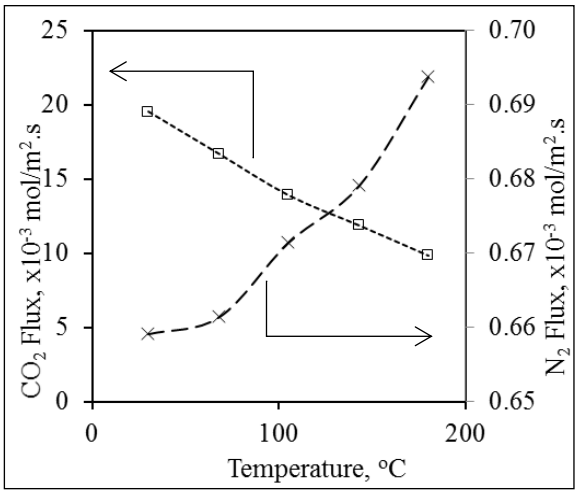

Figure 4. Single gas fluxes of CO_2 and N_2 through Ba-SAPO-34 membrane as a function of temperature at 100 kPa pressure difference across the membrane

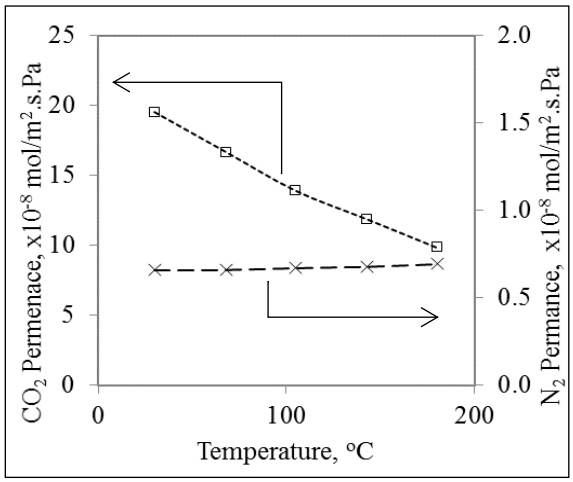

Figure 5. Single gas permeances of CO_2 and N_2 through Ba-SAPO-34 membrane as a function of temperature at 100 kPa pressure difference across the membrane

Figure 6 presents the effect of pressure difference on the CO_2/N_2 ideal selectivities through Ba-SAPO-34 membrane at different temperatures. The CO_2/N_2 ideal selectivity decreased from ~29.6 to ~24.8 with increase in pressure difference from 100 to 500 kPa at 30 ^oC. This phenomenon was due to higher extent of drop in CO_2 single gas

permeance compared to N_2 single gas permeance when the pressure difference was increased from 100 to 500 kPa as shown in Figure 3.

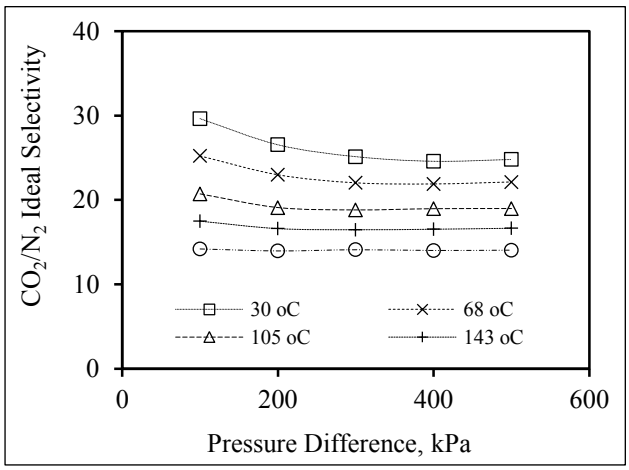

Figure 6. Ideal selectivities of CO_2/N_2 through Ba-SAPO-34 membrane as a function of pressure difference for different temperatures

As shown in Figure 6, it was found that the extent of drop in CO_2/N_2 ideal selectivities at higher temperature of 68 ^oC was lesser than the decline at 30 ^oC. As temperature was further increased to 180 ^oC, there was nearly no change in all the ideal selectivities with increase in pressure difference. This was due to the lower surface coverage of CO_2 on the membrane at higher temperature [28], which led to lower decrease in CO_2 permeances with increase in pressure difference at higher temperature. Therefore, increase in temperature from 30 to 180 ^oC resulted in the gradually dropped CO_2 adsorption strength on the membrane, and hence led to the reduced extent of change in the ideal selectivities with the change of pressure difference from 100 to 500 kPa in present study. Overally, maximum CO_2/N_2 ideal selectivity of 29.6 was obtained for gases permeation through Ba-SAPO-34 membrane at 30 ^oC and 100 kPa pressure difference.

Conclusion

Ba-SAPO-34 zeolite membrane was successfully formed by membrane synthesis process using microwave (MW) heating and followed by membrane ion-exchange process with Ba^{2+} cation. The Ba-SAPO-34 zeolite membrane was investigated for its gas permeations of CO_2 and N_2 under varying permeation temperature (30 – 180 ^oC) and pressure difference (100 – 500 kPa) across the membrane. In all of the range of permeation temperature and pressure difference studied in current study, CO_2 displayed higher single gas fluxes than N_2 due to (1) smaller kinetic diameter of CO_2 compared to N_2 and (2) stronger adsorption of CO_2 on Ba-SAPO-34 pore framework and subsequently followed by surface diffusion through the pore framework compared to N_2. Both CO_2 and N_2 single gas fluxes were found to increase with increase of pressure difference from 100 to 500 kPa. The N_2 single flux increased but the CO_2 single flux decreased with increase in permeation temperature from 30 to 180 ^oC, indicating that micropore diffusion dominated N_2 diffusion but surface diffusion dominated CO_2 diffusion through the Ba-SAPO-34 membrane in present study. CO_2 single permeance of ~9.4-19.5 x 10^{-8} mol/m^2.s.Pa and N_2 single permeance of ~0.635-0.694 x 10^{-8} mol/m^2.s.Pa were obtained for gases permeation through Ba-SAPO-34 membrane performed under the range of permeation temperature and pressure difference across the membrane studied. Maximum CO_2/N_2 ideal selectivity of 29.6 was obtained for gases permeation through Ba-SAPO-34 membrane at 30 ^oC and 100 kPa pressure difference.

Abstract

In this study, titanium dioxide nanotubes (TNT) were synthesis according to different concentration of sodium hydroxide (NaOH). The main purpose of this study was to investigate the effect of the high concentration NaOH towards formation of TiO_2 nanotubes structure. TNT was synthesized via hydrothermal method that was performed in a Teflon line stainless steel autoclave by using different concentration of NaOH (6 M to 12 M). The hydrothermal time and temperature is placed constantly for 24 hours and 110 ^oC respectively. The characterization of TNT was performed by Field Emission Transmission Electron Microscopy (FESEM), X-ray Diffraction (XRD), Fourier Transform Infrared Spectroscopy (FTIR) and Energy Dispersive X-ray (EDX) analysis for better understanding of its nanotubes structure and the chemical bonding present. Based on characterization analysis, the formation of nanotubes was in systematic arrangement and makes it easier for loading of noble catalyst. Furthermore, the replacement of sodium content by hydrogen ion, H^+ also seem to be increasing after the acid washing treatment. The investigation result proven that the best concentration of NaOH for TiO_2 nanotubes formation was 10 M (TNT-10).

Keywords: TiO_2 nanotubes, hydrothermal reaction, concentration of sodium hydroxide

Abstrak

Melalui kajian ini, nanotiub titanium dioksida disintesiskan mengikut kepekatan sodium hidrosida (NaOH) yang berbeza. Tujuan utama kajian ini adalah untuk mengkaji kesan kepekatan NaOH yang tinggi terhadap pembentukan struktur nanotiub. Nanotiub titanium dioksida (TNT) dihasilkan dengan menggunakan kaedah hidrotermal menggunakan turus teflon autoklaf keluli anti karat dengan mempelbagaikan kepekatan NaOH (6 M hingga 12 M). Tempoh dan suhu proses hidrotermal masing-masing dibiarkan sekata selama 24 jam dan 110 ^oC. Pencirian TNT dijalankan dengan menggunakan Mikroskopi Elektron Pengimbasan Pancaran Medan (FESEM), Pembelauan Sinar X (XRD), Spektroskopi Inframerah Transformasi Fourier (FTIR) dan Tenaga Serakan Sinar X (EDX) bagi memahami dengan lebih mendalam mengenai struktur nano dan juga ikatan kimia yang wujud. Berdasarkan analisis yang dijalankan, didapati nanotiub berada dalam keadaan yang sistematik dan memudahkan penempatan pemangkin adi. Tambahan pula, penggantian kandungan sodium oleh H^+ juga meningkat selepas proses pembasuhan menggunakan asid. Keputusan ujikaji menunjukkan kepekatan 10 M (TNT-10) adalah yang terbaik bagi menghasilkan nanotiub TiO_2.

Kata kunci: nanotiub TiO_2, tindak balas hidrotermal, kepekatan sodium hidroksida

Introduction

Since the discovery of carbon nanotubes (CNT) in 1990s, researchers are eager to find and develop more nanotubular structures with different types of materials that can be used for variable purpose. Due to over corrosive of carbon based materials, it seems to be less interesting for catalytic application and alternative materials is needed for overcoming the crucial problem. Titanium dioxide nanotubes (TNT) are one of the exclusive nanomaterial with nanotubular shape that can provide large surface area for deposition of noble catalyst in catalytic system. Moreover, the non-corrosive, environmentally friendly and inexpensive materials are the factors that make it interesting for TNT to be suitable candidate among other nanostructure materials. The strong metal support and high-stability in elevated temperature make it more preferable as potential nanostructure for various applications in science and technology field. TNT is promising nanomaterial due to its high properties that suitable for various applications in fuel cell technology, solar cell, storage energy material [1] and also gas sensing properties [2]. TNT receives numerous attention in fuel cell technology as different roles for each type of fuel cell including as catalyst support for main catalyst [3-6], photocatalyst [7-10], gas sensor [2,11,12] and composite membrane [13,14]. For the synthesized method, TiO_2 nanotubes can be produced via three common methods: (i) electrochemical anodization, (ii) template assisted and (iii) hydrothermal method. Anodization employs the using of power source for obtaining steady current in which longer nanotubes were achieved with larger anodization voltage [15]. However, the higher fabrication cost make it less ideal as the best method for synthesizing TNT.

Template assisted method can be performed by using stabilize template that was already in tube form and nanotubes was grown by using chemical vapor deposition (CVD) system [16] but due to the product that was hard to remove and may damage the structure of nanotubes itself make it less favorable among researchers as it can waste the materials itself. For hydrothermal method, it is more favorable due to lower apparatus cost and high quality products [17] but limit by long operation hours which is take for 24 hours or longer for a complete hydrothermal reaction. Furthermore, in hydrothermal method, a highly concentrated NaOH (10 M ~ 11 M) was used for producing highly nanostructure nanotubes together with TiO_2 (Degussa P25) powder. Nanotubes of titanium dioxide from hydrothermal method was firstly reported in 1998 by Kasuga et al. [18] with large surface area of 400 m^2/g and afterward research was still undergoing after that year for better quality of TiO_2 nanotubes by the same person [19,20]. In this research, hydrothermal method was applied in fabrication process of TiO_2 nanotubes and the brief method was discussed in the next section below.

Materials and Methods

Materials

For hydrothermal process, TiO_2 (P25 Degussa) powder with particle size of 21 nm was obtained from Sigma-Aldrich and NaOH in pellet form was purchased from Macron-USA. Hydrochloric acid with purity of 36.5 – 38% was purchased from J.T. Baker-USA for washing purpose to remove Na^+ ions.

Synthesis of TiO_2 nanotubes

Hydrothermal method was used in the synthesis process of TNT. The synthesis of TiO_2 nanotubes was started by mixing 50 ml of highly concentrated solution of NaOH varied from 6 M to 12 M with TiO_2 powder (3.0 g) and stirred for two hours to allow dispersion. After that, the hydrothermal reaction was performed by using Teflon line stainless steel autoclave at 110 ^oC for 24 hours. Next, the solution was collected and undergone washing process by using 0.1 M HCl and deionized water until pH 7. The crystal sample was then filtered and dried overnight at 80 ^oC in order to obtain pure product of TNT. Lastly, the TiO_2 nanotubes in powder form were obtained by undergoing calcinations process at 400 ^oC for 2 hours. The sample was then labeled as TNT-6, TNT-8, TNT-10 and TNT-12 based on the concentration of NaOH used which are 6 M, 8 M, 10 M and 12 M. The prepared samples were then characterized by FESEM, FTIR, EDX and XRD analysis for knowing the morphology, sodium content, crystal and bonding structure of TiO_2 nanotubes.

Characterization of TiO_2 nanotubes

The morphology structure of TiO_2 nanotubes was viewed by field emission scanning electron microscopy (FESEM) analysis. The structure of TiO_2 nanotubes (TNT) and chemical bonding present in the sample were examined by using X-ray diffraction (XRD) and Fourier Transform Infrared Spectroscopy (FTIR) analysis. The sodium content

was obtained from Energy dispersive x-ray (EDX) analysis. The data was then analyzed for further understanding of its nanostructure.

Results and Discussion

In hydrothermal method, TiO_2 nanotubes was obtained during the reaction of high concentration of NaOH and pure TiO_2 powder in Teflon line stainless steel autoclave. The process of TiO_2 nanotubes generation can be defined by sequence reaction step below:

i) High concentrated alkaline reaction

At the first reaction step, the high concentrated of NaOH (alkaline solution) will reacted with TiO_2 powder at temperature of 110°C for 24 hours. The sodium titanate ($Na_2Ti_2O_5.H_2O$) was the main product.

$$2TiO_2 + 2NaOH \longrightarrow Na_2Ti_2O_5.H_2O \quad (1)$$

ii) Replacement of Na^+ to H^+

The hydrogenotitanate was formed during the ion exchange between Na^+ and H^+ that happened during the acid wash treatment.

$$Na_2Ti_2O_5.H_2O + xH^+ \longrightarrow HxNa_{2-x}Ti_2O_5.H_2O + xNa^+, \quad (0 \leq x \leq 2) \quad (2)$$

iii) Dehydration process

The dehydration process is carried out by undergone drying process at 80 °C and followed by calcination process at high temperature for two hours. The reaction consists of two steps which can be seen below:

$$H_2Ti_2O_5.H_2O \longrightarrow H_2Ti_2O_5 + H_2O \quad (3)$$
$$H_2Ti_2O_5 \longrightarrow 2TiO_2 + H_2O \quad (4)$$

Field emission scanning electron microscopy (FESEM)

The morphology structure of TiO_2 nanotubes was viewed by field emission electron microscopy (FESEM). Figure 1 shown the image of TNT by FESEM as the hydrothermal product with different concentration of sodium hydroxide used (6 M, 8 M, 10 M and 12 M). From the image, it can be seen that only TNT-10 shown the complete structure of nanotubes TiO_2 with random alignment. The nanotubes were likely formed in overlapping with each other. Furthermore, the smooth and well-forming shape of TNT can be seen clearly. The nanotubes structure of TNT-6 was not discovered but instead of aggregated solid granules of TiO_2 nanoparticles was detected. This formation was due to the fact that at low concentration (< 6 M), the rate of Ti ion diffusion was too low with low alkaline solution. As for TNT-8, the early stage formation of TNT can be seen with non-complete tube-structure with agglomerate product formed [21]. As for TNT-12, the tube structure was disappeared and amorphous nanoparticles was discovered. This result can be correlated with Huang et al. [22] that also get the same result in which at too high concentration of NaOH, the amorphous particle is formed. During that condition, the alkaline solution tend to be very viscous and thus limited the diffusion of Ti (IV) ion (equation 1) due to the dissolution of Titania precursor. Besides, the crystallite titanate formed are said to be unstable in extreme condition (high alkaline solution) and decomposition rate of the crystallite titanate was faster. From this analysis, we can say that the concentration of NaOH was strongly influenced the formation of nanotubes TiO_2. As the concentration of alkaline solution was low (< 6 M), the nanotubes structure does not form instead of nanogranules generated while at too high concentration of alkaline solution, the amorphous nanoparticles was discovered with packed agglomerate. The best condition of synthesis TiO_2 nanotubes was 10 M.

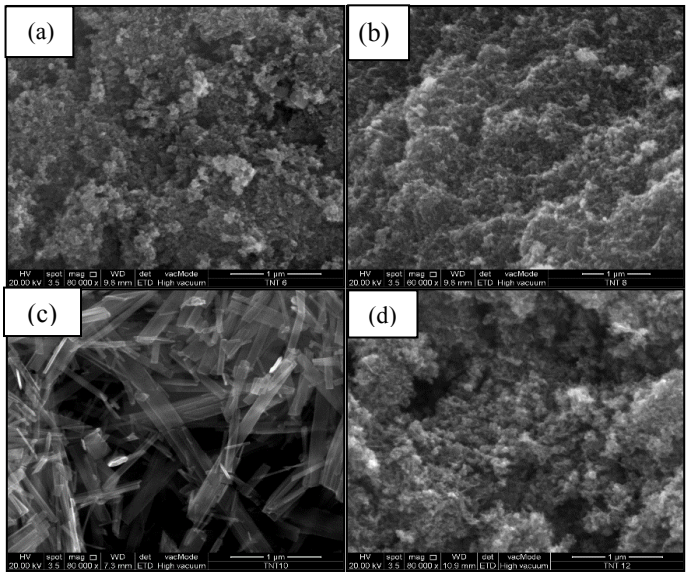

Figure 1. FESEM images of TNT after hydrothermal reaction at scale of 1 μm: (a) 6 M, (b) 8 M, (c) 10 M and (d) 12 M

X-ray diffraction (XRD)

The nanostructure of TiO_2 nanotubes was characterized by using X-ray diffraction (XRD) that were scanned from 10° to 90° at 2θ. Figure 2 illustrated the XRD pattern of titanium dioxide nanotubes that were fabricated by using different concentration of NaOH during hydrothermal treatment. Based on the XRD spectrum, the anatase peak of TiO_2 nanotubes for all concentrations can be detected at $2\theta = 25^o$, 37° and 47° which mark as "A" and rutile phase at $2\theta = 27^o$, 36° and 41° which mark as "R". The result indicated that there is mixture of both anatase and rutile phases in the TiO_2 nanotubes for all types of concentration used. The XRD pattern for TNT-6 and TNT-12 exhibit the same pattern while TNT-8 and TNT-10 show a bit different pattern with almost same properties. Both TNT-8 and TNT-10 gave the highest intense peak around d_{110} (25°) which means that the strong peak of TiO_2 nanotubes. In another word, it can be said that there are larger amount of Ti-O nanotubes bond at the peak compared to another two samples. The intense peak at d_{110} (25°) shown that there is interlayer spacing in tetragonal system with lattice constant value tabulated in Table 1. Moreover, the intense peak at d_{110} (25°) also decrease when approaching d_{600} peak (27.4^o). This proven that there was loss of water molecule during the dehydration process. The crystallite size for TNT-6, TNT-8, TNT-10 and TNT-12 were 140.2 A, 143.7 A, 137 A and 81.4 A respectively. Moreover, the relative ratio of d_{110}/d_{600} peaks can determined the content of Na^+ and was presented in Table 1 [23]. The ratio of d_{110}/d_{600} in Table 1 was seem to be increase as the theta increase which indicated that the Na+ content was decreased because of the replacement of Na^+ by H^+ was happened during the acid washing treatment after the hydrothermal treatment [4]. XRD analysis suggested that the TNT-8 and TNT-10 exhibit almost similar properties to TiO_2 nanotubes by previous studies [3, 4, 23, 24].

Table 1. XRD data for TiO_2 nanotubes

Lattice Constant	d_{110} (25°)	d_{600} (27.4^o)	d_{110}/d_{600}
a	3.872	4.6257	0.84
b	3.872	4.6257	0.84
c	9.616	2.9806	3.23

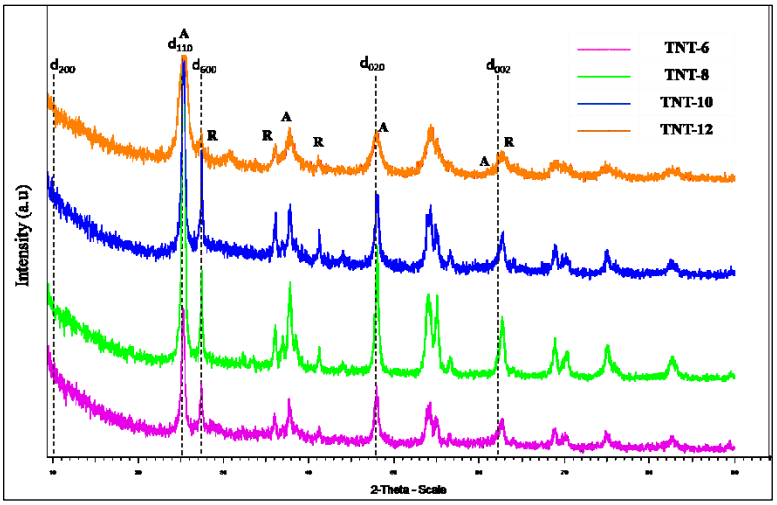

Figure 2. XRD spectrum for TNT-6, TNT-8, TNT-10 and TNT-12

Fourier transform infrared spectroscopy (FTIR)

The chemical bonding structure of prepared sample was checked by using FTIR analysis. Figure 3 present the FTIR spectra for TNT-6, TNT-8, TNT-10 and TNT-12. At 3200 to 3400 cm^{-1} wavenumbers, the strong intensity peak was discovered which ensured that there was O-H bond (hydroxyl group) present for all NaOH concentrations [5]. This result shows that there was large amount of O-H group on the surface of TiO_2 nanotubes due to stretching mode of Ti-OH bond. The sample TNT-10 exhibits the greatest vibrational modes for OH groups. Besides, the strong peaks were also discovered at 1400 to 1600 cm-1 which corresponds to the TiO_2 nanotubes bond that was present [6]. For TNT-12, the peak at this point was not strong enough as it shown the lowest peak among another three samples. This is compatible with the previous analysis (FESEM and XRD) as there were no nanotubes detected instead of amorphous nanoparticles TiO_2 was detected. The discovery of TiO_2 nanotubes bond was also due to the fact that the Ti-O planes was started to scroll to be nanotubes and give rise to site of bronsted acid and at the same time, it tend to modify the Lewis acid site rapidly [25]. In general, pure TiO_2 which in anatase, rutile and brookite phase, Lewis acid site was majorly in it but after NaOH concentration was take into the pure TiO_2, the bronsted acid site was formed directly. As the larger bronsted acid site generated, better nanostructure of TiO_2 nanotubes was achieved and formed. The large amount of O-H group in the TiO_2 nanotubes can be enhance for the purpose of the deposition of metal particles that ease the process of the dispersion and conjunction of the particles in the nanotubes surface. As overall, it can be said that the 10 M (TNT-10) concentration of NaOH was the best result as it has the highest peak intensity for both types of functional group which are hydroxyl group and TiO_2 nanotubes. The result totally suggests that the formation of TiO_2 nanotubes was influenced by the concentration of NaOH used during the hydrothermal reaction.

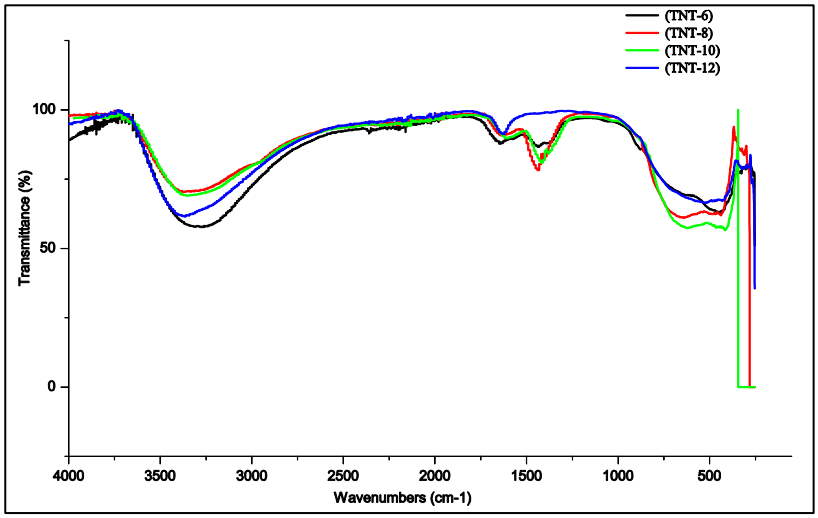

Figure 3. FTIR analysis for TNT-6, TNT-8, TNT-10 and TNT-12

Energy dispersive X-ray (EDX)

The energy dispersive x-ray (EDX) analysis was studied to determine the sodium content in TiO_2 nanotubes. The EDX pattern of various TNTs synthesized can be seen in Figure 4. The amount of Ti, O and Na was obtained in atomic percentage. The atomic ratio of Na to Ti was calculated and shown in Figure 5. Based on the bar chart in Figure 5, TNT-10 presented the lowest value (0.0504) of atomic ratio Na/Ti which directly indicated that many sodium ions was replaced by hydrogen ions during acid washing process with HCl. The loss of Na+ could enhance the rolling process of TiO_2 nanosheet into TiO_2 nanotubes. As for TNT-12, it shown highest value (0.1511) of atomic ratio which means that there is still huge amount of sodium ions even after ther acid washing process which also conjugated that there was least amount of TiO_2 nanotubes formed during hydrothermal reaction. The result can be correlated with FESEM analysis as we can see that as amorphous nanoparticle TiO_2 was generated instead of TiO_2 nanotubes for TNT-12. The lower amount of sodium ions, the higher amount of H+ ions was replaces during ion exchange process. When this condition happened, it will tend to increase the process of TiO_2 nanosheet rolling into TiO_2 nanotubes [23]. The result from EDX was compatible with the previous analysis and ensured that TNT-10 shown the greatest feature of nanotubes.

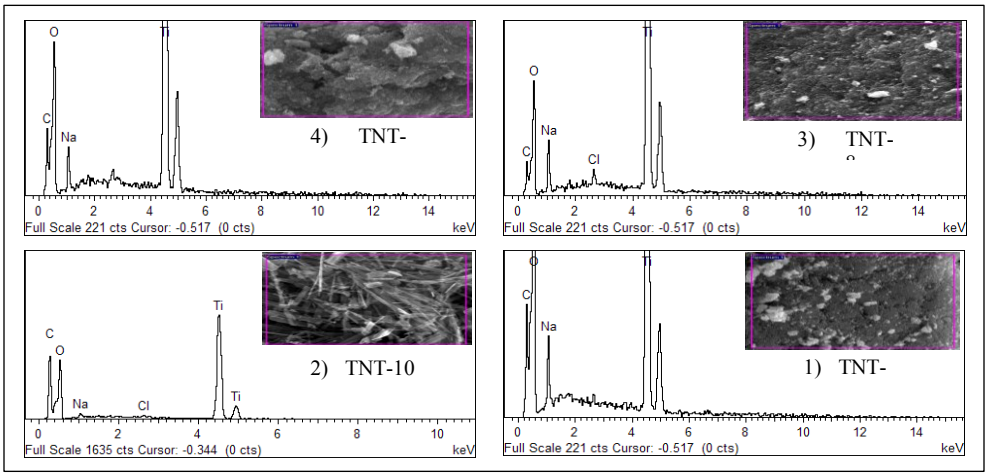

Figure 4. EDX pattern of various TNT synthesized

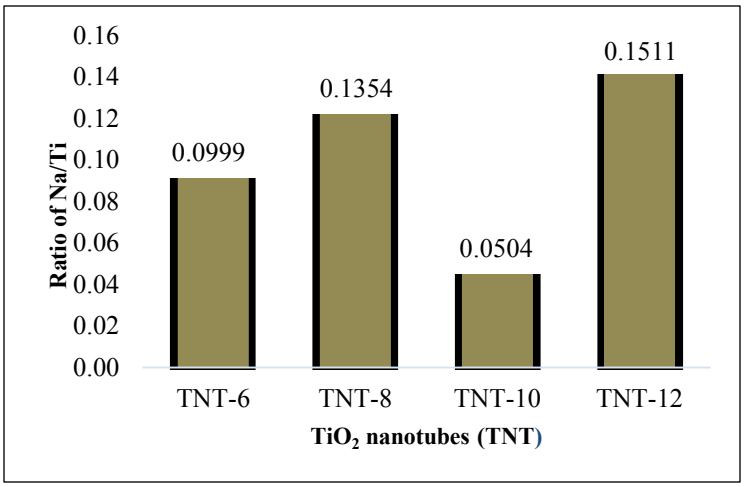

Figure 5. Value of atomic ratio of Na/Ti

Conclusion

The formation of TiO_2 nanotubes was successfully investigated by using different types of NaOH concentration (6 M, 8 M, 10 M and 12 M) during hydrothermal reaction. The effect of NaOH concentration was analyzed by using FESEM, XRD, FTIR and EDX analysis. Based on the four analysis, TNT-10 shown the best performance based on the FTIR, FESEM and EDX analysis while TNT-8 and TNT-10 was the best sample based on XRD analysis as it leads with high properties of TiO_2 nanotubes. In FESEM, only TNT-10 shown the greatest formation of TiO_2 nanotubes with clearly structure while for another samples do not show any clear tube formation. For FTIR analysis, the broad and strong vibrational peak was discovered on TNT-10 while for EDX analysis, the least amount of atomic ratio Na/Ti was obtained in TNT-10 sample which indicated that more Na+ ion was replaced by H+ ion during acid wash process with HCl. The result also suggests that the formation of TiO_2 nanotubes was strictly affected by the concentration of NaOH used in fabrication process during the hydrothermal reaction take places. The suitable concentration of NaOH for synthesized TiO2 nanotubes was 10 M which in moderate concentration. Too low concentration of alkaline solution does not help the TNT formation while too high concentration of alkaline solution lead to rupture structure of TiO_2 nanotubes with amorphous nanoparticle detected.

EFFECT OF pH ON FLUX DECLINE DURING FRACTIONATION OF GLUCOSE FROM CELLULOSE HYDROLYSATE THROUGH A POLYSULFONE MEMBRANE

(Kesan pH pada Penurunan Fluks bagi Pemeringkatan Glukosa daripada Hidrolisis Selulosa Melalui Membran Polisulfon)

Abstract

Concentrating glucose after enzymatic hydrolysis of lignocellulosic biomass is an important step in order to prepare the stream to undergo the fermentation process. However, glucose itself can be inhibitor for the enzymatic hydrolysis, hence in situ glucose removal is recommended. Ultrafiltration represents a promising procedure for isolation of enzymes from hydrolysate and for the removal of glucose. One of the obstacles in successfully utilizing ultrafiltration's membranes has been due to the membrane fouling. The flux behavior of polysulfone (PSF) membrane was studied in concentrating glucose from cellulose hydrolysate during dead end ultrafiltration. Different pH of solutions was used and Kumar's model was applied to analyse the fouling mechanism. The minimum fouling was obtained at pH solution above the IEP due to protein-protein and membrane-protein repulsions alleviating aggregation and fouling. Cake formation blocking was identified as the dominant mechanism for flux decline.

Keywords: enzyme hydrolysis, lignocellulosic biomass, ultrafiltration, polysulfone, fouling

Abstrak

Pemekatan glukosa selepas hidrolisis enzim bagi penghasilan bioetanol daripada biojisim lignoselulosa merupakan langkah yang penting bagi penyediaan untuk proses fermentasi selanjutnya. Penuras ultra menjadi pilihan bagi kaedah yang berpotensi untuk penyekatan enzim dan penyingkiran glukosa daripada larutan hidrolisis. Namun, salah satu rintangan bagi penggunaan maksima bagi penuras ultra adalah kotoran. Kriteria fluks bagi membran polisulfon di kaji dari pemekatan glukosa oleh larutan hidrolisis selulosa di penuras ultra hujung mati. Larutan yang berlainan pH digunakan untuk mengkaji profil fluks dan model Kumar digunakan untuk menganalisis mekanisma kotoran. Kotoran yang minima diperolehi pada larutan yang mempunyai pH yang lebih tinggi daripada nilai titik isoelektrik larutan hidrolisis. Halangan pembentukan kek telah dikenalpasti sebagai mekanisma yang dominan bagi pengurangan fluks.

Kata kunci: hidrolisis enzim, biojisim lignoselulosa, penuras ultra, polisulfon, kotoran

Introduction

Biorenewable products from lignocellulosic biomass has been the focus of attention around the world due to the depletion of petroleum derived product and its advantages of environmental friendly, cheap and widely available [1,2]. The main routes to produce fuels from biomass requires three major steps (1) pretreatment to delignify and

liberates cellulose and hemicelluloses from the matrix, (2) enzymatic hydrolysis to depolymerize carbohydrate polymers to release free sugars, and (3) fermentation [3]. The streams resulted from the pretreatment and enzymatic hydrolysis contains dilute sugars, along with excess components such as enzymes and biomass. The sugars released from hydrolysis may inhibit enzyme significantly, hence retarding the rate of enzymatic degradation [4,5]. In order to increase the conversion of enzymatic hydrolysis, the removal and concentration of the sugars from the hydrolysate can contribute towards not only in improving the hydrolysis but also in recovering the used enzymes. This can help to decrease the cost of enzymatic hydrolysis by reducing the consumption of enzyme [6,7].

Ultrafiltration (UF) membrane process provided an opportunity for retaining the free enzyme from discharge with the effluent after hydrolysis while at the same time separating the glucose for the subsequent fermentation process. The application of ultrafiltration membranes in biorefinery as an integrated process widens the scope of possible operating strategies, such as product removal and enzyme recycling to reduce the enzyme costs and enhance the hydrolysis [8]. The main drawback have been noted with the reduction of permeate flux over time in ultrafiltration, caused by the accumulation of feed component in the membrane porous structure, chemical interaction between solutes and membrane materials on the membrane surface. These macromolecules especially the polysaccharides caused the decrease in the permeate flow through the membrane which can be attributed to the fouling of its surface where the non-permeating solutes tending to form a gel layer [9,10].

A number of studies have shown that ultrafiltration is feasible to recover the enzymes and at the same time remove the fermentable sugars. However, limited study has been conducted on fouling characteristics and mechanism of cellulose hydrolysate and the effects of pH. For this study, a hydrophilic type membrane, polysulfone (PSF) with 20kDa MWCO was employed in a dead-end UF filtration mode. The influence of solution's pH and permeate flux was studied and the mechanism of fouling was modeled using Kumar's model.

Membrane blocking model was adopted by Kumar et al. [11], which was modified from the model by J. Hermia and J. Granger. Table 1 shows the linearized equation of the model. For the cake formation model, cake was formed when the particles larger than the average pore size accumulated on the membrane surface. For standard pore blocking, the particles in the fluids entered the pores and adhered to the innerpore walls, thus the adhesion of particles to the walls decreased the available pore diameter and increased the resistance of the membrane. For complete pore plugging model, the particles plugged individual pores and the flow diverted to other pores that plugged successively.

Table 1. Blocking filtration model

Type of Blockage	**Characteristic Equation**
Cake formation model	$\frac{t}{V} = X_1 V + Y_1$
Standard pore blocking	$\frac{t}{V} = X_2 V + Y_2$
Complete pore plugging model	$\frac{dV}{dt} = Y_3 - X_3 V$

Materials and Methods

Materials

Polysulfone commercial ultrafiltration (UF) membranes were chosen in order to minimize uncertainties with respect to the membrane material. The 20 kDa PSF membrane was purchased from Koch. The high purity cellulose was used to prepare the feed solution and was supplied by Sigma Aldrich. The analytical grade glucose, citric acid, tri-sodium citrate were purchased from Nacalai Japan and used as foulant model in the feed solution.

Characterization of model cellulose hydrolysate

In this study, a model of cellulose hydrolysate was formed by mixing microcrystalline cellulose powder, glucose and cellulase enzymes. The hydrolysate was analyzed for molecular weight and isoelectric point (IEP). 6% (w/w)

microcrystalline cellulose, 33.3 g/l glucose and 8FPU cellulase were added in reverse osmosis water and mixed well for 30 minutes. Gel electrophoresis in denaturing conditions was performed in sodium dodecyl sulfate (SDS-PAGE) according to the method by Laemmli (1970) resolving gel consisted of 15% polyacrylamide in Tris-HCl (1.5M, pH 8.8), while stacking gel consisted of 4.5% polyacrylamide in Tris-HCl (1.0 M, pH 6.8). Sample solutions were mixed at 1:2 (v/v) ratios with the sample buffer and heated at 90 °C for 3 minutes before loading. Aliquots of 40 – 42 µL samples were loaded into individual wells and a constant current was passed through the gel for 2 h to obtain separation of the peptides. Protein markers 10 – 260 kDa was used for molecular-weight determination. The gel sheets were stained with Gelcode Blue Safe Protein stain [12]. As for the determination of isoelectric point (IEP) of cellulose hydrolysate, the zeta potential at a given pH was recorded by a zeta potential titration apparatus using Malvern Zetasizer Nano ZS, UK. The IEP of the hydrolysate was determined where the zeta potential was zero at the pH value.

Ultrafiltration process

The 20 kDa polysulfone membrane purchase from Koch was employed throughout the present study. The active membrane surface area was 14.67 cm2. Fresh membranes were soaked in pure water overnight prior to each run to remove the preservative liquids from the manufacturer before used. Experiments were performed in the dead end stirred cell (Sterlitech HP4750). The stirred cell is equipped with single blade stirrer and rotates at 500 rpm to minimize the layer formation of high solution concentration in the adjacent areas at membrane surface and to prevent the formation of a series vortex in the cell. The operation pressure in the system was maintained by nitrogen gas. The feed solution was conducted under constant pressure at 2 bar. Permeate flux was calculated based on the mass of permeate collected on the balance for about 60 minutes.

Analytical methods

Glucose content was analysed by HPLC (Agilent G1311A) equipped with refractive index (RI) detector and Rezex ROA column (300 x 7.80mm). An amout 0.005 N H2SO4 was used as the mobile phase as a flow rate of 0.6 ml/min and the column temperature was maintained at 60 °C. Protein concentration was measured by the Bradford protein assay using bovine serum albumin (BSA) as standard [13].

Result and Discussion

Characterisation of cellulose hydrolysate

Fractionation is controlled by the membrane pore size and the operating parameters. Determination of molecular size of the retained macromolecules is essential as size can be the criterion for separation. UF membranes retain 90% of molecular mass in daltons of a macrosolute, so a specific small molecule can be fractionated into permeate from the hydrolysate. In concentrating glucose via ultrafiltration process, glucose will be allowed to pass through membrane pores while the enzymes will be retained for recycle. Molecular weight of cellulose hydrolysate was analyzed by SDS polyacrylamide gel electrophoresis (Figure 1). From Figure 1 it was shown that the molecular weight of hydrolysates was 70 kDa. Similar result has also been reported by Andersen et al. [14] as 70 kDa calculated with the average cellulase enzyme in MW.

Amino acids in the protein contain both a basic and an acidic group because of the amphoteric character that can be positive or negative charge depending on the pH of the solution. If the amino acids did not migrate in the electrical field, which is it is not positive nor is negative charge, this conditions called as the IEP of the amino acids [15]. The isoelectric point is one of the characteristics parameter for a protein, as different proteins have different value of isoelectric point. IEP has important effects on the properties of cellulose hydrolysate solution in membrane process. By adjusting the pH, a complete separation of various proteins can be obtained. The isoelectric point of cellulose hydrolysate was 3.9.

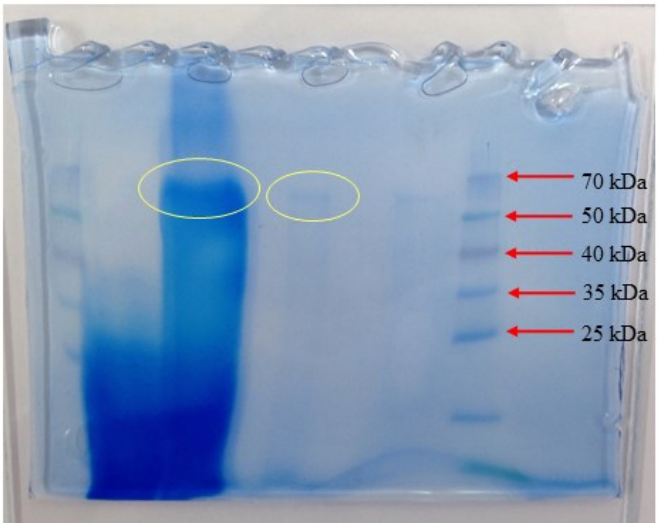

Figure 1. Electrophoresis profile of the cellulose hydrolysis

Effect of pH

The interaction between membrane and solute in different pH was studied in the dead-end stirred ultrafiltration with constant operating pressure at 2 bar. Figure 2 shows the fouling behaviour of cellulose hydrolysate for several pHs illustrated in terms of permeate flux relative to initial water flux (J/Jo). Initially the fouling behaviour for all solution can be seen as rapid flux decline and followed by gradual flux decline. It is noted that the permeate flux was responsive to the solution pH, thus low pH value exhibited severe flux decline as compared to high pH value. Similar experiment trends were reported by other researchers [7,16,17].

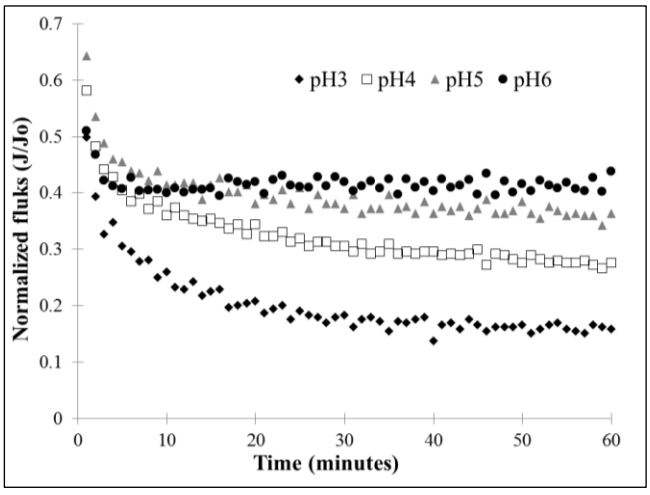

Figure 2. Normalized flux declines of cellulose hydrolysate in different pH of solution

The feasibility of fractionation depends on charge, thus more charged ions are retained better than monovalent ions [18]. In addition, the counterion exchange process between the ion exchanger and the counterions in the external solution has to be considered, specifically proteins of large molecular weight [19]. The net charge of the

macromolecular protein due to pH-based interactions of various constituent groups is positive if the pH is less than the isoelectric point; the net charge is negative if the solution pH is more than the IEP. Thus, as long as the solution pH is different from the IEP, the protein surface has some net positive or net negative charges.

All these could explain why the lowest permeate flux was obtained at pH below the hydrolysate's IEP (~pH3). Figure 3 illustrates the observation for pH3. Below the IEP, both the cellulose hydrolysate (positively charged) and PSF membranes (negatively charged) have opposite charges, thus attraction forces are dominant over repulsion forces and affect the initial flux decline rate at the initial fouling stage. At pH of solution near to IEP (~pH4), the solubility of a protein built out of amino acids is minimum and has tendency to form aggregates with other molecules [10]. As the pH was raised to pH 5 and pH 6 (away from the IEP), observation shows that the protein solubility increases and lead to much lesser accumulation on the membrane surface.

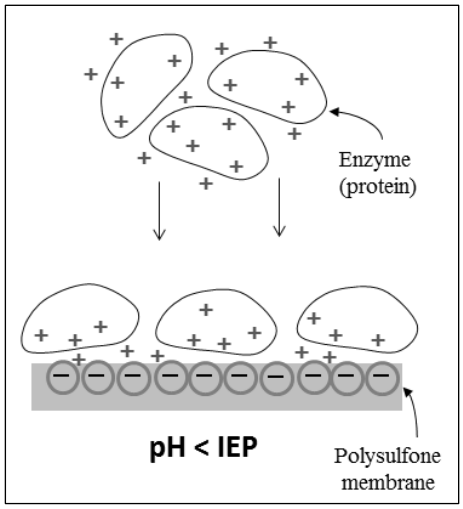

Figure 3. Schematic illustration of possible configurations of cellulose hydrolysate at pH lower than IEP

The membrane blocking resulted from the accumulation on the membrane surface would affected the permeation of glucose in the process. As illustrated in Figure 4, the permeation of glucose at pH 3 is the lowest compared to other pH, indicating that much glucose was unable to pass through the PSF membrane because of the blocking by the protein on the membrane surface, while at pH 5 the permeation of glucose is the highest.

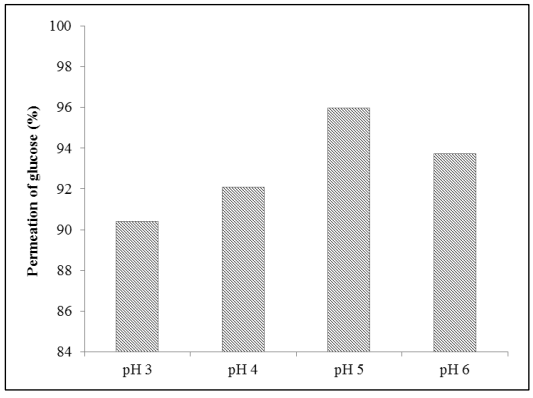

Figure 4. Permeation of glucose in different pH

Fouling mechanism

Kumar's equation was applied to identify the mechanism of fouling during ultrafiltration of cellulose hydrolysate. Y-axis and X-axis according to Table 1 was fitted using Matlab R2012a (Figure 5). The best fit parameter was obtained by minimizing the sum of squared residuals (SSR) that could explain the experimental data rationally (Table 2).

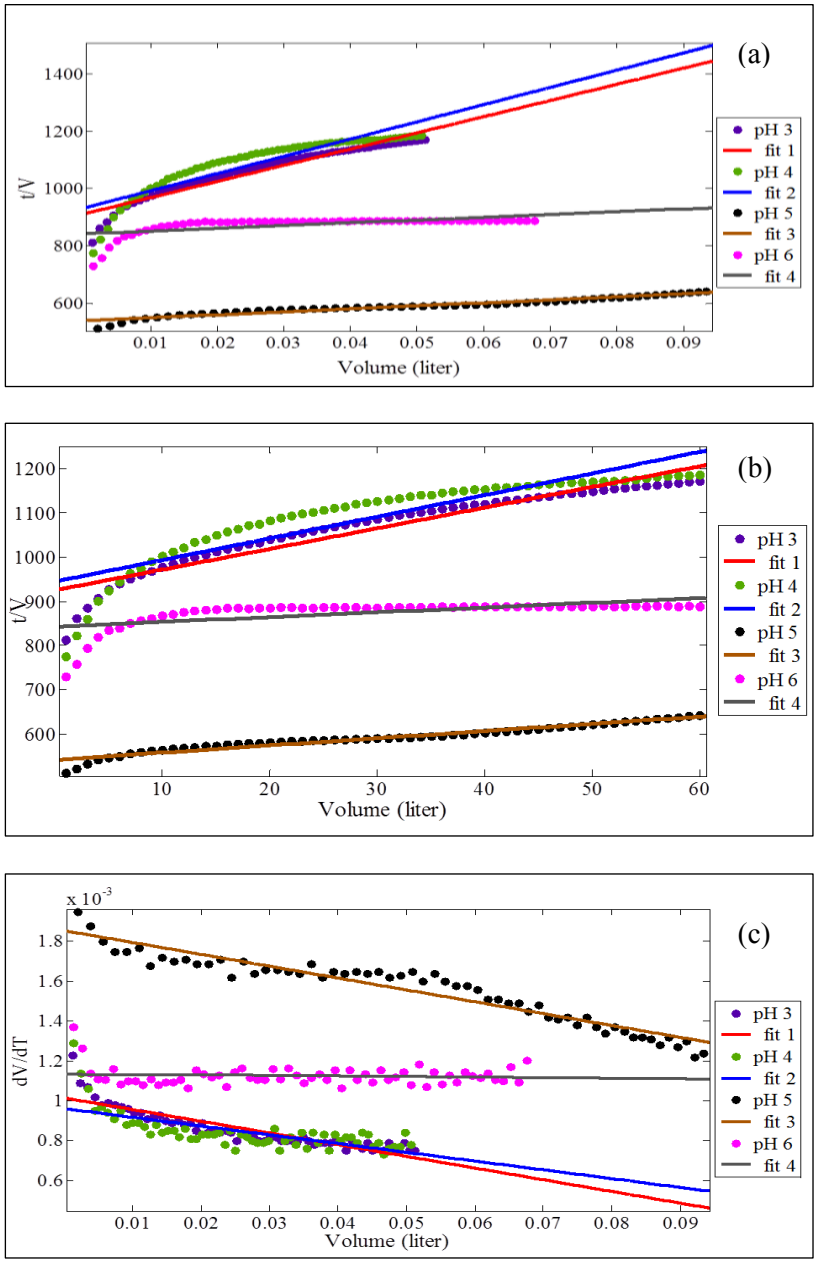

Figure 5. Cake formation model (a), standard pore blocking (b) and complete pore plugging model (c) for cellulose hydrolysate ultrafiltration

It may be observed from the figure that the fitting of experimental data to the all three types of blocking, the best fitting occurred in pH5, as the values of R^2 were higher than others R^2 values, which were mostly above 0.9. Thus

this indicated that at pH5 the possibility that the flux decline could be controlled by the combination of the three blocking model. Solution at pH3 were fouled mainly by cake formation, which could explain the electrostatic attraction between particles of protein and the fresh membrane that lead to the formation of cake layer impeding the entrance of molecules into the membrane pore and keeps them back on the cake layer.

Table 2. The value of R^2 obtained from the experimental data in the study of the effect of pH solution upon membrane fouling

pH	Cake Formation Mode	Standard Pore Blocking	Complete Pore Plugging Model
3	0.9282	0.9084	0.7968
4	0.8117	0.7937	0.8558
5	0.9449	0.9453	0.9133
6	0.3753	0.3769	0.0107

Similar results have also been observed for glucose permeation in hollow fibre membrane whereby formation of thin layer of cake denoted the membrane blocking [6]. Blocking mechanism for filtration at pH6 was found to be unsuitable with the fitted model, may be due to the less accumulation of protein on membrane surface due the stronger electrostatic repulsion between protein and the PSF membrane.

Conclusion

It has been shown that solution pH has significant effect on the extent of cellulose hydrolysate fouling in membrane process. At higher solution pH (pH 5 and 6), the samples showed minimum membrane flux decline due to protein-protein and membrane-protein repulsions alleviate aggregation and fouling. The permeate flux decline profiles of all the solution were compared to the Kumar's model. These results showed that the fouling at pH5 was predominantly contributed by three types of blocking. Under all the solution pH, it was observed that the values of R^2 of cake formation model were always greater than those obtained from other fouling mechanisms. This indicates that the cake formation model dominated in fouling studies, and followed by standard pore blocking and complete pore plugging model.

Abstract

Gynura procumbens (Sambung nyawa) is a bicolor (green and red) herbal plant, which is widely grown in Asia. This herbs are famously used for medicinal purposes as a safe alternative to chemical-based medicine. Recent studies proved that this plant has anti-herpes simplex virus, anti-flammatory and anti-hyperglycaemic properties. This work investigates the extraction of chlorophyll a and b in *Gynura procumbens* using Solid liquid extraction method. The solid to solvent ratio, temperature, solvent used and extraction time were varied to determine the optimum conditions for extraction. It was found that at 80 °C in 90 minutes with 2:5 solid to solvent ratio was the most favorable condition to extract chlorophyll a and b. Five valuable compounds were found from GC-MS analysis, which are 2-hexanal, phenol, oleic acid, copaene and phytol. This implies that *Gynura procumbens* promises a good source of many useful bioactive compounds.

Keywords: *Gynura procumbens*, sambung nyawa, chlorophyll, extraction, optimization

Abstrak

Sambung Nyawa ialah pokok herba dwi-warna yang tumbuh secara meluas di Asia. Herba ini sangat popular digunakan sebagai bahan alternatif yang selamat bagi tujuan perubatan berbanding ubatan berunsurkan bahan kimia. Penyelidikan terbaru membuktikan bawaha pokok ini anti-virus herpes simplex, anti-keradangan dan anti-sifat hiperglisemia. Eksperimen ini menyiasat tentang pengekstrakan klorofil a dan b dalam *Gynura procumbens.* Menggunakan pengekstrakan cecair pepejal. Nisbah cecair pepejal, suhu, pelarut dan masa mengekstrak telah dimanipulasi untuk menentukan keadaan yang optimum untuk proses pengekstrakan tersebut. Keputusan eksperimen mendapati bahawa pengekstrakan selama 90 minit pada suhu 80°C serta nisbah cecair pepejal 2:5 merupakan kondisi yang paling sesuai untuk mengekstrak klorofil a dan b. Lima kompoun berharga telah ditemui melalui keputusan analisa GC-MS iaitu 2-heksanal, fenol, asid oleik, copaene and fitol. Keputusan ini mencadangkan potensi *Gynura procumbens* sebagai sumber yang baik kepada sebatian bioaktif.

Introduction

For centuries, many plants have been used as a traditional medicine. However, the interest for natural products have grown significantly in recent years [1,2,3]. In the market, nowadays, there are tremendous numbers of natural products, which have a phyto origin such as food additives, cosmetics, and medicines [4]. One of the well-known medicinal plants in South-east Asia is *Gynura procumbens (Lour.) Merr.*, which is locally known as Sambung nyawa in Malaysia. *Gynura procumbens* is a fast growing evergreen herb from family of Compositae or Asteraceae and it is mostly found in Thailand, Malaysia, Indonesia, and Philippines [1,5].

The leaves of *Gynura procumbens* have been traditionally used for the treatment of eruptive fevers, rashes, kidney diseases, migraines, constipation, hypertension, cancer and diabetes mellitus, inflammation, rheumatism, viral diseases of skin, migraine, and constipation [5 – 9]. Modern research also has provided evidence for the above-mentioned medicinal properties of *Gynura procumbens*. For instance, Rosidah et al. [10] maintained that the ethanolic extract of *G. procumbens* showed anti-hyperglycaemic and anti-hyperlipidaemic activities in diabetic rats [5,9, 11,12]. Furthermore, *Gynura procumbens* has been reported to possess anti-herpes simplex virus, anti-hyperglycemic, anti-hyperlipidemic [13], anti-hypertensive effects [8], anti-hyperlipidemic [12,13], anti-sterility, anti-oxidative capabilities, and it has been found to be useful for prevention of rheumatism [5 – 7,9,12,13]. In addition, ethanol and methanol extracts from the leaves of *Gynura procumbens* showed anti-diabetic effects in streptozotocin (STZ)-induced diabetic rats [12]. Rosidah et al. [10] also reported that *Gynura procumbens* leaves increase insulin secretion in the insulin-secreting cell line [14]. According to Zurina et al. [15], it was reported that the aqueous extract of *Gynura procumbens* not only decreases the blood glucose levels, but also increase the glucose uptake by muscle tissues in STZ-induced diabetic rats [14].

Strong body of research supported the fact that chemical contents of *Gynura procumbens* leaf are flavonoid, glycoside kuersetin, phenolate acid, triterpenoid, alkaloid, saponin, and tannin [7,14]. Generally, most of the green vegetables and fruits contain chlorophyll, which accounts for their green colour. Chlorophyll a and b are the major pigments that can be found in the extract of green plants [16]. The presence of chlorophylls has also been observed in the solvent extract from leaves of *Gynura procumbens* [17,18,19]. Chlorophylls have been used as a traditional medicine for therapeutic and as antioxidant [17, 20]. Kaewseejan, et al. [17] reported that the usage of chlorophylls in human diet has increased significantly in recent years. According to Guil-Guerrero et al. [20], chlorophylls have antioxidant, anticarcinogenic, and cytotoxic activity, so, they may ameliorate drugs' side effects [17]. Chlorophyll has been used for many purposes. In chemical industry, chlorophylls have been used as natural dyes. Chlorophyll is registered as a food additive (colorant), and its E number is E140. Chefs use chlorophyll to colour a variety of foods and beverages such as pasta and absinthe. Other than that, in medical field chlorophyll has been introduced as bioactive compound which can help in blood production.

Hence, given the importance of chlorophylls and its beneficial compounds, the aim of this study is to extract the chlorophyll a and b in *Gynura procumbens* at optimum condition.

Materials and Methods

Sample preparation

The leaves of *Gynura procumbens* were bought from Pusat Herba, Taman Pertanian Universiti (TPU). The leaves were washed by distilled water to avoid contaminants on the surface of the leaves. After drying, the leaves were freshly stored at 4 °C for subsequent experiments.

Solvent extraction

The fresh leaves of *Gynura procumbens* were cut into small pieces before the extraction. Then, an amount 0.5 g of sample was used for each experiment and soaked in 5 ml of solvent in a test tube. In order to find the best solvent for this extraction, three different solvents (water, methanol, and ethanol) were used in each extraction. The conical flask was then covered with aluminum foil to avoid contamination and to protect from sunlight that may causes unwanted reaction. Water bath machine was used to heat the samples for extraction at different temperature and time. After each experiment, the extracts were filtered through a Whatman No.1 filter paper and the absorbance value measured by using Shimadzu UV-Vis spectrophotometer.

Ultraviolet visible spectrophotometer

In this study, Shimadzu ultraviolet visible (UV-Vis) spectrophotometer was used in determining chlorophyll content. The extract collected after filtration of samples through Whatman No.1 filter paper were filled in the cuvette. Chlorophyll-a showed maximum absorbance at 665 nm while chlorophyll-b at 652 nm. Then, the chlorophyll-a and chlorophyll-b content (μg/ mL) were calculated using equations 1 and 2 for ethanol-based extraction as reported by Kaewseejan et al. [17]:

$$\text{Chlorophyll-a} = 16.72\ (A665) - 9.15\ (A652) \quad (1)$$

$$\text{Chlorophyll-b} = 34.09\ (A652) - 15.28\ (A665) \quad (2)$$

The wavelengths used were at 666 nm for chlorophyll-a absorbance and 653nm for chlorophyll-b absorbance. The equations 3 and 4 were used for methanol-based extraction to determined chlorophyll-a and –b content:

$$\text{Chlorophyll-a} = 15.65\ (A666) - 7.340\ (A653) \quad (3)$$

$$\text{Chlorophyll-b} = 27.05\ (A653) - 11.21\ (A666) \quad (4)$$

Gas chromatography mass spectrometry

Extracted samples were analysed using Shimadzu gas chromatography mass spectrometry (GC/MS). A 30 m × 250 µm × 0.25 µm capillary column was used. The temperature used for this analysis was from 50 to 325 ˚C while the pressure was up to 10.5 psi. The injection volume was 3.0 µL. Split less mode was used and helium gas with the flow of 1mL/min and pressure of 10.5 psi was used as carrier gas. Response Surface Methodology software was used to obtain a mathematical model for extraction of chlorophylls.

Results and Discussion

The fresh leaves of *Gynura procumbens* were extracted by solvent extraction method, which is a traditional method to obtain chlorophylls.

Optimization of extraction method

The conventional extraction process can vary in different temperatures, solid/ liquid ratio, solvent, and time. So, the effect of these parameters was studied in order to find the optimum conditions, in which highest yield of chlorophylls was extracted.

Effect of solvents

As mentioned earlier, three different types of solvents of methanol, ethanol, and water were employed. The extractions were done at different times, from 5 to 30 minutes. The results from each solvent varied in the extracted amount of chlorophyll-a and chlorophyll-b. As Figure 1 depicts, one of the highest yield of chlorophyll-a was extracted using methanol as a solvent and followed by ethanol and water respectively. 30 minutes of extraction was found to be the best extraction time to obtain the highest amount of chlorophyll-a (34.63 µg/ml) by methanol. While the concentration of chlorophyll-a extracted by ethanol and water were 32.03µg/ml and 0.281µg/ml respectively.

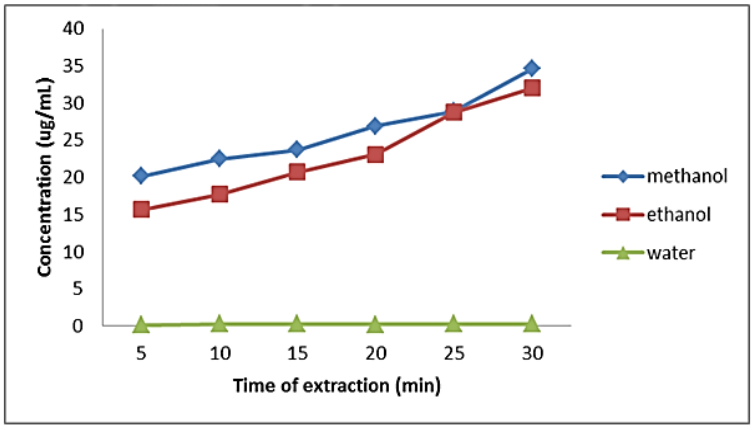

Figure 1. Concentration of chlorophyll-a against time of extraction at different solvents

Meanwhile, the highest yield of chlorophyll-b was extracted by using methanol as a solvent and followed by ethanol and water. After 30 minutes of extraction, the concentration of chlorophyll-b extracted by methanol was 6.82 µg/ml. While the concentration of chlorophyll-b extracted by ethanol and water was 6.08 µg/ml and 0.12 µg/ml respectively (Figure 2). Therefore, it clearly shows that methanol extracted the highest yield of chlorophylls compared to ethanol and water. The reason of these phenomena is because chlorophylls are readily soluble in alcohol, mostly insoluble in non-polar alkanes like butane and hexane, and has unique relationships with polar water, due to its polarity and the presence of ionic groups. Chlorophylls are basically composed of hydrocarbons, which are mostly insoluble in water.

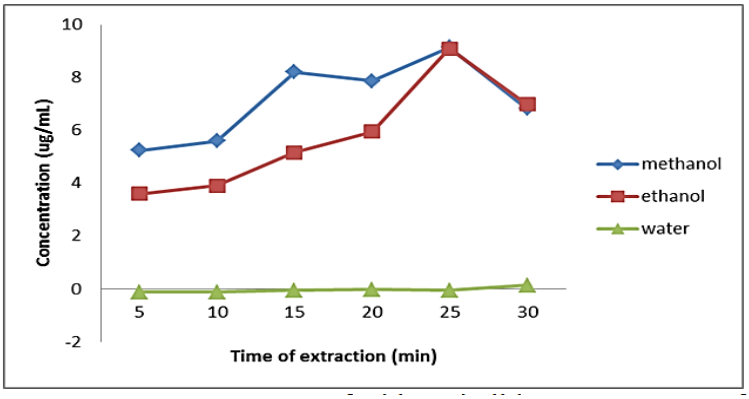

Figure 2. Concentration of chlorophyll-b against time of extraction of different solvent

Since the yield of chlorophylls were almost the same for ethanol and methanol extract, hence ethanol was chosen as solvent for the rest of experiments. This is because ethanol poses less threat to human consumption and health risks [21].

Effect of solid to solvent ratio

In this experiment, solid to solvent ratio was varied from 1:5 to 5:5 g/ml. The time of extraction was set to be at 30 minutes and 120 minutes. Figures 3 and 4 below shown the results obtained. As it is depicted in Figures 3 and 4, the optimum ratio for highest yield of chlorophylls was at 2:5 g/ml in 120 minutes of extraction. The concentration of chlorophyll-a and b was 72.32 µg/ml and 32.62 µg/ml respectively, while half of these amounts were extracted in 30 minutes. So, the result showed that the yield of chlorophylls doubled by increasing the time of extraction. The highest yield of chlorophylls at solid to liquid ratio of 2:5 mg/ml may be explained by the fact that at this ratio better mass transfer between sample and solvent occurs in comparison to other ratios.

Effect of extraction temperature

In this part, temperatures of extraction were varied from 40 to 80 ˚C at the constant solid to solvent ratio (2:5) and 30 minutes extraction time to find the optimum temperature. As it shows in Figure 5, the concentration of chlorophyll-a and b increase with respect to temperature from 41.47 µg/ml and 16.57 µg/ml to 84.78 and 77.63 µg/ml. At higher temperatures, plant cell wall, which is hydrocarbon chain and consists of phospholipid layer, breaks easier and the compounds in the leaf can leave the cell wall [22]. Higher temperatures also increase the solubility of sample in solvent and hence help to shorten the extraction time by increasing the mass transfer of solute into solvent. Based on the results, highest amount of chlorophylls was extracted at the 80 ˚C. The finding regarding the optimum temperature was consistent with the findings of other research such as Bucić-Kojić, et al. [23].

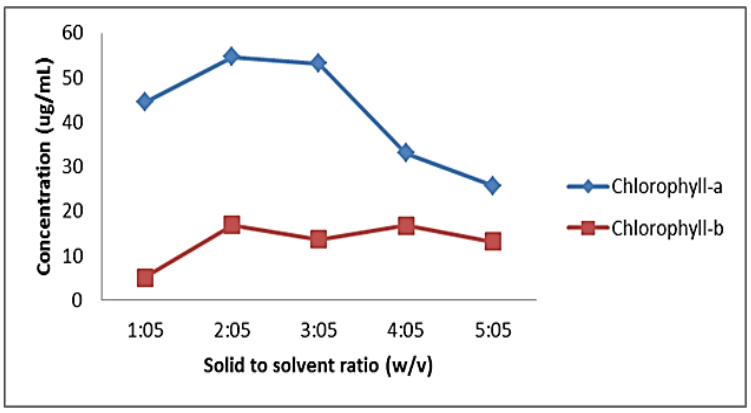

Figure 3. Concentration of chlorophyll against solid to solvent ratio for 30 minutes

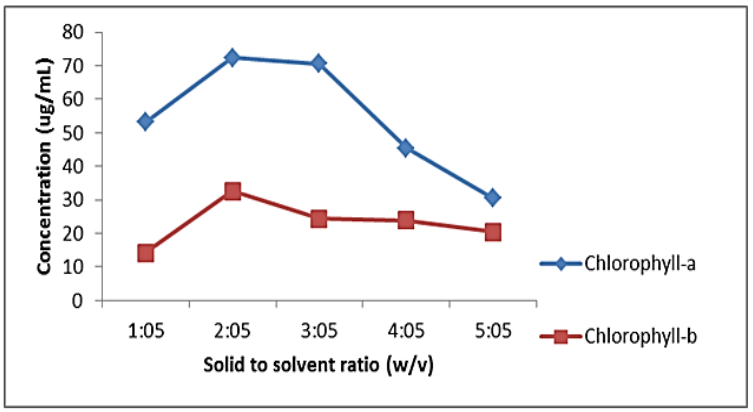

Figure 4. Concentration of chlorophyll at different solid to solvent ratio for 120 minutes

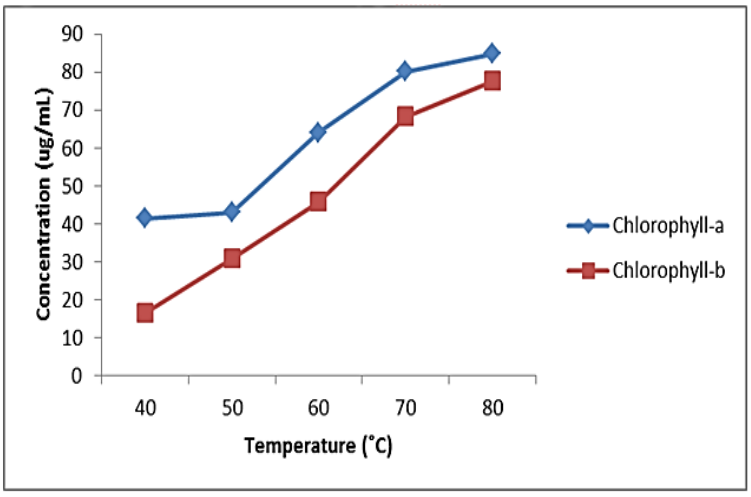

Figure 5. Concentration of chlorophyll against temperature

.

Effect of extraction time

In order to find the optimum time of extraction, constant amount of solid to solvent ratio and temperature was set at different times of extraction ranging from 5 to 120 minutes. Figure 6 shows results of concentration chlorophyll at constant temperature of 80 ˚C while the time of extraction was varied throughout the experiment. From the graph we can see that the concentration of chlorophyll increased as time of extraction increased. However, at 120 minutes of extraction the concentration decreased because the ethanol had vaporized totally and the mixture become dry in the conical flask. In 5 minutes of extraction concentration of chlorophyll obtained was 58.20 µg/ml for chlorophyll-a and 33.41 µg/ml for chlorophyll-b, while maximum amount of chlorophyll-a and chlorophyll-b obtained at 90 minutes of extraction with 173.25 µg/ml and 165.54 µg/ml respectively.

Thus as mentioned earlier, high temperature helps to reduce time of extraction with higher yield of extraction. In this case, the optimum time was 90 minutes at 80 ˚C for extraction highest amount of chlorophylls. Therefore, based on the results, the optimum parameters for conventional extraction of chlorophylls from *G. procumbens* leaves were at 80 ˚C for 90 minutes of extraction and solid to solvent ratio 2:5 g/ml.

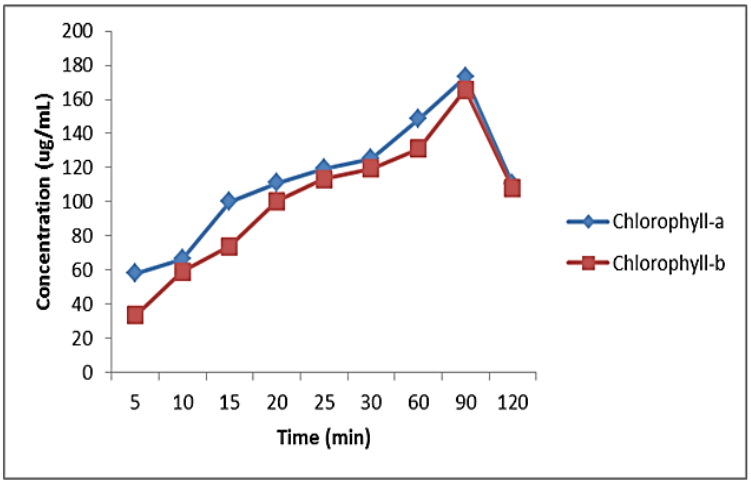

Figure 6. Concentration of chlorophyll against time of extraction at constant temperature (80˚C)

Response surface methodology

In order to find the mathematical model for the extractions, Response surface methodology software was used based on the obtained results for extraction of Chlorophylls at different solid to solvent ratio, temperature, and extraction time (three parameters). Central composite design and Box-Behnken design for historical data was used for each extraction method. Analysis of variance (ANOVA) was employed to evaluate the significance of each variable on the resulted model. Linear model was suggested for extraction of chlorophyll-a and chlorophyll-b by conventional method (equation 5 and 6).

$$\text{Chlorophyll-a concentration} = + 90.30 - 6.67A + 22.71B + 38.38C \quad (5)$$

$$\text{Chlorophyll-b concentration} = + 19.21 + 6.05A + 31.83B + 42.45C \quad (6)$$

where; A = Ratio (g/ml), B = Temperature (˚C) and C = Time (minutes)

As it shows in the Figure 7, the desirable concentration of chlorophylls obtained at 80 ˚C and 90 minutes of extraction by conventional method.

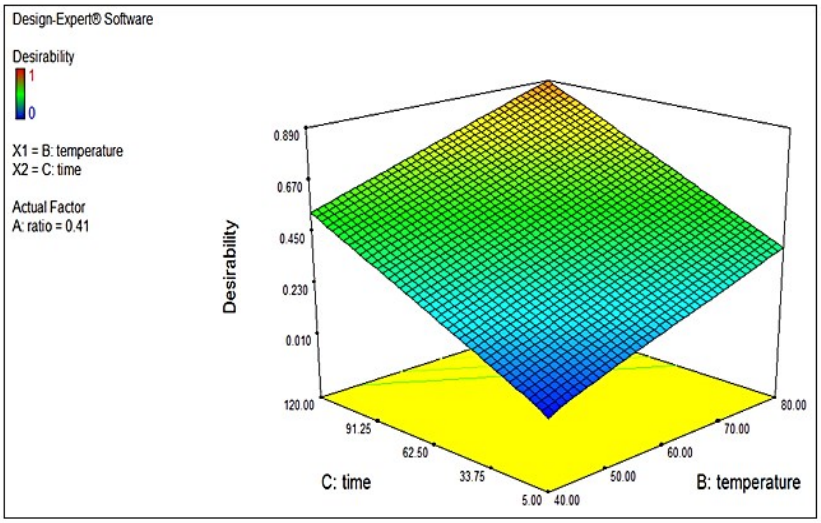

Figure 7. Desirability of concentration of chlorophyll for conventional extraction by optimization analysis

Gas chromatography-mass spectrometry analysis

The chemical compounds of ethanolic extracts obtained by solvent extraction from the leaves of *Gynura procumbens* were identified by GC-MS. The results showed five identified compounds. The identified compounds from solvent extraction sample were 2-hexenal, phenol, oleic acid, copaene and phytol. All the identified compounds are valuable and useful in medicine and they can be the reason of *Gynura procumbens* traditional medicinal usage, but further investigation is needed.

Conclusion

Based on the results, the highest yield of chlorophylls was extracted by conventional method at 80 ˚C with solid to solvent ratio of 2:5 mg/ml for 90 minutes. Also the samples extracted by conventional extraction method contained valuable compounds, which are useful in medicine. In short, the extract from leaves of *Gynura procumbens* has a promising medicinal potential and it can be used as a natural source of chlorophylls.

Abstract

Coating of apatite in a biomimetic fluid is an alternative technique for metallic coating. Key element for effective biomimetic apatite coating depends on the surface material that can be enhanced by physical and chemical pre-treatment process. Two different preparations of Titanium alloy (Ti6Al4V) have been studied namely *as* received (*as*-Ti) and abraded (*ab*-Ti) with SiC paper. Both samples were then immersed in 5M NaOH and 5M KOH at temperature of 60 °C for 24 hours. A passive oxide layer covered on the surface of Ti6Al4V generally changed to form alkali (Na/K) titanate layer which is mechanically unstable. Therefore, alkali-treated Ti6Al4V were heat-treated at 700 °C for 1 hour to consolidate a mechanically stable structure of amorphous alkali titanate layer. Both samples before and after heat treatment were characterized using field emission scanning electron microscope, 3D surface metrology, contact angle goniometry and X-ray diffraction. The result indicates that *as*-Ti treated in 5 M KOH showed an existence of porous network structure.

Keywords: titanium, active surface, alkali treatment, heat treatment

Abstrak

Penyalutan apatit dalam cecair biomimetik adalah teknik alternatif untuk salutan logam. Faktor utama dalam penyalutan logam dengan apatit secara biomimetik yang berkesan adalah bergantung kepada sifat permukaan bahan/logam. Sifat permukaan logam boleh ditambah baik melalui proses pra-rawatan secara fizikal dan kimia. Dua persediaan yang berbeza ke atas aloi Titanium (Ti6Al4V) telah dikaji iaitu seperti yang diterima (*as-Ti*) dan telah dilelas (*ab-Ti*) dengan kertas pasir silikon karbida (SiC). Kedua-dua sampel kemudiannya direndam ke dalam 5M NaOH dan 5M KOH pada suhu 60 °C selama 24 jam. Satu lapisan oksida pasif yang meliputi atas permukaan Ti6Al4V umumnya berubah untuk membentuk lapisan alkali (Na/K) titanat yang secara mekanikal adalah tidak stabil. Oleh itu, Ti6Al4V yang telah mengalami pra-rawatan alkali telah melalui proses pemanasan haba pada suhu 700 °C selama 1 jam untuk mengukuhkan kestabilan struktur mekanikal lapisan amorfus alkali titanat. Kedua-dua sampel sebelum dan selepas rawatan haba telah dianalisa menggunakan mikroskop elektron imbasan pancaran medan, metrologi permukaan 3D, sudut sentuhan goniometri dan pembelauan sinar-X. Hasil daripada kajian ini menunjukkan bahawa as-Ti yang dirawat dengan 5M KOH menunjukkan jelas kewujudan struktur jaringan berliang.

Kata kunci: titanium, permukaan aktif, rawatan alkali, rawatan haba

Introduction

Titanium and its alloy are widely used as dental, orthopaedic and maxillofacial implant materials due to their mechanical properties. It has a good biocompatibility, high corrosion resistance and better strength to the weight ratio as compared to 316L stainless steel. However, bone tissue does not bond directly to these materials due to the micromotion which leads to the formation of fibrous tissue encapsulated after implantation and drove to the loosening effects [1].

Enhancement of cell attachment and bone ingrowth promotion between cell-implant can be improved by coating with a bioactive surface such as calcium phosphate based material (i.e. hydroxyapatite) [2]. Various methods were introduced in producing calcium phosphate/ hydroxyapatite coating on titanium such as electrochemical deposition [3], sol-gel precipitate [4] and plasma spray coating [5]. High processing temperature in plasma spray easily induced decomposition of hydroxyapatite[6]. Indeed, the biomimetic process is one of the promising techniques for bioactive coating which conducted at the ambient temperature by immersion in simulated body fluid (SBF). This technique has ability in promoting uniform coatings on the porous and complex metal surface.

For optimizing rate of hydroxyapatite coating on the implant surface, pre-treatment of the metal is required to initiate an active surface. Many methods of pre-treatment on titanium surface before immersion into SBF solution has been widely studied, including sandblasting [7], alkali or acid treatment [8,9], heat treatment [10] or in a combination of these three approaches [11]. Nucleation of apatite is observed on alkali-heat treated metal after 4 weeks immersion in SBF which improved surface bioactivity with the formation of alkali titanate layer [12,13]. Chemical surface treatment changed Ti implant surface to form hydrogel layer (alkali titanate layer).

Thus, the present study aimed to explore different Ti metal surface preparations with and without SiC paper abrasion towards the formation of alkali titanate layer.

Materials and Methods

Material and chemical selection

Titanium alloy Ti6Al4V ELI (Ti), ASTM F136, Grade 23 long cylinder rods was cut into a small disc samples with diameter 5.5 mm and thickness of 5mm. Samples received in a mirror-liked polished and were categorized into two (2) groups of as received (*as*-Ti) and treated surface (*ab*-Ti). *ab*-Ti surface were abraded with silicon-carbide (SiC) paper up to #1000 grit. Then, *as*-Ti and *ab*-Ti disc were cleaned in acetone, ethanol and distilled water for 10 minutes each, consecutively in the ultrasonic bath (NEYTech, 208H, USA).

Alkali and heat treatment

Surface modification of alkali-heat treatment was conducted using established method from Krupa et al. [11], Kim et al. [14] and Qu & Wei [15] with some modification. The alkali treatment is a process of surface etching and was performed by soaking both *as*-Ti and *ab*-Ti disc in 50 ml of 200g/L NaOH and 50 ml of 280.53g/L KOH aqueous solution for 24 hours at 60 °C for each group. After 24 hours soaking in a water bath of 60 °C, *as*-Ti and *ab*-Ti discs were then rinsed thoroughly with distilled water and dried overnight at room temperature. Then, *as*-Ti and *ab*-Ti discs were heat-treated at 700 °C for 1 hour dwelling time with the heating rate of 3 °C/min in a CARBOLITE furnace (CARBOLITE, ELF 11/14B, UK) and allowed to cool down in the furnace after the heating process. Surface morphology, crystallinity, topography and wettability of Ti6Al4V were examined and studied using field emission scanning electron microscope (FESEM), X-ray diffraction (XRD), 3D surface metrology and contact angle goniometry, respectively.

Surface characterization

Surface roughness

Roughness of *as*-Ti and *ab*-Ti was analysed using optical 3D surface metrology (Alicona, InfiniteFocus, Austria). 3D surface metrology system operated based on combination of small depth of focus of an optical microscope setting at 5X optical zoom with vertical scanning. The analysis was conducted on the total surface area of Ø5.5mm by setting at 3x3 scan frame. Roughness profile calculated automatically using its software based on a line drew across the 2D image of scan surface. Average roughness measurement was taken from 3 different drew lines.

Surface wettability

The wettability of *as*-Ti and *ab*-Ti was determined using contact angle goniometry (AST Products, Inc, VCA-3000S, Massachusetts USA). The contact angle was measured using distilled water drops at room temperature. The angle was calculated manually from the baseline of surface-water contact. Image of water droplet was captured for measurement at about 15 seconds after delivery by using static sessile drop method. Average of three readings of contact angle was taken from each sample.

Surface morphology

Morphology for all samples of Ti treated was observed by using field emission electron microscope, FESEM **(**Carl Zeiss, *SUPRA* 40VP, Germany). The images were captured at magnification of 1k, 5k and 20k at accelerating voltage of 10kV.

Surface structure

Surface structural changes on Ti6Al4V treated specimen were examined by using X-ray diffraction, XRD (Rigaku, D/Max 2200-PC, Japan). All specimens were analyzed at 2θ angles from 10° to 90° with scan speed of 1° per minute.

Results and Discussion

Surface roughness

The surface roughness of *as*-Ti and *ab*-Ti when treated with NaOH and KOH at ambient and high temperature is illustrated in Figure 1.

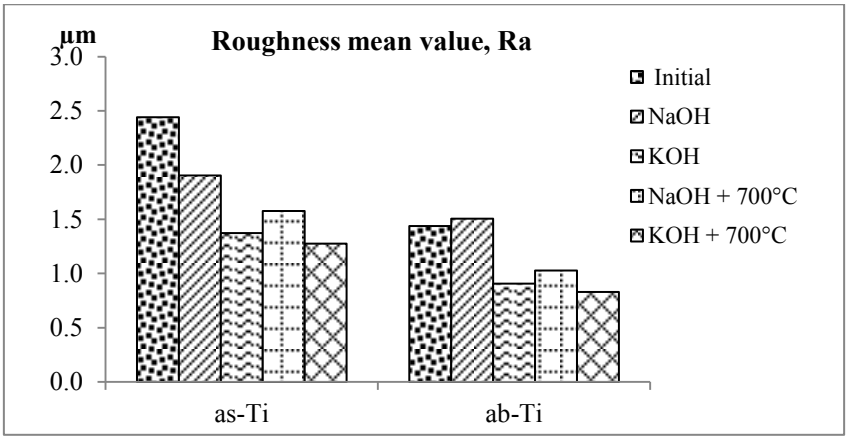

Figure 1. Mean surface roughness of alkali and alkali-heat treated on *as*-Ti and *ab*-Ti

The aim of the analysis is to determine the effect of alkali-heat treated *as*-Ti and *ab*-Ti render the resultant surfaces roughness. The results indicate that the mean value of surface roughness (Ra) on *as*-Ti and *ab*-Ti were 2.44±0.80µm and 1.44±0.40µm, respectively. Abrasion of SiC paper diminished uneven surface on *as*-Ti and lower the surface roughness of *ab-Ti* up to 41%. Initial soaking of *as*-Ti and *ab*-Ti in NaOH gave the Ra value ~0.3-0.5µm greater than Ra in KOH treatment. Alkali treatment leads to the development of submicron- or nano roughness on Ti surface[16] Theoretically, potassium was slightly reactive than sodium. This might cause the outer layer of oxide Ti surface to completely dissolved and activated to form a more homogeneous oxide film. The profile value of the surface roughness changed given a lower value as well. From the Figure 1, the surface roughness of *as*-Ti is decreased after treated with NaOH while it is increased slightly for the case of treating the *ab*-Ti with NaOH. Alkali etching is a process of corroding the surface of Ti. The even surface of *ab*-Ti after abraded with SiC paper was destroyed by NaOH etching process. Hence, Ra value after NaOH treatment is slightly increased. Meanwhile, for the case of *as*-Ti, the rough surface was attacked by NaOH etching reaction that attenuates surface roughness.

ab-Ti that start with lower Ra (1.44±0.40µm) apparently showed value is decreased to 0.83±0.01µm after alkali-heat treated. Heating changed the surface roughness concurrently with the change of surface morphology structure as per in FESEM image (Figure 3 and Figure 4). From the previous studies, a mean surface roughness of 1.38µm and 0.20µm did not differ significantly in the percentage of cell attachment [17]. On the other hand, the effect of SiC paper abrasion on the surface Ti did not show a significant impact in increasing the value of Ra as expected. Therefore, surface roughness value (Ra) range from 1.5µm to 2.0µm is a good start in promoting alkali titanate layer.

Surface wettability

Figure 2 shows the surface wettability study of *as*-Ti and *ab*-Ti. The contact angles of *as*-Ti and *ab*-Ti were 85.05±1.53° and 81.62±2.66°, respectively. A contact angle value indicates the affinity of the Ti surface work towards water molecules. As the contact angle value goes higher, the surface properties become more hydrophobic.

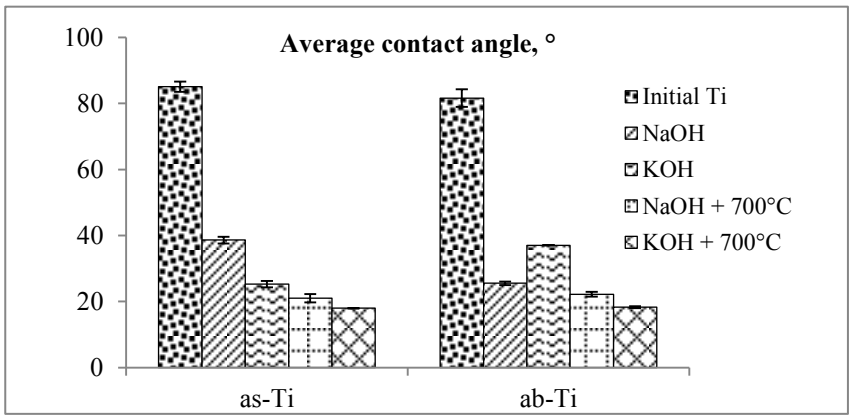

Figure 2. The contact angles measurement of alkali and alkali-heat treated on *as*-Ti and *ab*-Ti

Along the process treatment, *as*-Ti contact angles consistently decreased after alkali-heat treatment. Meanwhile, *ab*-Ti indicates otherwise, which *ab*-Ti after KOH etching is slightly hydrophobic than *as*-Ti with a difference of ~10°. On the other hand, NaOH etching *as*-Ti and *ab*-Ti, the water contact angles drastically reduced to 38.64±1.03° and 25.54±0.53° respectively. A similar result was reported by Zhou et al. [18]. In the case of NaOH etching, higher contact angle of *as*-Ti than *ab*-Ti is due to the presence of inhomogeneous porous network structure in the as-Ti surface (Figure 3b). A large clump cloud-like structure act as a multiscaled roughness of pillars forced the droplet of water to remain in Cassie state which increases the hydrophobicity of *as*-Ti [16]. Meanwhile in a KOH etching case, a porous network structure observed on the surface of *as*-Ti (Figure 3d) which contributed to geometrical air trapping effect due to wetting of hydrophilic pores [19]. Thus, lower the contact angle measurement. Analysis within *as*-Ti group found that KOH etching increased the wettability of the surface with contact angle value of 25.27±0.95° lower than NaOH etching of 38.64±1.03°. Similar results also reported by Kim et al. [16]. Potassium ion has a better reactivity compared to sodium ion. Hence, during the etching process, potassium ion etched and incorporated into the microstructure of passive oxide layer TiO_2 which slightly greater than sodium ion. Moreover, an attraction of hydroxyl group changed the wettability of treated Ti surfaces.

According to the result, chemical and heat treatment result in more hydrophilic surface of *as*-Ti and *ab*-Ti by lowering the contact angle. This can occur due to the reaction on the surface of Ti after chemical-heat treatment that creates the pores which contribute to the hydrophilic structure of Ti. This experiment had not shown obvious differences with the abrasion SiC paper on *as*-Ti surface. According to Rosales-Leal et al., the surface abraded with silicon carbide leaves an excess carbon which potentially modified surface energy[20].

Surface morphology

The surface morphology of *as*-Ti and *ab*-Ti before and after alkali-heat treatment is shown in Figure 3 and Figure 4 respectively. The visible abrasive mark on *ab*-Ti (Figure 4a) was affected the resultant surface structure after NaOH and KOH etching. The formation of porous network structure on *ab*-Ti surface was twice smaller than *as*-Ti. Clearly seen a porous structure on KOH treated at 60 °C with the presence of cloudy dense image (Figure 3d) compared with NaOH etching. However, *ab*-Ti alkali treated had not shown obvious different in morphology structure as shown in Figure 4b and Figure 4d.

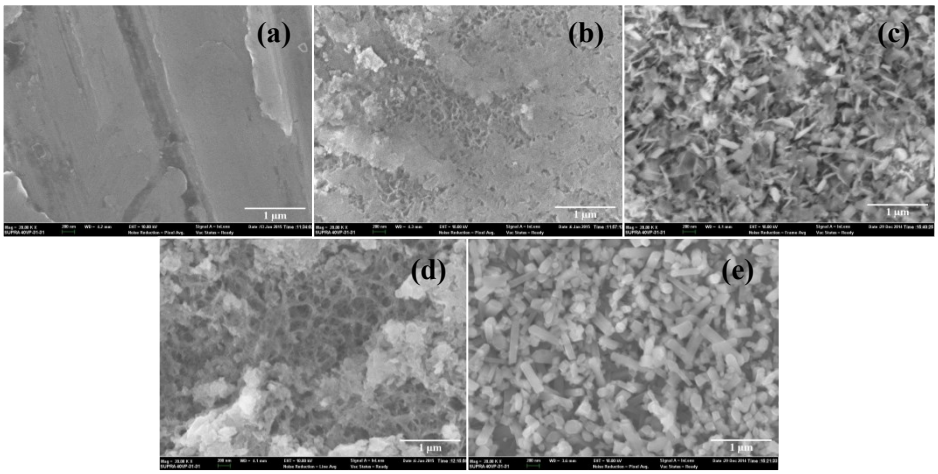

Figure 3. FESEM images at 20k magnification on the surface of *as*-Ti (a), after 5M NaOH-treated (b), after 5M NaOH-heat treated (c), after 5M KOH treated (d) and after 5M KOH-heat treated (e)

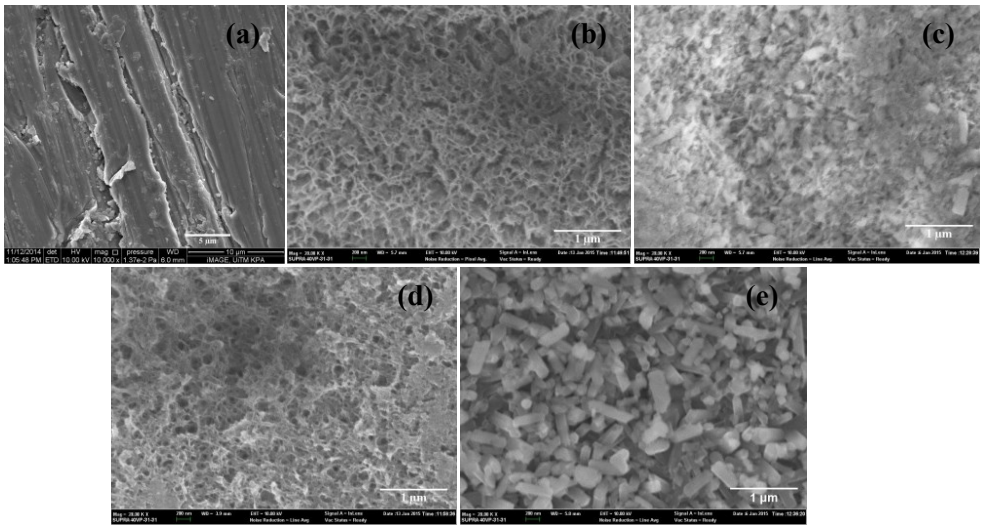

Figure 4. FESEM images at 10k magnification on the surface of *ab*-Ti (a); 20k magnification after 5M NaOH-treated (b), after 5M NaOH-heat treated (c), after 5M KOH treated (d) and after 5M KOH-heat treated (e)

Examination on *as*-Ti and *ab*-Ti surface revealed porous network structure was fully densified to form a homogenous flake-like shape structure (Figure 3c and Figure 4c) on its surface. According to Wei et al., no apatite

formation on the flake-like structure of NaOH-heat treated at 700°C due to heat treatment had changed the surface structure [21]. On the other hand, Ciobanu et al. [22] and Qu & Wei [15] shared similar findings of uniform petal rose-like morphology on Ti surface. Both claimed that petal rose-like structure was HA layer that exhibited on the treated after soaking in modified supersaturated calcification solution (M-SCS) and SBF at medium pH, respectively. Petal rose-like structure of HA coating layer on Ti surface is believe could enhance the osteoinductive and biochemical properties of coating by modification of physical structure [22].

A homogenous rod-like shape structure was observed on heat treated surface after soaking in KOH for 24 hours at 60 °C (Figure 3e and Figure 4e). The porous structure of KOH-treated was fully densified after heat treatment at 700 °C. A potassium hexatitanate ($K_2Ti_6O_{13}$) rod-like structure was observed by Wang et al. [23] and Li et al. [24], which produced from a mixing of potassium carbonate/nitrate and titanium dioxide powder as initial.

Surface structure

Figure 5 and Figure 6 show the XRD patterns of the surfaces of *as*-Ti and *ab*-Ti subjected to heating process at 700°C after soaking in NaOH and KOH, respectively.

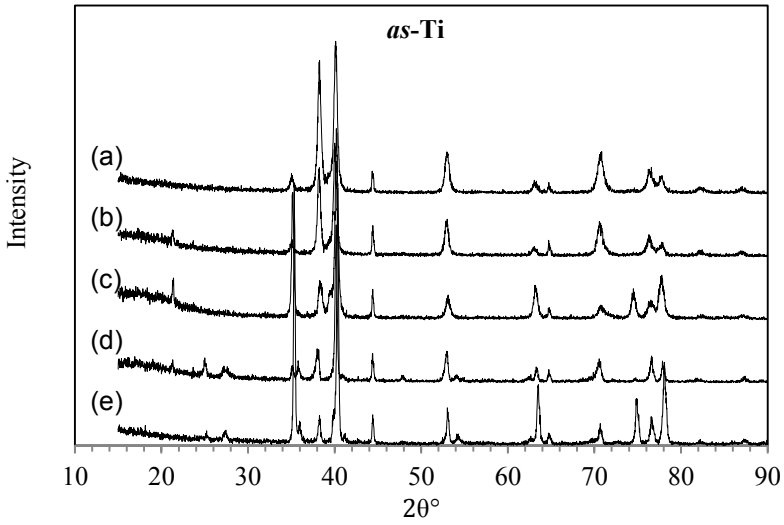

Figure 5. XRD pattern of as-Ti (a); after KOH treated at 60 °C (b); after NaOH treated at 60 °C (c); heat treated after soaking in KOH (d) and heat treated after soaking in NaOH (e)

The aim of XRD analysis is to determine surface structural changes or phase composition present on the treated Ti surface. A small bump was detected around 2θ = 21-22° in Figure 5 (b, c and d) on *as*-Ti. Results indicate a thin layer of either monoclinic phase of potassium titanate ($K_2Ti_6O_{13}$) [24] or sodium titanate ($Na_2Ti_6O_{13}$) depending on alkali solution that *as*-Ti was soaked in. Minor decrease of $K_2Ti_6O_{13}$ or $Na_2Ti_6O_{13}$ peak was hardly observable due to relatively high heating temperature (700 °C). However, neither potassium titanate nor sodium titanate major peak was detectable on *ab*-Ti surface as pattern on in Figure 6.

Meanwhile, at 2θ = 25-28° small amount of rutile (TiO_2) peak were detected for all specimens after heat treated except for *ab*-Ti after soaking in NaOH. These additional peaks indicate that titanium was further oxidized and formed oxide layers with a rutile structure. Other peaks most the same as initial Ti pattern for both *as*-Ti and *ab*-Ti which presenting the peaks of titanium. Intensity different from each treatment due to phase amount and sharp peak indicates phase crystallinity.

During the alkali (KOH/NaOH) etching at 60 °C for 24 hours, the passive oxide layer, TiO_2 partially dissolves into the alkaline solution because of hydroxyl group easily attacked hydrated TiO_2 which will produce negatively charged hydrates on the Ti specimen surface. Negatively charged species easily combined with alkali ions and result

in the formation of alkali titanate hydrogel layer which then densified and dehydrated to form amorphous or crystalline alkali titanate layer after heat treatment [25].

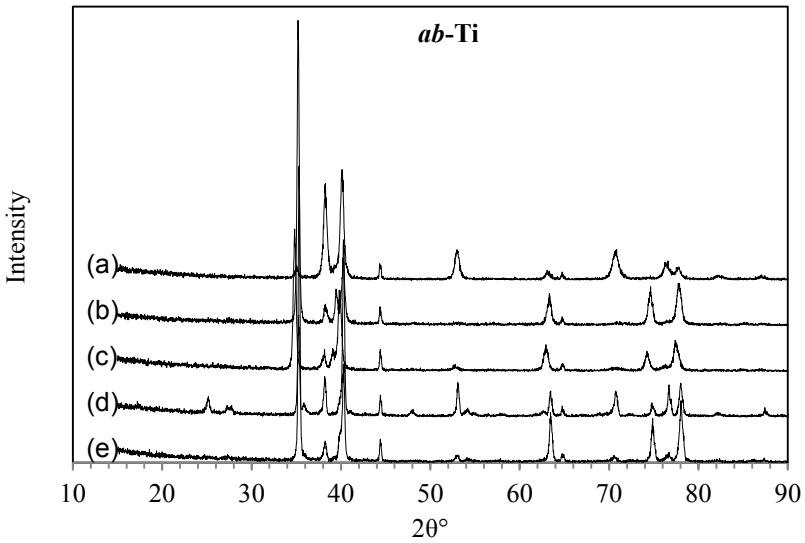

Figure 6. XRD pattern of abraded Ti with SiC paper, as received Ti (a); after KOH treated at 60 °C (b); after NaOH treated at 60 °C (c); heat treated after soaking in KOH (d) and heat treated after soaking in NaOH (e)

Theoretically, Wei et al. [21] claimed that more sodium ions can be released from thicker sodium titanate layer. This leads to easily apatite formation in SBF by increase amount OH^- concentration that release from titanate layer. Hence, further study is suggested to investigate the effect of temperature after alkali treatment on as-Ti.

Conclusion

In this study, roughness, wettability, morphology structure and crystallinity of as-Ti and ab-Ti alkali treated at ambient and 700 °C does not show an obvious different measurement. In fact, as-Ti treated with KOH showed a better porous network structure which is required for good bonding of apatite formation. For the future study, the apatite formation ability on the treated Ti surface in SBF is suggested to be tested.

Acknowledgement

The present study was made possible through a Research Acculturation Grant Scheme by University Technology MARA (600-RMI/RAGS5/3(71/2013)) and also facilities and constant encouragement from Faculty of Chemical Engineering, University Technology MARA is gratefully acknowledged.

Abstract

In this study, the biohydrogen production by microflora of palm oil mill effluent (POME) from glucose and xylose fermentation were investigated. Synthetic medium was prepared based on sugar composition present in POME at 7 g/L of glucose and 3 g/L of xylose was used as substrate carbon source. Prior to optimization, 10% of microflora POME was acclimatized in the synthetic medium with the help of granular activated carbon as their support media until consistent hydrogen percentage at 44 ± 1.7% was obtained. Optimization that was conducted using response surface methodology (RSM) by quadratic model of central composite design was found to give optimum parameters of thermophilic microbial growth at pH 6, temperature 60 °C and 10% (v/v) of sludge percentage. Results obtained for hydrogen productivity (1.32 ± 0.01 mmol H_2/L.h, 32.36 ± 0.75 ml H_2/L.h) and hydrogen yield (1.22 ± 0.10 mol H_2/mol sugar consumed) from an average of experimental data reached small error of different (0.8%, 1.0% and 8.3%) to predicted RSM data at optimum condition respectively. The model provided a useful approach for biohydrogen production by POME microflora sludge by using granular activated carbon as their support media.

Keywords: biohydrogen, thermophilic, palm oil mill effluent, synthetic medium, optimization

Abstrak

Melalui kajian ini, penghasilan biohidrogen oleh mikroflora sisa kilang minyak sawit (POME) dari glukosa dan xilosa penapaian telah dikaji. Media sintetik telah disediakan berdasarkan komposisi gula yang terkandung dalam POME sebanyak 7 g/L glukosa dan 3 g/L xilosa telah digunakan sebagai sumber substrat karbon. Sebelum pengoptimuman dijalankan, 10% daripada mikroflora POME telah disesuaikan dalam media sintetik dengan bantuan karbon berbutir aktif sebagai media sokongan mereka sehingga peratusan hidrogen secara konsisten pada 44 ± 1.7% telah diperolehi. Pengoptimuman yang dijalankan dengan menggunakan kaedah gerak balas permukaan (RSM) oleh model kuadratik reka bentuk komposit berpusat telah mendapati bahawa parameter optimum bagi pertumbuhan mikrob termofilik adalah pada pH 6, suhu 60 °C dan 10% (v/v) peratusan enapcemar. Keputusan yang diperolehi untuk pengeluaran hidrogen (1.32 ± 0.01 mmol H_2/L.h, 32.36 ± 0.75 ml H_2/L.H) dan hasil hidrogen (1.22 ± 0.11 mol H_2/mol gula yang digunakan) oleh nilai purata daripada kajian hanya memperolehi sedikit perbezaan (0.8%, 1.0% dan 8.3%) data perolehan saranan RSM pada keadaan optimum. Model ini telah menyediakan pendekatan yang berguna untuk penghasilan biohidrogen oleh enapcemar mikroflora POME dengan menggunakan karbon aktif berbutir sebagai media sokongan mereka.

Kata kunci: biohidrogen, termofilik, sisa kilang minyak sawit, media sintetik, pengoptimuman

Introduction

Fossil fuels have been broadly used to fulfil the needs of developed and undeveloped nations. Burning of fossil fuel in power generation contributes to major environmental destruction, climate changes, greenhouse gasses, and health problems. Hydrogen has been recommended as a new sustainable energy substitutes to fossil fuels because it is non-polluting to the environment and renewable. It only produces water as by-product when burns. Among the conventional hydrogen production technologies, biological hydrogen production through dark fermentation has received great attention due to its potential as an inexhaustible, economical, and carbon-neutral fuel [1, 2].

In Malaysia, wastewater known as palm oil mill effluent (POME) from oil palm industry is considered as an important renewable biomass energy source because it comprises of a mixture of carbohydrates. The high nutrient content in the biomass makes it as an ideal source of sugar feedstock and potentially to be used as fermentation medium in anaerobic treatment processes [2]. Former reports have utilized POME as a substrate for hydrogen production, however these studies only focused on suspended cell cultures, which are usually ineffective or difficult to be monitored in continuous process. Low cell density and washout of bacteria with effluents may happen from the reactor at shorter hydraulic retention time (HRT) in the suspended process [2, 3].

Considering the low biomass in the suspended systems, employing biofilms would appear to be a better approach since biofilms promote higher biomass density and more resistant to changes in environmental conditions. Support carriers like granular activated carbon (GAC) have been well recognised as a support medium in thermophilic fermentation because it can perform effectively at high working temperatures, has a high surface area and highly porous structure that enable to sustain cell feasibility and colonization density [4].

In the view of above, the current research work aimed to evaluate the viability of thermophilic hydrogen production using GAC in an immobilised attached-biofilm system culture. Hence, in a process of developing the biofilm, environmental parameters such as cultivation temperature, initial pH of the culture medium and microbial inoculums play an important role in determining the optimum conditions for ideal microbial growth. Synthetic media comprised of mimicking sugar composition in POME was developed and used as a fermentation media. The optimization of the operating microbial growth condition is essential to attain the maximum hydrogen productivity and hydrogen yield. Response surface methodology (RSM) is recognise as a numerical method which is used in the formation of an empirical model to evaluate the effects of operating process parameters on the desired responses studied. In this regard, RSM was used to determine the relationship between the responses studied, the necessary controllable input factors and represents a sequence of mathematical practises by giving a model equation in evaluating the thermophilic hydrogen production.

Materials and Methods

Microorganism and medium

Microorganism used in this research study was obtained from mixed culture POME-sludge from the sludge pit at Sime Darby Plantation, West Oill Mill, Pulau Carey, Selangor, Malaysia. The synthetic medium used was slightly modified from [4] and contained (per litre of deionized water): NH_4Cl 1.0 g, NaCl 2.0 g, $MgCl_2.6H_2O$ 0.5 g, $CaCl_2.2H_2O$ 0.05 g, $K_2HPO_4.3H_2O$ 1.5 g, KH_2PO_4 0.75 g, $NaHCO_3$ 2.6 g, yeast extract 2.0 g. The mixed cultures sludge was cultivated in the synthetic medium contained glucose and xylose as the sole carbon and energy source.

Sludge growth conditions

The inoculums were grown in 200 ml working volume provided 10% (v/v) of sludge with 90% (v/v) of synthetic medium in batch cultivation in 250 ml modified Scott Duran. The opening mouth of 250 ml Scott Duran was fabricated by allowing the free flow of gas produced from fermentation medium to gas collection in inverted measuring cylinder which contained HCl solvent (pH 2). The HCl solvent was used to prevent biogas dissolved in the liquid and disappear to environment.

The microbial support carrier used in the cultivation process were granular activated carbon (GAC) with particle size of 2 – 3 mm. The cell attachment were studied by adding 1 to 1 GAC weight (g) to heat treated POME sludge volume (ml) ratio as a support media for the inoculum sludge in the serum bottle. The pH of the cultures initially

was adjusted to pH 6 and they were cultivated in a water bath shaker at a temperature of 60 °C and 200 rpm for 48 hours cultivation at 43±2% H_2 gas percentage (OD 0.7 – 0.8 at 600 nm).

Optimization in serum bottles

The optimization of growth parameters at thermophilic condition was designed based on response surface methodology by using Design Expert version 6.0.6. Central composite design was used to optimize the manipulating factors. A total of 20 experiments need to be carried out based on the 3 selected growth parameters namely pH, temperature (°C), and sludge composition (v/v) and resulting to hydrogen productivity rate, HPR (mmol H_2/L.h and ml H_2/L.h) and the hydrogen yield (mol H_2/mol substrate consumed) as the outcomes responses. pH and temperature are one of the most important factors to be regulated in anaerobic digestion processes [5,6].

The optimum conditions were predicted using quadratic equation. Experiments were conducted in triplicates after the optimize parameters were obtained. Analyses of variances (ANOVA) was used as the chosen model to analysis the results obtained and generating the 3D plots. The center line of pH 6, temperature 60 °C and sludge percentage 10(%) was chosen based on thermophilic hydrogen production from sucrose fermentation [4].

The optimization experiments were conducted using 50 ml working volume in 100 ml anaerobic crimped-seal bottles with subsequent flushing of the headspace with nitrogen gas for 1 L/h to create an anaerobic condition. The fermentation was carried out in a water bath shaker by adjusting the temperature according to desire experimental temperature. Samples were analyzed at every 5 hours interval until stationary phase of growth profile was obtained and the cumulative hydrogen productivity was calculated.

Analysis of hydrogen production

Biogas productions were analyzed for CO_2 and H_2 by gas chromatography, using (GC, model SRI 8600C, USA) consist with two detectors, helium ionization detector (HID) and the thermal conductivity detector (TCD). Highly purity helium gas (MOX 99.99%) was used as carrier gas at 25 ml/min. The samples gases were injected to the GC using a gas-tight syringe (0.5 ml injection volume) at 43 °C temperature and pressure 2.7 psi initially and followed by a ramping of 30 °C per minute and been hold for 10 min once the temperature reached 220 °C.

A modified Gompertz equation was performed to quantify the cumulative hydrogen production in the batch experiment by using Matlab 7.9.0 (R2009b). Theoretically, the modified Gompertz equation used in this research was expressed as equation 1 below [5]:

$$Ht = Hm.\exp\{-\exp[(Rm.e/Hm)(\lambda-t)+1]\} \quad (1)$$

where Ht is the cumulative hydrogen production (ml), Hm is the maximum hydrogen production (ml), Rm is the maximum hydrogen production rate (ml/h), e is euler number, λ is the lag phase time (h), and t is the incubation time (h). In this study, the data presented also considered the cumulative of total biogas to compare with the cumulative hydrogen production. Therefore the modified Gompertz was also applied to quantify the total biogas production.

Determination of sugar concentration

Samples were prepared by filtration through a 0.22 µm syringe filter in vials tube and sugar concentration and the soluble volatile fatty acids (VFAs) were quantified by HPLC analysis using an Agilent 1200 HPLC system (California, USA) with a REZEX ROA column (Phenomenex, USA) equipped with a refractive index detector (RID). The mobile phase used was 5 mM H_2SO_4 at a constant 0.6 mL min^{-1} at room temperature. Standard curves of every peak detection were generated at different concentration until straight line R squared was obtained.

Yield and productivity

The amount of sugars consumed and the hydrogen productions obtained were used to calculate the hydrogen yields and the productivity. Yields were expressed as moles of hydrogen per moles of sugar consumed. The VTAs production were used to quantify the capability of the microorganism to reach highest theoretical yields. The maximal volumetric hydrogen productivity was calculated based on the highest percentage of hydrogen gas obtained during the exponential phase of the growth profile in the batch fermentation.

FESEM microbial morphology

The view image of the cell that attached on the surface of GAC after conducting the experimental model validation was further observed with Field Emission Scanning Electron Microscopy (FESEM). The GAC samples were prepared using a Critical Point Dryer (Model Leica EM CPD 300, Leica Microsystems, Germany) for 1 hour and 30 minute prior to be viewed with the FESEM. An amount of 4% glutaraldehyde was used to fix the samples of GAC-attached biofilm for 12 − 24 hours at 4 °C. The samples were then washed with 0.1 M phosphate buffer solution three times per ten minutes each. A series of alcohol dilutions at 30, 50, 70, 80, 90, and 100% (w/w) alcohol were used to dehydrate the samples. The dehydrated samples were then transferred to the CPD and were sputter-coated with platinum before being analyzed with FESEM.

Results and Discussion

Optimization of biohydrogen production

Results of manipulating the selected key factors used during fermentation process towards the hydrogen productivity and yield for each experimental condition produced was shown in Table 1. Based from the experimental conditions shown in Table 1, the hydrogen productivity range from 0.01 to 1.70 mmol H_2/L.h, 0.14 to 41.69 ml H_2/L.h and the hydrogen yield range from 0.06 to 1.61 mol H_2/mol substrate consumed. Results obtained shown the variation of hydrogen production under similar fermentation conditions but with different variable parameters (pH, temperature and sludge percentage) were indicated the importance of each selected parameter on the thermophilic fermentative hydrogen production.

Table 1. Numeric factors of experimental designs with three independent variables and hydrogen productivity and hydrogen yield

17	6.00	51.59	10.00	0.03	0.85	0.06
18	6.50	55.00	5.00	0.86	20.98	0.82
19	6.50	65.00	5.00	0.18	4.38	0.48
20	5.50	55.00	15.00	0.55	13.50	0.77

The predicted responses at centre point at pH 6, temperature 60 °C and sludge percentage 10(v/v) were 1.32 ± 0.23 mmol H_2/L.h, 32.32 ± 5.61 ml H_2/L.h and 1.33±0.15 mol H_2/mol substrate consumed (total of glucose and xylose consumed). The responses as a function of three independent factors are shown in the regression equation after performing the analysis of variances. The quadratic polynomial relating the factors and the responses are shown as equation 2, 3, 4, respectively.
HPR (mmol H_2/L.h):

$$1.31 + 0.12A – 0.08B + 0.01C – 0.32A2 – 0.36B2 – 0.32C2 + 0.15AB +0.04AC + 0.19BC \quad (2)$$

HPR (ml H_2/L.h):

$$32.05 + 2.97A – 1.90B + 0.28C – 7.80A2 – 8.86B2 – 7.90C2 + 3.65AB + 0.97AC + 4.59BC. \quad (3)$$

Hydrogen yield (mol H_2/mol substrate consumed):

$$1.33 + 0.13A – 0.03B + 0.10C – 0.28A2 – 0.34B2 – 0.15C2 + 0.14AB - 0.01AC + 0.14BC \quad (4)$$

where A is the pH, B is the temperature (°C) and C is the sludge percentage (v/v).

Statistical analysis (ANOVA)
An analysis of variance (ANOVA) was conducted to investigate the significance of fit for the quadratic model based on experimental data Table 2 and 3, respectively. The p-value was used to investigate the significance of each coefficient and the degree of interaction between each of the independent factors studied. The independent variables of selected factors are more significant with greater F-value and small p-value [7]. From analysis of ANOVA for response data of hydrogen productivity (mmol H_2/L.h) as summarize in Table 2, the model F-value of 5.76 implies the model was significant. There was only a 0.57% chance that a model F-value this large could occur due to noise. Values of Prob > F of 0.0057 less than 0.05 indicated model terms were significant. The lack of fit F-value of 2.53 implies the lack of fit is not significant relative to the pure error. There is a 16.55% chance that a lack of fit F-value this large could occur due to noise.

For hydrogen yield response, statistical ANOVA was shown that the model F-value of 8.19 implies the model was significant (Table 3). There was only a 0.14% chance that a model F-value this large could occur due to noise. Values of Prob > F of 0.0014 was shown less than 0.0500 indicated model terms were significant. The lack of fit F-value of 2.87 implies the lack of fit is not significant relative to the pure error. There is a 9.56% chance that a lack of fit F-value this large could occur due to noise. The model terms with p-value greater than 0.10 indicate they are insignificant. The large F-value clearly suggest that the variance in the response can be explained by the regression equation [8].

Effect of selected factors on response variables

3D plots are a useful approach in interpreting the response surface. Each 3D plot represent the effect of two independent variables at an optimum level at which the third variable was maintained as constant value. The 3D plot shape indicates whether the mutual interaction between the variables are significant or insignificant. Figure 1 shows the effect between two variables at which the third variable was constant. 3D plots are estimates and if data from repeated experiments were used in the same design, the response of the exchange will change to some extent [9,10].

Figure 2. 3D plots for different experimental conditions. H_2 yield (mol H_2/mol substrate consumed) as a function of (a) pH and temperature, (b) pH and sludge percentage, and (c) temperature and sludge percentage

Validation of the models

Three experimental replications from suggested optimum condition by RSM (pH 6, temperature 60 °C and sludge percentage 10% (v/v)) were conducted to confirm the model validity. From the RSM, the estimated responses of the hydrogen productivity and yield were 1.31 mmol H_2/L.h, 32.04 ml H_2/L.h and 1.33 mol H_2/mol sugar consumed in batch fermentation experiments respectively.

The actual experimental data obtained was tabulated in Table 4. From experimental data, the hydrogen productivity of 1.32 ± 0.01 mmol H_2/L.h obtained in this study was comparable to the predicted data by RSM with only up to 0.76% error of differences. Change in unit of productivity to ml H_2/L.h would not give much different of error compare in unit of mmol H_2/L.h. For yield of hydrogen, 4.4% error of different between the experimental of 1.27 ± 0.11 to predicted data by RSM of 1.33 (mol H_2/mol sugar consumed). Experimental data obtained was also analyzed by modified Gompertz equation as tabulated in Table 4.

Table 4. Confirmation of model validity based from optimum condition predicted by RSM

Model experiment	**Hydrogen**			**Modified Gomertz equation parameter values for H_2 production (per working volume)**		
	Productivity		**Yield**	**Hm**	**Rm**	**λ**
	mmol H_2/L.h	**ml H_2/L.h**	**mol H_2/ mol sugar**	**ml**	**ml/h**	**h**
Predicted Value	1.31	32.04	1.33	-	-	-
Experimental Value	1.32 ± 0.01	32.36 ± 0.75	1.22 ± 0.10	44.17 ± 10.31	3.31 ± 0.39	4.90 ± 0.31
Error (%)	0.8	1.0	8.3	-	-	-

From the statistical quality of modified Gompertz equation, biohydrogen production from experimental data (R^2 = 0.982), it could be inferred that the predicted result are in good agreement with the experimental data. The maximum hydrogen production of 44.17 ± 10.31 ml H_2 and the hydrogen production rate based on the Gompertz equation was 3.31 ± 0.39 ml H_2/h with lag phase of 4.90 ± 0.31h has explained that at optimum condition of thermophilic fermentative hydrogen production, the hydrogen production rate obtained was capable to reach high hydrogen production rate.

Graph of cumulative biohydrogen and biogas production (ml) over fermentation time (hour) were plotted in Figure 3 by using Matlab 7.9.0 (R2009b). 42.0 ± 1.6% of hydrogen gas obtained (44.17 ± 10.31 ml) from total biogas produced (105.0 ± 20.81 ml).

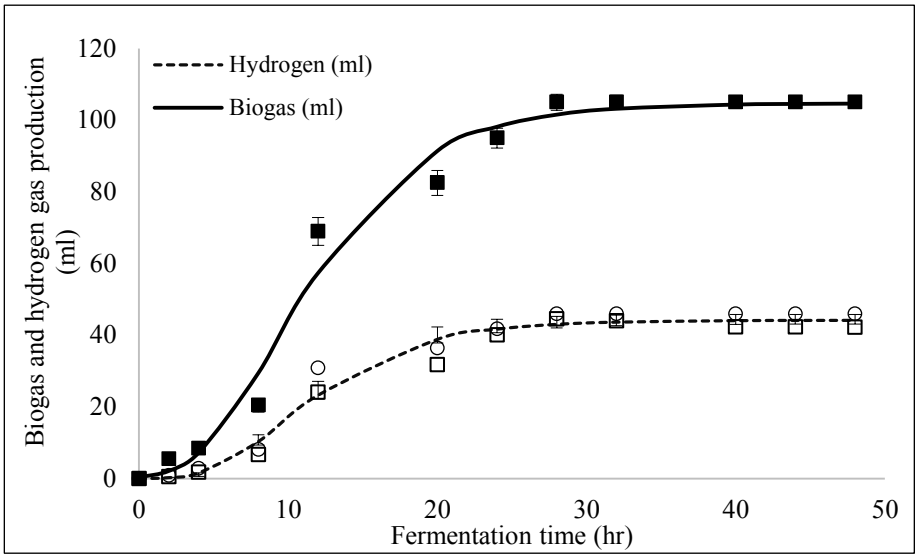

Figure 3. Hydrogen and biogas production (ml) examined by using modified Gompertz equation

FESEM images

The images of microbial cell culture were further observed under Field Emission Scanning Electron Microscope (FESEM). Figure 4(a) represents clean GAC meanwhile 4(b) shows the image of attached cell on GAC after cultural at optimum conditions obtained from the RSM. Figure 4(a) shows that the porosity of clean GAC were acted as suitable place for sludge to self-attach in the pore provided thus forming high density of microbial population, while the images of 4(b) shows that the cells have been successfully adhered on the GAC surface, forming a biofilm attached cell. Immobilisation by adhesion through self-attachment of microorganism and activated carbon is noticeably enhanced cultural cell density at thermophilic operating condition. The GAC provide a structural template directing cell growth and prominent to increase hydrogen production performance compared to suspended culture [11, 12].

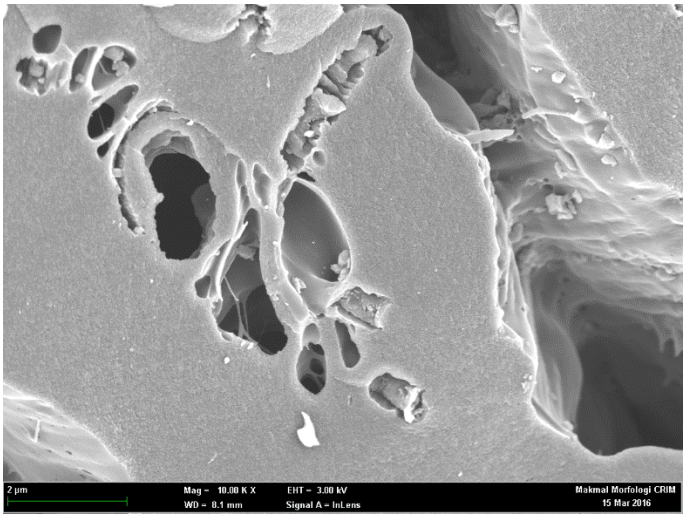

Figure 4(a). FESEM image of clean GAC in the cultural medium at 10.00k x magnification

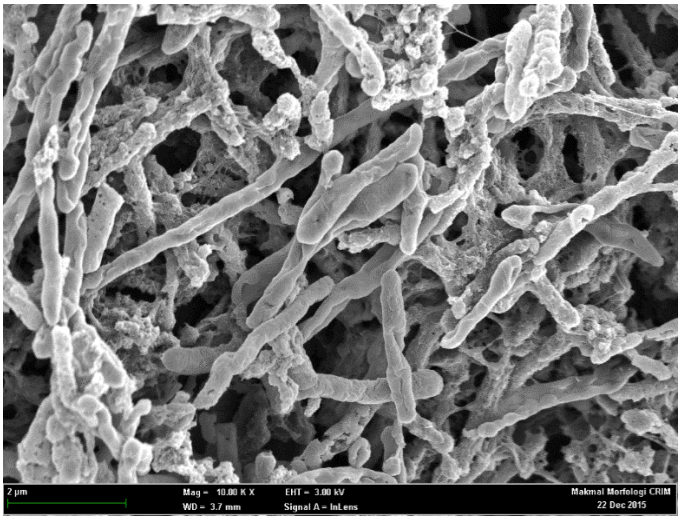

Figure 4(b). FESEM image of attached cell on micro-pores GAC in the cultural medium at 10.00k x magnification

Conclusion

The present study emphasize the mutual effects of the selected parameters in thermophilic biohydrogen production. In this study, the optimum condition obtained from the selected growth parameters were identified to reach optimum through experimental data. The experimental data obtained for hydrogen productivity was 1.48 ± 0.27 in mmol H2/L.h, 36.14 ± 6.65 in ml H2/L.h, and hydrogen yield 1.27 ± 0.11 mol H2/mol sugar consumed at pH 6, temperature 60°C and sludge percentage 10% with error of different 11.3, 11.3 and 4.4% from estimated data by RSM respectively. Under high temperature at thermophilic condition, the hydrogen community producer become energetically favorable and hydrogen consuming reactions become less favorable. The quadratic design model from initial central composite design based on RSM for selected parameters and responses factors were significant to each other. The model provided a useful approach for biohydrogen production by POME microflora sludge by using granular activated carbon as their support media.

Abstract

Disposal of food waste either by land-filling or incineration will cause environmental pollution and engaged in high treatment cost. Composting can be a viable food waste management, however, less research works have focused on the degradation of small scale kitchen waste. In this study, co-composting of model kitchen waste, dried leaves and rice bran were inoculated with four different sources of microbial inoculants (MI) namely commercial Effective Microorganism (EM), *Tempeh*, *Tapai*, a mixture of *Tempeh* and *Tapai* and water as a control. It was found that the temperature of all four composting materials with MI can be heated up to a higher temperature (>50 ^{o}C) than the control and produced less offensive smells. All composts ended with a neutral or weakly alkaline pH value (pH 7 – 8) and a C:N ratio of around 10 which indicating the maturation of composts. For enzymatic activities, the highest activity of amylase (73 – 129 U/g) and cellulase (75 – 148 U/g) occurred at the beginning of the composting process. The maximum activities of lipase (5 – 10 U/g) and protease (46 – 72 U/g) were at the middle stage of the composting process. The germination indexes of the five composts were larger than 100% indicating non-phytotoxic. Although the temperature profile and odour performance were outstanding in the presence of MI, most other parameters did not show significant differences when co-compositing of small scale model kitchen waste was carried out with an adequate initial C:N ratio and moisture content. Further study is needed to distinguish the potential beneficiary effects of MI for the composting of kitchen waste. Nevertheless, the comparable performance of *Tempeh* and *Tapai* with EM in composting suggested that *Tempeh* and *Tapai* can be used to substitute the function of EM as a cheaper and more available microbial source for the household.

Keywords: composting, kitchen waste, effective microorganisms, *tempeh*, *tapai*

Abstrak

Pelupusan sisa makanan sama ada di tapak pelupusan atau pembakaran akan menyebabkan pencemaran alam sekitar dan menglibatkan kos rawatan yang tinggi. Pengkomposan merupakan cara pengurusan sisa makanan yang berpotensi tetapi kerja penyelidikan terkini kurang memberi tumpuan kepada degradasi sisa dapur yang berskala kecil. Melalui kajian ini, sisa model dapur, daun kering dan dedak padi telah dirawat dengan empat sumber mikrob yang berbeza iaitu komersial Mikroorganisma Efektif (EM), Tempeh, Tapai, campuran Tempeh dan Tapai dan air sebagai kawalan. Didapati bahawa suhu keempat – empat bahan kompos yang dirawat dengan inokulan mikrob boleh mencapai suhu yang lebih tinggi (>50 ^{o}C) berbanding kawalan dan menghasilkan bau yang kurang busuk. Semua kompos telah berakhir dengan nilai pH yang neutral atau beralkali lemah (pH 7-8) dengan nisbah C:N lebih kurang 10 yang menunjukkan kematangan kompos. Untuk aktiviti enzim, aktiviti tertinggi amilase (73 – 129 U/g) dan selulase (75 – 148 U/g) berlaku pada awal proses pengkomposan. Manakala, aktiviti maksimum lipase (5 – 10 U/g) dan protease (46 – 72 U/g) berada di peringkat pertengahan proses pengkomposan. Indeks percambahan kelima-

lima kompos adalah lebih besar daripada 100% menunjukkan ketiadaan fitotoksik. Walaupun profil suhu dan prestasi bau adalah cemerlang, inokulan mikrob tidak menunjukkan keperluannya dari segi aspek – aspek lain. Keperluan inokulan mikrob dalam proses pengkomposan sisa dapur perlu ditentusahkan secara lebih mendalam dengan analisis yang lain. Walau bagaimanapun, prestasi inokulasi yang disediakan daripada tempeh dan tapai adalah setanding dengan EM. Ini mencadangkan bahawa ia boleh menggantikan EM sebagai sumber yang lebih murah dan lebih tersedia kepada rumah tangga.

Introduction

Malaysia has implemented mandatory separation of waste at source starting from September 2015 [1]. Households are required to separate their solid waste before disposal. This action was critical to support effective waste management in order to minimize the management cost, environment pollution and to converse energy. Landfilling and incineration are not suitable for the disposal of kitchen waste as kitchen waste contains high moisture and organic matter contents. Pay-as-you-throw food waste policy as implemented in other countries such as in the Northern Europe, Japan and Korea is a best practice to encourage food waste reducing and recycling. Composting provides an alternative way to convert organic waste into useable and saleable compost. Composting can be a lengthy process and with the possibility of producing immature or low-quality compost when the composting techniques are sub-optimal.

There are two extreme opinions on the uses of microbial inoculants (MI) during composting. Some of them stated that MI is able to increase enzymatic activities [2,3], promote biodegradation of organic matter [4,5] and accelerate the process [4,6]. In contrast, part of them suggests that microbial community naturally present in the waste is able to carry out the degradation satisfactorily when optimum environmental conditions were given [7, 8,9]. In this study, co-composting of model kitchen waste, rice bran and dried leaves in the total size of 4 kg under five different treatments were used to study the necessity and effect of MI for composting. Four MI were tested, namely, the commercial Effective Microorganism^{TM} and three formulations of MI prepared accordingly to the concept of Takakura method [10] using locally available fermented food namely *Tempeh*, *Tapai*, and a mixture of *Tempeh* and *Tapai* where water was used as the control. Various parameters including temperature, moisture content, pH value, C: N ratio, odour performance as well as four enzymatic assays were monitored along the composting process and the resultant compost was evaluated by germination test.

Materials and Methods

Preparation of microbial inoculants (MI)

The microbial inoculants (MI) from *Tempeh* and *Tapai* were prepared as followed: An amount 200 g of brown sugar was dissolved in 3 L of distilled water and autoclaved at 121 ^{o}C for 15 min. Next, 100 g of *Tempeh* and 100 g of *Tapai* was separately added into two 5 L containers each of which contained 3 L of brown sugar solution to produce the respective MI for *Tempeh* and *Tapai*. The containers were placed in room temperature at a static condition for 2 – 3 days until the optical density reading was 0.7 at 545 nm with the appearance of sweet and sour smells and a layer of mold which is an indicator of success fermentation as stated by Takakura [10, 11]. The commercial MI Effective Microorganism^{TM} (EMRO Malaysia Sdn Bhd, Johor, Malaysia) was activated according to the user manual where one part of EM stock was mixed with one part of molasses and twenty part of water for 5 – 7 days until the pH was below 3.5.

Composting of kitchen waste

Composting was carried out in plastic bins under static condition. Aeration of these passively aerated composting was improved with the use of shredded dried leaves as bulking agents, the breathable fabric was used to cover the plastic bin and controlled turning was conducted manually once in a week instead of using an air pump or blower. Each composting bin consists of a total of 4 kg composting materials (2 kg kitchen waste, 1 kg dried leaves,1 kg rice brain) with the initial C:N of around 25:1. Each bin was mixed with different compositions of microbial inoculants (MI) to prepare five composts (Te, Ta, Te+Ta, EM and water as a control) as summarized in Table 1. The model kitchen waste was prepared according to Hafid et al. [12]. The dried leave collected from the landscape within the campus of Universiti Teknologi Malaysia (UTM) was autoclaved before being mixed with the model kitchen waste and the rice bran as purchased from Syarikat Faiza Sdn. Bhd, Batu Pahat, Malaysia.

Each composting material (4 kg) as stated above was mixed with 1.2 L of MI or water (for control) to achieve the acceptable level of initial moisture content between 40 – 60% using the squeeze test [13]. The moisture content of the compost was also monitored weekly based on the dry oven method at 105 ^{o}C for 24 hours [14]. The initial C:N ratio and the moisture content along the composting process were fixed within the suggested range for efficient composting [15].

Table 1. Composition of composting materials

Compost	Composition
Te	Composting material + MI (1.2 L *Tempeh* solution)
Ta	Composting material + MI (1.2 L *Tapai* solution)
Te+Ta	Composting material + MI (0.6 L *Tempeh* solution and 0.6 L *Tapai* solution)
EM	Composting material + MI (1.2 L commercial EM)
Wa (Control)	Composting material + 1.2 L distilled water

Physico-chemical analysis

The temperature of compost was determined daily using thermometer where three-points were measured at 50% depth [9]. Odour performance was examined by smelling [16]. Simple random sampling method [17] was used to obtained representative samples for laboratory analysis where five sub-samples [18] with a total weight of 50 – 70 g was selected. pH values were indicated using SI Analytics Handylab 680FK with the extraction ratio of 1 g of composts in 5 ml of distilled water [19]. For C:N ratio, it was firstly dried at 60 ^{o}C, ground and analyzed using CHNS/O elemental analyzer [6].

Phytotoxicity was evaluated by the effects on seed germination and root growth of aqueous compost extracts prepared from 1.5 g of solid (dry basis) with 15 ml of distilled water (1:10), shaked for one hour at room temperature before centrifuged for 20 min at 5000 rpm. The supernatant was filtered and 5 ml of extract was placed in a Petri dish with 10 radish seeds. Two replicates per sample were incubated at room temperature in dark condition for 72 h. A control test was prepared with distilled water. The number of germinated seeds and their root length was measured. The relative seed germination (RSG), relative root elongation (RRE) and germination index (GI) were calculated using the formulation (equation 1 – 3) as follow [6]:

$$\text{RSG}\ (\%) = \frac{\text{number of seeds germinated in the aqueous extract}}{\text{number of seeds germinated in control}} \times 100\% \quad (1)$$

$$\text{RRE}\ (\%) = \frac{\text{mean root length in the aqueous extract}}{\text{mean root length in control}} \times 100\% \quad (2)$$

$$\text{GI}\ (\%) = \frac{\text{RSG} \times \text{RRE}}{100} \quad (3)$$

Biological analysis

Enzymatic activities were evaluated weekly during the composting process. Amylase, cellulose, protease and lipase activity of all the five samples was determined using aqueous compost extracts extracted using different buffer solution. Amylase activity was evaluated using 1.1% w/v soluble starch as substrate [20]. The colorimetric determination of reducing sugar released from 2% w/v carboxymethyl cellulose was used to estimate the cellulase activity [21]. Glucose was used as a standard substrate for both assays. Protease activity was quantified using 0.65% casein as substrate and tyrosine as standard [22]. Lipase activity was analyzed using 10 µL of *p*-nitrophenyl butyrate as substrate and nitrophenol as standard [23]**.** All measurements were performed in duplicates and calculated in the unit of micrograms per minute per grams (U/g).

Results and Discussion

Temperature

The change of temperature during the composting process indicated the change of microbes in the composts. The high temperature is the results of the accumulation of microbial metabolic warmth and indicating the occurrence of degradation where organic matter was being transformed. Composting is required to go through a thermophilic phase to ensure the safety of compost from pathogens [24]. According to Sundberg et al., thermophilic temperatures are approximately from 45 to 70 ^{o}C [25]. It was found that the temperature of all four composting materials with microbial inoculants (MI) can be heated up higher (>50 ^{o}C) than the control as shown in Figure 1.

The control (composting materials without MI) was not heated up to 45 ^{o}C for at least three days continuously. The maximum temperature was 46 ^{o}C and appeared for only two days. This was probably that the compost contained less diverse communities of microorganisms compared to the inoculated composting materials [9,26]. The composting materials with MI produced from fermented food performed better than those inoculated with EM as their temperature rose higher and continued for a longer period. Among all, Te+Ta shows the best temperature profile. It has a longer thermophilic phase which has continued for 8 days and was heated up to 52 ^{o}C.

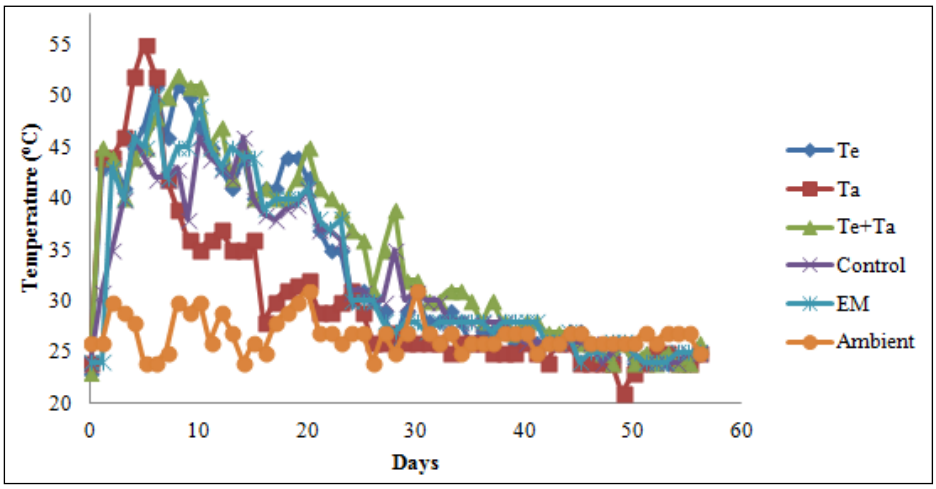

Figure 1. Temperature profile of the composting materials

In this study, the temperatures of the five composting materials started to enter cooling phase after 3 weeks of composting. This suggests that the maturation and stabilization of organic matter have been reached. However, the drop in temperature can be due to the lost of composts volume and lead to insufficient self-insulation as the composting scale in this study was initially undersized [26]. Consequently, it makes the use of temperature for predicting maturation less effective. Therefore, the temperature profile is employed together with other additional parameters to further determine the maturity and stability of composts. The ambient temperatures were ranged between 24 to 31°C during the composting process.

pH value and odour

After 8 weeks, the pH values of all composts were approximately at neutral (7 – 8) as shown in Figure 2 which indicating the stability of organic matter [27]. There were no significant different ($p > 0.05$) between the compost with and without microbial inoculants (MI) in term of pH. According to the pH profile, all of the five composting materials were no longer acidic in week 3.

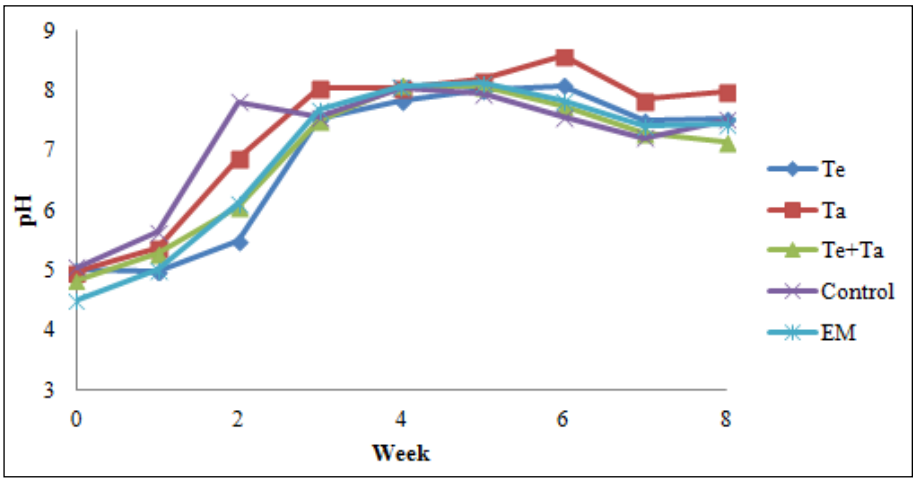

Figure 2. pH profile of the composting materials

In contrast, there are notable differences in term of the odour of the composts. Table 2 shows the summary of odour produced during the composting. The unpleasant smell of the composting materials decreased with time [16]. MI successfully suppressed the growth of bad microbes that contributed to foul smell by week 3. By comparison, control set produced very unpleasant smells which were pungent on week 1 and 2. These results correlate with the pH profiles where the pH values were higher than the others in the control samples. According to Miller et al., high pH leads to the loss of N through ammonia volatilization that was associated with the odour problem [28]. Besides, composts with MI produced earthy smells faster than the control. Among the compost treated with MI, Te+Ta produced earthy smell in the shortest time which was on week 4.

Table 2. Odour performance of composting materials

Week/ Sample	Te	Ta	Te + Ta	Control	EM
0	+++	+++	+++	+++	+++
1	++	++	++	++	++
2	++	++	++	+	++
3	+++	+++	+++	+	+++
4	++++	++++	+++	++	+++
5	++++	++++	+++	+++	++++
6	++++	++++	++++	+++	++++
7	++++	++++	++++	++++	++++
8	++++	++++	++++	++++	++++

+ very unpleasant, ++ moderate unpleasant, +++ odourless, ++++ earthy

C:N ratio

Figure 3 shows the changes of C:N ratio. For all samples including for the control, the C:N ratio decreased significantly with time and stabilized on week 2 which means that significant degree of degradation took place in

the first 3 weeks. C:N ratio decreased as the carbon content in the compost valorised as carbon dioxide along the composting process. Although nitrogen might lose due to volatilization, it does not contribute to the increase of C:N ratio as the decrease of carbon is more markedly during the composting process. The values of C:N for all of the composts in week 8 was less than 10, indicating the approaching of the mature stage [29]. The C:N ratio of about 10 is the ideal ratio for well-matured compost [30] but as C:N ratio was highly depending on the initial and type of feedstock used, two or more parameters are needed to verify the maturity of compost. There was no significant different ($p > 0.05$) between the compost with and without microbial inoculants (MI) in term of C: N ratio. These phenomena might have suggested that the degradation rate was similar in all cases.

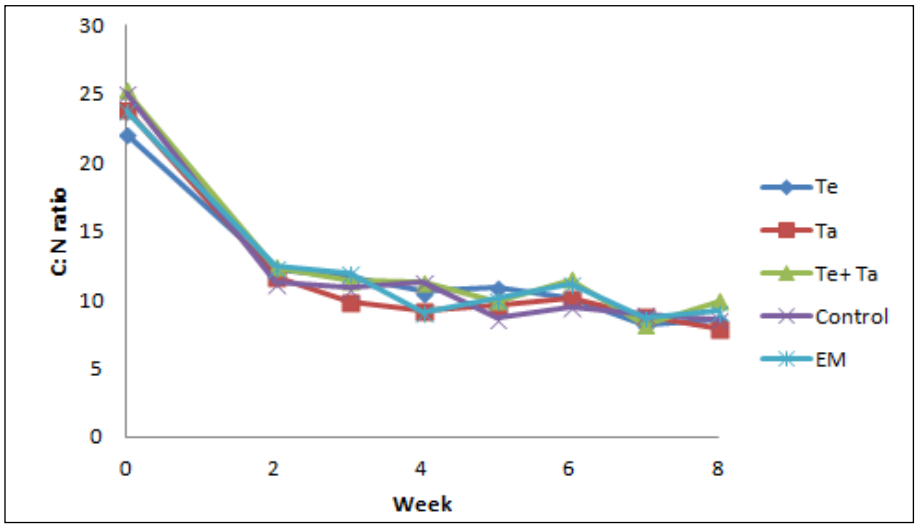

Figure 3. Changes of C: N ratio during the composting process

Enzymatic assays

Enzymes are the main mediators of degradation process and they control the degradation rates of different substrate [16]. Measurement of enzymatic activities illustrates the enzymes which participate in the bioconversion of the composting materials. In this study amylase, cellulase, lipase and protease were measured during composting due to the possible available inducers in the composting materials. The enzymatic assays (amylase, cellulose, lipase and protease) for all composts, namely Te, Ta, Te+Ta, EM and Wa (control), showed a similar ending trend as shown in Figure 4 to 7. The lower activity during the end phase indicated the completion of decomposition process [11]. The cellulase and protease activity decreased and stabilized on week 3 while amylase, lipase was on week 4 and 5, respectively. Figure 4 to 7 are plotted using the average values from the duplicated test.

Referring to Figure 4, the highest activity of amylase occurred at the beginning of the composting process and decreased gradually until a stabilized level. This trend was similar to the finding by Ismail et al., the high activity at the beginning could be due to the starchy materials available in the kitchen waste which was easier to be degraded [16].

Cellulose activity also has an analogous trend with amylase, the maximum activity occurred at the beginning as shown in Figure 5. These findings agree with the result that has been stated by Gómez-Brandón et al. in the composting of cattle manure where the cellulase activity was low during the active and maturation stage [31]. However, the decline shown in the cellulase activity was sharper than that for the amylase activity. This was most probably due to the limited substrate (cellulose) in the composting materials.

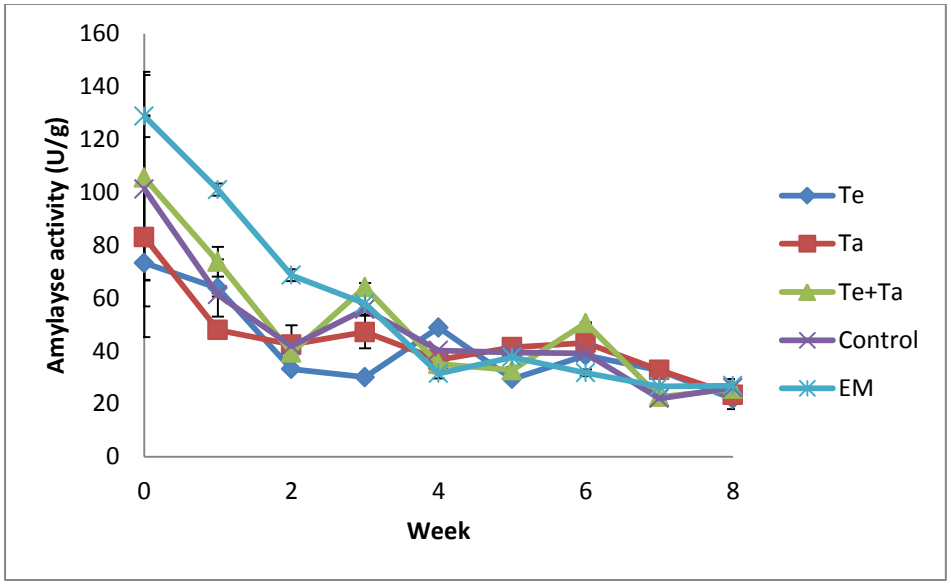

Figure 4. Amylase activity of composting materials

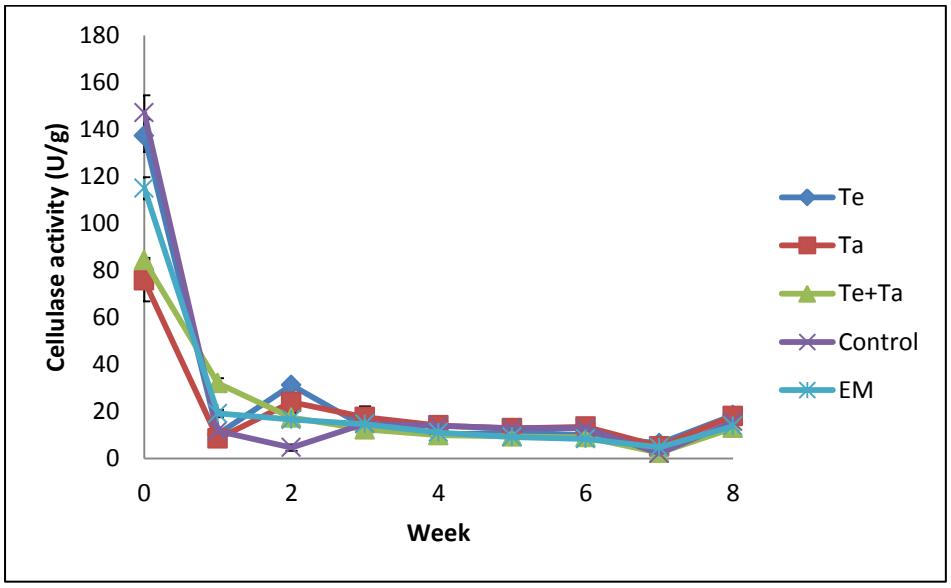

Figure 5. Cellulase activity of composting materials

The composting material used in this study was made up of kitchen waste, rice bran and dried leaves. These materials contained recalcitrant carbon due to the present of lignin. Lignin minimizes the accessibility of cellulose to microbial enzymes. Rice bran contains 27% cellulose, 37% hemicellulose, 5% lignin [32], the available and easier degradable cellulose was mainly from rice bran and kitchen waste. Therefore, the dramatic decrease in the cellulase activity was likely due to the fast degradation in the beginning contributed by the easier degrading cellulose materials and the low remaining cellulose content after one week. Moreover, the type of cellulase determined in this study is endoglucanase. The enzymatic hydrolysis of cellulose requires endoglucanase,

exoglucanase and cellobiases to work together [33], the later composting process might be taken over by exoglucanase or cellobiases.

On the other hand, the lipase and protease activity shows a pattern that is normally obtained in the previous studies where the enzymatic activities increased with time as the composting proceeded until a maximum activity at the middle stage followed by a declining trend [11,34]. These results indicated the capability of microorganisms in synthesizing enzymes essential for hydrolysis of various complexes organic compounds. Figure 6 and 7 shows the lipase and protease activities respectively.

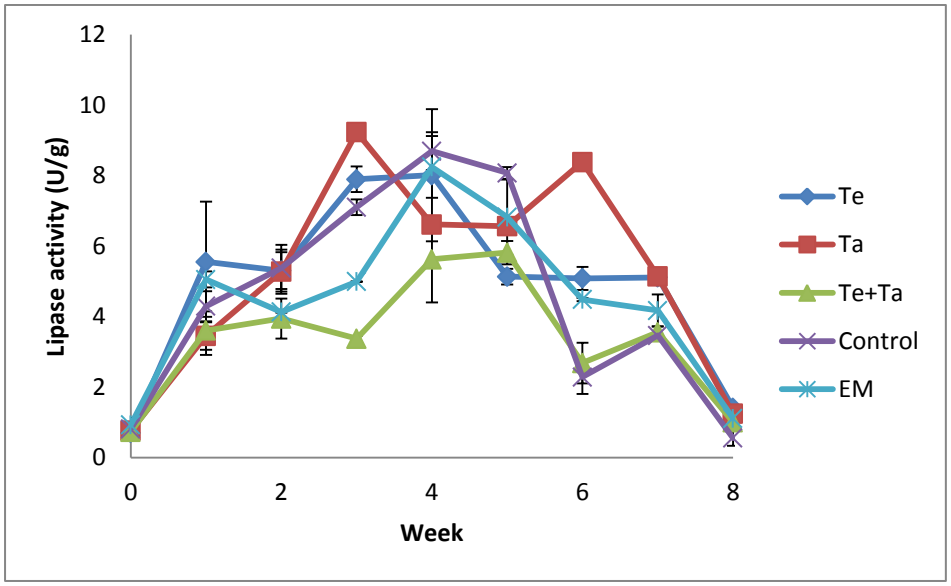

Figure 6. Lipase activity of composting materials

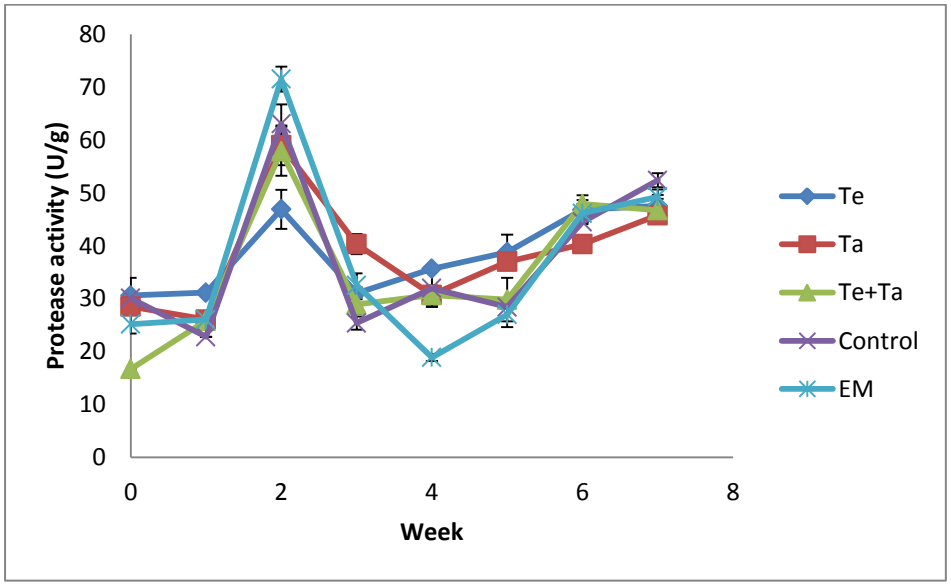

Figure 7. Protease activity of composting materials

No significant different was found among the composting materials inoculated with or without microbial inoculants (MI). The enzymatic activities of the composting materials treated with MI developed from the fermented food were almost the same as the composting materials treated with EM and also with bare water. In term of the total accumulated enzymatic activity along the whole composting process for a 8 weeks duration, EM has the highest amylase activity (510.47 U/g), Te has the highest cellulase (247.63 U/g) as well as protease activity (347.13 U/g) and Ta has the highest lipase activity (46.64 U/g). Table 3 shows the maximum enzymatic activity occurred during the composting process. The maximum amylase and cellulase activity occurred on the initial stage of composting process (week 0). While the maximum lipase and protease activities were observed on week 4 and week 2, respectively.

Table 3. Maximum enzymatic activity during the composting process

Maximum activity (U/g)	**Composts**				
	Te	**Ta**	**Te+Ta**	**Water (Control)**	**EM**
Amylase	73.23	83.03	105.48	101.2	128.82
Cellulase	137.3	75.64	84.25	147.03	114.94
Protease	46.87	58.98	57.86	63.06	71.5
Lipase	8.01	9.23	5.62	8.69	8.24

Germination Index

All composts showed non-phytotoxic (> 80%) on germination test using radish seeds [29]. Table 4 shows the germination index of composts on week 8. Measurement of phytotoxic present in the compost is an accurate and efficient method to check the maturation of organic matter. The results obtained indicated that all composts have matured within two months time. By comparison, it was far faster than the normal duration of traditional composting (6 months to 1 year), vermicomposting (3 – 6 month) and Takakura home composting method (3 months).

Table 4. Germination index on week 8

Composts	**Germination Index (%)**
Te	317.93 ± 23.06
Ta	321.32 ± 7.47
Te+Ta	323.37 ± 97.31
Control	401.57 ± 86.92
EM	306.05 ± 97.01

Conclusion

Based on the results, it shows the potential of using *Tempeh* and *Tapai* as microbial inoculants (MI) to degrade small scale kitchen waste. The technique is user-friendly and the sources of MI are readily accessible by households. The temperature profile and odour performance of Te, Ta, Te +Ta were outstanding. Besides, the enzymatic assays are comparable with the composting performance of EM even though no difference can be indicated when compared with the control (water). In addition, the pH values, C: N ratio and germination index of the five composts under different treatments also showed satisfactory values. According to the examined parameter, all of the composts were in matured stage within two-month duration of composting or even earlier. The continuous

study can be carried out on the humic acid content, nutrient content and pathogen analysis to further comparing the effectiveness of *Tempeh* and *Tapai* as MI against EM and water.

Abstract

A simple low temperature synthesis route has been presented for the preparation of single perovskite phase of $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSCO) for cathode application in intermediate temperature proton conducting solid oxide fuel cell (SOFC). A wet chemical method namely a modified sol-gel method has been applied in this work. In this method, a combined citric acid and ethylenediaminetetraacetic acid (EDTA) has been used as a chelating agent. Ethylene glycol (EG) and activated carbon (AC) have been used as surfactants in this process. The synthesized powders were characterized by X-ray diffractometer (XRD), scanning electron microscope (FESEM) equipped with energy dispersive X-ray (EDX) spectrometer and particle size analyzer (PSA) for phase formation, morphology and particle size analysis, respectively. XRD result revealed that a single LSCO perovskite phase for both surfactants formed at calcination temperature of 900 °C. The produced single phase powders consist of homogeneous and almost identical shape of particles as shown in SEM images. However, the powder prepared using EG has a smaller average particle size diameter as compared with the powder prepared using AC which is 149 nm and 190 nm, respectively.

Keywords: modified sol-gel, surfactant, cathode, solid oxide fuel cell, single perovskite phase of $La_{0.6}Sr_{0.4}CoO_{3-\delta}$

Abstrak

Satu kaedah sintesis ringkas pada suhu rendah telah dibentangkan untuk menyediakan fasa tunggal perovskit $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSCO) bagi aplikasi katod di dalam konduktor proton sel bahan api oksida pepejal (SFOP) suhu sederhana. Satu kaedah kimia basah, iaitu, kaedah sol-gel terubahsuai telah digunakan dalam penyelidikan ini. Melalui kaedah ini, gabungan asid sitrik dan asid atelindiamintetrasetik (EDTA) telah digunakan sebagai agen pengikat. Etilena glikol (EG) dan karbon teraktif (AC) telah digunakan sebagai surfaktan dalam proses ini. Serbuk yang disintesis telah dicirikan dengan menggunakan pembelauan sinar-X (XRD), mikroskop elektron pengimbas (SEM) dilengkapi dengan spektroskopi sinar-X sebaran tenaga (EDX) dan penganalisis saiz zarah (PSA) bagi analisis pembentukan fasa, morfologi dan saiz zarah, masing-masing. Keputusan XRD menunjukkan fasa tunggal perovskit LSCO bagi kedua-dua surfaktan telah terbentuk pada suhu pengkalsinan 900 °C. Serbuk berfasa tunggal yang terhasil terdiri daripada zarah yang homogen dan mempunyai bentuk yang hampir sama seperti ditunjukkan dalam imej SEM. Walau bagaimanapun, serbuk yang dihasilkan menggunakan EG mempunyai purata diameter saiz zarah yang lebih kecil iaitu 149 nm berbanding serbuk yang dihasilkan menggunakan AC iaitu 190 nm.

Kata kunci: sol-gel terubahsuai, surfaktan, katod, proton sel bahan api oksida pepejal, fasa tunggal perovskit $La_{0.6}Sr_{0.4}CoO_{3-\delta}$

Introduction

Nowadays, solid oxide fuel cells (SOFCs) have received considerable attention worldwide. It has been deemed as one of the most promising future power generation as if offers few remarkable advantages including high energy conversion efficiency, low/zero pollutant emission and fuel flexibility compared to the conventional energy power generator. The challenge in the SOFC development is to lower the operating temperature from high (800 - 1000 °C) to intermediate (500 - 700 °C) temperatures. The fabrication cost is then expected to be reduced which would boost the commercialization of such energy conversion devices [1,2].

One the most promising SOFC technologies operating at intermediate temperature is proton conducting SOFC (H^+-SOFC). However, only few reports have dealt with H^+-SOFC technology especially in cathode materials for the H^+-SOFC in the literature [3-6]. In this context, our main goal is to synthesis suitable cathode materials for the H^+-SOFC.

In the last two decades, cobaltite oxides have been widely studied due to the fact that many of these compounds have shown good electrical conductivity and remarkable thermoelectric properties that could be used in practical applications. Among these oxides, lanthanum cobaltite, $LaCoO_3$-based materials are frequently employed as cathode material for H^+-SOFC. The material does not form oxygen vacancies at temperatures below 600 °C and it is therefore a pure electronic conductor in the expected operating temperature range of the H^+-SOFC. Additionally, the material has shown to be stable with no phase changes were observed after 350 hours stability test at 600 °C in air as well as in humidified air (ρH_2O = 0.2 atm) [4]. Furthermore, the $LaCoO_3$ does not react with solutions of barium cerate-zirconate at temperatures below 1100 °C due to its stability in air and wet atmosphere [7].

To this date, $LaCoO_3$-based cathode material such as strontium-doped $LaCoO_3$, $LaSrCoO_3$ is still lack in the literature particularly for H^+-SOFC application which uses barium cerate-zirconate as its electrolyte. Therefore, in this present work, a ceramic based on $LaCoO_3$ material which is $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSCO) has been prepared to be used as cathode material for H^+-SOFC application later. The LSCO material was synthesized by a modified sol-gel method. This method allows the preparation of a single crystalline materials at relatively low processing temperature with good stoichiometry control and preserves the homogeneity of the composition along with relatively large surface area after heat treatment [8,9]. Two different surfactants namely, ethylene glycol (EG) and activated carbon (AC) have been used in producing the LSCO materials and their effects on phase formation, morphology and particle size of the produced powders have been presented in this work.

Materials and Methods

$La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSCO) powder was prepared via a modified sol-gel method. Citric acid and ethylenediaminetetraacetic acid (EDTA) was used as a combined chelating agent; ethylene glycol (EG) and activated carbon (AC) were used as surfactants. Analytical grade of metal nitrate salts of lanthanum, $La(NO_3)_3.6H_2O$, strontium, $Sr(NO_3)_2$ and cobalt, $Co(NO_3)_3.6H_2O$ were used as precursor materials. A mixture of these precursor materials was firstly dissolved in 100 mL deionized water. Then, calculated amount of citric acid was added into the solution mixture with stirring. Next, calculated amount of EDTA was slowly added into the solution mixture. After that, pH of the solution was adjusted to be 0.5. Finally, the respective surfactant (EG and AC) was added and the solution was continuously stirred and heated for several hours to obtain a viscous gel. The resulting viscous gel was dried at 150 ºC (12 hours) and 250 ºC (5 hours) accordingly. The as-synthesized powder was calcined at temperatures of 500, 600, 700, 800 and 900 ºC with heating/cooling rate of 5 ºC min^{-1} for 5 hours. The LSCO prepared with the EG and AC as surfactant and caclcined at different calcination temperatures are labelled as EG500, EG600, EG700, EG800, EG900, AC500, AC600, AC700, AC800 and AC900, respectively.

X-ray diffractometer (XRD Bruker D8 Advance) using a monochromatic Cu-K_α radiation source (λ = 0.1540 nm) with Ni-filtered was used to confirm the phase formation of LSCO perovskite powder. The XRD was operated at 40 kV and 30 mA using a step scan procedure of 0.02º s^{-1} for 2 theta (θ) ranging from 20º to 80º. The percentage of perovskite phase present in the calcined powders was calculated using equation (1) as proposed by Swarts and Shrout [10].

$$\text{Perovskite phase} = \frac{I_p}{I_p + I_m} \times 100\% \quad (1)$$

The *Ip* refers to the maximum intensity of the perovskite phase and *Im* is the maximum intensity of the impurity phases. Morphology of the powder was examined by a Merlin Compact Zeiss field emission scanning electron microscope (FESEM) equipped with energy dispersive X-ray (EDX) spectrometer. The imaging was performed in Secondary Electron (SEI) mode using an accelerating voltage of 15 kV at magnification of 15000 times. Particle size distribution analysis of the powders was done using Nano-ZS Particle Size Analyzer (PSA) manufactured by Malvern using deionized water as a dispersant.

Results and Discussion

Phase formation analysis

Figures 1 and 2 show the XRD profiles of LSCO powders prepared with different surfactants and calcined at different calcination temperatures, respectively. Both of the XRD profiles have almost similar patterns. The strongest peaks of all the XRD patterns were matched with Joint Committee of Powder Diffraction Standards (JCPDS) file no. 48-0121 with cubic (Pm-3m) structure. The pronounce peaks can be indexed to their Miller indices (hkl) of (100), (110), (111), (200), (210), (211), (220), (300) and (310), accordingly. Besides that, some additional peaks corresponded to the trace of impurity phases such as cobalt oxide (CoO), strontium oxide (SrO) and strontium cobalt oxide ($SrCoO_x$) were also presence in the XRD patterns of the calcined powders.

As the calcination temperature increases, the peaks intensity in both XRD profiles was further enhanced and become the dominant phase. The calcined powders at 500, 600, 700 and 800 °C have shown weak crystallinity of the LSCO perovskite phase since the trace of the impurity phases appeared in their XRD patterns. The full crystallization of a single perovskite phase of LSCO was formed at calcination temperature of 900 °C for the powders prepared using both surfactants. The works done by Tao et al. [8], Heel et al. [11] and Acuña et al. [12] also obtained a single phase of the LSCO at calcination temperature of 900 °C but using different synthesis methods namely citrate-EDTA, flame spray and free-drying, accordingly. Furthermore, as the calcination temperature increases, the calculated amount of perovskite phase percentage also increased. A summary of phase formation analysis was presented in Table 1.

Powder morphology and particle size distribution analysis

SEM micrographs of the single LSCO perovskite phase powders of the EG900 and AC900 are shown in Figure 3. The powders consist of homogeneous and almost identical particles. They are basically spherical in shape. The particles are well connected with each other and formed well-bonded porous network. Figures 4 and 5 show the EDX patterns of LSCO in EG900 and AC900 powders, respectively. The figures reveal the presence of lanthanum (La), strontium (Sr), cobalt (Co), oxygen (O) and carbon (C) peaks in the powders.

The analysis of elemental composition of each of the element in the EG900 and AC900 powders is presented in Table 2 and Table 3, accordingly. The weight percent (wt %) of each element is obtained from the EDX analysis and has been used to calculate the mole fraction. The site fractions were calculated assuming pure ABO_3 perovskite phase of LSCO with La and Sr on A-sites and Co only on B-sites. From the table, it can be seen that the elemental fraction of La/Sr in the EG900 was close to the nominal fraction of LSCO. However, the elemental fraction of La/Sr in the AC900 is slightly deviated from the nominal fraction. Additionally, residual carbon element is higher in the

AC900 compared to the EG900 as the activated carbon contains many C element. The high residual carbon content might block the La/Sr from being detected in the EDX spectrum which then contributes to the deviation.

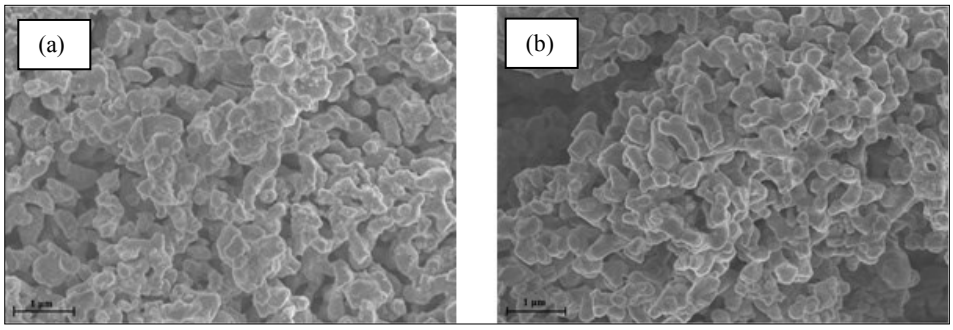

Figure 3. SEM micrographs of (a) EG900 powder and (b) AC900 powder

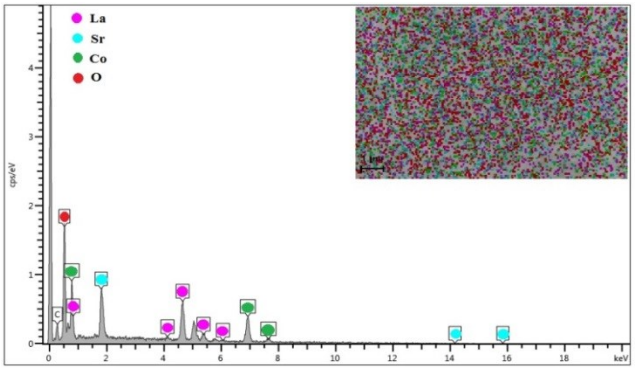

Figure 4. EDX spectrum of EG900 powder

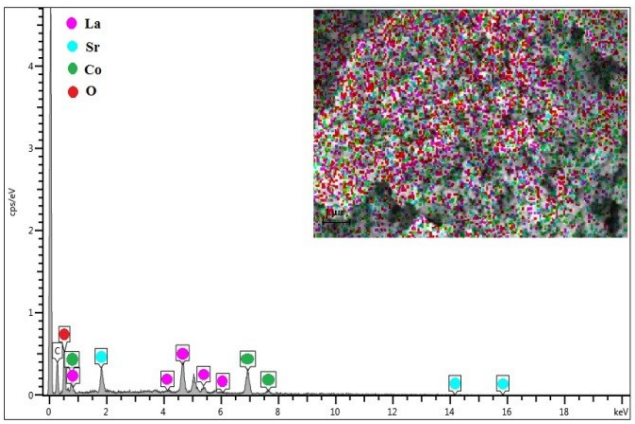

Figure 5. EDX spectrum of AC900 powder

Table 2. EDX data of weight percentage (wt %) and Mole fraction for EG900 powder

Element	Wt. %	Formula Wt.	Mole	Calculated Mole Fraction	Nominal Mole Fraction
La	37.15	138.905	0.267	0.61	0.60
Sr	12.65	87.620	0.144	0.33	0.40
Co	25.65	58.933	0.435	1.00	1.00
				1.94	**2.00**

C	11.60	12.011	0.966		

Table 4 shows the average particle size of secondary particles for EG900 and AC900 powders measured using PSA. It can be seen that the average particle size of the EG900 is smaller than the average particle size of the AC900. The bimodal particle size distribution of the EG900 and AC900 powders are shown in Figure 6 and Figure 7, respectively. Two groups of particle size were observed in the particle size distribution for both samples. For EG900, the powder sample showed about ~ 87% of its particles lying between ~ 450 and 1300 nm and only ~ 13% in the ~ 160 - 340 nm range. For AC900, the powder sample showed about 85% of its particles lying between ~ 530 and 1300 nm and only 15% in the ~ 190 - 400 nm range. The difference in the particle size diameter and particle size distribution between both powders might be resulted from the properties of the surfactants used as they have different molecular structure and different relative bond strength towards compound (metal cations) during synthesizing process. Besides that, surfactant complexes concentration might also contribute to the results as it affects particle growth pathways which then leading to various morphologies.

Table 4. Average particle size diameter of EG900 and AC900 powders measured using PSA

Sample	Average Particle Size Diameter (nm)
EG900	751.2
AC900	1046.3

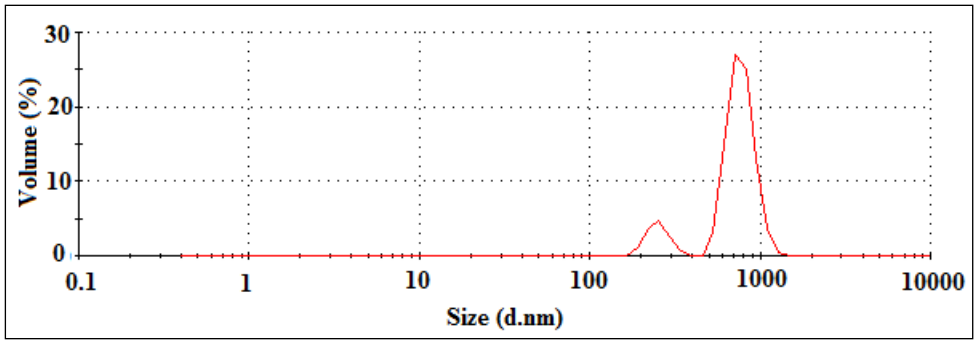

Figure 6. The bimodal particle size distribution of the EG900 powders

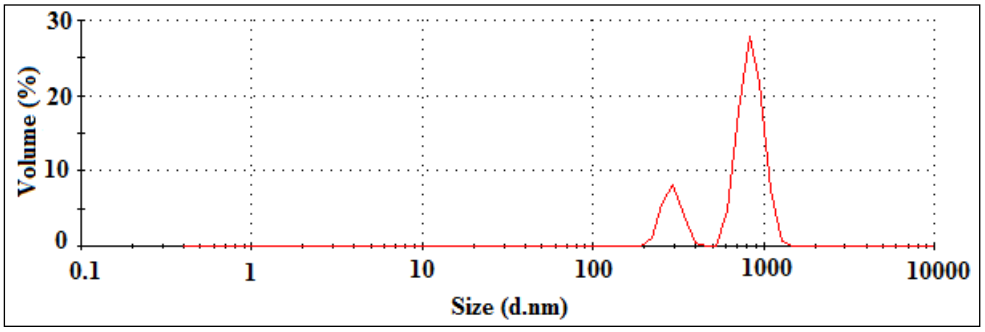

Figure 7. The bimodal particle size distribution of the AC900 powders

Table 5 shows the comparison of particle size diameter of primary particles obtained from this work with another reported works. It can be seen that the particle size obtained from this work is bigger than those reported works. The discrepancy between the results is due to the different synthesis methods and chemical agents used such as chelating agent, fuel or surfactant for the production of LSCO-based powders. The different synthesis methods with different chemical agents will produce materials with different microstructures and properties. Additionally, all the reported works have optimized or controlled their synthesizing parameters such as the amount of surfactant, pH and others in order to produce the nano-size powder but not for this work. Therefore, to obtain the nano size particles (< 100 nm) of LSCO, the relative bond strength and concentration of surfactant will be studied and controlled in our future work and the progress will be reported elsewhere.

Table 5. Average particle size diameter of LSCO powders produced by various methods

Synthesis method	**Chemical agent**	**Calcination temperature (°C)**	**Average particle size diameter (nm)**	**Reference**
Modified sol-gel	EG as surfactant	900	~ 149[a]	[This work]

[a,b]measured using image processing software from SEM analysis

Conclusion

LSCO powders was successfully prepared using a modified sol-gel method with different surfactants namely ethylene glycol (EG) and activated carbon (AC). A single perovskite phase of LSCO was obtained at calcination temperature of 900 °C for both surfactants as confirmed by XRD measurement. The pure phase powders of EG900 and AC900 obtained consists of uniform particle size with almost identical spherical shape as revealed by the SEM analysis. EDX measurement confirmed the presence of La, Sr, Co, O and C elements in both powders. Elemental fraction of La/Sr in the AC900 powder is slightly deviated from its nominal fraction. Both of the powders have different particle size diameter and particle size distribution as confirmed by particle size analyzer. The EG900 and AC900 powders have average particle size diameter of 751.2 nm and 1046.3 nm for secondary particles, and 149 nm and 190 nm for primary particle, respectively. Proton conducting SOFC cathode fabricated using EG900 powder is expected to perform better than AC900 powder due to the fact that the former has finer particle size with reduced residual carbon.

Abstract

In this work, activated carbon nanofibers (ACNFs) from precursor polyacrylonitrile (PAN) and magnesium oxide (MgO) were prepared via electrospinning process. The morphological properties of the PAN/MgO-based ACNFs were characterized by using Scanning Electron Microscopy (SEM) and the specific surface area (SSA) were investigated using nitrogen adsorption, Brunauer-Emmett-Teller (BET) methods. Moreover, the functional groups were analyzed by using Fourier Transform Infrared (FTIR). Besides that, the sorption study has been conducted in order to determine the adsorption capacity between electrospun ACNFs/MgO, pristine ACNFs and granular activated carbon (GAC) towards cadmium (II) ions. The results showed that the SSA of modified ACNFs (198.80 m^2/g) is significantly higher compared to the precursor ACNFs (15.43 m^2/g), however the SSA obtained is quite lower compared to the average theoretical value. SEM micrograph of pristine ACNFs depicted more compact nanofibers compared to aligned nanofibers with average diameter of 200-700 nm. Under batch adsorption study, it was found out that Cd(II) removal of both ACNFs and ACNFs/MgO is higher compared to the commercial GAC. It has been demonstrated that the adsorption capacity of both electrospun ACNFs (ACNFs/MgO and pristine ACNFs) is higher when compared to the adsorption capacity of commercial GAC towards Cd (II) ions.

Keywords: polyacrylonitrile, activated carbon nanofiber, magnesium oxide, cadmium (II) ion adsorption

Abstrak

Kajian ini membincangkan tentang proses penyediaan karbon nano-gentian teraktif (ACNFs) berasaskan poliakrilonitril (PAN) dan magnesium oksida (MgO) melalui teknik putaran elektro. Ciri-ciri morfologi bagi ACNFs telah dicirikan menggunakan Mikroskopi Elektron Pengimbasan (SEM) dan luas permukaan kawasan tertentu (SSA) telah disiasat menggunakan kaedah penjerapan nitrogen, Brunauer-Emmett-Teller (BET). Selain itu, kumpulan berfungsi dianalisis dengan menggunakan Inframerah Transformasi Fourier (FTIR). Melalui kajian ini juga, kapasiti penjerapan diantara ACNFs, ACNFs/MgO dan karbon berbutir teraktif (GAC) terhadap ion (II) kadmium telah dijalankan. Hasil kajian menunjukkan bahawa SSA daripada ACNFs yang telah diubah suai (198.80 m^2/g) adalah lebih tinggi berbanding dengan pelopor ACNFs (15.43 m^2/g), walau bagaimanapun SSA yang diperoleh agak rendah berbanding dengan nilai purata teori. SEM mikrograf bagi pelopor ACNFs menunjukkan nano-gentian yang lebih padat berbanding nano-gentian berstruktur sejajar dengan diameter purata 200-700 nm. Di bawah kajian penjerapan berkumpulan, pembuangan ion (II) kadmium bagi kedua-dua ACNFs dan ACNFs/MgO adalah lebih tinggi berbanding dengan GAC komersial. Hal ini telah membuktikan bahawa kapasiti penjerapan kedua-dua ACNFs yang diperbuat daripada kaedah

putaran elektro (ACNFs/MgO dan ACNFs) terhadap ion (II) kadmium adalah lebih tinggi jika dibandingkan dengan kapasiti penjerapan GAC.

Kata kunci: poliakrilonitril, karbon nano-gentian teraktif, magnesium oksida, penjerapan ion kadmium (II)

Introduction

Nowadays, water contamination by heavy metals remains a major environmental concern as heavy metals persistently present in water subjected by their non-degradable properties [1]. Besides, their tendency to being over-accumulated in biosystem will negatively affect public health and environment despite they play roles in biochemical processes at trace level [2,3,4]. Among the common heavy metals that present in water, cadmium (Cd) has attracted great attention for the studies of its removal as this metal are proved to pose adverse effects on human health even at minimum level [5]. Moreover, the emission of Cd may occur naturally or anthropogenically.

Various methods have been implied upon removal of cadmium laden in water streams such as ion exchange, precipitation, coagulation-flocculation and flotation where each of this method possesses their own limitations more likely to be incomplete removal, generation of secondary waste and inefficient removal efficacies [6,7]. Adsorption is another technique that is frequently applied for removal of heavy metals laden in water. There is wide range of adsorbents available; one good example is activated carbon nanofibers (ACNFs) as it has small inter-fibrous pore size with high porosity and also high specific surface area per unit mass that will lead to high adsorption capacity [8]. One of the challenges to activate the nanofibers is to increase the SSA and capacitance without damaging the graphitic fiber structure, which controls their mechanical properties [9].

Many polymers can be used for preparation of carbon nanofibers such as polyacrylonitrile (PAN), pitch and cellulose. Out of the aforementioned polymers, PAN is an excellent polymer selection because of its outstanding properties which contains a proper functional group(s), adsorbent for metal ion removal, inexpensive, common commercial product and can easily prepared into nanofibers by electrospinning. Preparation of ACNFs with incorporation of nano-scaled metal oxides such as magnesium oxide (MgO) has received great attention as it can solve the major concern of large pores of ACNFs upon removal of heavy metals. Moreover, many previous studies have been conducted on sole MgO due to its large SSA and were proven to be good adsorbent [10]. Thus, in this study the adsorption capacity of prepared ACNFs/MgO were determined and compared with neat PAN-based ACNFs and commercial granular activated carbon (GAC).

Materials and Methods

Materials

Polyacrylonitrile (PAN) with MW of 150, 000 was purchased from Sigma-Aldrich. Dimethylformamide (DMF; ~99.98% purity), magnesium oxides (MgO, ≥99% trace metal basis) and activated carbon (GAC, untreated, granular, 8-20 mesh) were also purchased from Sigma-Aldrich (USA). Stock solution of 1000 mg/L cadmium ions was prepared by using analytical grade cadmium (II) chloride, which was further diluted to the required concentrations before used.

Preparation of PAN nanofibers with dimethylformamide and metal oxides

The dope solution was prepared by adding 1 wt% of MgO into 89 wt% of DMF. The mixture was stirred for at least 5 hours to ensure the MgO dispersed well in the solution before adding up the PAN 10 wt%. The dope was left to stir for 24 hours. The electrospinning process was carried out at fixed electric field of 12kV, the infusion rate is 1 ml/hour and the distance of the tip of needle to the collector is 20 cm, where aluminium foils were used as the collectors.

Activation of PAN-based carbon nanofibers

In stabilization process, the nanofibers were heated up until 275 °C in the furnace (Carbolite) from room temperature with pure air gas flow rate of 0.2 L/min at heating rate of 2 °C/min with resting time of 30 minutes at 275 °C. The treated nanofibers were further heated up until 600 °C with nitrogen gas flow rate of 0.2 L/min at heating rate of 5 °C /min with 30 minutes of dwelling time and were left for cooling down until room temperature.

For activation process, the carbonized nanofibers were burnt in the tube furnace until 800 °C at rate of 5 °C/min with carbon dioxide gas flow rate of 0.2 L/min and 30 minutes of dwelling time.

Characterization

The surface properties, such as morphology and composition of various adsorbents were determined using scanning electron microscopy (SEM) and the specific surface area were investigated using nitrogen adsorption Brunauer-Emmett-Teller (BET). Fourier Transform Infrared (FTIR) analysis was used to analyze the functional groups appeared in the ACNFs.

Batch adsorption study

Adsorption study of Cd ions was analyzed by investigating the effect of initial concentration upon adsorption rate of Cd. 0.05 g of the prepared samples were placed into conical flask containing 50 mL of Cd solution with initial concentration of 3 ppm respectively. The samples were agitated on rotary shaker with the speed of 180 rpm at 30 °C for 48 hours to reach equilibrium [11,12]. The sample solutions were later filtered and examined by using Atomic Absorption Spectrometer (AAS).

The adsorption capacity of the GAC, ACNFs and ACNFs/MgO and the percentage of removal of metallic ions by adsorbent were calculated by following Equation (1) [13].

$$q_t = \frac{(C_0 - C_t)V}{W} \quad (1)$$

and the removal efficiency was calculated using Equation (2).

$$R(\%) = \frac{(C_0 - C_t)}{C_0} \times 100 \quad (2)$$

where C_o and C_t are the initial and final concentration of the metallic solution (mg/L), V is the volume of the solution (L), and M is the weight of the adsorbent used (g) [11].

For batch adsorption study, the ACNFs were rinsed with distilled water in order to eliminate any residual solutions. Then, the ACNFs were further dried in oven at room temperature. Desorption of ACNFs have been used to identify the recovery rate and reusability PAN-based ACNFs/MgO. Desorption of metal ions were carried out by immersing the ACNFs in 1M HCl and agitated at 30 ^{o}C with speed of 100 rpm for 5 h. The concentration of Cd ions in the solution was analyzed using atomic absorption spectrometer (AAS) and the desorption ratio (D) was calculated as Equation 3 follows:

$$D(\%) = \frac{mg\ of metal\ desorbed}{mg\ of\ metal\ ion\ adsorbed\ into\ ACNFs} \times 100 \quad (3)$$

Results and Discussion

SEM for morphology characterization

Figure 1 (a and b) showed that both neat PAN-based ACNFs and modified ACNFs (ACNFs/MgO) possessed straight line fibers, bent fibers, rougher and wrinkled fibers due to the shrinkage effect during pyrolysis process. Moreover, in Figure 1(b), the presence of MgO in the ACNFs can be observed by the presence of white spots while the appearance of few beads was believed due to capillary instability [14] during electrospinning.

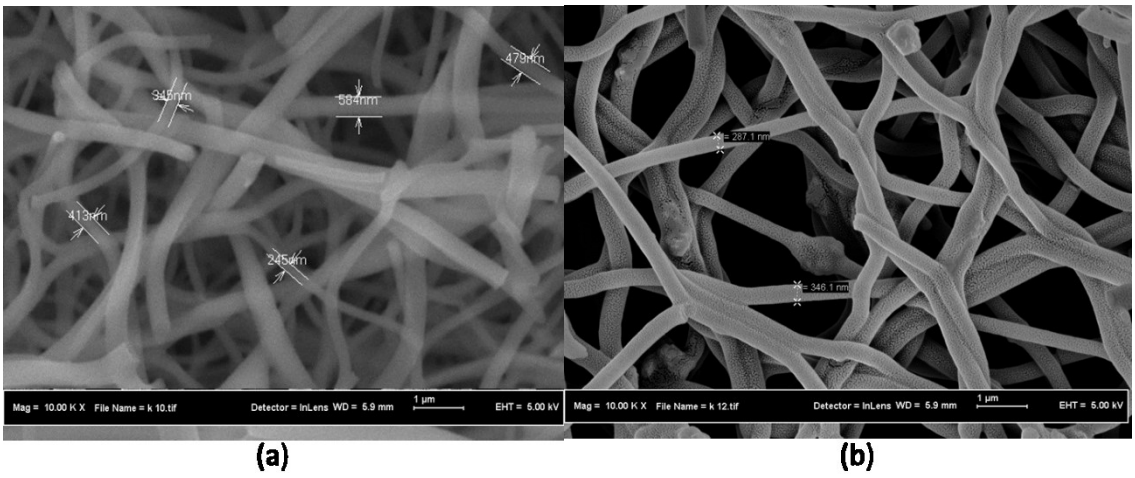

Figure 1. SEM images of (a) ACNFs; and (b) ACNFs/MgO with 10000x magnification

Meanwhile, in comparison of physical observation of SEM micrographs between neat ACNFs and ACNFs/MgO, it can be found that the average diameter of ACNFs without metal oxide is 413.2 ± 128.8 nm (Figure 1a) while for ACNF with MgO is 316.6 ± 41.72 nm as shown in Figure 1(b). As expected, the diameter of ACNFs/MgO is smaller compared to the neat ACNF, as smaller diameter will lead to larger SSA [15,16]. However, even the diameter of the ACNFs obtained not in nano-meter range (below 100 nm), still this study was a success as this result is comparable to other studies on ACNFs.

BET analysis for specific surface area

In this study, the single point BET method was employed to analyze nitrogen adsorption isotherms in order to determine the specific surface area (SSA) of ACNFs and ACNFs/MgO compared to commercial GAC.

Table 1. BET specific surface area of GAC, ACNF, ACNF/MgO

Samples	BET surface area (m^2/g)
GAC	729.82
ACNF	15.43
ACNF/MgO	198.80

From Table 1, the pristine ACNFs show the lowest SSA of 15.43 m^2/g while GAC has the highest SSA of 752.60 m^2/g. Theoretically, the SSA of both ACNFs and ACNFs/MgO were expected to be much higher compared to the results obtained as tabulated in Table 1. For instance, in a study conducted by Dadvar et al. [17], they have obtained SSA of ACNFs/MgO of 600 m^2/g and it was expected in future study, the results for ACNFs/MgO at least comparable or exceeded this value. The low SSA obtained in this study might be due to the incomplete pyrolysis process where the temperature used not high enough to create new micropores instead creating macro- and mesopores that led to low SSA. In our future study, the higher activation temperature with slower heating rate will be used in order to make sure the nanofibers undergo complete pyrolysis stage [18,19].

FTIR for functional group studies

Typically, PAN-based nanofibers will show the existence of CH_2, C≡N, C=O, C−O and C−H bonds but after activation all of these transition compounds were expected to evolve as volatilities and only carbon and hydrogen

atoms remain [20]. As shown in Figure 2, there are six major peaks observed located at 2330.98, 2115.36, 1997.37, 1791.34, 1095.37 and 476.12 cm^{-1}. The peak 2330.98 cm^{-1} is assigned as O-H stretch from strongly hydrogen-bonded- COOH. Peaks 2115.36 and 1997.37 cm^{-1} basically attributed to the strong stretching of C=C groups while peaks 1791.34 cm^{-1} and 1095.37 cm^{-1} indicated as stretching vibrations of C-O groups and C-C stretching, respectively. Last of all, peak 476.12 cm^{-1} were the proofs of the existence of MgO in the ACNFs as the MgO bonds are expected to be presence in the range of 600-450 cm-1 [21]. These detected functional groups may play vital role for adsorption of Cd(II).

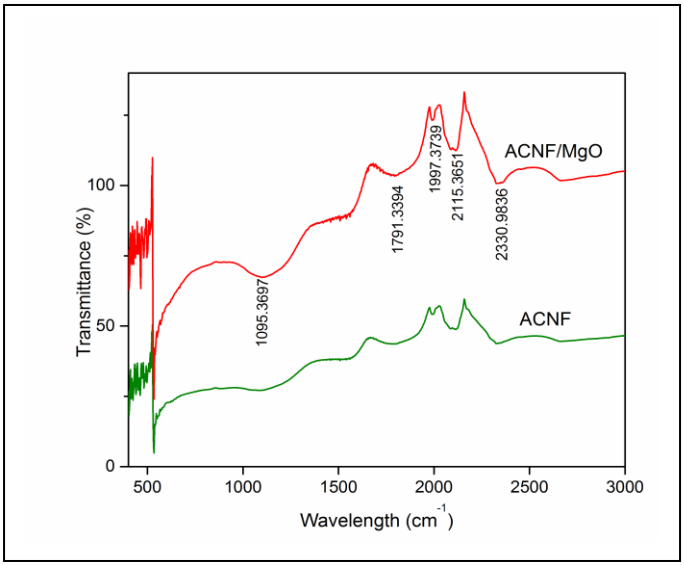

Figure 2. FTIR spectrum of both ACNF and ACNF/MgO

Batch adsorption studies

In this research, the adsorption of heavy metals onto activated carbon nanofibers has been studied using batch-adsorption technique. This study was carried out to examine the adsorption performance of GAC, ACNFs and ACNFs/MgO for the removal of Cd from aqueous solution.

Table 2 shows the percentage removal of cadmium for GAC, ACNFs and ACNFs/MgO it show promising results of 97%, 100% and 100%, respectively. The obtained results revealed that both ACNFs and ACNFs/MgO has good adsorption capacity and effective for the removal of heavy metals from wastewater. Moreover, previous studies have shown that MgO was one of the good adsorbent with high SSA and the incorporation between ACNFs and MgO has proven to be good adsorbent [22] for Cd removal. Based on the results obtained, it can be said that both ACNFs and ACNFs/MgO can be good adsorbent for Cd removal.

Table 2. Removal of cd on GAC, ACNF AND ACNF/MgO

Samples	Removal of Cd (%)
GAC	97
ACNF	100
ACNF/MgO	100

Conclusion

This study investigated the adsorption capabilities of different types of activated carbon on cadmium as a function of adsorbent. Although GAC showed highest SSA compared to both ACNFs, however it was found that pristine and modified ACNFs provided better performance compared to commercial GAC in removal of cadmium from aqueous solution.

Abstract

In this study, a pretreatment of empty fruit bunch (EFB) using supercritical carbon dioxide (SC-CO_2), acid and alkaline were investigated for glucose yield from enzymatic hydrolysis. The chemical composition, X-ray diffraction (XRD) and Scanning Electron Microscopy (SEM) analysis of EFB before and after pretreatment were determined. From this study, the chemical composition of EFB (% g/g dry biomass) before pretreatment for cellulose, hemicellulose and Klason lignin were recorded as 36.7%, 22.8%, and 24.2%, respectively. After pretreatment, the highest cellulose composition was obtained from EFB treated with alkaline followed by acid and SC-CO_2 which gave the results of 48.5%, 47.7% and 38% respectively. The glucose yield after enzymatic hydrolysis for untreated EFB was 17% (w/w). After pretreatment, the glucose yield increased to 84.4%, 34% and 24% for alkaline, acid and SC-CO_2 of the treated EFB, respectively. Other than that, XRD analysis showed increase in the crystallinity index after each pretreatment. Morphology analysis showed the surface of the treated EFB looked swollen and ruptured as compared with the surface of the untreated EFB. Between the three pretreatments, alkaline pretreatment gives the highest cellulose composition and glucose yield. Thus, it shows that alkaline pretreatment was the best pretreatment method on EFB compared to acid and SC-CO_2 pretreatments.

Abstrak

Melalui kajian ini prarawatan tandan buah kosong (TKKS) menggunakan kaedah supergenting karbon dioksida (SC-CO_2), asid dan alkali telah dilakukan untuk mendapatkan hasil glukosa daripada hidrolisis berenzim. Analisis komposisi kimia, pembelauan sinar-X (XRD) dan mikroskopi pemgimbasan elektron (SEM) terhadap TKKS sebelum dan selepas prarawatan telah ditentukan. Dari kajian ini komposisi kimia TKKS (% g/g biomas kering) sebelum prarawatan bagi selulosa, hemiselulosa dan lignin ialah 36.7%, 22.8%, and 24.2%. Selepas prarawatan, komposisi selulosa yang paling tinggi diperolehi daripada TKKS terawat dengan prarawatan alkali diikuti dengan prarawatan asid dan SC-CO_2 iaitu 48.5%, 47.7% dan 38%. Hasil glukosa selepas hidrolisis berenzim bagi TKKS yang tidak terawat ialah 17% (w/w). Selepas prarawatan, hasil glukosa telah meningkat kepada 84.4%, 34% dan 24% bagi prarawatan alkali, asid dan SC-CO_2. Selain daripada itu, analisis XRD menunjukkan peningkatan indeks penghabluran terhadap TKKS terawat. Analisis morfologi menunjukkan perubahan pada permukaan TKKS terawat dimana ia kelihatan bengkak dan pecah berbanding dengan permukaan TKKS yang tidak terawat. Antara ketiga-tiga kaedah prarawatan, prarawatan alkali memberikan komposisi selulosa dan hasil glukosa yang paling tinggi. Oleh itu, kajian ini menunjukkan bahawa prarawatan alkali adalah kaedah prarawatan terbaik terhadap TKKS berbanding prarawatan asid dan SC-CO_2.

Introduction

Malaysia produces approximately 43% of the world's palm oil supply and is the second largest exporters in the world after Indonesia, which produces 44% of palm oil [1]. Crude palm oil production has increased every year due to high demand in the market which also leading to massive production of biomass in the form of trunks, fronds, fibers, shells and empty fruit bunch (EFB) [2]. The potentials of this biomass are yet to be fully exploited that currently leads to waste disposal problems [3].

EFB is a lignocellulosic material consists of carbohydrate sugars, lignin, extractives and ash with inorganic minerals. Carbohydrate sugars such as cellulose and hemicellulose, which can be used as a source of biomass energy when hydrogen is produced via bioconversion process. However it is difficult to yield high amount of reducing sugars from bioconversion of lignocellulosic materials as its end product due to their complex structure and component [4]. Thus, EFB has to undergo pretreatment in order to break the complex structure of lignocellulosic and thus improves enzymatic hydrolysis process for the production of high sugar yields [5].

Many studies have been done on pretreatment of lignocellulosic biomass material either physical, chemical or biological [6]. Chemical pretreatments using acid and alkaline have been claimed as a potential technique for lignocellulose degradation [7]. Acid pretreatment is one of the most extensively studied pretreatment methods that results in hydrolyzes hemicellulose from lignocellulose [8]. Alkaline pretreatment disrupts the cell wall by breaking down the α-ether linkages between lignin and/or hemicelluloses and solubilized thus increasing the enzymatic digestibility of cellulose [9].

Besides the most widely used of chemical methods, physico-chemical pretreatment such as supercritical carbon dioxide (SC-CO_2) has also been of interest in recent years because it uses a low-cost of CO_2, non-toxic and environmentally friendly [10]. During pretreatment, CO_2 molecules penetrate into the micropores of lignocellulose and destroy the structure of the biomass by rapidly release CO_2 [11].

The objectives of this research are to characterize the chemical composition of EFB and to study the effects of alkaline, acid and supercritical carbon dioxide (SC-CO_2) pretreatments on EFB for sugar production during enzymatic hydrolysis.

Materials and Methods

Materials

Empty fruit bunch fibers (EFB) were collected from Sime Darby Sdn. Bhd. palm oil milling, Pulau Carey, Selangor, Malaysia. The EFB was dried using oven (less than 10 wt. % moisture content) and then was milled into particles (0.25 – 0.42 mm). The samples were stored at room temperature until they were used for the pretreatment process. The CO_2 gas was purchased from Gas Pantai Timur, Malaysia and had the purity of 99.9%. The commercial enzymes used in this study were cellulase enzyme and β-glucosidase purchased from Sigma Aldrich.

Pretreatment procedure

Three pretreatment methods were employed in this study. The SC-CO_2 pretreatment was carried out in static type at 75% moisture content, 250 bars and 130 °C. An amount 5g of samples was introduced into a high pressure stainless steel reactor vessel. The supercritical CO_2 was fed into the reactor until desired pressure after the system reached the set temperature. Then, the system was maintained at constant pressure and temperature for 60 min. After the reaction process finished, the supercritical CO_2 was immediately released to atmospheric pressure [12]. NaOH and H_2SO_4 solution at concentration level 4% were used to pretreat EFB. The samples were treated in a 250 mL Erlenmeyer flask at temperature of 121 °C for 1 hour and with ratio of biomass to liquid was 1:10. Later, the treated fibers were washed until all chemicals used were removed [13]. Then, the treated fibers were dried in an oven at 50 ºC overnight.

Enzymatic saccharification

Enzymatic hydrolysis of untreated and treated EFB were carried out in 250 mL Erlenmeyer flasks containing 1% (w/v) glucan loading in 0.05 M citrate buffer, pH 4.8 and together with desired cellulase and cellobiase enzymes.

Cellulose and cellobiase enzymes were added at 60 FPU per g glucan loading and 64 ρNPGU per g glucan loading, respectively. An amount of 10% sodium azide was added at concentration of 20 mg/mL act as an antibiotic. The saccharification was done in a shaker incubator at 200 rpm at 37 ºC for 48 hours. Samples were taken periodically, filtered and stored at -8 °C for sugar determination using High Performance Liquid Chromatography (HPLC) [14].

Analytical method

The chemical composition of EFB was determined according to NREL standard method [15]. In this method, the structural carbohydrates and insoluble lignin (Klason lignin) in biomass were analyzed. The sugar monomers in untreated and treated EFB fiber samples after enzymatic hydrolysis were determined by high performance liquid chromatography. HPLC system (Model G1311A, Agilent Technologies) equipped with reflective index detector and Rezex ROA column was used for the analysis. The mobile phase used was 0.005 N sulfuric acid with a flow rate of 0.6 mL/min at 60 °C. The samples were centrifuged for 5 minutes and filtered with 0.2 µm syringe filter for HPLC analysis. The glucose yield from EFB was measured based on the glucose released after both pretreatment and enzymatic hydrolysis as proposed by Srinivasan and Ju [16].

Scanning electron microscope

SEM analysis was conducted using SEM model Philips XL30 to determine the surface changes before and after pretreatment. For sample preparation, the samples were coated with a thin layer of gold using sputter coater system Model Q150 RS.

X-ray diffraction

The crystallinities of untreated and pretreated Tamarix solids were measured using a Bruker D8 Advance instrument. The data analysis was calculated from XRD data and determined based on the formula by Segal follows [17]**.**

$$CrI = 100 \times [(I002\text{-}Iam)/I002] \quad (1)$$

where I002 is the maximum intensity of 002 reflections from the crystalline and amorphous portions at about $2\theta = 22.5^{\circ}$, and Iam is the minimum intensity of diffraction from the amorphous portion at a $2\theta \approx 18.7^{\circ}$ of the EFB fibers in most literatures [18]. During the calculation, the height of (002) peaks were used at a $2\theta \approx 22^{\circ}$, while the intensity of Iam was taken at a $2\theta \approx 16^{\circ}$.

Results and Discussion

Effect of various pretreatments on chemical composition of EFB

The chemical compositions of untreated and treated EFB fibers were shown in Figure 1. Chemical composition of untreated EFB fiber for cellulose, hemicellulose and Klason lignin were 36.7%, 22.8%, and 24.2%, respectively. The cellulose, hemicellulose and lignin content in untreated EFB fiber were similar to that reported by Chong et al. who studied the chemical composition of EFB [8]. These results proved that more than 30% -50% of EFB component is cellulose, followed by hemicellulose 20% - 30% and lignin 15% - 20% of the overall components in biomass [4,19]. After pretreatment, it was observed that the composition of cellulose increased in the treated EFB as the results after SC-CO_2, acid and alkaline pretreatment were 38%, 47.7% and 48.5%, respectively. While the composition of hemicellulose was increased after SC-CO_2 and alkaline pretreatment but decreased after acid pretreatment as the results obtained were 25.5%, 29.1% and 0.012% respectively.

The composition of Klason lignin showed that the percentages reduced after SC-CO_2 and alkaline pretreatment but increased after acid pretreatment which were calculated at 23.8%, 20.4% and 31.2%, respectively. The result showed differences in the composition of EFB after pretreatments because of different effects of pretreatment on EFB fiber. SC-CO_2 is a physicochemical pretreatment in which at supercritical conditions and high temperatures, carbonic acid possibly formed by the interaction of SC-CO_2 with water and may have hydrolyzed hemicellulose [20]. Whereas acid and alkaline are chemical pretreatment which chemically changing the structure of lignocellulose EFB and destroying its crystalline structure [6]. The acid pretreatment enhances the hydrolysis of hemicelluloses and portion of amorphous cellulose while alkaline pretreatment disrupts the cell wall by dissolving hemicelluloses and lignin from lignocellulose [21,22].

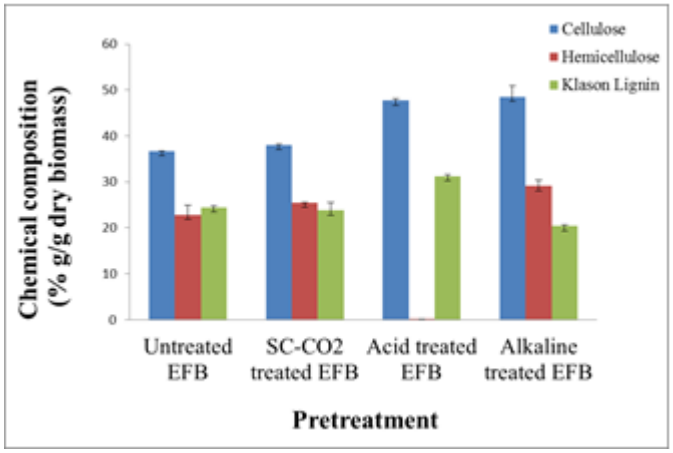

Figure 1. Chemical compositions of untreated, supercritical carbon dioxide, acid and alkaline treated EFB.

Effect of various pretreatments on glucose yield

The trends of glucose yield after 48 hours' enzymatic hydrolysis over different pretreatments were shown in Figure 2. After enzymatic hydrolysis, the glucose yield for untreated compared with supercritical carbon dioxide, acid and alkaline treated EFB were calculated at 17%, 24%, 34% and 84.4%, respectively. The results showed that all the three pretreatments caused an increase of the glucose yield after enzymatic hydrolysis compared to untreated EFB. The highest glucose yield was obtained in EFB treated with 4% NaOH showing that alkaline pretreatment gave significant effect on glucose yield. Alkaline pretreatment enhancing enzymatic hydrolysis by removing lignin that linked to both hemicellulose and cellulose from lignocellulose [2]. Acid and SC-CO_2 pretreatment also help in enzymatic hydrolysis however the glucose yield is lower than alkaline pretreatment. During acid and SC-CO_2 pretreatment, most of the hemicellulose was hydrolyzed leaving lignin as a barrier that preventing penetration of enzymes and difficult for the enzyme to access the cellulose [4].

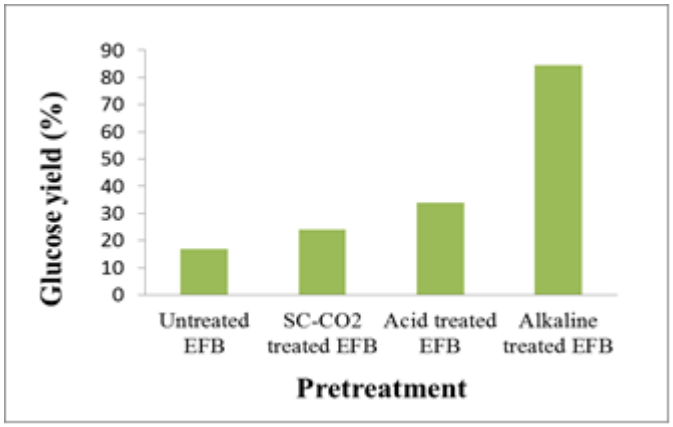

Figure 2. Glucose yield of the enzymatic hydrolysis for untreated, supercritical carbon dioxide, acid and alkaline treated EFB after 48 hours enzymatic hydrolysis.

X-ray diffraction analysis

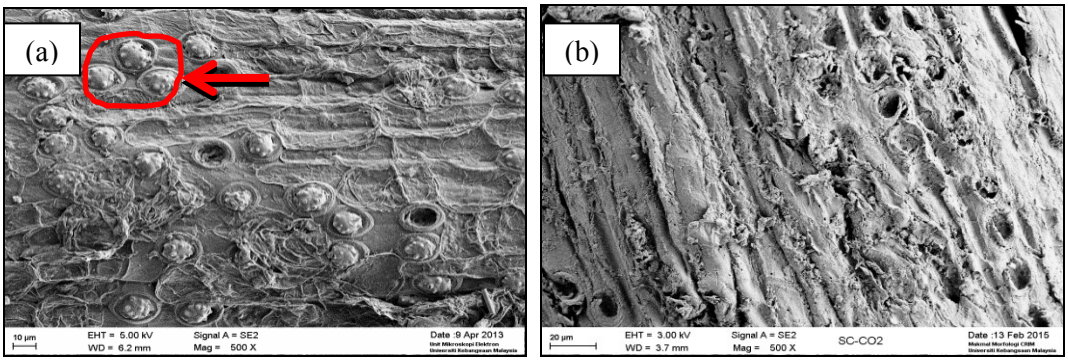

Table 1 showed the crystallinity index of untreated EFB, SC-CO_2 treated EFB, acid treated EFB and alkaline treated EFB. Crystallinity index for each sample was calculated using the formula by Segal et al. [17]. It was determined that crystallinity index of cellulose in untreated EFB was 44%. The crystallinity increased after each pretreatment as for SC-CO_2 treated EFB (45.3%), acid treated EFB (47%) and alkaline treated EFB (50%), respectively. Crystallinity index had been used in various studies to interpret the changes in the structure of cellulose after pretreatment [23]. Cellulose crystallinity index was the main factor affecting the hydrolysis since degradation of cellulose crystallinity will increase the rate of enzymatic hydrolysis [24]. This concept was used because cellulose structure can be divided into two parts which amorphous part that was easy to hydrolyze and crystalline part that was more difficult to hydrolyze [23]. However, in this study, it showed that the crystallinity index was increased for each pretreatment similarly in previous studies conducted by Singh et al. [21] on rice straw using alkaline pretreatment which increased the crystallization index of 2.35%. Therefore, it can be concluded that the crystallization is not the only factor affecting the enzymatic hydrolysis of biomass but other parameters such as hemicellulose and lignin also involve in enhancing the enzymatic hydrolysis.

Table 1. Chemical compositions of untreated, supercritical carbon dioxide, acid and alkaline treated EFB

Samples	**Crystallinity Index (%)**
Untreated EFB	44
SC-CO_2 treated EFB	45.3
Acid treated EFB	47
Alkaline treated EFB	50

Scanning electron microscopy

Scanning electron microscopy (SEM) analysis was used to observe the structure changes in EFB before and after pretreatment. Figure 3 shows SEM images of EFB samples for (a) untreated EFB (b) SC-CO_2 treated EFB (c) acid treated EFB and (d) alkaline treated EFB. From the SEM images, it showed that untreated EFB had a rough surface with the silica bodies on the surface strand. The structure looked very rigid and solid because the surface of the fiber was covered by a layer of matrix material like lignin or waxes. On the other hand, after pretreatment the SEM showed the structural damage EFB. After SC-CO_2 pretreatment process, the structure of EFB became porous and visible cracks formed were seen due to quick release of CO_2 [25]. A significant effect can be observed after alkaline and acid pretreatment where these pretreatments caused greater disruptions on the fiber structure by destroying the cell wall, hydrolyzing lignin or hemicellulose of lignocellulose and creating number of large pores [14]. Thus after pretreatment more cellulose was exposed to the enzymes, resulting in increment of glucose yield.

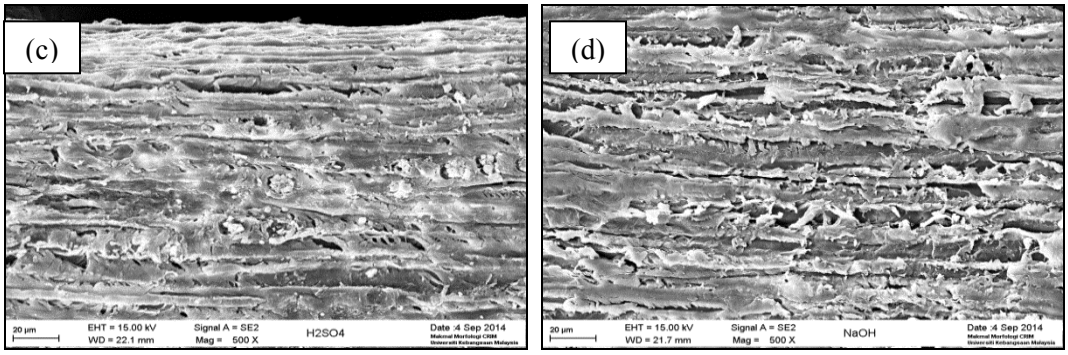

Figure 3. SEM images of EFB samples (a) untreated EFB, (b)SC-CO_2 treated EFB, (c) acid treated EFB and (d) alkaline treated EFB; Arrow indicates silica bodies on the EFB strand

Conclusion

In summary, SC-CO_2, acid and alkaline pretreatment on EFB enhances the glucose yields of enzymatic hydrolysis. The highest glucan composition and glucose yield were obtained from EFB treated with alkaline followed by acid and SC-CO_2. After pretreatment, SEM images demonstrated that the structure of treated EFB was swollen and ruptured as compared with the untreated EFB. A significant effect can be observed after alkaline and acid pretreatment which were the chemical pretreatment. XRD analysis showed increase in the crystallinity index for EFB treated using SC-CO_2, acid and alkaline pretreatment by 1.3%, 3% and 6% compared to untreated EFB. Therefore based on these findings, it could be concluded that alkaline pretreatment using NaOH was the best pretreatment method on EFB which gives the highest glucose yield through enzymatic hydrolysis.

Abstract

Succinic acid displays promising properties as a precursor for synthesizing valuable chemicals. However, its recovery experiences difficulty due to the formation of by-products with similar physicochemical properties, namely acetate and formate. The succinate separation process via pressure filtration membrane technology demonstrates polyimide (PI) membrane as a potential candidate due to its high resistance and selectivity to many organic solvents from its imide groups, an important feature in separation of biomass fermentation broth. This study aims to investigate the performance of newly synthesized PI (P84) membrane prepared by phase inversion for succinate recovery from fermentation broth (simulated model solution is used). PI polymer composition 14 – 17 wt% were cast to investigate the effect of varying polymer compositions on the performance of NF membrane determined from the recovery of succinate, and removal of formate and acetate from ternary organic salt solutions at concentration range between 10 – 50 g/L. PI membrane (15 wt%) shows the highest selective succinate retention of 73%. Succinate selective retention was observed to increase whereas rejection of by-products decreased at increasing mixed salt solution concentration from 20 – 50 g/L. Field Emission Scanning Electron Microscope (FESEM) results showed a PI membrane with dense and thick top layer, with porous middle substructure to support membrane performance.

Abstrak

Asid suksinik mempunyai kepentingan sebagai pelopor dalam mensintesis bahan kimia yang bernilai. Namun, pengumpulannya menghadapi kesukaran kerana pembentukan satu lagi produk sampingan yang mempunyai sifat fizikokimia yang sama seperti asetat dan format. Dalam proses pemisahan/pengumpulan suksinat menerusi tekanan teknologi membran penapisan, membran poliimida (PI) didapati berpotensi sebagai calon membran kerana ia bersifat perintang yang tinggi kepada banyak pelarut organik dan juga mempunyai pemilihan yang tinggi ke atas air melalui kumpulan imida yang penting dalam pengasingan sup penapaian biojisim. Oleh itu, kajian ini bertujuan untuk menyiasat prestasi membran PI (P84) yang baru disintesis dan disediakan dengan teknik fasa songsangan dalam bidang pengumpulan suksinat dari sup penapaian (model simulasi digunakan). Kepekatan PI polimer sebanyak 14 – 17 wt% telah disediakan dan kesan kepekatan polimer dalam penyediaan membran PI telah disiasat untuk mencapai membran PI berprestasi tinggi yang ditentukan dari pengumpulan suksinat dan penyingkiran asetat dan format pada julat kepekatan antara 10 – 50 g/L. Melalui kajian ini, membran PI (15 wt%) menunjukkan pengumpulan suksinat tertinggi sebanyak 73%. Pengumpulan suksinat diperhatikan meningkat manakala penyingkiran produk sampingan berkurangan dengan peningkatan kepekatan garam campuran dari 20 – 50 g/L. FESEM yang menunjukkan lapisan atas membran PI yang padat dan tebal serta lapisan substruktur tengah yang berliang untuk menyokong prestasi membran PI.

Introduction

Succinic acid is a dicarboxylic acid (consists of two carboxyl) and is of high interest as a precursor for synthesizing a variety of valuable chemicals in the production of food [1], pharmaceutical products [2], and in the chemicals industry [3,4]. The versatility of succinic acid has attracted many attentions to find an alternative production route over the traditional process of using petroleum feedstock due to long-term environmental concern. This thus gives rise to the production of succinic acid from fermentation process using abundant biomass for a cleaner technology approach. Presently, studies have reported high production of succinate at various amounts via fermentation process when using different producing bacteria; 50 g/L by *Mannheimia succiniciproducens* [5], 83 g/L by *Anaerobio-spirillum succiniciproducens* [6], 99.2 g/L by *E. coli* [7] and 100 g/L by *Actinobacillus succinogenes* [8]. However, along with the succinic acid production, other by-products such as acetic acid, formic acid, lactic, and pyruvic acids (depending on the producing bacteria) with similar physicochemical properties were also produced [9]. In addition to that, the requirement of pre-treating the fermentation broth prior to succinic acid separation has made the downstream processing of succinic acid difficult and costly which could mount up to about 50 – 70% of the production cost [10].

Many separation processes have been intensively studied for the separation/recovery of succinic acid including precipitation and crystallization [11], reactive extraction [12] and chromatography [13]. However these processes are subjected to limitations of either low recovery rate or purity, contamination of process by impurities, high energy consumptions or the need of frequent regeneration [14]. Among the separation technologies, intensive study using membrane filtration including microfiltration, ultrafiltration and nanofiltration (NF) have been carried out using commercial membranes [15-19]. Initial study was carried out by Glassner in 1992 on succinic acid purification process using integrated desalination electrodialysis and bipolar membrane electrodialysis. The former stage is applied to separate the ionic species such as acids from the fermentation broth containing the uncharged compounds such as sugars, saccharides or proteins. The charged molecules then passed through a membrane, and sodium succinate was collected. Meanwhile at the latter stage, bipolar membrane electrodialysis is used to convert sodium succinate into succinic acid while recycling back the NaOH to maintain the pH of the fermentation broth. However, this type of membrane filtration was found to be prone to low product yield due to loss of succinic acid and membrane pollution [20]. Later, succinic acid separation from fermentation broth was investigated using ultrafiltration. Wang et al. carried out a study on succinic acid separation which focused more on the membrane fouling mechanism in treating succinate acid from fermentation broth using dead-end ultrafiltration. Their study investigated the type of fouling experienced by different membranes including RC 10 kDa, PES 30 kDa, PES 100 kDa, and PES 10 kDa during succinate separation using Hermia's model. It was found that most of the membranes tended to foul by cake layer or concentration polarization [21].

Among membrane filtration separation technologies, NF membranes for acid mixtures separation was highly reported due to the NF membrane characteristic that has high selectivity towards divalent anions compared to monovalent anions especially for separation of divalent anion from multivalent anions solution [15, 19]. Choi et al. [16] reported the retention of succinic acid using NF membrane, NF270 of Filmtec. The retention of organic salts was found to be dependent on the molecular weight cut off (MWCO) of membrane. Furthermore, the retention of succinic acid was over 90% irrespective of operating pressure and concentration due to close molecular weight (MW) of succinic acid to the MWCO of the NF270 membrane used. However for organic acid with lower MW (i.e. formic acid, acetic acid and propionic acid) than the MWCO of membrane, the retention is found to be dependent on the operating pressure and concentration. They also reported that the retention of succinic acid increases with increasing pH, depending on the degree of dissociation [16].

Therefore, the successful recovery of succinate/succinic acid using the commercial polymeric NF membrane has become the main motivation of this study. In this work an investigation on the succinate recovery from biomass fermentation broth was carried out using newly synthesized PI NF membrane fabricated via phase inversion, which to our knowledge has not yet been investigated in this field of succinate recovery from fermentation broth. The introduction of PI in the field of recovering succinate from fermentation broth is due to its excellent chemical resistance, good thermal and mechanical properties, easy processing, and good solubility in a variety of common solvents. It also possesses high negative surface charge that could effectively impede bio-fouling unlike the

commercial membranes [22]. This material is also chosen due to its recent introduction in organic solvent separation [23,24], which is found to be also suitable for the targeted application in purifying the biomass fermentation broth that is composed of a complex mixture of alcohol, organic acid/salts, sugars, and biomass. A robust membrane such as PI polymer is required to withstand the extreme environment during separation and recovery of the desired product.

In this study, succinate retention was investigated based on the manipulation of polymer compositions during the doped solution preparation. This varying composition is expected to give different morphologies of the membrane thus influencing the retention of desired product. Phase inversion was used as it created an asymmetric membrane suitable for the application targeted. In the phase inversion, the cast polymer is immersed in a coagulation-bath containing poor solvent (non-solvent) such as water to create polymer rich and polymer lean phases from the diffusion of non-solvent into the cast film and of solvent out of it, inducing liquid-liquid demixing due to thermodynamic instability [22]. The former and latter polymer phases are then subsequently transformed into membrane matrix and membrane pores respectively [25]. The fabricated membranes were characterized using FESEM and salt retention to determine the membrane morphologies and retention properties. The performance of the fabricated membranes was also tested with a modelled ternary solution consisting succinate, formate, and acetate at different concentrations to investigate the selective recovery of succinate from the ternary solution.

Materials and Methods

Materials

For membrane preparation, polyimide (P84) fibers was purchased from Good Fellow and dried overnight at 120 °C prior to use. N–methyl–2–pyrrolidinone (NMP, Merck) was used as solvent. De-ionized H_2O was used as coagulation media while 2–propanol (2–PrOH, Merck) was used for membrane post-treatment. For model solution preparation, succinic acid (with molecular weight [MW] 118.09 g/mol, R&M Chemicals), formic acid (MW 46.03 g/mol, R&M Chemicals) and acetic acid (MW 90.09 g/mol, R&M Chemicals) were used to prepare the model fermentation broth solution at different concentration for retention analysis. Sodium hydroxide (NaOH, R&M Chemicals) was used to adjust pH to 7.0. All chemicals were used without further purification.

Membrane preparation

Homogeneous PI solutions were prepared by adding NMP solvent to the PI chopped fibers, which was subsequently heated at 60 °C for 4 hours until completely dissolved. The solution was stirred overnight until homogeneous for casting at room temperature using an automated film applicator (Elcometer 4340, UK). The cast speed, membrane thickness and evaporation time were set at 10 cm/s, 250 μm and 30 s, respectively. After casting, membrane films were exposed to ambient air to allow evaporation of the solvents and subsequently immersed in a coagulation bath of de-ionized water at room temperature for 10 min, after which the de-ionized water was replaced to remove all solvents. For post treatment by a solvent exchange procedure to avoid pore collapse upon drying, all cast membranes were immersed in 2–PrOH for 3 hours [26] and finally air dried naturally [27].

Salt rejection

To determine the level of membrane separation towards divalent and monovalent anions, salt rejections were carried out using dead end filtration cell (HP4750 Stirred Cell, Sterlitech) with a filtration area of 0.00146 m^2. A fixed pressure of 20 bar was used with feed consisting of NaCl and Na_2SO_4 at 20 mM concentration each. The salt rejection of membrane was determined by analysing the salt permeate using conductivity meter (METTLER TOLEDO). The flux was calculated based on the following Equation (1) while retention was calculated based on the following Equation (2):

$$J = \frac{\Delta V}{A.t} \tag{1}$$

where J is the flux ($L/m^2.h$), V is the volume of permeate (L), A is the effective area of membrane (m^2) and t is time (h).

$$R\ (\%) = \left[1 - \left(\frac{C_P}{C_R}\right)\right] \quad (2)$$

where R is the percentage retention, C_P is the concentration of permeate and C_R is the concentration of retentate.

Membrane morphology

For membrane morphology, membrane cross-sections were observed with field emission scanning electron microscopy (FESEM) (SUPRA 55VP, ZEISS). Dried membrane samples were fractured in liquid nitrogen and mounted on aluminum stubs for platinum sputter-coated using sputter-coater (QUORUM Q150RS, UK) to make samples appear to have electrical conductivity. The samples were observed in standard high-vacuum conditions of 5 kV.

Succinate recovery

The recovery of succinate from multi-salt solutions using PI membranes were carried out using dead end filtration cells similar as in salt retention analysis. After every run, membranes used were rinsed with ultra-pure water until the initial water flux was recovered. Please note that the flux and rejection calculation are based on the salt rejection also. The flux and rejection were measured at various mixed-salt solution concentrations between 10 – 50 g/L at 15 bar. All mixed-salt solution concentrations were carried out at 1:1:1 ratio of succinate, formate, and acetate respectively (for simplification, 33.33:33.33:33.33 ratio in percentage).

The organic acid salts were measured using a high performance liquid chromatography (HPLC) (G1313A series, Agilent) with a separating column (REZEX ROA ORGANIC ACID H+ [8%], 300 x 7.8 mm, PHENOMENEX). The analysis was run with a refractive index (RI) detector at column temperature of 60 °C. An amount 0.005 M H_2SO_4 was used as the mobile phase at 0.6 ml/min of flow rate [19].

Results and Discussion

Salt retention

A desired NF membrane is a membrane that possesses high rejection of divalent anions while low rejection of monovalent anions. This means the succinate is to be retained in the retentate while other organic salts (formate and acetate) are to be removed in the permeate in this study. In order to investigate the retention of monovalent and divalent anions of the synthesized membranes, four different compositions of PI in the range of 14 – 17 wt% were prepared and tested using 20 mM of NaCl (monovalent anion) and Na_2SO_4 (divalent anion).

Table 1. NaCl and Na_2SO_4 retention and solution flux of PI membrane at different composition

PI membranes composition (wt%)	Flux for NaCl ($L/m^2.h$)	Rej. for NaCl (%)	Flux for Na_2SO_4 ($L/m^2.h$)	Rej. for Na_2SO_4 (%)
14	35.34	9.94	34.52	18.90
15	15.41	6.57	15.31	39.10
16	6.26	60.16	5.94	52.19
17	1.51	66.89	1.92	53.84

Table 1 shows the retention of each salt and the solution flux. From the results, it was observed that the fabricated PI membrane started to show NF characteristics at composition above 14 wt% based on the retention of NaCl and/or Na_2SO_4 of above 20%. Based on The DOW Chemical Company membrane specification, a typical NF membrane shows retention of dissolved salts between 20–80% [28]. Figure 1 shows the comparison between the retention of monovalent and divalent anions at different membrane compositions. Among the tested membranes, PI at 15 wt% composition shows the largest retention difference between monovalent anion, Cl^- and divalent anion, SO_4^{2-} with approximately 83% retention difference. It was also observed that below 15 wt% PI, the divalent anions shows

higher retention compared to monovalent anions but above 15 wt% PI, monovalent anion has slightly higher retention than the divalent anion. It seemed that below 15 wt% PI composition, Donnan exclusion and sieve effect play important roles in ion separation while above 15 wt%, only Donnan exclusion acted as the major factor in the ion separation [19,29]. From the salt retention test, 15 wt% PI shows the highest potential for selective retention of succinate from mixture solution containing both mono- and divalent anions (Cl^- and SO_4^{2-} respectively) as it shows the highest retention difference between these two anions.

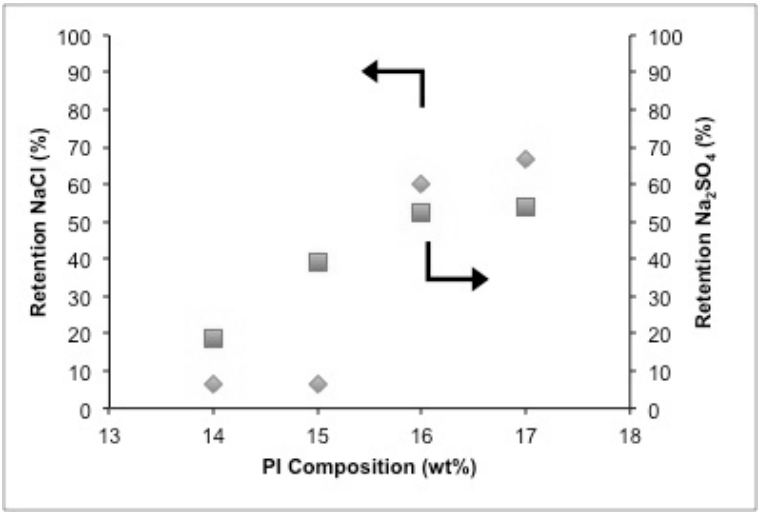

Figure 1. Comparison between retention of NaCl and Na_2SO_4 using PI membrane at different doped solution compositions (14, 15, 16 and 17 wt%). (Membrane synthesis conditions: membrane thickness of 250 µm, evaporation time of 30s. Filtration conditions: 20 bar, room temperature)

Membrane morphology

In order to further investigate the influence of polymer composition on the retention performance, the morphology of the membranes were examined using FESEM. Figure 2 shows the magnified cross-sections of PI membranes at different composition between 14 – 17 wt% of PI. Overall cross-section of the PI membrane images shows three layers of i) thin top skin layer, ii) intermediate nodular structure and iii) finger like porous sub-structure with macro voids. This top skin layer and nodular structure indicated an NF membrane properties as reported by [22,24]. The images observed as in Figure 2(c), within 10 µm of the top skin layer of the membranes exhibit dense sponge like morphologies leaving small channels reaching the surface of the membrane. At increasing PI composition, the membrane skin layer was observed to become denser while the middle sub-structure became less porous especially above 15 wt% PI composition. This observation explained the overall increase in retention of the tested solutes and the reduction in fluxes at composition higher than 15 wt%. The phenomenon is due to the slow down and delay on the non-solvent in diffusion and demixing of the polymer/non-solvent interface upon immersion when a higher composition of PI is used and thus resulting in a denser skin layer [22]. A dense skin layer may strongly affect the transport process of solute during rejection process thus making the rejection of the ions to be more effective. This result will be further discussed in the succinate recovery in the following section.

Meanwhile for the surface morphology of the fabricated membrane at different PI compositions, the FESEM images as in Figure 2(d) show an overall rough surface area at magnification of 100000x. It is also observed that as the composition of PI increases, the surface morphology becomes more wrinkled, which increases the surface roughness of the membrane. Lin et al. reported that the increase in surface roughness indicates that the membrane would have higher retention [30], which is in agreement with the results of salt retention test presented in Table 1. The results show that the retention of monovalent and divalent salt increases from 6.64 to 66.89% and from 18.9 to 53.84% respectively with increasing PI composition from 14 to 17 wt%.

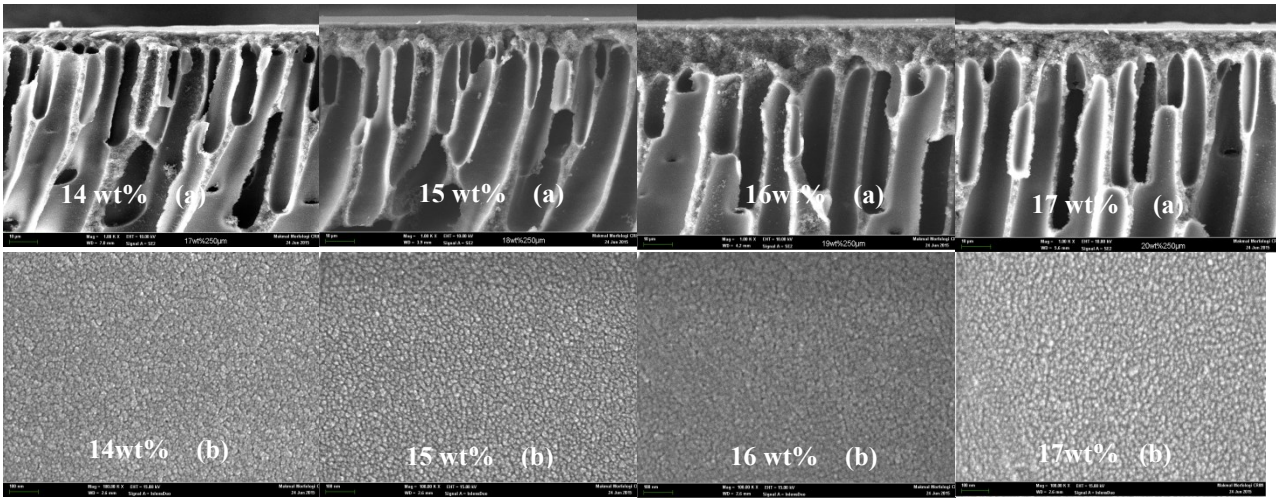

Figure 2. Effect of PI compositions (14, 15, 16 and 17 wt%) on morphology of membranes: (a) cross-section 500x and B) surface 100,000x (Membrane synthesis conditions: membrane thickness: 250 μm, evaporation time of 30s).

Succinate recovery

The performance of the membrane was also tested for the retention of succinate from ternary solution containing succinate, formate, and acetate at different concentration between 10 – 50 g/L. Figure 3 represents the flux of the ternary solutions and Figure 4 shows the succinate retention at different polymer compositions. From Figure 3, overall it was observed that the fluxes of ternary solution decreases with increasing concentrations, and polymer composition with 14 wt% PI membrane showed the highest fluxes. Meanwhile Figure 4 shows that the retention of succinate overall increased as the polymer composition increased irrespective of the ternary solution concentration. This observation is in agreement with the morphology of the membrane obtained in Figure 2(b) where the membrane skin layer becomes denser as the polymer composition increases thus resulting in the reduction of fluxes and increase of succinate retention. Similar results were also reported in previous studies using PI for rejection of isopropanol [22] and toluene [24].

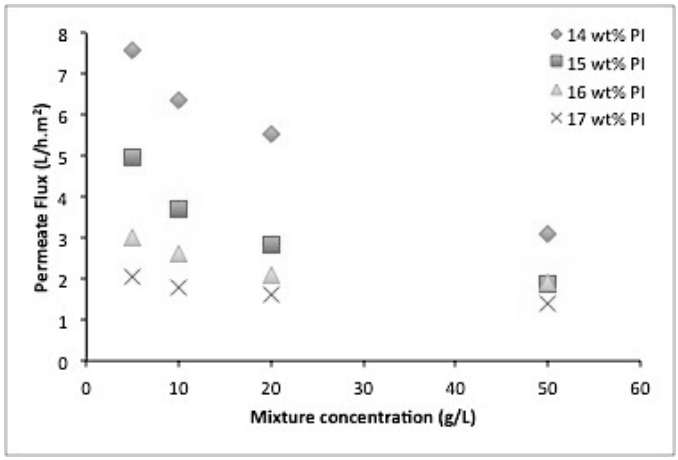

Figure 3. Permeate flux of mixed salt solution as a function of mixture concentrations for 4 different PI compositions (14, 15, 16 and 17 wt% PI). (Membrane synthesis conditions: membrane thickness of 250 μm, evaporation time of 30s. Filtration conditions: 15 bar, room temperature).

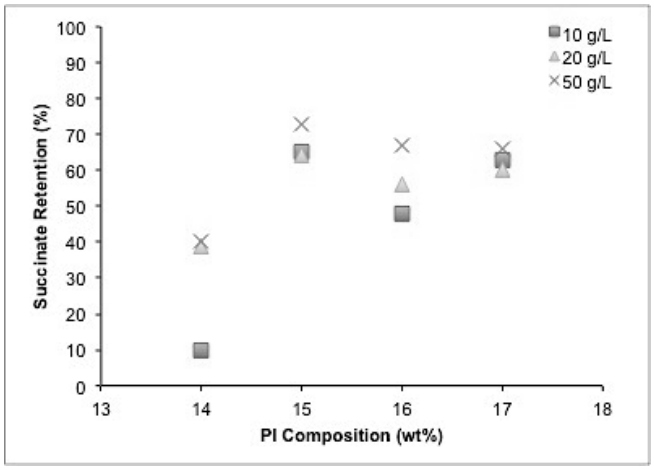

Figure 4. Succinate retention from 10, 20 and 50 g/L mixed salt solution concentrations as a function of PI composition (14 – 17 wt%) PI. (Membrane synthesis conditions: membrane thickness of 250 µm, evaporation time of 30s. Filtration conditions: 15 bar, room temperature).

However, for the selective separation of succinate in the mixed salt solution, in which succinate is recovered (retained in the retentate) while acetate and formate are removed in the permeate, 14 wt% PI membrane shows poor performance compared to the 15 wt% PI. Figure 5(a) shows that the retention of succinate by PI membrane at 14 wt% is approximately 40% for all concentration tested except at 10 g/L mixed salt solution concentration, in which a lower retention of 10% was obtained. The retention of formate and acetate were also found to be equivalent or higher than succinate retention indicating that 14 wt% PI membrane is not suitable for the selective separation of succinate. Such phenomenon can be explained by the large MWCO of membrane determined from the low retention of NaCl (MW = 58.44 g/mol) and Na_2SO_4 (MW = 142.04 g/mol) obtained in Table 1.

As the polymer composition increases to 15 wt% as shown in Figure 5(b), it was observed that succinate was able to be selectively retained while removing acetate and formate at high concentration of above 10 g/L. The succinate retention increased from 64 to 73%, while the retention of formate reduced from 42 to 39%, and acetate retention did not change much with the increasing of ternary solution concentration from 20 – 50 g/L. This increase in difference between succinate, formate, and acetate retentions indicates that the selectivity of succinate increases at high mixture concentration. It is expected that, if multiple filtrate tests are carried out, higher succinate retention and selectivity could be achieved. In a normal practice, multi-run/multi-celled, and integrated system of membrane coupled with other separation technologies are usually applied to get higher selectivity.

The increase in selectivity observed at increasing concentration could be explained by the pumping effect of monovalent anion (formate and acetate) by the divalent anion (succinate) [19]. Having a higher valency, divalent anions tend to stay further away from the membrane surface due to strong repulsion while pushing monovalent anions towards the membrane surface to meet electroneutrality in the membrane phase. Consequently this increases the concentration of monovalent anions in the membrane phase, thus the monovalent ions permeate preferentially at higher fraction compared to the divalent ions resulting in the observed lower retention of acetate and formate, compared to succinate [19]. This phenomenon was also found to be more significant at higher mixed salt solution concentration of above 10 g/L as observed in Figure 5(b) because at higher concentration, succinate, a divalent anion could effectively balance the charge of counter ion, Na^+ thus acetate/formate is no longer required for electroneutrality, causing its retention to decrease [31]. Moreover it was also observed that the retention of formate decreases more compared to acetate at increasing mixed salt solution concentration from 20 to 50 g/L. This can be explained by the smaller degree of dissociation of formic acid (pK_a 3.8) compared to acetic acid (pK_a 4.7), thus formic acid was more completely dissociated than acetic acid at the pH tested [15,32].

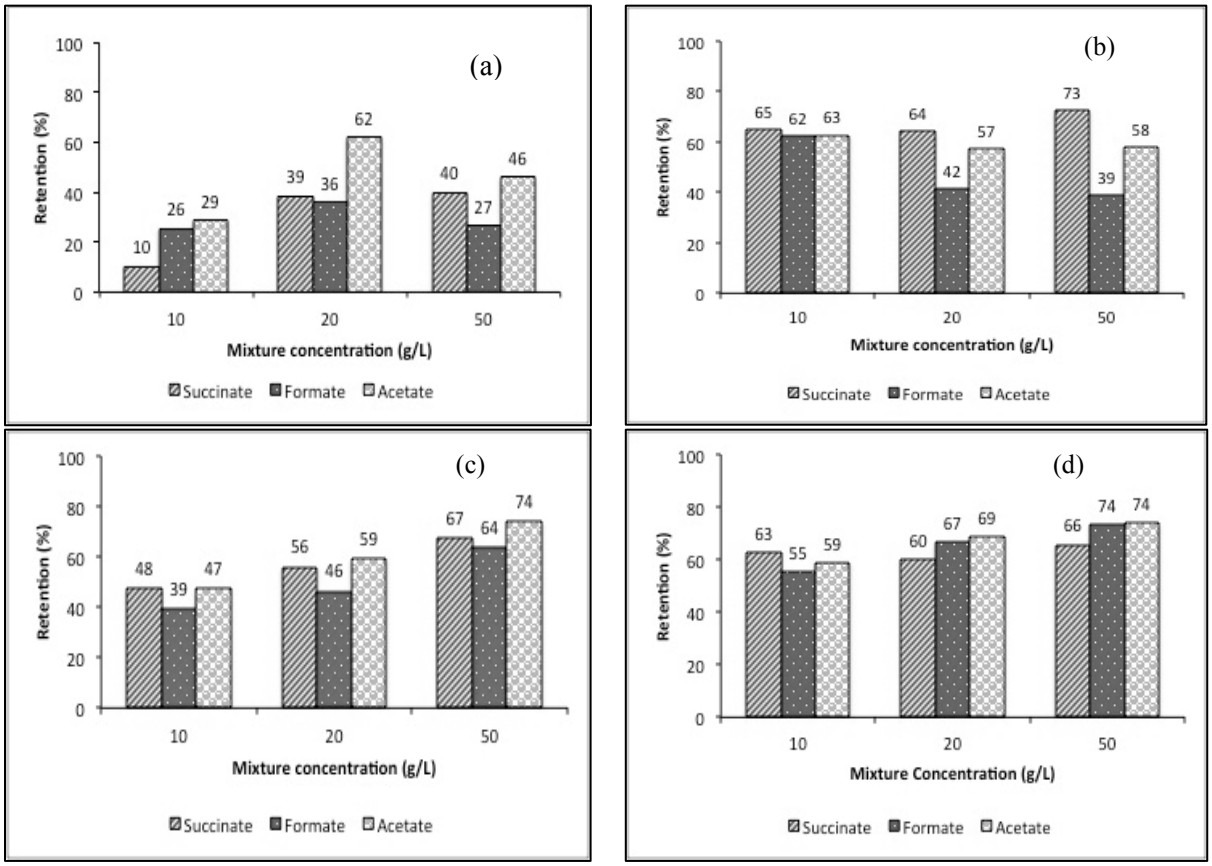

Figure 5. Retention of succinate, formate and acetate from mixed salt solution at 10, 20 and 50 g/L concentrations for (a) 14, (b) 15 (c) 16 and (d) 17 wt% PI membranes. (Membrane synthesis conditions: membrane thickness of 250 μm, evaporation time of 30s. Filtration conditions: 15 bar, room temperature).

However, when the polymer composition increased above 15 wt%, it was observed that succinate was not able to be selectively separated from the mixed salt solutions irrespective of the concentration of salt solutions tested, as shown in Figures 5 (c) and (d). All compounds (succinate, formate, and acetate) show similar retention percentage and only slight increase in succinate selectivity was observed as the mixture concentration increases from 10 to 50 g/L. This result is found to be consistent with the salt retention test that was carried out as discussed in section 3.1. Membranes with higher PI composition of above 15 wt% show a reduction in the retention difference between monovalent and divalent anions. Thus it is not suitable for selective separation of divalent anions from solution containing both monovalent and divalent anions.

Conclusion

Overall, PI shows high potential to be fabricated into NF membrane via phase inversion by manipulating the polymer composition. The NF characteristic was observed when PI composition is above 14 wt% based on the salt retention obtained. Based on the salt retention of NaCl and Na_2SO_4, 15 wt% PI membrane was found to have relatively low retention to monovalent ions and high retention to divalent ions. It also shows the best performance in selectively separated and retained succinate while rejecting formate and acetate from the model fermentation broth solution. The highest succinate retention of 73% was obtained at 50 g/L mixture solutions. Succinate selectivity was also observed with increasing mixture solution concentration from 20 to 50 g/L which was determined from the reduction in formate retention from 42 to 39%. As the test was only carried out in a single test with single cell

filtration, it is expected that a higher purity can be achieved with a multi-run/multi-celled or/and integrated system of membrane coupled with other separation technologies processes, which are usually used in a normal practice. FESEM images showing dense and thick skin layer with porous substructure resembling common NF membrane morphology also supported the result of the succinate retention.

Abstract

Biogas is produced from decomposition of organic waste such as sewage sludge, animal manure, and municipality solid wastes by microorganisms in anaerobic conditions. Biogas, which consist mainly of methane is a renewable energy source. It can be used for heating, power generation or upgrading to natural gas quality. In this study, the anaerobic treatability and biogas generation potential of *Cabomba furcata* (*C. furcata*) were examined in batch digesters. *C. furcata* collected from Chini Lake, Pahang was utilized as a substrate in biogas production. Slurry samples of *C. furcata* were prepared in 2 different mixture i.e., *C. furcata*/water ratio (1:1, 1:2 and 1:3) and *C. furcata*/inoculums ratio (1:1, 1:2 and 1:3). Throughout the experiment, the pH range was 5.5 to 7.0 while temperature range was 25 to 30 °C to enable anaerobic digestion in mesophilic condition for a retention time of 28 days. The results showed that the maximum methane production achieved at ratio of 1:3 for both mixture *C. furcata*/water and *C. furcata*/inoculums with production percentages up to 1.1 and 11.9%, respectively. Moreover, the result indicated that the production of methane increased as the retention time increased. Therefore, native plant of *C. furcata* is a great potential as a substrate in the production of biogas for future renewable energy.

Keywords: *Cabomba furcata*, methane production, anaerobic digestion, renewable energy

Abstrak

Biogas terhasil daripada penguraian sisa organik seperti kumbuhan enapcemar, baja haiwan dan sisa pepejal perbandaran oleh mikroorganisma dalam keadaan anaerobik. Biogas terdiri daripada metana sebagai sumber tenaga yang boleh diperbaharui. Ia boleh digunakan untuk pemanasan, penjanaan kuasa atau peningkatan kepada kualiti gas asli. Melalui kajian ini, kebolehrawatan anaerobik dan kebolehan penjanaan biogas oleh *Cabomba furcata* (C. *furcata*) telah diperiksa di dalam penghadam kelompok. C. *furcata* telah dikumpul dari Tasik Chini, Pahang dan digunakan sebagai substrat dalam penghasilan biogas. Sampel cair *C. furcata* disediakan dengan 2 campuran yang berlainan i.e., nisbah *C. furcata*/air (1:1, 1:2 dan 1:3) dan nisbah *C. furcata*/inokulum (1:1, 1:2 dan 1:3). Sepanjang kajian dijalankan, nilai pH adalah 5.5 hingga 7.0 manakala julat suhu ialah 25 – 30 °C menjadikan keadaan operasi penghadaman anaerobik sebagai mesofilik dan masa tahanan selama 28 hari. Keputusan kajian menunjukkan penghasilan biogas yang maksimum berlaku pada nisbah 1:3 untuk kedua-dua campuran *C. furcata*/air dan *C. furcata*/inokulum dengan peratusan penghasilan masing - masing meningkat kepada 1.1 dan 11.9%. Selain itu, keputusan juga menunjukkan penghasilan semakin meningkat apabila masa tahanan meningkat. Oleh itu, *C. furcata* mempunyai potensi yang bagus sebagai substrat dalam penghasilan biogas untuk tenaga yang boleh diperbaharui pada masa depan.

Kata kunci: *Cabomba furcata*, penghasilan metana, penghadaman anaerobik, tenaga yang boleh diperbaharui

Introduction

Biogas is one of the clean renewable energy where the source is easily controlled such as organic waste. Biogas is produced from decomposition of organic material by microorganisms in absence of oxygen. Besides that, biogas also can be produced by anaerobic digestion or fermentation of biodegradable materials such as biomass, fertilizer, municipal waste, crop, crop residue and other plants. Biogas consist of methane, carbon dioxide, nitrogen, hydrogen, hydrogen sulfide and oxygen. In Malaysia, the source for biogas generation such as agriculture waste, animal manure, domestic waste, crops, household waste and others are widely available. Using these materials as biogas sources can provides a number of advantages such as reduce the utilization of fossil fuel, increase farmers income and provide employment opportunities. In addition, biogas production has a great potential to produce neutral carbon dioxide that can prevent the occurrences of emission of greenhouse gases into the atmosphere and simultaneously reduce air pollution as well.

Anaerobic digestion is one of widely used process and attractive method for converting organic waste into for biogas as alternative energy sources [1]. Anaerobic digestion is a natural process in which bacteria decompose the carbon in organic matter. The digestion occurs in three process steps which are hydrolysis, acidogenesis and methanogenesis. In hydrolysis stage, complex organic compounds are broken down by hydrolytic bacteria. Subsequently, in the acidogenesis stage, compounds are further broken into simple molecules by acid-forming bacteria. Then, in methanogenesis stage, methanogenic bacteria will convert the acids into methane gas and carbon dioxide. These processes occur without the presence of oxygen [2]. A few studies have been conducted on biogas production using aquatic plants by applying anaerobic digestion process such as water hyacinth [3], *Eichhornia azurea, Pistia stratiotes* and *Salvini* [4], and water hyacinth and water chest nut [5].

Cabomba furcata is a fully submerged aquatic plant that grows readily in Chini Lake, Pahang. Unfortunately, *C. furcata* gives negative impact towards ecosystem in Chini Lake. Recent research indicates *C. furcata* adversely affects water quality by imparting colour and taint. Cabomba thickets interfere with swimming, boating and fishing, increased the habitat of disease carriers like mosquitoes and reduce habitat available other native plants, fish and others species [6]. Recommendations to utilize an aquatic plant as a renewable feedstock is a good solution for controlling overgrowth of *C. furcata*, save the ecosystem and cost effective. Therefore, this study was conducted to evaluate the potential of *C. furcata* as a substrate for biogas production in a batch digester. The effect of substrate/water ratio and substrate/inoculums ratio were also investigated extensively.

Materials and Methods

Substrate and inoculums

C. furcata plant was used as a substrate for biogas production. The plant was collected from Chini Lake, Pahang while inoculums of activated sludge was obtained from sewage treatment plant located in Putrajaya.

C. furcata preparation

The raw sample of *C. furcata* was weighted and transferred into six different 2000 mL conical flasks, as batch digesters for carrying out the anaerobic digestion process. Each conical flask contained 500 g of *C. furcata* substrate at different ratio of sample mixture. Conical flask 1, 2 and 3 were filled with 500, 1000 and 1500 g of water for 1:1, 1:2 and 1:3 of *C. furcata*/water ratio respectively. Meanwhile, conical flask labelled with 4, 5 and 6 contained 500, 1000 and 1500 g of inoculums for 1:1, 1:2, 1:3 of *C. furcata*/inoculums ratio respectively as shown in Table 1.

Setup of anaerobic digester

Anaerobic digester system was setup using 2000 mL conical flask and 1000 mL cylinder that filled with water was upturned to trap gas produced during experiment. Both unit was connected using silicon tube as depicted in Figure 1. Each reactor consists of different sample mixture as stated in Table 1. Laboratory anaerobic digester system was developed as shown in Figure 1.

Table 1. Sample preparation method

Digester	Sample Mixture	Mixture Ratio
1	500 g *C. furcata* + 500 g water	1:1
2	500 g *C. furcata* + 1000 g water	1:2
3	500 g *C. furcata* + 1500 g water	1:3
4	500 g *C. furcata* + 500 g inoculums	1:1
5	500 g *C. furcata* + 1000 g inoculums	1:2
6	500 g *C. furcata* + 1500 g inoculums	1:3

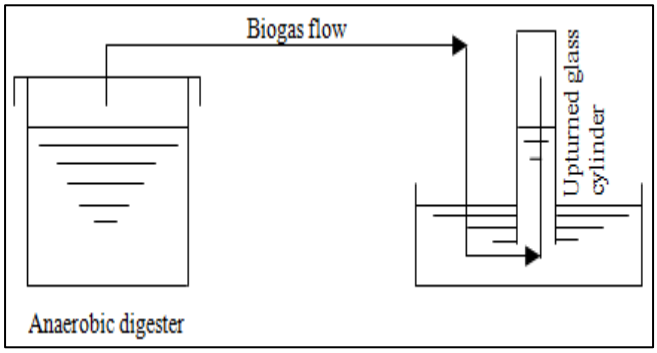

Figure 1. Schematic diagram for anaerobic digester system

Results and Discussion

Effect of *C. furcata*/water ratios

As can be seen in Figure 2, a graph of percentage of biogas production versus time was plotted for the sample mixture of *C. furcata* and water for once in week until 28 days. Cumulative biogas production for sample mixture of 1:1 and 1:2 *C. furcata*/water ratio increased according to time but for ratio of 1:3 *C.furcata*/water the biogas production increased after day 22 onwards. For sample mixture of 1:1 and 1:2 *C. furcata*/water there were no CH_4 detected during 28 days. Meanwhile for sample mixture of 1:3 *C. furcata*/water ratio produced 1.1% of CH_4 started on day 22. At ratio of 1:1 of *C. furcata*/water only 3.6%, 4.4%, 2.1% and 1.4% CO_2 were produced on day 7, 14, 21 and 28, respectively and only 61.3% hydrogen was detected on day 28. The sample mixture of 1:2 *C. furcata*/water ratio produced 0.95% of CO_2 and 50.9% of H_2 on day 7. Biogas composition majorly consists of methane and carbon dioxide. Meanwhile, nitrogen, hydrogen, hydrogen sulphide and oxygen are minority gases produced during digestion process [7]. Others gases produced during this study might consist of nitrogen, oxygen and hydrogen sulphide. Based on the results, only sample mixture of 1:3 *C. furcata*/water produced 1.1% CH_4. The methane produced from the digestion process could be initiated from native microbes that naturally attached to the *C. furcata*. On top of that, sample mixture of 1:3 *C. furcata*/water has higher fluid properties compared to others. According to Sara and Veronica [7], fluid properties is an important parameter for feedstock to facilitate the methane bacteria to contact with feedstock and makes the digestion faster.

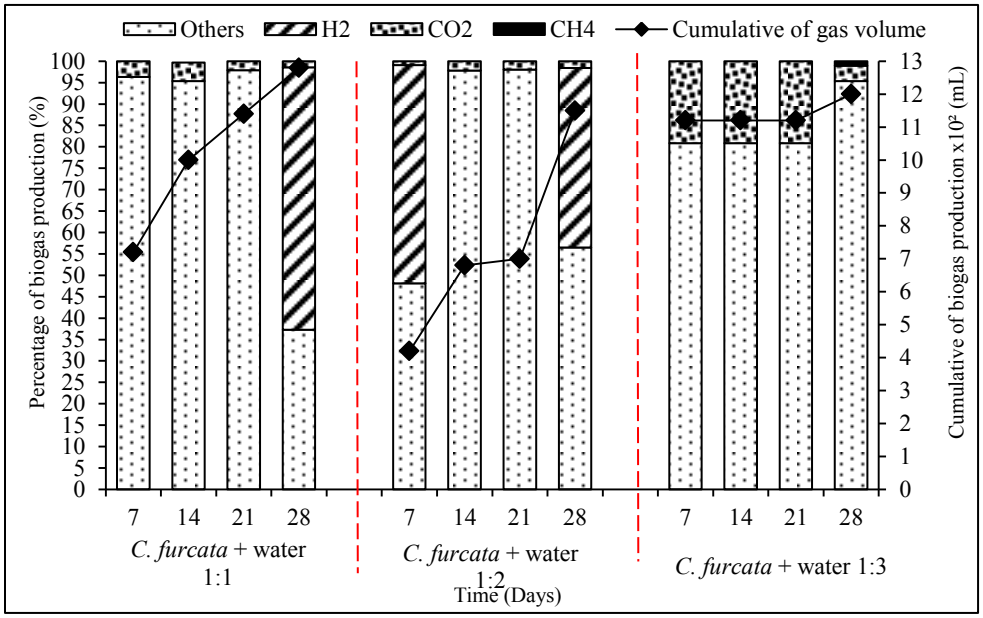

Figure 2. Biogas production from *C. furcata*/water slurry at different ratio

Effect of *C. furcata*/inoculums ratios

In Figure 3, the cumulative biogas production for sample mixture of *C. furcata*/inoculums ratio (1:1, 1:2, and 1:3) increased according to time. For sample mixture of 1:1 *C. furcata*/inoculums ratio, no CH_4 detected. Otherwise, CO_2 detected on days 7, 14, 21 and 28 as 1.3%, 2.7%, 2.6% and 2.7% respectively while 49.3% of hydrogen produced on day 7. However, for sample mixture of 1:2 *C. furcata*/inoculums ratio, about 2.1% of methane detected within days 22 to 28 followed by CO_2 produced on days 7, 14, 21 and 28 as 1.2%, 8.2%, 3.5% and 7.3% respectively. But H_2 only produced on day 7 about 85.1%. The percentage of CH_4 yield increase can be seen for sample mixture of 1:3 *C. furcata*/inoculums ratio up to 11.9% during 28 days. While, CO_2 production increase day by day as 2.2%, 5.5%, 3.1% and 8.5% on day 7, 14, 21, and 28 respectively. H_2 only detected on 7, 14 and 28 as much as 58.7%, 37.0 and 49.4% respectively. Based on the previous research, Neo et al. [8] reported that wheat straw produced highest percentage of biogas production up to 59% when inoculated with cattle manure. Other than that, Sunorso et al. [9] proved that substrates (manure) and inoculums (rumen fluid) exhibit higher cumulative biogas production. Besides, Abu Darieh et al. [10] reported that, methane yield produced from grass mixed with inoculums up to 80%. As a result, inoculums is one of the most important factor affecting the biogas production. In order to produce high CH_4 content, inoculums that contain high microbial loading needs to be added in the mixture of biomass to initiate the biochemical processes from anaerobic digester [11]. During this digestion, CO_2 produced is less than 10% for the sample mixture of 1:1 *C. furcata*/inoculums ratio and 1:2 *C. furcata*/inoculums ratio compared to H_2 produced up to 85% for 1:3 *C. furcata*/inoculums ratio. H_2 and CO_2 are the two other products converted by acidifying bacteria during acidogenesis stage. Khanal et al. [12] reported that optimum pH for hydrogen produced is at pH 5. Content of liquid in the digester is the main factor in producing of CO_2. Reducing in CO_2 level in gas phase resulted from higher liquid content in digester and elevated the concentration CO_2 dissolved in water [13].

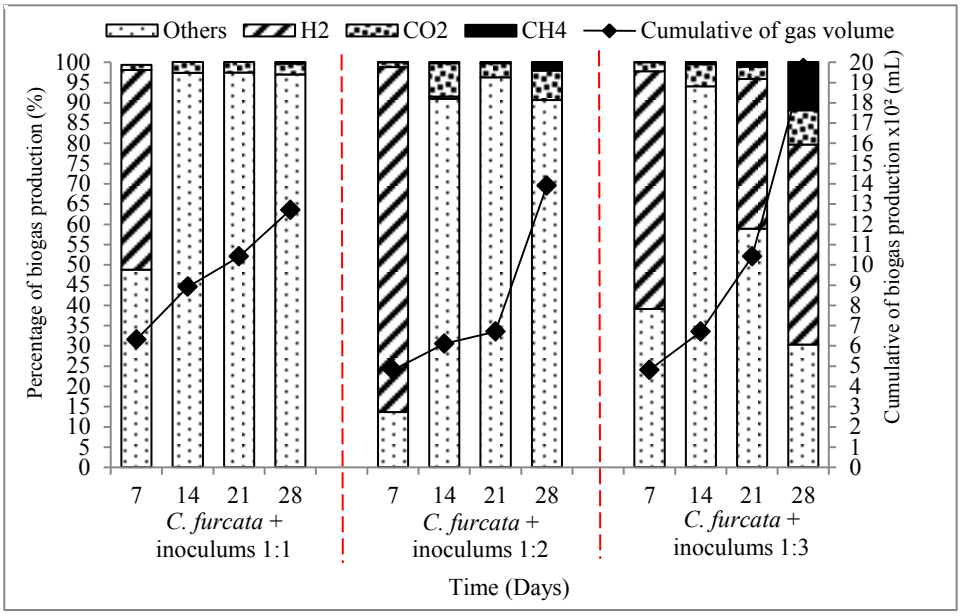

Figure 3. Biogas production from *C. furcata*/inoculums slurry at different ratios

Variation of pH and temperature during CH_4 production

During digestion occurred, the variation pH value was monitored and plotted in Figure 4. pH value and temperature were monitored regularly at every 3 days and continued until 35 days. The profile of the pH and temperature for both types of sample mixture were similar. The pH value dropped from an initial reading of around pH 5.5 - 6.9 for all samples. The decline of pH reading from 4.5 to 5 for each sample causes acidic conditions that lead to the failure of methanogenic activity because it inhibits of microbial growth. This occurs when the pH value drops below 6.5 [14]. Based on these factors, the sample mixture of 1:3 *C. furcata*/water ratio managed to produce little CH_4 on the 28th day since the final of pH value in the range of 5 - 6.2 because the pH is less acidic. Similarly, sample mixture of 1:3 *C. furcata*/inoculums, which resulted in the highest percentage of CH_4 as final pH value of the sample was approaching pH 6.5 that suitable for bacteria involved in anaerobic digestion. During the digestion process, protein degradation might occur and result in increasing ammonia presence that contributed to the elevated pH during day 17 for all sample mixtures and had inhibited the process [15]. The pH value decreased on day 20 due to the utilization of ammonia by microbes as nitrogen source for growth. As a result, pH decreased below than 6.5, and the conversion of mainly H_2 or CO_2 to methane and, acetate acid to methane and carbon dioxide by methanogenic bacteria could be reduced during methanogenesis process [16].

As shown in to Figure 5, the temperature for all the samples in the range of 25 - 30°C during the digestion. Ozmen and Aslanzadeh [17] reported that the possible temperature for anaerobic digestion from 3 to 70 °C and for mesophilic conditions in the range of 20 – 40 °C. It means that the process of digestion occurred within the mesophilic range. The temperature control of the process is important to ensure the optimum temperature range for the bacteria during methanogenic activity. Based on Figure 2 and Figure 3, the highest percentage of CH_4 produced in mesophilic condition up to 11.9 %. However, according to Tchobanogous et al. [18], this digestion temperature in this study considered as optimal temperature for the support of biological-reaction rate.

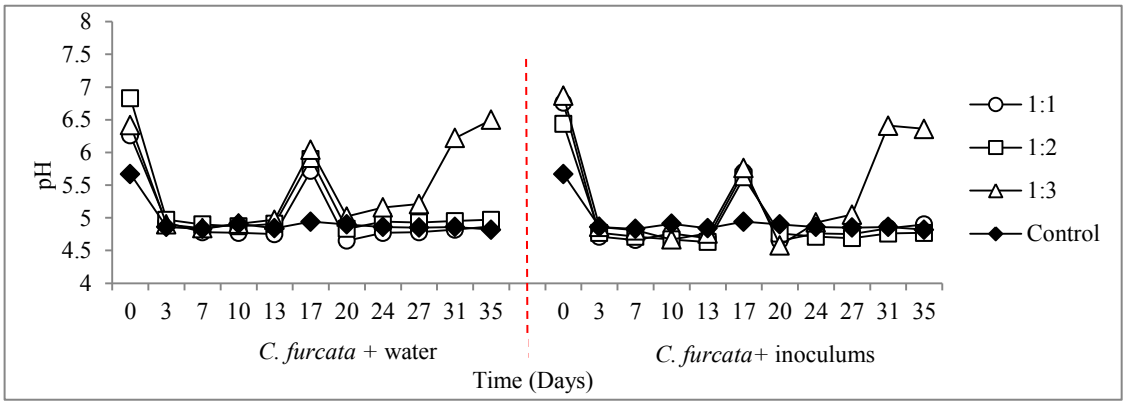

Figure 4. Comparative of pH value in anaerobic digestion process

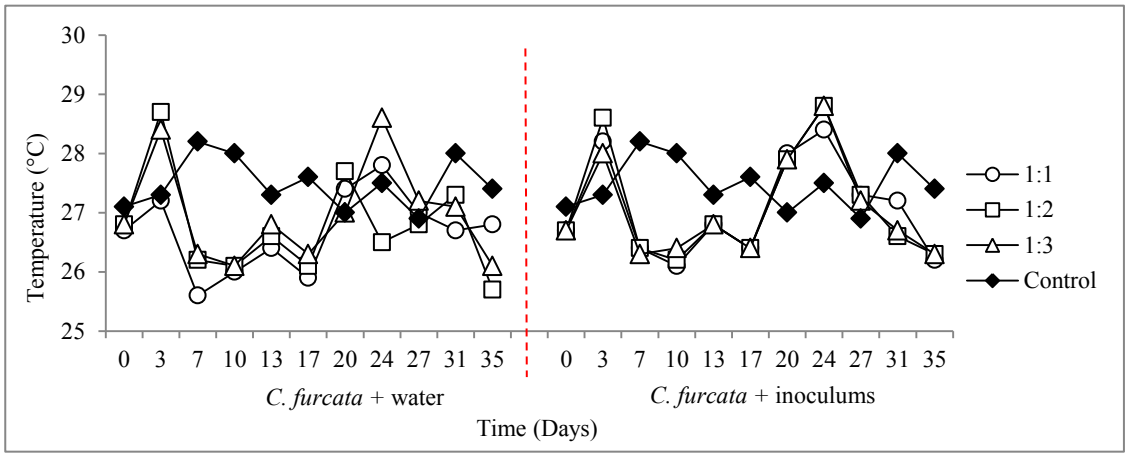

Figure 5. Comparative of temperature in anaerobic digestion process

A sample mixture of *C. furcata*/inoculums shows the percentage increase in CH_4 quite significantly up to 11.9% for sample mixture of 1:3 *C. furcata*/inoculums ratio as shown in Figure 3. This is because this sample contained of highest soluble/degradable organic load for methanogens. Verma et al. [5] reported that the role of the inoculums, supplying microbial culture and a slurry substrate to begin the process methanogenisis assume equals importance in biogas production. Besides that, the retention time which the period spent by the feed or substrate inside the digester has a significant effect on methane production. The appropriate retention time for mesophilic bacteria is around 20 days. If the retention time is in the short period, the concentration of methane in the formed biogas is less than 50% and it is not longer combustible [7]. This was proven by the highest amount of biogas produced which started from days 22 for sample mixture of 1:3 *C. furcata*/water ratio and 1:3 *C. furcata*/inoculums ratio.

Conclusion

The result revealed that *C. furcata* has a great potential for utilization as substrate in biogas production. In mesophilic phase, the cumulated biogas volume increased with respect to substrate/water ratio and substrate/inoculums ratio. The most important finding in this research is that the sample mixture ratio of the substrate significantly affect the biogas production. The sample mixture of *C. furcata*/inoculums produced up to 11.9% of CH_4 during 28 days of anaerobic digestion process compared to sample mixture of *C. furcata*/water ratio only produced about 1.1% of CH_4. Besides that, activated sewage sludge can be used as inoculums for anaerobic digestion since it has important roles for start-up of the biochemical processes from anaerobic digesters.

Abstract

In this study, silicone rubbers were used to achieve the desire absorbing properties of PANI onto polyvinylidene fluoride (PVDF) microporous support. Poly (methyl-vinyl ether-alt-maleic acid) (PMVEA) polymeric acid was used as acid dopant to enhance the membrane filtration performance. Initially PVDF micro-porous support was dip-coated with silicone rubber elastomer solution followed by deposition with PANI by *in-situ* chemical oxidative polymerisation techniques using two-compartment cell in presence of PMVEA and ammonium persulfate as the oxidizing agent. The PANI multilayer composite membranes were characterized by gravimetric for PANI content measurement namely Scanning Electron Microscope (SEM), Fourier-Transform Infrared (FTIR), Differential Scanning Calorimetry (DSC) and contact angle. The PANI content was found to be more than 30 %. SEM, FTIR and DSC analysis have confirmed the presence of PANI onto the multilayers membrane while the contact angle of the membrane in presence of high loading PANI was 0 ^{o} indicating the super hydrophilicity than without the PANI presence of 78.8 ^{o}. The pressure filtration of PANI multilayer composite filtration membrane with a range of polyethylene glycols at different molecular weights was obtained based on the high flux up to 904.11 L/m^2.h and reasonable molecular weight cut off of below 20,000 g/mol were obtained for the synthesized membrane.

Keywords: polyaniline, silicone elastomer, polyvinylidene fluoride, chemical oxidative polymerisation, polymeric acid

Abstrak

Melaui kajian ini, getah silikon telah digunakan untuk mencapai keinginan menyerap sifat-sifat PANI ke polivinilidin fluorida (PVDF) sokongan mikrobeliang. Poli (vinil metil-eter-alt-asid malik) (PMVEA) asid polimer digunakan sebagai asid pendopan untuk meningkatkan prestasi penapisan membran. Pada mulanya mikro-berliang sokongan PVDF telah disalut dengan larutan elastomer getah silikon diikuti dengan pemendapan PANI oleh teknik pempolimeran kimia oksidatif sel *in-situ* menggunakan dua bahagian sel dengan kehadiran PMVEA dan ammonium persulfat sebagai agen pengoksidaan. Membran komposit PANI multilapis telah dicirikan secara gravimetrik untuk mengukur kandungan PANI, seperti Mikroskop Imbasan Elektron (SEM), Inframerah Transformasi Fourier (FTIR), kalorimeter pengimbasan pembezaan (DSC) dan sudut sentuhan. Kandungan PANI didapati melebihi 30%. Analsis SEM, FTIR dan DSC telah mengesahkan kehadiran PANI pada membran PANI multilapisan manakala sudut sentuhan membran dengan kehadrian PANI yang tinggi adalah 0 ° menunjukkan keadaan super hidrofilik berbanding tanpa kehadiran PANI adalah 78.8 °. Tekanan penapisan membran komposit PANI multilapis dengan pelbagai julat polietilena glikol pada berat molekul yang berbeza telah diperolehi berdasarkan fluks yang tinggi sehingga 904.11 L/m^2.h dan berat molekul yang munasabah iaitu di bawah 20.000 g/mol bagi membran yang telah di sintesis.

Introduction

Interest in conducting polymer from polyaniline (PANI) has grown due to its conducting properties: electronically conductive and electrochemically active polymer [1], good redox properties and high environmental stability, relatively simple synthesis, and also low cost [2-7]. These advantages have led PANI to be used in numerous applications including filtration membranes [8], battery electrodes [9, 10], electromagnetic shielding devices [11], and anticorrosion coatings [12-14]. To cope with the rising energy costs, emerging contaminants, stricter environmental regulations, and industrial demand, the next generation of filtration membranes must be more selective, robust, and require low chemical and energy inputs. New membrane materials must be explored to meet these goals in applications such as water and wastewater treatment, in addition to other well-established industrial, biomedical and analytical separations [8]. High permeation flux and high selectivity are the essential requirement for successful separation membrane. One way of achieving this is by self-synthesizing filtration membranes that meet the criteria. Additionally this membrane can be tailored utilizing intrinsic polymer such as PANI to meet specific requirement for the targeted application. The fabrication of high-performance multilayer composite membrane specifically from PANI base from microporous support substrate is essential to obtain the most suitable surface structure, roughness and surface porosity for the separation.

Multilayer composite membrane has been reported for various applications especially for water filtration [15-18]. The multilayer composite membrane usually has three layers and can be divided into two types based on the membrane configuration: (selective layer)/(gutter layer)/(support substrate) and (sealing or protective layer)/ (selective layer)/(support substrate) [19-21]. In the former, the selective layer might be as thin as a few tens nanometers and slightly defective; the gutter layer is a permeable material which serves as a channelling and adhesive medium between the selective layer and the support substrate. In the latter, the selective layer is thicker (about 0.04 ± 1 mm) and essentially defect-free. The sealing or protective layer not only functions as a protective layer but also improves the membrane performance [21]. Therefore this motivates the synthesis of the multilayer composite membrane to be used in the field of pressure filtration namely nano- (NF) and ultra-filtration (UF). The used of PANI in forming multilayer composite membranes have been reported in the application of fuel cell [22], desalination of saline water that consists of charged solutes [17, 23], separation of carbon dioxide from methane [24] and also as electrochemical energy storage [25]. However the application in pressure filtration membrane under neutral solutes has yet to be reported.

The main aim of this work is to fabricate multilayer composite membrane from PANI coated with silicone elastomer onto PVDF and further characterize it. Multilayer composite membrane is prepared in the form of (sealing or protective layer)/(selective layer)/(support substrate) in series. PANI works as the sealing layer, silicone rubber as the selective layer acts as barrier to attach more PANI onto PVDF (support substrate). Silicone rubber is used for selective support as it has low density, easy to form, good chemical resistance and weather resistant [26]. The functionalization of silicone rubber has been reported can improve the membrane performance either in pervaporation, gas separation or extraction to serve for better separations [27-29]. Chemical oxidative polymerization of aniline is conducted in the presence of 1M HCl to dilute the aniline and ammonium persulphate (APS) to form PANI. These aniline and APS solutions further reacted in a specially fabricated two compartment cell, each solution is filled at each side of the cell and the PVDF membrane is sandwiched between the cell. Meanwhile polymeric acid of poly (methyl- vinyl ether-alt-maleic acid) (PMVEA) is used as the dopant for functionalizing the PANI together with HCl. PANI doped with PMVEA was reportedly used for covalent attachment of oligonucleotides through the carboxylic acid functionality [30, 31]. The chemical structure of PANI, PVDF, silicone rubber and PMVEA used for producing the multilayer composite membrane is presented in Figure 1.

The characterization of the synthesized membranes was performed using Fourier Transform Infrared (FTIR) spectroscopy. Thermal properties of the membrane were investigated by Differential Scanning Calorimetry (DSC) while surface morphology is investigated by Scanning Electron Microscope (SEM). Drop shape analysis was used to examine surface wettability changes contact angles (θ) for liquid water droplets on the multilayer membrane surfaces. The performance of the multilayer membrane is tested via rejection of different molecular weights (MW) of neutral and non-charged solutes from Polyethylene glycols (PEG) in a dead-end filtration. Solutions with

different molecular weight (MW) were used for the identification of the nominal pore sizes of the membrane fabricated [32,33].

Materials and Methods

Materials

Aniline monomer, poly (methyl vinyl ether-alt-maleic acid) (PMVEA), of MW 216,000 g/mol and ammonium persulfate (APS) were obtained from Aldrich Chem. Co. The microporous polyvinylidene fluoride (PVDF) membrane (0.1 µm) was purchased from Hangzhou ANOW Microfiltration Co. Ltd., China. Liquid silicone elastomer was purchased from Portal Trading, Penang, Malaysia. N-hexane and hydrochloric acid (HCl) were supplied by Merck and used as received.

Preparation of PVDF/silicone membranes

The commercial microporous PVDF membranes were kept in a desiccator for overnight and weighed. Next, the membranes were dipped in 50% ethanol solution for 1 min and washed with ultrapure water to loosen the shrunken membrane pores due to the long-term storage [34]. The dipped membranes were then coated with a mixture of 3 wt.% of silicone (with curing agent) and 97% n-hexane for 30 minutes. This was to ensure that membrane surface has been completely covered by the mixture of silicone and curing agent [19]. The ratio of silicone to curing agent was fixed at 10:1.The silicone coated layer membranes were then cross-linked with each other by keeping the silicone coated membranes in an oven at 60 ^{o}C for 1 hour [21].

Multilayer membrane composites

The microporous PVDF coated with silicone rubber were further coated with PANI in presence of polymeric acid from PMVEA to enhance the performance of the multilayer coated membranes for application in pressure filtration especially in UF and NF range. The polymerization of PANI onto the silicone coated PVDF support was performed by sandwiching aniline/PMVEA and APS aqueous solutions in a specially fabricated two-compartment cell via diffusion technique. The schematic diagram of the cell is presented in Figure 2. Silicone elastomer, which was initially coated on PVDF microporous support, was clamped in between the two cell loaded with aniline and APS aqueous solutions, respectively, in a way to enhance the absorption of PANI/PMVEA onto the microporus PVDF/silicone support. Initially, 0.8 mol.L^{-1} aniline and 4 wt.% PMVEA were dissolved in 1 M HCl while the molar ratio of APS to aniline in the final solution was set at 1: 1.25 mol.mol^{-1}. The stirring speed was maintained at 400 rpm and a stainless steel ring clamp was used to tighten the two compartment cells where the membrane was placed in the middle of the cells. During the polymerization period, aniline/PMVEA and APS oxidant solutions were allowed to counter-diffuse, simultaneously, through the silicone/PVDF coated membrane. After the polymerization reaction for 6 h completed, the multilayer composite membrane was removed from the cell, cleaned with ultrapure water several times and further soaked in 1M HCl for 24 hours to achieve a complete protonation and doping of PANI in the membranes [6].

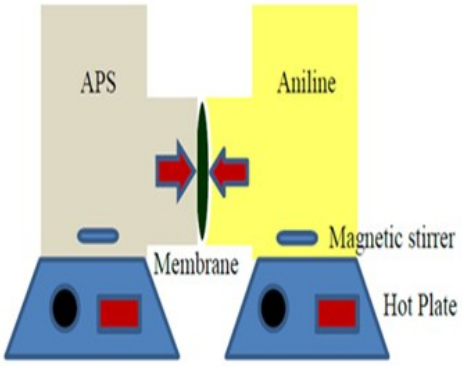

Figure 2. Schematic diagram of the two-compartment cell

PANI deposition levels in the base membranes were measured by using the gravimetric technique. The PANI deposition was calculated by measuring the weight difference between the modified and silicone/PVDF membranes. The PANI/PMVEA deposition % PANI was calculated using Equation (1):

$$\text{PANI/PMVEA (\%)} = \frac{Wf - Wi}{Wf} \text{ X } 100 \quad (1)$$

where, W_i is the initial weight of PVDF/silicone membrane before PANI/PMVEA coating and W_f is the final weight of the multilayer membrane after polymerization.

Membranes characterization

Fourier transform infrared spectroscopy (FTIR) spectra of the multilayer membranes were recorded using Thermo Scientific, Nicolet 6700 FT-IR (ATR) at a resolution of 4 cm^{-1} using pressed potassium bromide (KBr) pellets in a transmittance mode. A wavenumber between 4000 to 600 cm^{-1} was scanned for 16 times with the scan time of 1 min.

The surface and cross-sectional morphology of the multilayer membranes were examined with Scanning Electron Microscopy (SEM) (Leo 1550 VP) using activation voltage ranging from 2 kV to 5 kV. For cross-sectional morphology, the membranes were initially dipped in liquid nitrogen to crack the membrane. All membranes were coated with gold with thickness of 6 nm by using Polaron SC 500 prior to analyses. Samples were mounted on a Aluminium stub and further analyzed in SEM.

Meanwhile, the thermal investigation of the membranes was measured using DSC under an inert static flowing of nitrogen gas. The temperature was increased at a rate of 10 $^{o}C\ min^{-1}$ with temperature range between 25 ^{o}C to 500 ^{o}C.

Easy Drop Goniometer (Kruss GmbH, Germany) was used to determine the membranes' contact angle (^{o}) via dropping a water droplet with a volume of 2 mL onto the film surface and a high speed camera was used to record the droplet permeation images. The measurements were carried out in air at room temperature. At each activation potential, an average contact angle was determined from measurements of 3 separate droplets within a region of 2 mm^2.

Sterlitech HP4750 Stirred Cell was used to obtain the water flux and the rejection of the synthesized membrane having an active surface area of 14.6 cm^2 using Equation (2) [33,35,36]. Membrane water filtration properties were determined by using pure water flux measurement at pressure ranged from 1 to 5 bar at 27 ^{o}C.

$$\text{Flux, J} = \frac{V}{A \times t} \quad (2)$$

where, J is the permeate flux ($L.m^{-2}.h^{-1}$), V is volume of permeate (L), A is effective membrane area (m^2) and t is operating time (h).

Molecular weight cut-off (MWCO) value was obtained from the PEG rejection profile of the multilayer membranes from 90% molecular rejection which were calculated using Equation (3). Solute rejection (SR) of the multilayer membranes were evaluated with various MW of PEG solutions from 6000 to 20 000 $g.mol^{-1}$ with concentration of 100 $mg.L^{-1}$ at 5 bar.

$$SR\ (\%) = \left[1 - \frac{C_p}{C_f}\right] x\ 100 \quad (3)$$

C_f and C_p are the polyethylene glycol concentrations in the feed solution and permeate solution, respectively [37]. The concentration of PEG was determined based on their absorbency in a UV-spectrophotometer at a wavelength of 535 nm.

Results and Discussion

Gravimetric PANI/PMVEA content

PANI/PMVEA deposition amount in the based membrane supports were measured by using the gravimetric technique. The PANI/PMVEA coated onto the composite membrane support was calculated by measuring the weight difference between modified and coated PVDF membranes with silicone elastomer (Table 1). The results showed that longer reaction time resulted in higher PANI deposition onto the membrane to form the PANI/PMVEA multilayer membrane. The highest PANI/PMVEA coating of 61.8% was obtained at 10 hours while the lowest of 32.4% was obtained at 6 hours. In this work, PANI/PMVEA was assumed to be deposited inside the pores and on the surface of the silicone/PVDF membrane during the polymerization period in the two-compartment cell (refer Figure 2). PANI has formed in bulk membrane by the counter-diffusion of aniline and oxidant (APS) through the membrane [6]. The amount of PANI/PMVEA deposited onto the membrane was calculated via gravimetry technique. During the polymerization process, PANI deposition was initiated on the aniline-facing side of the membrane and maintained its asymmetric growth in the bulk membrane throughout the polymerization.

Table 1. The amount of PANI/PMVEA deposited (%) onto silicone/PVDF

Polymerisation Time (h)	PANI/PMVEA Deposition (%)
6	32.4
8	40.0
10	61.8

Donnan exclusion may be used to explain the deposition mechanism of PANI onto microporous support in the diffusion cell [38]. In the polymerization period using the two-compartment cell, APS solution was used in the compartment with ANI. The negatively charged $S_2O_8^{2-}$ species would then be generated from the decomposition of APS on the support polymer. This resulted in the polymerisation of PANI from positively charged anilinium ions ($C_6H_5NH^3+$) onto the ANI-facing side of the diffusion cell. This occurred right after the mixing of the monomer and oxidant attached to the microporous support sites. Subsequently, the PANI polymerisation would be enriched on the surface of the ANI-facing side of the membrane, through a continuous polymerisation process with a counter diffusion of ANI and APS with time. The surface coverage and in-bulk PANI deposition increased with the polymerisation time.

Similar phenomenon was observed upon coating of PANI onto other supports. The difference in coating amount between the supports over the time can be explained by the difference in the support layer's interaction with PANI (the in-situ chemical oxidative polymerisation of PANI onto PVDF has been reported to be inhibited by the nature

of the PVDF matrix compared to polyethylene terpthalate (PET)) [39]. High amounts of PANI coating have also been reported for PET [39] and Nylon 6 [40] supports. This indicates that it is the physicochemical interaction of ANI with the hydrogen bonding of the NH_2-group of the ANI molecule with the silicone/PVDF that plays the role, as this is similar to the interaction with the carboxyl group in PET [39] and Nylon 6 [40]. Thus, in presence of silicone layer, it is assumed that the coating would be much better on the membrane support rather than directly coated onto the pure PVDF surface.

FTIR analysis

Figure 3 shows the FTIR spectra of the PANI/PMVEA multilayer membranes in comparison to the PVDF and silicone/PVDF coated membranes. The main peaks at 1588 and 1584 cm^{-1} correspond to the C=C stretching deformation of quinoid and benzenoid rings, respectively. The 1259.7 cm^{-1} band is assigned to the C-N stretching of the secondary aromatic amine. The peak at 796.1 cm^{-1} is assigned to an out-of-plane deformation of C-H in the 1,4-disubstituted benzene ring. A peak at 1291.9 cm^{-1}, ascribed to the $C\text{-}N^+$ stretching vibration in the polaron structure, is also observed, indicating that the PANI is in a doped state [31]. In addition to the common peaks representing PANI, a peak at 1716.5 cm^{-1} that belongs to the C=O stretching vibration of a carboxylic acid group is seen in the spectra of PANI–PMVEA indicating the presence of the polymeric acid (PMVEA) that was incorporated into the PANI structure.

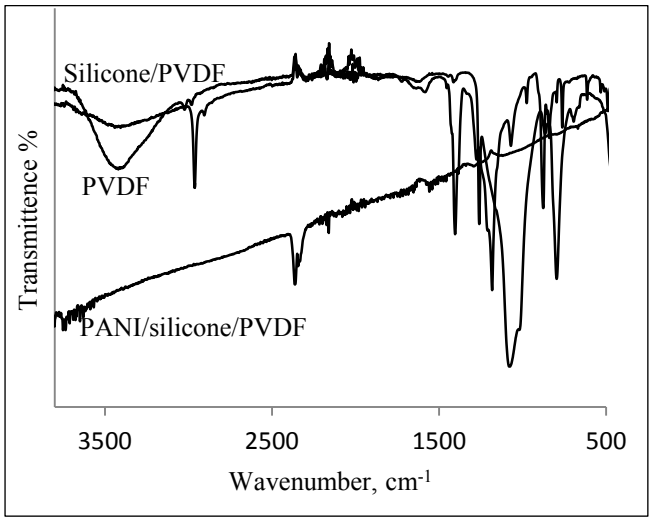

Figure 3. vFTIR spectra for the PANI/PMVEA, silicone/PVDF, PVDF multilayer composite membranes

Morphology of multilayer membranes

SEM images of the PANI/PMVEA composite membrane obtained from the chemical oxidation of aniline are shown in Figure 4. The images reveal that the molecular structure of the PVDF without coating is totally different with the PVDF/silicone. Figure 4(b) shows the silicone structural image on the surface of the PVDF membrane. The images of the coated PANI/PMVEA at different (%) in Figure 4(c), 4(d) and 4(e) are found to possess lumpy and granular morphological structures and the PANI/PMVEA growth seems to be bigger at a higher polymerisation time. From these three images, a better deposition of PANI/PMVEA can be seen in Figure 4(c) and 4(d) compared to 4(e) although higher PANI/PMVEA content was obtained at 10 hours polymerization time (refer Table 1). The more reaction times are taken for polymerization, the more PANI/PMVEA is coated on the silicone/PVDF surface.

From the SEM images, the morphology of PVDF membranes have changed after silicone elastomer is coated onto them. The polymerisations of PANI/PMVEA onto the micro-supports have altered the morphology of silicone elastomer onto PVDF. The molecular structure of the multilayer membrane is also affected by polymeric acid

involved and the properties of oxidant (APS) which is hydrophilic [31]. The formation of molecular structure happens through hydrogen bonding and hydrophilic/hydrophobic interaction that act as a template. The scanning electron micrograph in Figure 4(a) shows the surface morphology of the PVDF support. The surface was smoother compare the pristine PVDF (Figure 4(a)). The PVDF/silicone (Figure 4(b)) is rougher but the roughness of PVDF/silicone/PANI is lesser than the PVDF/silicone after coated with PANI. The deposition of PANI/PMVEA layer on the membrane support increases with the polymerisation time [6].

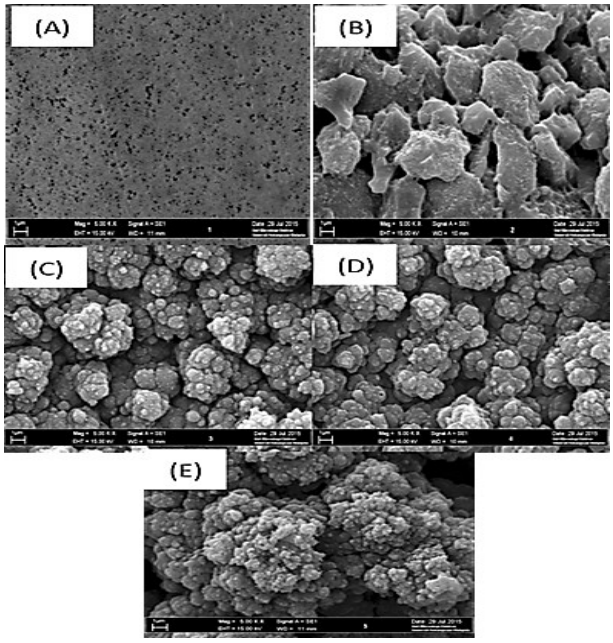

Figure 4. SEM surface images obtained; (a) PVDF support, (b) silicone/PVDF support, (c) PANI/silicone/PVDF 6 h (50%), (d) PANI/silicone/PVDF 8 h (63.3%) and (e) PANI/silicone/PVDF 10 h (83.3%) with the PMVEA, Magnification 5000 x.

Contact angle (CA) analysis

The contact angle (CA), θ, of a liquid drop on a solid surface is a useful measurement of the interactions at the solid-vapor, solid liquid, and liquid-vapor interface. The surface tension of a material determines its wettability. Typically, high CA values are an indication of low wettability, whereas low CA values correspond to high wettability [24,41]. Table 2 shows the equilibrium values of contact angle onto the membrane. The different contact angle shows the wettability of the membrane either possesses hydrophilic or hydrophobic characteristic. Based on the table, the coated membrane with PANI at all different polymerisation time has completely changed their characteristic of the PVDF/silicone support used from hydrophobic to hydrophilic properties. The contact angles recorded at 0° for the newly synthesized membrane shows that it possesses super-hydrophilic properties based on the lowest contact angles recorded. This is probably because the membranes were doped with 1 M HCl that protonate the PANI, and give the highest contact angle value. This result indicates a preliminary data for the pressure filtration of the membrane, which would be highly permeable in water. Therefore the flux is expected to be high thus a good membrane is produced. The membrane flux value is presented in the following section.

Table 2. Contact angle values of the different form membranes

Sample	Contact Angle (^{o})
PVDF	78.8
Silicone/PVDF	143
PANI-PMVEA/silicone/PVDF	
6 hours	0
8 hours	0
10 hours	0

Thermal properties of multilayer membrane

Figure 5 shows the melting temperatures of PVDF and PANI/silicone/PVDF composites membranes at different PANI content. The DSC curve peaks indicates the endothermic processes, where energy is required to break the bonds in the successive elimination of H_2O, CO and CO_2. The first peak is the evaporation of moisture and residual organic solvent in the membrane. The second peak is the endothermic process of the loss of the doping acid instead of a glass transition [42]. The sharp melting peak of PVDF is observed at 250 ^{o}C. The peaks representing PANI and silicon rubber is observed at 280 and 170 ^{o}C, respectively. The elimination of water molecules can be clearly seen at 100 ^{o}C especially for the PANI coated membranes. This is because PANI membrane in the form of emeraldine (doped with acids) carries high hydroxyl molecules, which will be evaporated at their boiling temperature. Meanwhile no shift in the peaks were observed for the major components of PVDF, PANI and silicone indicating the stability of the components used to produce the membrane.

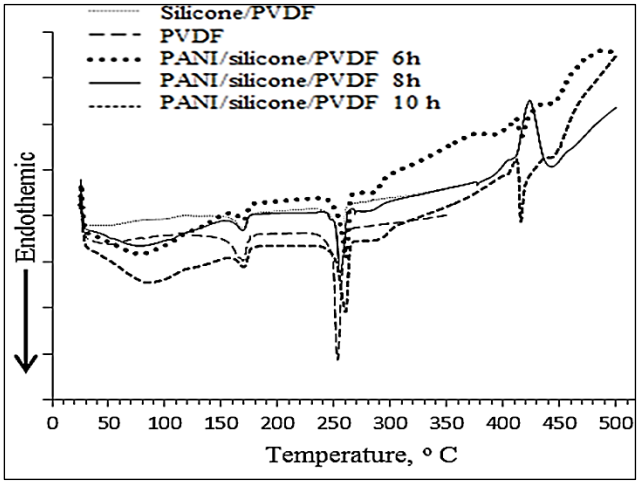

Figure 5. DSC for the different polymerization times of multilayer membranes

Based on the physical, chemical, morphological and thermal properties of the membranes analyzed in this work, the synthesized membranes are found to possess reasonable properties suitable for the application in pressure filtration. For example, the contact angles of the membranes have shown super-hydrophilic properties upon addition of the PANI/PMVEA indicating high water permeation and flux. The presence of PANI/PMVEA is supported by the FTIR, SEM and DSC analysis. Though the intrinsic properties of the membranes are confirmed from these analyses, the best membrane that could be used for pressure filtration at different polymerization time is yet to be identified. Further characterization for the membrane performances in pressure filtration is presented in the next section.

Multilayer pressure filtration membrane test

The permeation performances of the synthesized membranes were investigated by the water flux and the PEG rejection. Figure 6 and Table 3 show the respective variation of flux and rejection profile for membrane with different polymerization times performed at different pressure. Figure 6 shows the PANI membrane produced at 6 hours polymerisation has high water flux followed by the membranes produced at 8 and 10 hours, respectively. The highest water flux was recorded at the lowest polymerisation time of 6 hours. This result is supported by the membrane morphological properties with higher PANI % that have a tighter structure resulting in a lower flux value.

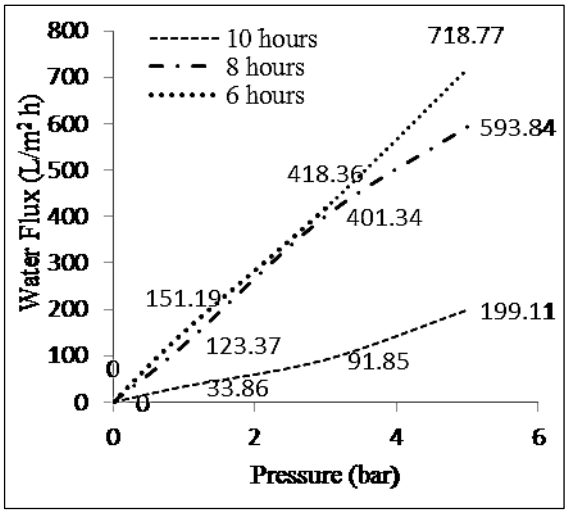

Figure 6. Water flux of multilayer filtration membrane

Table 3. Rejection of PEG below 20,000 g/mol

PANI Content %	Polymerisation Times (h)	Permeate Flux ($L/m^2.h$) (3 bar)		Rejection PEG (g/mol)	
		6000	10 000	6000	10 000
32.4	6	904.1	799.3	39.3	18.7
40.0	8	233.8	208.8	10.7	3.04
61.8	10	297.3	257.5	39.1	5.81

Membrane rejection at different MWs of PEG (presented in Table 3) shows that the lowest polymerisation times resulting the lowest PANI % have a comparable rejection value with the 10 hours polymerisation time, though the PANI content % is almost doubled for 10 hours. These results can be supported by the SEM images where the PANI deposition at higher polymerisation time than 6 hours does not help in sealing the membrane pores but has elongated the polymer on the membranes surface. It is expected that longer polymerization time supposed to form a better surface coverage. However, bigger micelles are formed and elongated (refer Figure 4 (e)). This has caused un-even coating as well as inconsistent porosity at different membrane area. The same results were reported by [31,43] under extended polymerisation time causing the PANI/PMVEA to form a micelle structure and elongate on the polymer surface. Therefore the rejection is found to be not improving by prolonging the reaction time. Lower rejection is obtained possibly due to the pores leakage on the membranes at higher pressure (5 bar) during the compaction prior to the PEG filtration. This is supported by the presence of filtration traces of PANI observed in the permeate stream

after the compaction process. Based on this result also, it can be concluded that the membrane prepared at 6 hours possesses the highest rejection and the highest flux to be further tested for a higher MW PEG.

Conclusion

PANI/PMVEA multilayer composite membranes were fabricated by chemical polymerization in a specially fabricated two-compartment cell. The amount of PANI/PMVEA % coated onto the silicone/PVDF support has increased with the increase in polymerisation time. The physical, chemical, thermal and morphological characteristic of the PVDF/silicone elastomer microporous support has changed in the presence of PANI/PMVEA. FTIR spectra have confirmed the incorporation of polymeric acid (PMVEA) into the PANI. DSC analysis has confirmed that the multilayer coating does not change much on the thermal stability of the membranes based on the melting peaks position. Contact angle shows that the water permeability of the membrane has twisted from hydrophobic to super-hydrophilic in presence of HCl doped PANI/PMVEA. The water flux of multilayer membrane decreased with the increased in PANI/PMVEA content. The higher PANI % gave the lowest water and permeate flux. The rejection result shows that the membrane has reasonable rejection at 6 hours than 8 or 10 hours while maintaining the highest flux than the others. It is suggested by optimizing the polymerization time will enhance the rejection properties of the membrane.

Abstract

The reduction behaviour of tungsten dioxide (WO_2) under both non-isothermal and isothermal conditions in various concentrations of carbon monoxide (CO) were investigated by using temperature-programmed reduction (TPR) and X-ray diffractometry (XRD) techniques. The influences of carbon monoxide concentration (20 and 40% v/v CO in N_2) on the reducibility of WO_2 to tungsten metal W have been investigated in the temperature range 40 – 900 ºC. The TPR profile shows that reduction using 40% CO produce higher thermal conductivity detector (TCD) signal in comparison by using 20 % CO. XRD results show that, by increasing the concentration of CO, the intensity of WO_2 decreases and tungsten carbide (WC) peak appeared. Moreover, holding the reduction time for 30 min in 20 and 40% of CO resulted in the formation of new peak of tungsten hemi carbide (W_2C) and WC, respectively. It can be concluded that by using CO, reduction steps comprise of $WO_2 \rightarrow W \rightarrow W_2C \rightarrow WC$. The reduction behaviour of WO_2 is strongly dependent on the concentration of CO and hold time of reaction. Furthermore, excess of CO by isothermal reduction results in the formation of WC.

Keywords: tungsten dioxide, tungsten, tungsten carbide, carbon monoxide

Abstrak

Kelakuan penurunan tungsten dioksida (WO_2) melalui penurunan bukan isotermal dan isotermal menggunakan kepekatan karbon monoksida (CO) berbeza telah dikaji dengan menggunakan suhu penurunan berprogram (TPR) dan pembelauan sinar-X (XRD). Kesan kepekatan karbon monoksida (20 dan 40% v/v CO dalam N_2) terhadap kadar penurunan WO_2 kepada W telah dikaji dalam suhu 40 – 900 °C. Profil TPR menunjukkan bahawa penurunan dengan menggunakan 40% CO menghasilkan isyarat TCD lebih tinggi berbanding dengan menggunakan 20% CO. Keputusan XRD menunjukkan bahawa, dengan meningkatkan kepekatan CO, keamatan WO_2 menurun dan puncak tungsten karbida (WC) muncul. Selain itu, dengan penambahan masa tindak balas selama 30 minit menggunakan 20 dan 40% CO menghasilkan puncak baru masing-masing tungsten hemi karbida (W_2C) dan WC. Dapat disimpulkan bahawa dengan menggunakan CO, langkah penurunan terdiri daripada $WO_2 \rightarrow W \rightarrow W_2C \rightarrow WC$. Tingkahlaku penurunan WO_2 amat bergantung kepada kepekatan CO dan penambahan masa tindak balas. Tambahan pula, pendedahan kepada CO berlebihan daripada penurunan isotermal menyebabkan pembentukan WC.

Kata kunci: tungsten dioksida, tungsten, tungsten karbida, karbon monoksida

Introduction

Tungsten is used in four main different applications that are WC, as an alloy additive, pure tungsten, and tungsten chemicals [1]. Due to superior properties, such as high melting point (3422 °C), high conductivity, thermal and chemical stability, high hardness and strength, etc. Tungsten is widely used in the contemporary industry and especially for high-temperature structural applications [2]. Tungsten is often used because of its superior thermal properties and low vapour pressure. The best known its application is as lamp filament and as electron emitters because it can be used at very high temperature. Furthermore, tungsten also used as organic tungsten dyes and pigments that can be used in variety materials. While, tungsten carbide is the most common hard materials in use today for cutting tools and other high strength application due to its high hardness at high temperatures [1].Tungsten oxides are frequently used as raw materials for recovering metal tungsten powder by reduction process for hardmetal industry and doping process for decades [1].

To further lower the temperature of oxide reduction, a reducing agent can be used [3]. The reducing agent can be hydrogen, carbon, methane, magnesium and carbon monoxide [2,4]. Tungsten oxide having several compositions like $WO_{2.9}$, $WO_{2.72}$, WO_2, WO and W_3O [5]. Venables et al. [6] studied the reduction of WO_3 with carbon monoxide using TGA. The intermediate phases $W_{20}O_{58}$, $W_{18}O_{49}$ and WO_2 were observed in the reduction, and the final product is WC. Generally reduction of tungsten oxide divided into two stages: (i) a low-temperature stage (< 777 ºC) which reduce $WO_3 \rightarrow WO_2$ involving formation and reduction of three intermediate sub oxide of ($WO_{2.96}$, $WO_{2.9}$ and $WO_{2.72}$, and (ii) high temperature stage which reduce WO_2 to W at > 777 ºC [5]. Studies on reduction of WO_3 using hydrogen and carbon monoxide as reducing agent have been published. However, there are limited studies were reported on the reduction of WO_2. This work focuses on the reduction of tungsten WO_2 in the presence of different concentration of CO as reducing agent. The effects of isothermal reduction on the formation of the product were also investigated.

Materials and Methods

Chemicals and raw materials

$WO_2 \geq 99\%$ and $W \geq 99\%$ powder Sigma Aldrich was used. The gas mixture CO in N_2 (20, and 40 vol % of CO) from MOX was used as reducing agents.

Reduction of WO_2

Reduction of WO_2 was performed using TPR instrument Micromritics Autochem 2920 Chemisorption Analyzer apparatus. An amount 5 – 8 mg of the samples were introduced in nonisothermal mode up to 900 °C under two different concentration of gas mixture of 20% and 40% of (CO in N_2) with a heating rate of 10 ºC/min with flow rates 20 ml/min. In another experiment, the measurement was carried out using the same method, and continued with isothermal mode at 900 °C for 30 min, under the similar reducing gas.

Characterization method

XRD analysis of samples were performed using XRD's Bruker AXS D8 Advance type with X-ray radiation source of Cu Kα (40kV, 40 mA) to record the 2θ diffraction angle from 10° to 80° at wavelength (λ = 0.154 nm) of 1 g sample. For identification purposes of crystalline phase composition, diffraction pattern obtained were matched with standard diffraction data (JCPDS) files.

Results and Discussion

Thermodynamic consideration data

Thermodynamic analysis of WO_2 was performed for the reduction as in Equation 1 and CO as a reducing agent. The Gibbs free energy change due to reaction and the equilibrium composition of the oxides were calculated. From the calculation, clearly indicates that the reduction by CO reaction is spontaneous (ΔG_r = +6 up to +15 kcal/mol) temperature 400 to 1000 ºC. Enthalpy (ΔH_r) reduction is endothermic, where the value of ΔH_r is +24 kcal/mol.

$$WO_2 + 2CO \rightarrow W + 2CO_2 \quad (1)$$

TPR analysis

The TPR profile obtained for non-isothermal and isothermal reduction of WO_2 under 20% and 40% CO in N_2 as reducing gas shown in Figure 1. Profile (a) indicates that reduction by 20% CO in N_2 of WO_2 up to 900ºC while (b) is reduction by 40% CO in N_2 of WO_2. The shoulder and peaks monitor in the both profile look quite similar. However, for reduction using 40% CO produce higher signal in comparison by using 20% CO. It is due to the low rate of reaction which resulted to low reducibility in 20% CO in N_2. A similar TPR experiment was performed on a sample of WO_2 and continued with isothermal condition at 900 ºC for 30 minutes. According to the profile, no obvious peak was observed upon holding the reaction time for 30 minutes for all the reactions. The residual obtained after reduction were then subjected to XRD analysis for recording XRD pattern.

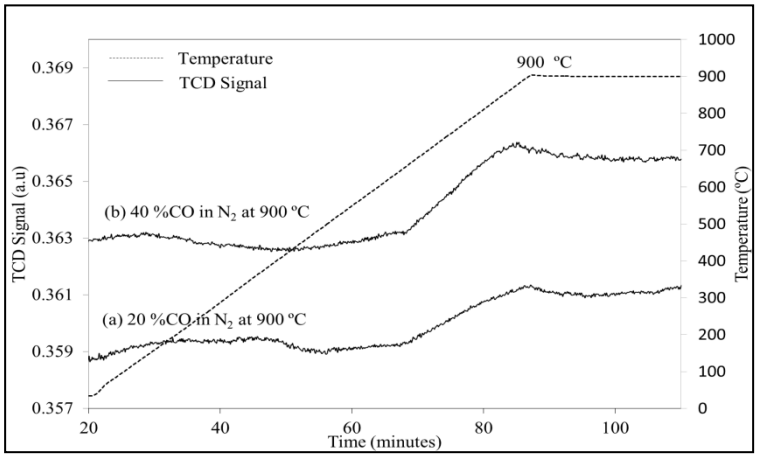

Figure 1. TPR profile obtained for non-isothermal and isothermal reduction of WO_2 by 20% and 40% (CO in N_2) up to 900 ºC and hold for 30 minutes respectively

XRD analysis

The X-ray diffraction patterns of the reduction product were analyzing to study the behavior of WO_2 reduction. The comparison of sample XRD pattern of the non-isothermal reduction under various concentration of CO in N_2 (20% and 40%) was in Figure 2. From the results, the non-isothermal reduction product of WO_2 under 20% and 40% CO in N_2 were rather similar with small reduction which 3 peaks of W metal assigned (JCPDS 04-0806) and major peak of remaining unreduced WO_2 (JCPDS 32-1393) was observed. However, reduction product by 40% CO shown low intensity of crystalline phase of W metal in comparison of reduction product by 20% CO which shown higher intensity of W. Nevertheless, by increasing the concentration of CO lead to the appearance of a new peak of WC (JCPDS 51-0939). From the results, it was obvious shown that by increasing the concentration of CO, the intensity of WO_2 decreases and WC peak appeared due to transformation of W phase to WC [6].

The reduction was continued for isothermal reduction at same temperature for 30 min. The XRD pattern were compared to the various concentration of CO in N_2 (20 and 40%) in Figure 3. From the results, isothermal reduction with 20% CO showed in identifying of higher intensity of W metal in comparison to reduction with 40% CO. The limited formation of W phases may attribute to the excessing CO introduced to the system which results to the formation of carbide. It was in agreement with previous study [6], where the formation of WC was transform from W metal phase. The XRD pattern shows the new peak observed correspond to the W_2C and WC appeared under gas of 20% CO and 40% CO respectively.

It can be concluded that, higher the concentration of CO introduced to the system, lead to the formation of WC. The WC observed in XRD pattern is in agreement to previous study working on VI transition metal carbide catalysts. It is obvious that suitable concentration of CO and reaction time need to consider in order reducing WO_2 to W metal. It is probably since, among phase transitions in the reduction of WO_3 to W, from $WO_3 \rightarrow WO_{2.9}$, $WO_{2.9} \rightarrow W_{18}O_{49}$,

and $W_{18}O_{49} \rightarrow WO_2$ and $WO_2 \rightarrow W$, transition WO_2 to W proceed very limited [7]. It was matched with the thermodynamic calculation in Eq. (1) where the enthalpy value for reduction WO_2 to W and WO_3 to W are endothermic and exothermic respectively in carbon monoxide atmosphere. The traces of WO_3 were observed in the pattern of reduction WO_2 sample; this is probably due to the slight oxidation on the WO_2 commercial sample prior undergoing the reduction process.

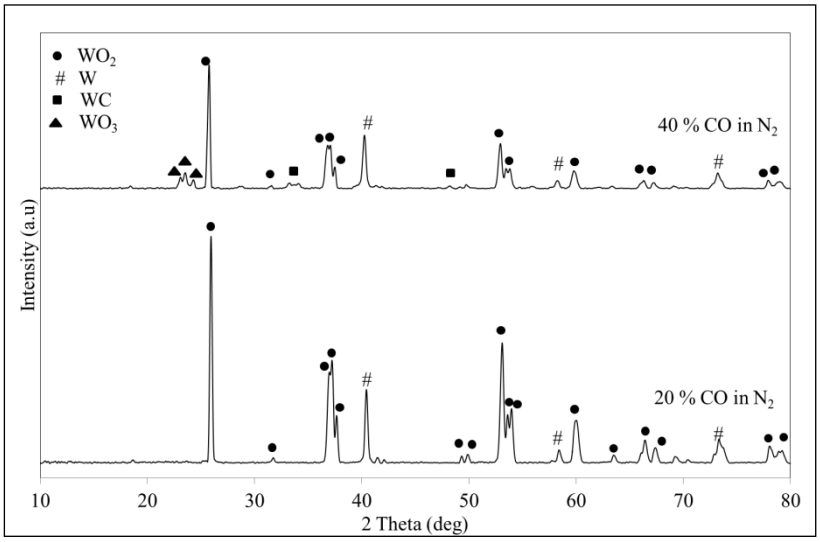

Figure 2. XRD profile obtained for non-isothermal reduction of WO_2 by 20% and 40% (CO in N_2) up to 900 ºC

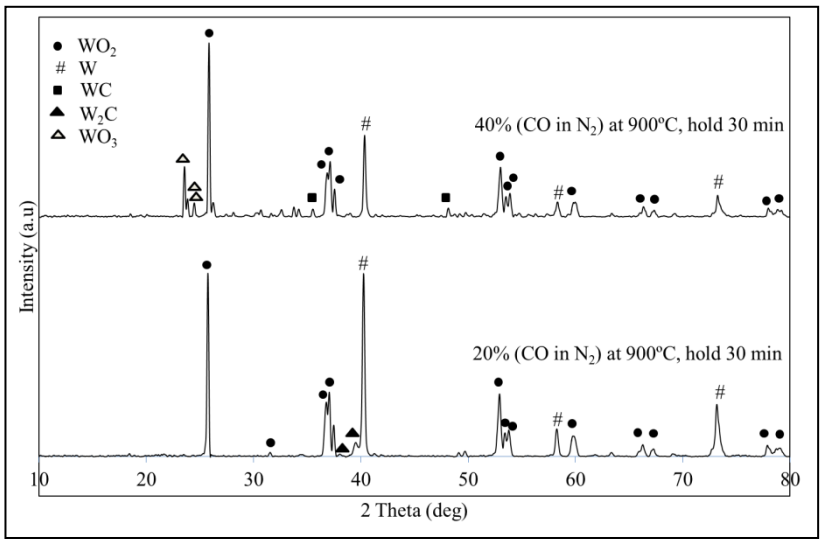

Figure 3. XRD profile for isothermal reduction of WO_2 by 20 and 40 % (CO in N_2) up to 900 ºC and hold for 30 min

Conclusion

Tungsten (IV) oxide (WO_2) samples were characterized using the TPR and XRD methods to investigate the reduction behavior. The WO_2 was reduced to W and some remaining unreduced WO_2 in both concentrations. However, by increasing the concentration of CO to 40%, the remaining WO_2 peaks were decreases and low crystalline phase of W peaks were observed. Furthermore, reduction of WO_2 is improved by hold the reaction at 900 ºC for 30 min. It can be proved by formation of higher peak of W phase for both concentrations compared to nonisothermal reduction. However, excess of CO introduced lead to the formation of tungsten semi carbide (W_2C) and tungsten carbide (WC) under 20% and 40% CO in N_2 respectively.

Abstract

Heterocyclic compounds of benzimidazole and oxadiazole are considered as important class of compounds in medicinal chemistry because of their interesting diversified biological activities. A series of new benzimidazole bearing oxadiazole derivatives have been conveniently synthesized by intermolecular oxidative cyclization of benzimidazole benzoyl hydrazide promoted by iodobenzene diacetate as an oxidant. The structures of the synthesized compounds were characterized by spectroscopic methods namely ^{1}H Nuclear Magnetic Resonance (NMR), Infrared (IR), Mass Spectrometry (MS) and melting point.

Keywords: synthesis, benzimidazole, oxadiazole, hydrazide, nuclear magnetic resonance

Abstrak

Sebatian heterosiklik daripada benzimidazol dan oksadiazol dianggap sebagai satu kelas sebatian penting dalam kimia perubatan kerana aktiviti biologinya yang pelbagai. Satu siri baru terbitan oksadiazol dari benzimidazol telah disintesis dengan mudah oleh siklisasi oksidatif antara molekul daripada benzoil hidrazida benzimidazol dimangkin oleh diasetat iodobenzena sebagai oksidan. Struktur sebatian disintesis telah dicirikan oleh kaedah spektroskopik seperti ^{1}H Resonans Magnet Nukleus (NMR), Inframerah (IR), Spektrometri Jisim (MS) dan takat lebur.

Kata kunci: sintesis, benzimidazol, oxadiazol, hidrazida, resonan megnetik nukleus

Introduction

Benzimidazole and oxadiazole have received attention in recent years due to widespread applications notably in the field of medicinal chemistry due to their privileged biological activity. Recently, benzimidazole derivatives have been reported as antidiabetic [1], antimicrobial [2-3], antiviral [4-6] antispasmodic [7] and antiasthmatic [8] agents. Similarly, oxadiazole derivatives are also recognized for their pharmacological importance and are reported to possess wide spectrum of activities such as antibacterial [9-11], antifungal [12] anti-inflammatory [13-14] analgesic [15], anticonvulsant [16-17], hypoglycemic [18] and anticancer [19] properties. The synthesis of both compounds has emerged as an essential need for development of new pharmaceutical entities.

In the present study, a series of novel oxadiazoles were synthesized from benzimidazole and their physical characterization are reported. The structures of the synthesized compounds were characterized using different spectroscopic methods namely ^{1}H Nuclear Magnetic Resonance (NMR), Infrared (IR), Mass Spectrometry (MS) and melting point.

Materials and Methods

Melting point was taken on Buchi M-560 melting point instrument and was uncorrected. IR spectra were recorded on a Spectrum One FT-IR spectrometer (Perkin Elmer), using KBr discs and values were signified in cm^{-1}. The ^{1}H NMR and ^{13}C NMR spectra were measured on Bruker 500 Ultrashield Plus NMR (500 MHz) in DMSO-*d*6 as solvent, using tetramethylsilane (TMS) as an internal standard, and chemical shifts are expressed as ppm. ESI MS were determined on Agilent 6330 Ion Trap, using positive/negative mode. HR-ESI-MS were determined on Agilent 6224 TOF-LC/MS using positive mode.

Synthesis of methyl 4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)benzoate (a)

Sodium metasulfite adduct was synthesized according to literature protocol [20]. Equimolar solution of sulphite adduct and 4,5-dimethyl-*O*-phenylenediamine in DMF was refluxed for 6 hours. After the completion of reaction, it was poured into ice water and the solid product (a) was filtered, dried and crystallized.

Synthesis of 4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)benzohydrazide (b)

A solution of compound (a) (40 mmol) in methanol (50 ml) was refluxed for 12 hours in the presence of hydrazine hydrate (95%) mixture (10 ml). The reaction mixture was evaporated and the residue was washed with water, filtered, dried, and crystallized.

General procedure for the synthesis of 4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl) benzohydrazide Schiff bases (1-14)

Equimolar mixture of 4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl) benzohydrazide (0.280 g, 0.01 mol) selected aldehyde (0.01 mol), in *n*-butanol (25 mL) containing acetic acid (1 mL) was heated under reflux for 3 hours. The reaction mixture was filtered, dried and crystallized.

General procedure for the synthesis of 2,5-disubstituted-1,3,4-oxadiazoles (15-28)

Compounds **1-14** (100 mg, ±0.25 mmol) were dissolved in DMF (5 ml) and iodobenzenediacetate (IBD) (±0.27 mmol) were added [21]. The content was stirred overnight and the progress of reaction was monitored by thin layer chromatography. Cold water was added and the precipitate obtained was filtered, washed with diethyl ether and dried to afford **15-28**.

Results and Discussion

Characterization: methyl 4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)benzoate (a)

Light brown solid; yield (96%); m.p. 208.9 °C; IR(KBr) (ν_{max}, cm^{-1}): 2954, 1720, 1273, 1107. ^{1}H NMR (500 MHz, DMSO) δ: 2.33 (s, 6H, CH_3-5,6-benzimidazole), 3.88 (s, 3H, OCH_3-benzoate), 7.39 (s, 2H, H-4,7-benzimidazole), 8.09 (d, J = 8.4 Hz, 2H, Ar), 8.27 (d, J = 8.4 Hz, 2H, Ar). ESI MS (m/z): 280.1 (M^+).

4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)benzohydrazide (b)

Light brown solid; yield (93%); m.p. 316.5 °C; IR(KBr) (ν_{max}, cm^{-1}): 3020, 1625, 1560, 1350. ^{1}H NMR (500 MHz, DMSO) δ: 2.33 (s, 6H, CH_3-5,6-benzimidazole), 4.56 (s, 2H, NH_2), 7.32 (s, 1H, H-7-benzimidazole), 7.46 (s, 1H, H-4-benzimidazole), 7.98 (d, J = 7.5 Hz, 2H, Ar), 8.21 (d, J = 7.5 Hz, 2H, Ar), 9.88 (s, 1H, NH-hydrazide), 12.74 (s, 1H, NH-benzimidazole). ESI MS (m/z): 280.1 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(3-fluorobenzylidene) benzohydrazide (1)

Light brown solid; yield 89%; m.p. 324.3 °C; IR(KBr) (ν_{max}, cm^{-1}): 3465, 1657, 1557, 1276, 1237. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 7.31 (m, 2H, Ar), 7.55 (m, 4H, Ar), 8.09 (d, J = 7.7 Hz, 2H, Ar), 8.29 (d, J = 8.0 Hz, 2H, Ar), 8.51 (s, 1H, CH=N), 12.05 (s, 1H, NH-hydrazide), 12.80 (s, 1H, NH-benzimidazole). ESI MS (m/z): 386.2 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(2-hydroxybenzylidene) benzohydrazide (2)
Light brown solid; yield (90%); m.p. 352.7 °C; IR(KBr) (ν_{max}, cm^{-1}): 3427, 1623, 1291. ^{1}H NMR (500 MHz, DMSO) δ: 2.35 (s, 6H, CH_3-5,6-benzimidazole), 6.99 – 6.92 (m, 2H, Ar), 7.33 (t, *J* = 7.7 Hz, 1H, Ar), 7.41 (s, 2H, H-4,7-benzimidazole), 7.58 (d, *J* = 7.4 Hz, 1H, Ar), 8.11 (d, *J* = 8.2 Hz, 2H, Ar), 8.30 (d, *J* = 8.2 Hz, 2H, Ar), 8.69 (s, 1H, CH=N), 11.28 (s, 1H, NH-hydrazide), 12.19 (s, 1H, NH-benzimidazole). ESI MS (m/z): 384.3 (M^-).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(3-hydroxybenzylidene) benzohydrazide (3)
Light yellow solid; yield (90%); m.p. 316.1 °C; IR(KBr) (ν_{max}, cm^{-1}): 3200, 1642, 1560, 1271. ^{1}H NMR (500 MHz, DMSO) δ: 2.34 (s, 6H, CH_3-5,6-benzimidazole), 7.13 (d, *J* = 7.2 Hz, 1H, Ar), 7.24 (s, 1H, Ar), 7.28 (t, *J* = 7.7 Hz, 1H, Ar), 7.41 (s, 2H, H-4,7-benzimidazole), 8.08 (d, *J* = 7.9 Hz, 2H, Ar), 8.28 (d, *J* = 8.0 Hz, 2H, Ar), 8.41 (s, 1H, CH=N), 9.66 (s, 1H, OH), 11.88 (s, 1H, NH-hydrazide), 12.80 (d, *J* = 1.0 Hz, 1H, NH-benzimidazole). ESI MS (m/z): 384.3 (M^-).

(E)-N'-(3,4-dimethoxybenzylidene)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl) benzohydrazide (4)
Light yellow solid; yield (92%); m.p. 316.4 °C; IR(KBr) (ν_{max}, cm^{-1}): 3434, 1658, 1564, 1272. ^{1}H NMR (500 MHz, DMSO) δ: 2.35, 2.34 (s, 6H, CH_3-5,6-benzimidazole), 3.84 (s, 6H, OCH_3-3,4-Ar), 7.05 (d, *J* = 8.2 Hz, 1H, Ar), 7.23 (d, *J* = 7.8 Hz, 1H, Ar), 7.33 (s, 1H, Ar), 7.38 (s, 1H, Ar), 7.47 (s, 1H, Ar), 8.07 (d, *J* = 8.1 Hz, 2H, Ar), 8.28 (d, *J* = 8.1 Hz, 2H, Ar), 8.42 (s, 1H, CH=N), 11.83 (s, 1H, NH-hydrazide), 12.81 (s, 1H, NH-benzimidazole). ESI MS (m/z): 428.3 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(4-nitrobenzylidene) benzohydrazide (5)
Light yellow solid; yield (92%); m.p. 323.6 °C; IR(KBr) (ν_{max}, cm^{-1}): 3269, 1637, 1560, 1519, 1343, 1282. ^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 7.32 (s, 1H, H-7), 7.46 (s, 1H, H-4), 8.00 (d, *J* = 8.1 Hz, 2H, Ar), 8.09 (d, *J* = 7.7 Hz, 2H, Ar), 8.32 – 8.27 (m, 4H, Ar), 8.57 (s, 1H, CH=N), 12.23 (s, 1H, NH-hydrazide), 12.83 (s, 1H, NH-benzimidazole). ESI MS (m/z): 413.3 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(4-fluorobenzylidene) benzohydrazide (6)
Light brown solid; yield (94%); m.p. 330.7 °C; IR(KBr) (ν_{max}, cm^{-1}): 3256, 1630, 1287, 1236. ^{1}H NMR (500 MHz, DMSO) δ: 2.34 (s, 6H, CH_3-5,6-benzimidazole), 7.32 (t, *J* = 8.6 Hz, 2H, Ar), 7.40 (s, 2H, Ar), 7.87 – 7.78 (m, 2H, Ar), 8.08 (d, *J* = 8.0 Hz, 2H, Ar), 8.28 (d, *J* = 8.1 Hz, 2H, Ar), 8.49 (s, 1H, CH=N), 11.96 (s, 1H, NH-benzimidazole). ESI MS (m/z): 386.9 (M^-).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(4-methoxybenzylidene) benzohydrazide (7)
Light brown solid; yield (91%); m.p. 276.0 °C; IR(KBr) (ν_{max}, cm^{-1}): 3234, 1611, 1512, 1258. ^{1}H NMR (500 MHz, DMSO) δ: 2.34 (s, 6H, CH_3-5,6-benzimidazole), 3.82 (s, 3H, OCH_3), 7.04 (d, *J* = 8.6 Hz, 2H, Ar), 7.51 – 7.29 (m, 2H, Ar), 7.71 (d, *J* = 8.5 Hz, 2H, Ar), 8.08 (d, *J* = 8.2 Hz, 2H, Ar), 8.28 (d, *J* = 8.2 Hz, 2H, Ar), 8.44 (s, 1H, CH=N), 11.83 (s, 1H, NH-benzimidazole). ESI MS (m/z): 398.9 (M^-).

(Z)-N'-(4-chlorobenzylidene)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)benzohydrazide (8)
Light brown solid; yield (90%); m.p. 338.7 °C; IR(KBr) (ν_{max}, cm^{-1}): 3253, 1634, 1565, 1286, 669. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.33 (s, 1H, Ar), 7.47 (s, 1H, Ar), 7.55 (d, *J* = 8.0 Hz, 2H, Ar), 7.79 (d, *J* = 8.1 Hz, 2H, Ar), 8.08 (d, *J* = 7.9 Hz, 2H, Ar), 8.28 (d, *J* = 8.0 Hz, 2H, Ar), 8.49 (s, 1H, CH=N), 12.01 (s, 1H, NH-hydrazide), 12.80 (s, 1H, NH-benzimidazole). ESI MS (m/z): 402.3 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(pyridin-4-ylmethylene) benzohydrazide (9)
Light brown solid; yield (90%); m.p. 306.7 °C; IR(KBr) (ν_{max}, cm^{-1}): 3277, 1634, 1560, 1288. ^{1}H NMR (500 MHz, DMSO) δ: 2.33 (s, 6H, CH_3-5,6-benzimidazole), 7.40 (s, 2H, Ar), 7.69 (s, 2H, Ar), 8.10 (d, *J* = 7.2 Hz, 2H, Ar), 8.30 (d, *J* = 7.9 Hz, 2H, Ar), 8.48 (s, 1H, CH=N), 8.67 (s, 2H, Ar), 12.22 (s, 1H, NH-benzimidazole). ESI MS (m/z): 384.3 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(pyridin-3-ylmethylene) benzohydrazide (13)
Light yellow solid; yield (92%); m.p. 348.3 °C; IR(KBr) (ν_{max}, cm^{-1}): 3194, 1647, 1552, 1281. ^{1}H NMR (500 MHz, DMSO) δ: 2.33 (s, 6H, CH_3-5,6-benzimidazole), 7.40 (s, 2H, Ar), 7.50 (s, 1H, Ar), 8.10 (d, *J* = 7.5 Hz, 2H, Ar), 8.17 (d, *J* = 6.9 Hz, 1H, Ar), 8.30 (d, *J* = 7.7 Hz, 2H, Ar), 8.55 (s, 1H, Ar), 8.63 (s, 1H, Ar), 8.89 (s, 1H, CH=N), 12.12 (s, 1H, NH-hydrazide), 12.81 (s, 1H, NH-benzimidazole). ESI MS (m/z): 369.3 (M^+).

(E)-4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)-N'-(3 methylbenzylidene) benzohydrazide (14)
White solid; yield (93%); m.p. 321.2 °C; IR(KBr) (ν_{max}, cm^{-1}): 3422, 1656, 1564, 1283. ^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.35, 2.38 (s, 9H, $3CH_3$-5,6-benzimidazole, 3''-Ar), 7.27 (d, *J* = 6.9 Hz, 1H, Ar), 7.33 (s, 1H, H-7), 7.37 (t, *J* = 7.3 Hz, 1H, Ar), 7.47 (s, 1H, H-4), 7.54 (d, *J* = 7.1 Hz, 1H, Ar), 7.59 (s, 1H, H-2''), 8.08 (d, *J* = 7.6 Hz, 2H, Ar), 8.28 (d, *J* = 7.8 Hz, 2H, Ar), 8.46 (s, 1H, CH=N), 11.93 (s, 1H, NH-hydrazide), 12.82 (s, 1H, NH-benzimidazole). ESI MS (m/z): 382.3 (M^-).

2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(3-fluorophenyl)-1,3,4-oxadiazole (15)
Pale yellow powder, yield: 0.075 g (75%), m.p.: 346.5 °C. IR (KBr) (ν_{max}, cm^{-1}): 3308, 1611, 1317, 1262, 1070, 999, 848. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.34 (s,1H, Ar), 7.48 (s, 1H, Ar), 7.54 (td, 1H, *J* = 8.6, 1.9, Ar), 7.55 (t, 1H, *J* = 7.6 Hz, Ar), 7.72 (dd, 1H, *J* = 13.8, 8.0 Hz, Ar), 8.03 (dd, 2H, *J* = 15.7, 8.6 Hz, Ar), 8.33 (d, 2H, *J* = 8.5 Hz, Ar), 8.38 (d, 2H, *J* = 8.4 Hz, Ar), 12.9 (s, 1H, NH). HR-ESI-MS: m/z 384.2288 (M^+).

2-(5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazol-2-yl)phenol (16)
Pale yellow powder, yield: 0.081 g (81%), m.p.: 375.7 °C; IR (KBr) (ν_{max}, cm^{-1}): 3235, 1612, 1317, 1256, 1155, 1062.^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.18 – 7.05 (m, 2H, Ar), 7.34 (s, 1H, Ar), 7.56 – 7.42 (m, 2H, Ar), 7.97 (dt, 1H, *J* = 10.1, 5.1 Hz, Ar), 8.26 (d, 2H, *J* = 8.5 Hz, Ar), 8.38 (d, 2H, *J* = 8.5 Hz, Ar), 10.36 (s, 1H, OH), 12.89 (s, 1H, NH). HR-ESI-MS: m/z 382.2325 (M^+).

3-(5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazol-2-yl)phenol (17)
Pale yellow powder, yield: 0.082 g (82%); m.p.: 369.9 °C; IR (KBr) (ν_{max}, cm^{-1}): 3236, 1610, 1315, 1262, 1069, 1008.^{1}H NMR (500 MHz, DMSO) δ: 2.33 (s, 6H, CH_3-5,6-benzimidazole), 7.06 (d, 1H, *J* = 6.6 Hz, Ar), 7.40 (s, 2H, Ar), 7.45 (t, 1H, *J* = 7.8 Hz, Ar), 7.54 (s, 1H, Ar), 7.59 (d, 1H, *J* = 7.5 Hz, Ar), 8.25 (d, 2H, *J* = 8.3 Hz, Ar), 8.35 (d, 2H, *J* = 8.3 Hz, Ar), 10.04 (s, 1H, OH). HR-ESI-MS: m/z 382.1843 (M^+).

2-(3,4-dimethoxyphenyl)-5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazole (18)
Pale yellow powder, yield: 0.076 g (76%); m.p.: 293.4 °C; IR (KBr) (ν_{max}, cm^{-1}): 3255, 1611, 1315, 1275, 1106, 1025. ^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 3.88, 3.92 (s, 6H, OCH_3-3'',4''-Ar), 7.20 (d, 1H, *J* = 8.5 Hz, Ar), 7.39 (s, 2H, Ar), 7.65 (d, 1H, *J* = 1.9 Hz, Ar), 7.76 (dd, 1H, *J* = 8.4, 2.0 Hz, Ar), 8.28 (d, 2H, *J* = 8.5 Hz, Ar), 8.36 (d, 2H, *J* = 8.5 Hz, Ar), 12.87 (s, 1H, NH). HR-ESI-MS: m/z 426.2690 (M^+).

2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(4-nitrophenyl)-1,3,4-oxadiazole (19)
Pale yellow powder, yield: 0.076 g (76%); m.p.: 361.2 °C; IR (KBr) (ν_{max}, cm^{-1}): 3302, 1612, 1523, 1340, 1264, 1108, 1082. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.35 (s, 1H, Ar), 7.49 (s, 1H, Ar), 8.33 (d, 2H, *J* = 8.4 Hz, Ar), 8.40 (d, 2H, *J* = 8.4 Hz, Ar), 8.45, 8.48 (d, 4H, *J* = 8.9 Hz, Ar), 12.90 (s, 1H, NH). HR-ESI-MS: m/z 411.2255 (M^+).

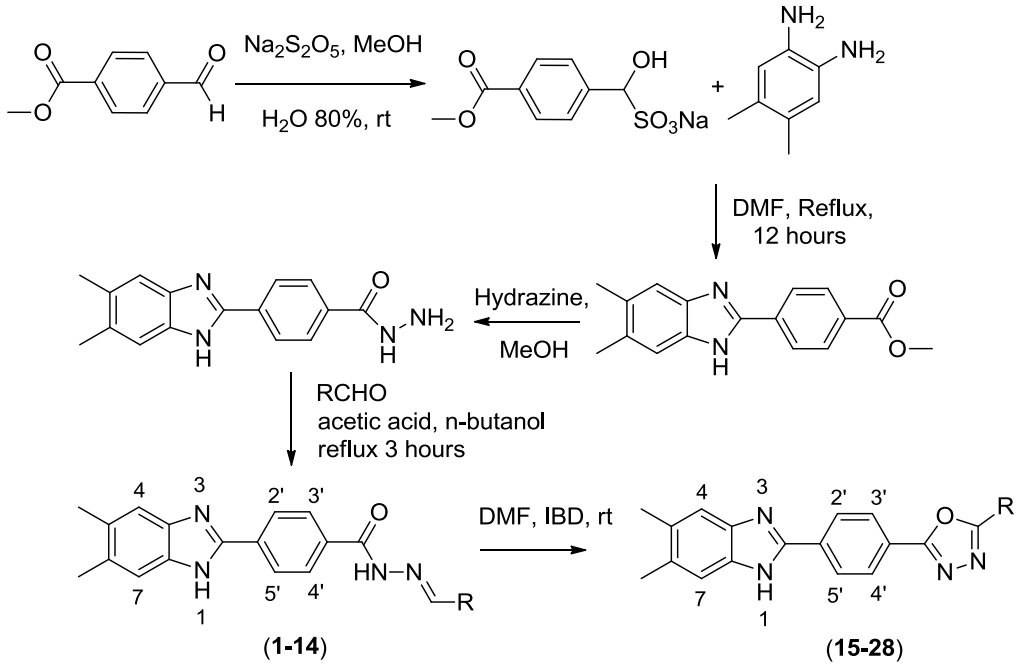
2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(4-fluorophenyl)-1,3,4-oxadiazole (20)
Pale yellow powder, yield: 0.083 g (83%); m.p.: 372.7 °C; IR (KBr) (ν_{max}, cm^{-1}): 3292, 1610, 1318, 1264, 1164, 1002, 845. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.34 (s, 1H, Ar), 7.49 (d, 2H, *J* = 9.0 Hz, Ar), 7.54 (d, 2H, *J* = 9.0 Hz, Ar), 8.26 (dd, 2H, *J* = 8.8, 5.4 Hz, Ar), 8.30 (d, 2H, *J* = 8.5 Hz, Ar), 8.38 (d, 2H, *J* = 8.5 Hz, Ar), 12.90 (s, 1H, NH). HR-ESI-MS: m/z 384.2288 (M^+).

2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(4-methoxyphenyl)-1,3,4-oxadiazole (21)
Pale yellow powder, yield: 0.077 g (77%); m.p.: 342 °C; IR (KBr) (ν_{max}, cm^{-1}): 3244, 1614, 1311, 1263, 1174, 1033. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 3.89 (s, 3H, OCH_3-4''-Ar), 7.20 (d, 2H, *J* = 8.8 Hz, Ar), 7.34 (s, 1H, Ar), 7.48 (s, 1H, Ar), 8.12 (d, 2H, *J* = 8.8 Hz, Ar), 8.28 (d, 2H, *J* = 8.4 Hz, Ar), 8.37 (d, 2H, *J* = 8.5 Hz, Ar), 12.89 (s, 1H, NH). HR-ESI- MS: m/z 396.2500 (M^+).

2-(4-chlorophenyl)-5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazole (22)
Pale yellow powder, yield: 0.075 g (75%); m.p.: 369.7 °C; IR (KBr) (ν_{max}, cm^{-1}): 3280, 1611, 1317, 1264, 1093, 1016, 844. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 7.35 (s, 1H, Ar), 7.48 (s, 1H, Ar), 7.74 (d, 2H, *J* = 8.5 Hz, Ar), 8.20 (d, 2H, *J* = 8.5 Hz, Ar), 8.30 (d, 2H, *J* = 8.4 Hz, Ar), 8.37 (d, 2H, *J* = 8.4 Hz, Ar), 12.92 (s, 1H, NH). HR-ESI-MS: m/z 400.2004 (M^+).

2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(pyridin-4-yl)-1,3,4-oxadiazole (23)
Pale yellow powder, yield: 0.068 g (68%); m.p.: 373.0 °C; IR (KBr) (ν_{max}, cm^{-1}): 3051, 1612, 1571, 1321, 1272, 1061, 1002. ^{1}H NMR (500 MHz, DMSO δ: 2.35 (s, 6H, CH_3-5,6-benzimidazole), 7.41 (s, 2H, Ar), 8.10 (d, 2H, *J* = 5.5 Hz, Ar), 8.33 (d, 2H, *J* = 8.4 Hz, Ar), 8.39 (d, 2H, *J* = 8.4 Hz, Ar), 8.89 (d, 2H, *J* = 4 Hz, Ar). HR-ESI-MS: m/z 367.1948 (M^+).

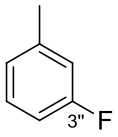
2-(3-chlorophenyl)-5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazole (24)
Pale yellow powder, yield: 0.071 g (71%); m.p.: 356.2 °C; IR (KBr) (ν_{max}, cm^{-1}): 3053, 1614, 1316, 1266, 1032, 1003, 847. ^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 7.34 (s, 1H, Ar), 7.48 (s, 1H, Ar), 7.69 (t, 1H, *J* = 8, 7.5 Hz, Ar), 7.75 (d, 1H, *J* = 8 Hz, Ar), 8.14 (d, 1H, *J* = 7.5 Hz, Ar), 8.22 (s, 1H, Ar), 8.32 (d, 2H, *J* = 8 Hz, Ar), 8.37 (d, 2H, *J* = 8 Hz, Ar), 12.89 (s, 1H, NH). HR-ESI-MS: m/z 400.2009 (M^+).

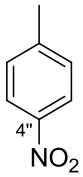


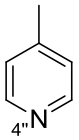
2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(o-tolyl)-1,3,4-oxadiazole (25)
Pale yellow powder, yield: 0.083 g (83%); m.p.: 348.1 °C; IR (KBr) (ν_{max}, cm^{-1}): 3179, 1614, 1317, 1287, 1055, 1000. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.36 (s, 6H, CH_3-5,6-benzimidazole), 2.73 (s, 3H, CH_3-2''-Ar), 7.34 (s, 1H, Ar), 7.52 – 7.44 (m, 3H, Ar), 7.56 (td, 1H, *J* = 7.5, 1.1 Hz, Ar), 8.13 (d, 1H, *J* = 7.6 Hz, Ar), 8.28 (d, 2H, *J* = 8.5 Hz, Ar), 8.38 (d, 2H, *J* = 8.4 Hz, Ar), 12.88 (s, 1H, NH). HR-ESI-MS: m/z 380.2535 (M^+).

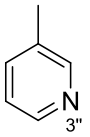
4-(5-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-1,3,4-oxadiazol-2-yl)phenol (26)
Pale yellow powder, yield: 0.079 g (79%); m.p.: 335 °C; IR (KBr) (ν_{max}, cm^{-1}): 3200, 1609, 1315, 1263, 1079, 1016. ^{1}H NMR (500 MHz, DMSO) δ: 2.34 (s, 6H, CH_3-5,6-benzimidazole), 7.00 (d, 2H, *J* = 8.5 Hz, Ar), 7.41 (s, 2H, Ar), 8.01 (d, 2H, *J* = 8.5 Hz, Ar), 8.25 (d, 2H, *J* = 8.3 Hz, Ar), 8.36 (d, 2H, *J* = 8.3 Hz, Ar), 10.40 (s, 1H, Ar). HR-ESI-MS: m/z 382.2328 (M^+).

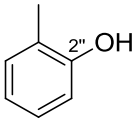
2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(pyridin-3-yl)-1,3,4-oxadiazole (27)
Pale yellow powder, yield: 0.073g (73%); m.p.: 327.9 °C; IR (KBr) (ν_{max}, cm^{-1}): 3326, 1611, 1565, 1317, 1257, 1054, 999. ^{1}H NMR (500 MHz, DMSO) δ: 2.34, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 7.36 (m, 2H, Ar), 7.48 (s, 1H, Ar), 8.00 (t, 1H, *J* = 4.6 Hz, Ar), 8.25 (d, 2H, *J* = 8.4 Hz, Ar), 8.37 (d, 2H, *J* = 8.4 Hz, Ar), 12.91 (s, 1H, NH). HR-ESI-MS: m/z 367.1932 (M^+).

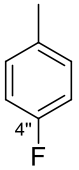


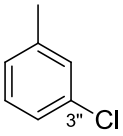


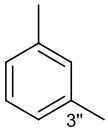


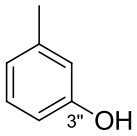


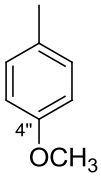


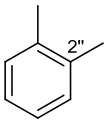


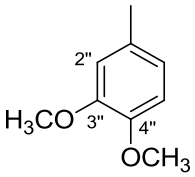


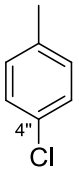


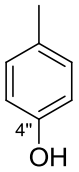












2-(4-(5,6-dimethyl-1H-benzo[d]imidazol-2-yl)phenyl)-5-(m-tolyl)-1,3,4-oxadiazole (28)
Pale yellow powder, yield: 0.079 g (79%); m.p.: 315.4 °C; IR (KBr) (ν_{max}, cm^{-1}): 3198, 1612, 1314, 1274, 1080, 999.^{1}H NMR (500 MHz, DMSO) δ: 2.33, 2.35 (s, 6H, CH_3-5,6-benzimidazole), 2.45 (s, 3H, CH_3-3''-Ar), 7.33 (s, 1H, Ar), 7.48 (d, 2H, *J* = 9.3 Hz, Ar), 7.54 (t, 1H, *J* = 7.6 Hz, Ar), 7.97 (d, 1H, *J* = 7.6 Hz, Ar), 8.00 (s, 1H, Ar), 8.28 (d, 2H, *J* = 8.4 Hz, Ar), 8.37 (d, 2H, *J* = 8.4 Hz, Ar), 12.88 (s, 1H, NH). HR-ESI-MS: m/z 380.2536 (M^+).

The synthesis of the target compounds began with the synthesis of sodium metasulfite adduct according to the literature protocol [5]. The resulting sulfite adduct was refluxed with 4,5-dimethyl-*O*-phenylenediamine in DMF for 6 h to give the arylester substituted benzimidazole. The benzohydrazide of benzimidazole was formed by refluxing arylester of benzimidazole with methanolic hydrazine hydrate (Scheme 1). The synthesis of benzimidazole benzohydrazide Schiff bases (**1-14**) was accomplished by reacting different aldehydes with benzimidazole benzohydrazide in *n*-butanol in the presence of a catalytic amount of acetic acid as shown in Scheme-1. A series of new 2, 5-disubstituted-1,3,4-oxadiazoles (Table 1) have been accomplished in excellent yields by the oxidation of of various aryl aldehydes with one equivalent of iodobenzenediacetate (IBD) in DMF. Compounds **15-28** were synthesized based on the reported procedure.

Scheme 1. Synthesis of oxadiazole derivatives from benzimidazole benzoyl hydrazide

Table 1. Benzimidazole benzohydrazide bearing oxadiazole derivatives

Comp. No.	R	Comp. No.	R	Comp. No.	R	Comp. No.	R
1, 15		5, 19		9, 23		13, 27	
2, 16		6, 20		10, 24		14, 28	
3, 17		7, 21		11, 25			
4, 18		8, 22		12, 26			

The IR spectra of the synthesized compounds exhibited characteristic absorption bands at 1600 – 1700 cm^{-1} and 3100 – 3300 cm^{-1} due to carbonyl or C=N; and NH group, respectively. The ^{1}H NMR spectra of compounds **1-14** showed two singlets due at N=CH and NH, respectively. The structure of all compounds was confirmed by their spectral data (IR, ^{1}H NMR, LCMS) and melting point. The characterization of products **15-28** was based upon a careful comparison of their IR and ^{1}H NMR spectra with those of **1-14**. IR spectra of **15-28** were found to be transparent in the region of NH stretch and CO stretch. In ^{1}H NMR spectra of **15-28** the disappearance of their singlet due to N=CH and NH proton confirms the oxidation of **1-14** into **15-28**.

Conclusion

A series of new 2,5-disubstituted-1,3,4-oxadiazoles derivatives of benzimidazole (**15-28**) were synthesized in good yield and characterized by ^{1}H NMR, IR, MS spectroscopic methods and melting point. A further study to acquire information concerning the pharmacological activity is in progress.

THE EFFECT OF POLYMER CONCENTRATION AND SURFACTANT TYPES ON NANOFILTRATION-SURFACTANT MEMBRANE FOR TEXTILE WASTEWATER

(Kesan Kepekatan Polimer dan Jenis Surfaktan pada Membran Surfaktan Penurasan-Nano untuk Air Sisa Tekstil)

Abstract

In this study, an asymmetric nanofiltration-surfactant (NFS) membrane was prepared via simple dry/wet phase inversion technique. A newly dope formulation consisting of different surfactants (SDS, CTAB) and polymer concentration (17 wt% - 21 wt%) were developed. The effect of these parameters on dyes performance in terms of dyes flux, rejection and morphological structure were examined. Experimental data showed that, at different ranges of polymer concentration, NFS membranes shows low permeation flux of dyes ranging from 9.256 L/m^{2}h to 14.315 L/m^{2}h at 4 bar operating pressure. Significantly, the addition of SDS and CTAB surfactants were found to promote the increasing of dyes flux and rejection up to 79.698 L/m^{2}h and 99.5% respectively. Addition of surfactant shows the membrane surface morphology with upper layer and support layer consists of finger-like structure, finger-like channel, macrovoids and spongy structure.

Keywords: nanofiltration, surfactant, flux, rejection, morphological structure

Abstrak

Dalam kajian ini, membran surfaktan penurasan-nano telah disediakan melalui teknik fasa berbalik kering/basah mudah. Satu formulasi baru polimer yang terdiri daripada surfaktan yang berbeza (SDS,CTAB) dan kepekatan polimer (17 wt% - 21 wt%) telah disediakan. Kesan parameter ini terhadap prestasi pewarna dari segi fluks warna, penolakan dan struktur morfologi telah diperiksa. Data ujikaji menunjukkan bahawa, pada jarak yang berbeza kepekatan polimer, keputusan fluks membran NFS menyerap rendah pewarna antara 9.256 L/m^{2}h kepada 14.315 L/m^{2}h pada 4 bar tekanan operasi. Lebih penting lagi, penambahan SDS dan CTAB sebagai surfaktan didapati menggalakkan peningkatan fluks pewarna dan penolakan sehingga masing – masing adalah 79.698 L/m^{2}h dan 99.5%. Penambahan surfaktan menunjukkan morfologi permukaan membran dengan lapisan atas dan lapisan sokongan yang terdiri daripada struktur jejari, saluran jejari, makrovoid dan struktur lembut.

Kata kunci: penurasan-nano, surfaktan, fluks, penolakan, struktur morfologi

Introduction

Nanofiltration (NF) membrane one of the promising technologies which has been largely developed and commercialized for the separation of neutral and charged solutes in the aqueous solutions. NF membranes has two remarkable features which are has molecular weight cut-off (MWCO) between reverse osmosis (RO) membranes

and ultrafiltration (UF) membranes ranges from 200 to 2000 Da. The other advantage of NF where it can separate electrolytes due to the materials containing charged groups [1]. According to these features, the separation mechanisms involve both steric and electrostatic partitioning effects between the membrane and external solutions. The combination between steric and electrostatic allows NF membranes more effective for the separations of mixtures of organic molecules and salts. An NF membranes main feature is that most of them are charged either positively or negatively depends on their materials [2].

In this study, asymmetric nanofiltration membranes were prepared via dry/wet phase inversion techniques. This technique has been introduced by Loeb and Sourirajan which is the most extensively used technique for the preparation of asymmetric membranes. In this technique, the solution was cast on a substrate/glass was immersed and precipitated in a water bath. In dry/wet phase inversion technique, solvent in the casting solution was exchanged with non-solvent and phase separation will occurs in the film. This will be resulted to the morphology of asymmetric membranes showing a dense top layer and porous sub-layer membranes [3]. Addition of surfactant as additive in the polymer solution was the new materials used in formulating new NF membranes. Surfactant has been used in soaps, laundry detergents, dishwashing liquids and shampoos are organic chemicals that reduce surface tension in water and other liquids. Surfactant also can be considered as amphiphilic due to the two parts which are hydrophilic and hydrophobic parts [4].

Addition of surfactant has been studied by several researchers which gives high membrane performance. According to Tsai et al. [5], addition of surfactants in the casting solution can influence the formation process of macrovoids. Moreover, the size of macrovoids decreases when the surfactant content increase [5]. Furthermore, Amirilargani et al. [6] discovered that addition of non-ionic surfactant in the casting solutions shows that the macrovoids and finger-like pores in the sub-layer can be induced or suppressed depending on their miscibility. It was also found that the addition of small amount of surfactant will increase the water content, porosity and thickness of the prepared membranes [6].

Materials and Methods

Chemicals and raw materials

Polyethersulfone (PES) was purchased from SOLVAY Advanced Polymers Company (RADEL A-300). 1-Methyl-2-Pyrrolidone (NMP) with analytical purity of 99.5% (Merck), ethanol and n-hexane (Merck) was used as pre-treatment solutions in membrane fabrication. Polyethylene glycol (PEG) with average molecular weight of 600g/mol (Merck) used as additive. Cetyltrimethylammonium bromide (CTAB) with molecular weight of 364.5g/mol from EMD Chemicals and Sodium dodecyl sulfate (SDS) with molecular weight of 288.37g/mol (Merck) were used as surfactant addition in the polymer solution. Methyl violet from Blulux Laboratory Reagents and Methyl blue (Merck) were used as synthetic dyes.

Membrane preparation and fabrication

NMP was used to dissolve polymer in polymer solution method. NMP was heated at about 50 °C and PES was dissolved. PEG 600 was added when polymer has been dissolved. The solution was stirred for 8 hours to get homogenous solution. Then, surfactant was added 3 hours before the polymer solution was completed. After formation of polymer solution has been completed, casting process will take place in fabricated thin film of membrane. The casting process was conducted at room temperature (30±2 °C). Small amount of polymer solution was poured onto glass plate as support layer with casting knife setting at 150 μm. After the membrane has been casted, the glass plate support together with membrane was immersed into the coagulation bath. When the coagulation process was completed, the membrane was immersed in water bath for 24 hours before it was immersed in ethanol for another 24 hours. Finally, the resulted membrane was soaked in n-hexane for 2-3 hours before dried at room temperature at least for 24 hours. The prepared polymer solution concentration was varied from 17 wt% to 21 wt%.

Membrane performance evaluation

The permeation test was conducted by using a simple dead-end permeation cell. Prior to the testing, each membrane was subjected for the passages of the first 10 ml permeate was collected. The pure water permeation was calculated using equation 1 below:

$$\text{Pure Water Permeation} = \frac{\text{Volume of Permeate Solution Collected}}{\text{Effective Membrane Area x Time}} \quad (1)$$

To study the effect of dyes rejection, operating pressure at 4 bar was used to obtain respective flux. Permeation flux test of dyes was carried out using three types of dyes (methyl violet, methyl blue, acid orange) at 3 different concentrations (10ppm, 15ppm, 20ppm). The volume flux and rejection was calculated using formula equation 2 below:

$$\text{Percentage of Rejection} = 1 - \frac{\text{Concentration Permeate}}{\text{Concentration Feed}} \times 100\% \quad (2)$$

Results and Discussion

Dyes permeation flux and rejection

Three different dyes were used in this study (Methyl Violet, Methyl Blue, and Acid Orange) in order to determine the membrane performance in terms of permeation flux and dye rejection. Three different concentrations (10 ppm, 15 ppm, 20 ppm) of Methyl Violet has been used in order to find the significance difference of each prepared membrane and each concentration will give difference permeation flux and rejection results. Figure 1(a) shows the permeation flux of Methyl Violet at three different dyes concentration of membrane with SDS surfactant. Since 10 ppm is the lowest dye concentration, it shows highest flux among other concentration of about, 38.836 L/m^{2}h. However, the permeate flux keep increasing as polymer concentration increase up to 79.697 L/m^{2}h. The rejection of 10 ppm concentration of Methyl Violet shows that as polymer concentration increase, the rejection will decrease from 79% to 66.2%. Unlike the lower dye concentration, at 13.776 L/m^{2}h, the membrane can reject dye only 33.3% at 15ppm dye concentration. Since polymer concentration also plays an important role in this study, the color rejection of Methyl Violet increase sharply up to 79% at higher polymer concentration (21 wt%). As dye concentration increase to 20 ppm, the permeate flux decreased to 11.0843 L/m^{2}h. However, for 20 ppm of dye concentration, the three different polymer concentrations resulted to the same rejection. Research revealed that addition of surfactants in casting solution will influence the formation of macrovoids [7].

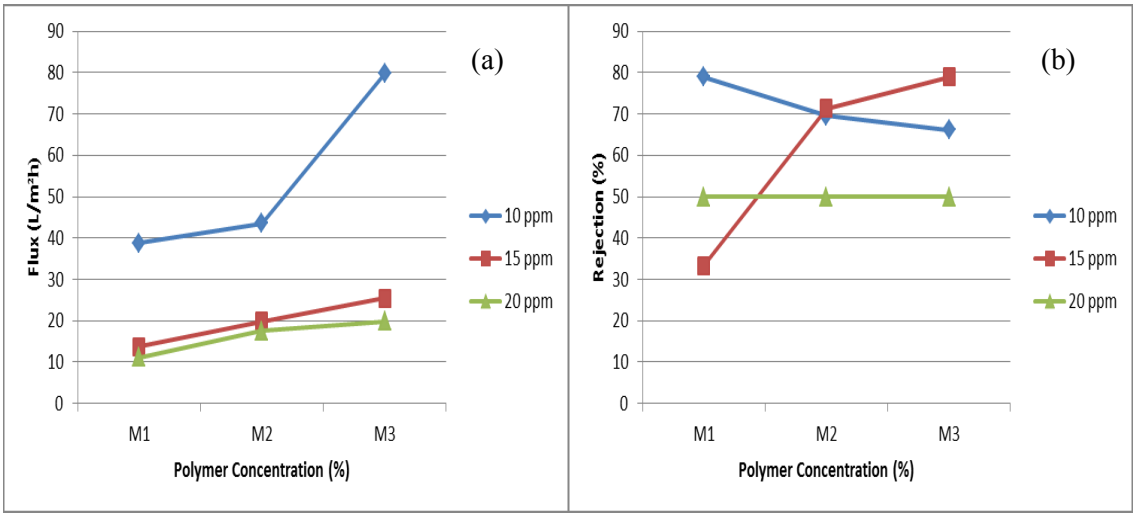

Figure 1. (a) Permeate flux and (b) % rejection of Methyl Violet

Experimental data shows that addition of SDS in polymer solution is not good for dyes rejection. Figure 2(a) and 2(b) shows permeation flux and percentage rejection of Methyl Blue when CTAB was used as surfactant. The highest permeate flux were obtained from the lowest polymer concentration at the lowest dye concentration. At 44.565 L/m^{2}h, M1 can remove dye of about 99.2% at 10ppm dye concentration. The results also show that, as polymer concentration increased, the permeate flux decreased up to 13.682 L/m^{2}h and increase the rejection to 99.5% for M3. According to Rahimpour et al. [7], addition of CTAB surfactant in polymer solution will gives membrane with large pores that formed in the sub-layer of the membrane. Moreover, addition of CTAB was known to be capable to increase the porosity of membrane support layer and result in high rejection of Methyl Blue [8]. At 15 ppm of dye concentration, the permeate flux shows the same results where the flux decrease when polymer concentration increase from 27.758 L/m^{2}h to 9.272 L/m^{2}h. Moreover, the rejection of Methyl Blue at 15ppm dye concentration increasing up to 99.1% for M3. An amount of 21wt% PES shows 8.972 L/m^{2}h of permeation flux and can reject dye up to 99.9% at 20 ppm of dye concentration.

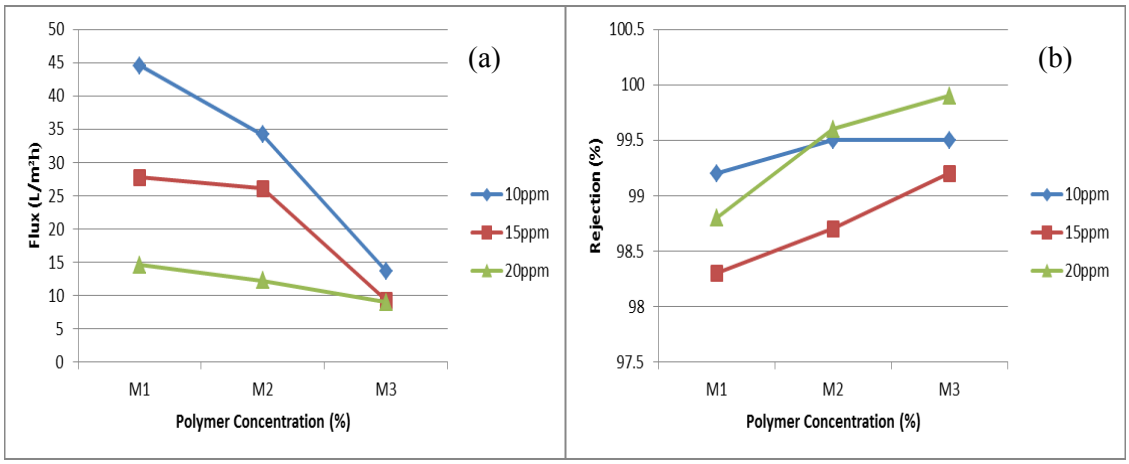

Figure 2. (a) Permeate flux and (b) % rejection of Methyl Blue

In order to complete the study, acid orange also was used to test the membrane performance (Figure 3). The same trend shown between Methyl Blue and Acid Orange in which the permeation flux decreased as polymer concentration increased with increasing of dye concentration. On the other hand, the rejection of acid orange was increased as polymer concentration increase also with increasing of dye concentration. At 51.044 L/m^{2}h, M1 gives dye rejection of 90.7% for 10 ppm dye concentration. Research proved that concentration of feed solutions is one of parameters that affects the membrane performance [9]. Permeate flux of Acid Orange decreased and rejection also increased when dye concentration increased. For 15 ppm dye concentration, M1 gives 46.898 L/m^{2}h of permeation flux and decreased to 15.871 L/m^{2}h indicate as the polymer concentration increased to M3 (21 wt%). Permeation flux of Acid Orange decreased and has increased the rejection up to 94.9%. Furthermore, morphological structures of prepared membrane also was the most important parameters that gives high or low rejection towards dye solutions. At 12.175 L/m^{2}h, 20 ppm of Acid Orange dye concentration gives 94.1% of dye rejection. This can be conclude that, for Acid Orange with lower molecular weight will decreased the permeation flux and increased the rejection as polymer concentration increased as well as dye concentration increased.

Morphological study

Figure 4a shows the image of nanofiltration membrane without surfactants. It can be seen that the resultant asymmetric membranes consist of dense top-layer and finger-like substructure. The cross-sectional image revealed that increasing of polymer concentration will increase the number of pores on the top-layer of the membranes. The long finger-like substructure is the key towards the performance of membranes. The support layer is thick that make the solutions harder to pass through the membranes. Addition of small amount SDS surfactant was shown by Figure

4b where different morphological structure produced. SDS makes the membrane structure more porous in terms of formation of larger macrovoids. Moreover, the support layer of membranes also containing microvoids that leads to the lower mechanical strength of the membrane. In order to study the effect of different type of surfactant on membrane performance, Figure 4c shows SEM image of membrane with CTAB. Addition of CTAB on polymer solution shows the formation of long finger-like structure across the substructure of the membrane. From the previous study, the SEM images shows the formation of large pores in the sub-layer of membrane with addition of CTAB. This phenomenon is due to the miscibility of the surfactant and coagulant. Other than that, addition of CTAB revealed that it will induces and extends the formation of macrovoids as well as finger-like pores in the support layer of membranes [10]. From the experimental data, membrane with CTAB shows lower flux and high rejection of dyes.

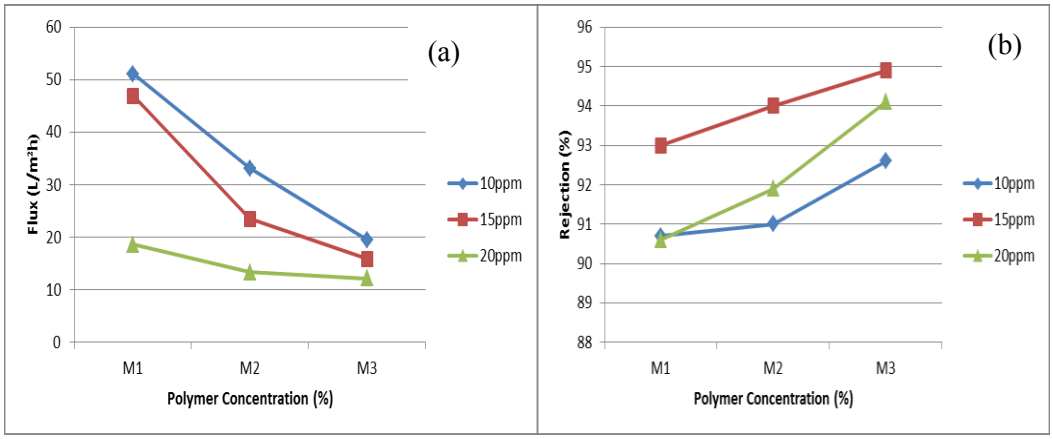

Figure 3. (a) Permeate flux and (b) % rejection of Acid Orange

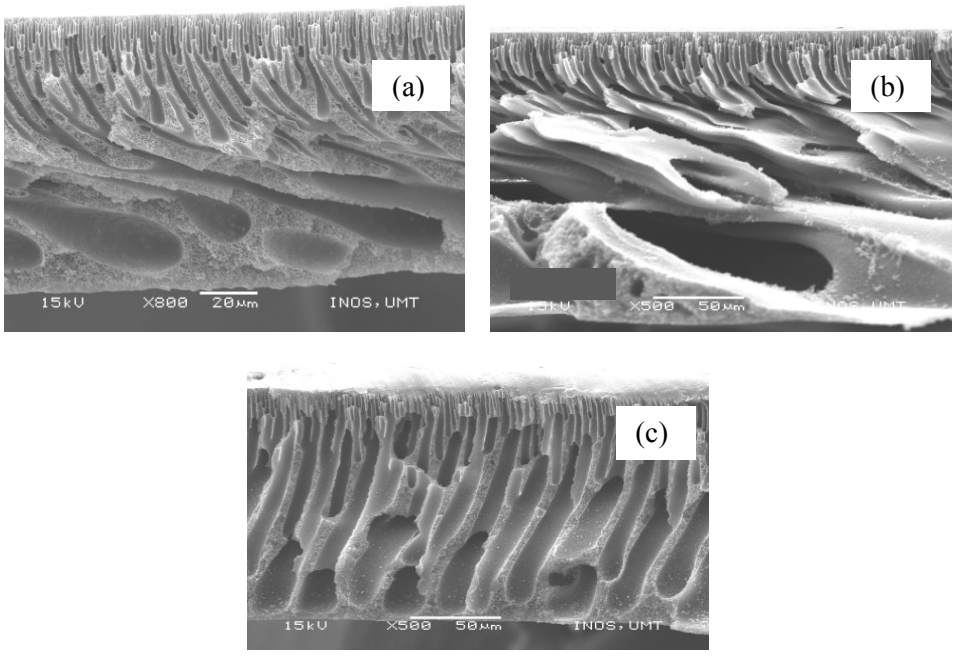

Figure 4. SEM images on (a) NF membrane (b) NF membrane with SDS and (c) NF membrane with CTAB at 800x of magnification

Conclusion

Experimental data shows the highest rejection of dyes was obtained by membrane contains CTAB as surfactant. Increased the rejection p to 99.9% it could be comparable to commercial membrane in the industry. With fine morphological structure consists of dense top-layer, long finger-like structure and stable support layer, membrane with CTAB is the best membranes to be used in textile industries in Malaysia. Besides, CTAB is readily available and very economical to use in making membrane.

Abstract

Calliandra surinamensis or Pinkpowder puff is a tropical shrub, named after Suriname. In Borneo, such as Sarawak and East Kalimantan area, it was known as "daun assam jawa". This species belonging to the family of Leguminosae and subfamily of Mimosoideae originated from tropical America. *Calliandra surinamensis* has been used in folk medicine to treat various diseases and infections such as cough, wound healing and inflammation. In this study, the flowers of *Calliandra surinamensis* was extracted by successive extraction. The phytochemical procedures adopted were vacuum liquid chromatography (VLC), and radial chromatography (RC). Phytochemical investigation of *Calliandra surinamensis* flower afforded three flavonol glycosides identified namely (1) 3-*O*-rhamnosylkaempferol (2) 3-*O*-rhamnosylmyricetin and (3) Myricetin-3-*O*-heptoseptanoside. The molecular structures of the isolated compounds were established based on spectroscopic methods such as 1D-NMR (^{1}H, ^{13}C, DEPT) and 2D-NMR (COSY, HMQC, HMBC) and comparison with literature.

Keywords: leguminosae, *Calliandra surinamensis*, 3-*o*-ramnosilkaempferol, 3-*o*-ramnosilmyricetin, myricitrin-3-*o*-heptoseptanoside

Abstrak

Calliandra surinamensis atau Pinkpowder puff adalah pokok renek tropika, dinamakan sempena nama Negara Surinam di Utara Amerika Selatan. Di Borneo seperti kawasan Sarawak dan Kalimantan Timur, ia dikenali sebagai "daun asam jawa". Spesies daripada keluarga Leguminosae dan subkeluarga Mimosoideae ini berasal dari Amerika bahagian tropika [4]. *Calliandra surinamensis* telah digunakan dalam perubatan tradisional untuk merawat pelbagai penyakit dan jangkitan seperti batuk, penyembuhan luka dan keradangan. Melalui kajian ini, bunga – bunga *Calliandra surinamensis* telah diekstrak melalui pengekstrakkan berturut-turut. Prosedur fitokimia yang digunakan adalah kromatografi cecair vakum (VLC) dan kromatografi jejarian. Kajian fitokimia daripada bunga *Calliandra surinamensis* telah menghasilkan tiga flavonol glikosida yang dikenalpasti sebagai (1) 3-*O*-ramnosilkaempferol (2) 3-*O*-ramnosilmyricetin dan (3) myricetin-3-*O*-heptoseptanosida. Struktur molekul sebatian terpencil telah dikenalpasti berdasarkan kaedah spektroskopi seperti 1D-NMR (^{1}H, ^{13}C, DEPT) dan 2D-NMR (COSY, HMQC, HMBC) serta perbandingan dengan data literatur.

Kata kunci: leguminosae, *Calliandra surinamensis*, 3-*o*-rhamnosilkaempferol, 3-*o*-rhamnosilmyricetin, myricitrin-3-*o*-heptosepta-nosida

Introduction

The genus *Calliandra* is one of the largest genera of the Leguminosae (Fabaceae), with approximately 200 species. It grows mostly in the tropical and sub-tropical regions of America with a few native also found in Madagascar and India. Various species in the genus have been reported for the treatment of eye diseases, diarrhea, indigestion [1],

diabetes and obesity [2]. Previous studies on the phytochemistry of several *Calliandra* species revealed different classes of compounds such as flavonoids, diterpenes, triterpenes, amino acids and polyphenols.

In the search of biologically active and interesting compounds from plants, the investigation on *Calliandra surinamensis* was carried out. *Calliandra surinamensis* locally known in Malaysia as "Kaliandra bunga merah" is a flowering plant endemic to southern Asia, Africa, Australia and America. Previous investigation reported the stem bark was used as traditional medicine by the folklore to treat various diseases and infections, antioxidants and antimicrobial activity [3,4]. The knowledge on isolation of the chemical constituents from this species is still limited. A preliminary study by Falodun and Qiu [5] on the rootbark of the plant reported some secondary metabolites such as flavonoid, β-sitosterol 3-*O*-β-D-glucopyranoside and recursterol. This paper reports on the isolation and structure elucidation of flavonoid compounds from the flower of *Calliandra surinamensis* which has not been reported before.

Materials and Methods

Experimental procedures

The ^{1}H-NMR and ^{13}C-NMR spectra were recorded on a Bruker 300 Ultrashield NMR spectrometer (Switzerland) measured at 300 and 75 MHz, respectively, using chloroform-D and methanol-D (Merck) as solvent. Chemical shifts are reported in δ ppm (part per million) with coupling constants given in Hertz (Hz). The infrared (IR) spectra were recorded using Perkin-Elmer 1600 series FTIR spectrometer (USA) using KBr pellets. The ultraviolet (UV) spectra were recorded on Shimadzu UV-Vis 160i spectrometer. The mass spectra were measured on Perkin Elmer Clarus 600T spectrometer 70 eV. Vacuum liquid chromatography (VLC) used Silica gel 60, 70-230 mesh ASTM (Merck 1.07747), Radial chromatography used Si-gel 60 PF254 (Merck 1.07749). For TLC analysis, pre-coated silica gel plates (Merck Kieselgel 60 GF254 0.25 mm) were used and visualized under UV light [6].

Plant material

The fresh flowers of *Calliandra surinamensis* was collected from the Universiti Teknologi MARA Shah Alam, Malaysia in September 2011. Botanical identification was done by a taxonomist Prof. Dr Mohd Nazip Suratman from Faculty of Applied Sciences, Universiti Teknologi MARA, Malaysia.

Extraction and isolation procedure

The dried powdered of flower (70 grams) of *Calliandra surinamensis* was defatted in methanol (40 $^{\circ}$C – 60 $^{\circ}$C) for 48 hours repeated for three times and was evaporated under reduced pressure to give brown residues. The methanol extract (40 g) was subjected to vacuum liquid chromatography (VLC) using gradient elution system of Hexane: EtOAc. Thirty-nine fractions from two separate fractionations were obtained and spotted on TLC and similar profile was pooled to yield four major fractions. Further purification of fraction 4 by radial chromatography (silica gel, $CHCl_3$: MeOH) yielded compound 1 (1.21 mg). Compound 2 and 3 also were obtained from radial chromatography.

Results and Discussion

Three flavonol glycosides isolated from the flower of *Calliandra surinamensis* were identified as 3-*O*-rhamnosylkaempferol, 3-*O*-rhamnosylmyricetin and myricetin-3-*O*-heptoseptanoside (Figure 1).

3-*O*-rhamnosylkaempferol (1)

Yellow solid. MS m/z: 432, $C_{21}H_{20}O_{10}$. UV λ_{max} nm (MeOH) 265 and 342. IR ν_{max} (KBr):1675 and 3197 cm$^{-1.}$ For ^{1}H NMR and ^{13}C NMR data, see Table 1.

Compound 1 was obtained as yellow solid and the mass spectral of the data gave a molecular weight of $C_{21}H_{20}O_{10}$ corresponding to 21 carbon in ^{13}C NMR spectral data. ^{1}H NMR spectra of compound 1 showed signals for aromatic hydrogen at δ_H 6.39 (d, J=2.1) and 6.21 (d, J=2.1) indicated H-6 and H-8, respectively at ring A of the flavonol skeleton. The ortho-coupled hydrogen at signal δ_H 7.79 (d,J=9.0) and 6.96 (d, J=9.0) were assigned for H-2'/6' and H-3'/5', respectively at ring B. A signal at δ_H 5.39 (d, J=1.2) was assigned to the anomeric proton of H-1''. One sugar moiety detected at C-3 of ring C assigned as rhamnose unit gave signals at δ 5.39 (d, J=12), 4.24 (dd, J=3.3, 1.5), 3.73 (dd, J=9.3,3.6), 3.35 (d, J=1.8), 3.31-3.33 (m) and 0.94 (d, J=5.7).

The APT NMR spectrum displayed 18 signals corresponding to 21 resonances. A signal at δc 178.20 was appointed to carbonyl carbon (C=O) attached to oxygen at C-4 whereas other signals at δc 98.42, 93.34, 115.11 and 130.50 were corresponded to quaternary carbon attached to OH at C-6, C-8, C-3'/5' and C-2'/6', respectively. Additional of one rhamnose unit at C-3 of ring C was proved by signals at δc 102.09, 70.51, 70.63, 71.76, 70.70 and 16.24. This compound was previously isolated from the leaves of *Schima wallichii* and was reported to have potential for anti-cancer therapeutics [7].

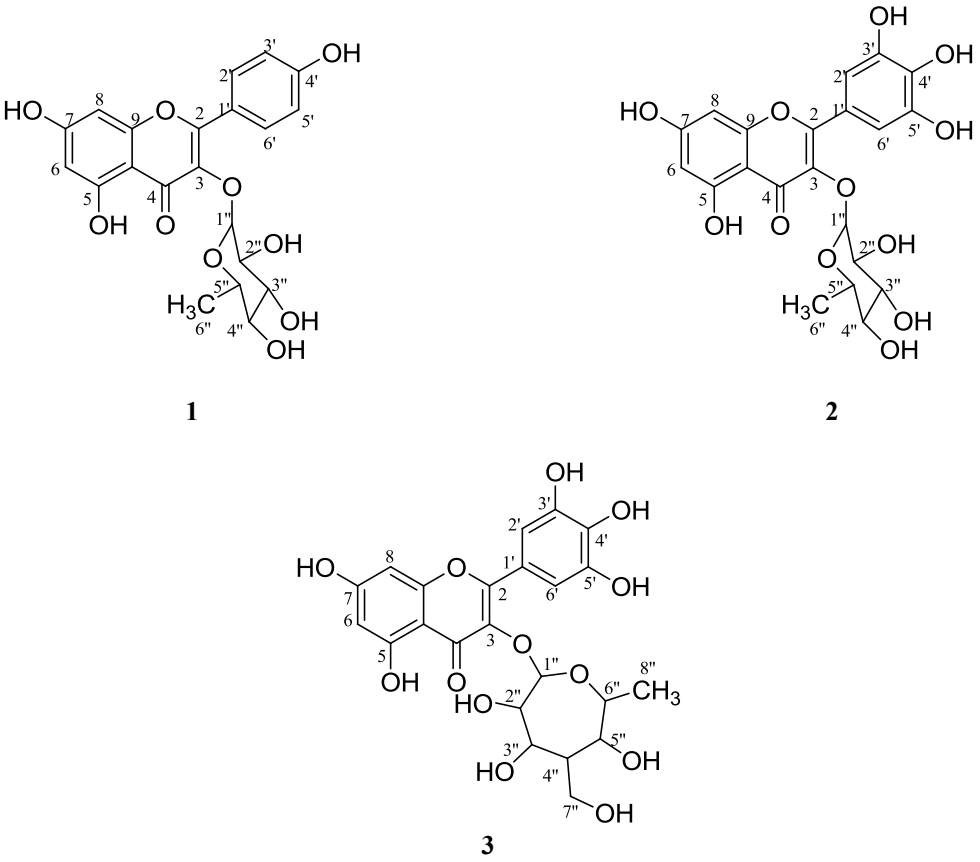

Figure 1. Structures of compound 1-3

3-*O*-rhamnosylmyricetin (2)
Mass Spectrum m/z: 464, $C_{21}H_{20}O_{12}$. UV λ_{max} nm (MeOH) 258, 302 and 352. IR ν_{max} (KBr): 1678 and 3186 cm^{-1}. For ^{1}H NMR and ^{13}C NMR data, see Table 1.

Compound 2 was obtained as yellow solid. The mass spectral of the data exhibit an M+ at m/z 464, corresponding to molecular weight $C_{21}H_{20}O_{12}$. Its ^{1}H NMR and ^{13}C NMR spectral data for 2 were closely related to compound **1** except that the AA'BB'-type coupling system in the B-ring of 1, was replaced by an AB-type coupling system in B-ring for 2. The ^{13}C NMR spectrum exhibited 16 signals corresponding to 17 carbon resonances. Signals at δ_C 178.24 was appointed to carbonyl carbon attached to oxygen (C-4) whereas other signals at δ_C 145.01 and δ_C 148.40 were corresponded to a quarternary carbon attached to OH at C-3' and C-5' respectively. Rhamnose was presence at C-3, [δ_C 102.1, 70.4, 70.6, 71.8, 70.6, 16.25 ppm] as similar to compound **1**. This compound was isolated from the leaves of *Myrica rubra* and showed good anti-inflammatory activity [8].

Myricetin-3-*O*-heptoseptanoside (3)
Mass Spectrum m/z: 508, $C_{23}H_{24}O_{13}$. UV λ_{max} nm (MeOH) 245 and 252. IR ν_{max} (KBr): 1679 and 3174 $cm^{-1.}$ For ^{1}H NMR and ^{13}C NMR data, see Table 1.

Compound 3 was obtained as pale yellow solid. The mass spectral of the data exhibit an M+ at m/z, corresponding to molecular weight $C_{23}H_{24}O_{13}$. Compound 3 gave the ^{1}H NMR and ^{13}C NMR spectra shown in Table 1, show the aglycone moiety at signal δ 6.79 (d, J=1.8), 6.92 (d, J=2.1), 7.92 (dd, J=2.1,16.8) and 7.48 (d, J=8.4). The APT NMR spectrum exhibited 18 signals corresponding to 21 resonances. Signals at δ_C 179.2 was appointed to carbonyl carbon attached to oxygen (C-4) whereas other signals at δ_C 146.0 and δ_C 149.3 were corresponded to a quarternary carbon attached to OH at C-3' and C-5' respectively. Additional of one sugar moiety at C-3 was confirmed with extra signals detected at δ_C 103.1, 71.5, 72.9, 73.4, 64.0, 71.6, 71.7 and 17.2. Thus, compound 3 was determined to be myricitrin-3-*O*-heptoseptanoside and this is the first report on the isolation of this constituent.

Conclusion

Three flavonol glycoside compounds identified as 3-*O*-rhamnosylkaempferol (1), 3-*O*-rhamnosylmyricetin (2) and myricetin-3-*O*-heptoseptanoside (3) were successfully isolated from the flower of *Calliandra surinamensis.*

Abstract

Phytochemical investigation has been carried out on the stem bark of *Shorea bracteolate* . Three known oligomeric stilbene compounds, namely vaticanol A (1), stepnophyllol C (2) and hopeaphenol A (3) were isolated from the acetone extract of the plant. The structure of the isolated compounds were determined based on the analysis of spectroscopic data, including Nucleus Magnetic Resonance (NMR), Ultra Violet (UV), Infrared (IR) and comparison with literature.

Keywords: ε-viniferin, hopeaphenol, Vaticanol A, Stepnophyllol C, *Shorea bracteolate*, dipterocarpaceae

Abstrak

Kajian fitokimia telah dilakukan ke atas bahagian kulit batang *Shorea bracteolate.* Tiga sebatian oligomerik stilbene iaitu vatikanol A (1), stepnofilol C (2) dan hopeafenol A (3) telah diasingkan daripada ekstrak aseton *S. bracteolate*. Struktur sebatian-sebatian ini telah ditentukan menggunakan analisis data spektroskopi termasuk Resonans Magnet Nukleus (NMR), Ultra Violet (UV), Infra merah (IR), dan perbandingan dengan literatur.

Kata kunci: ε-viniferin, hopeaphenol, Vaticanol A, Stepnofilol C, *Shorea bracteolate*, dipterocarpacea

Introduction

Shorea is a subfamily of Dipterocarpaceae family. A large number of stilbene derivatives have been isolated from plants belonging to the families of the Vitaceae, Leguminosae and Dipterocarpacea [1]. Plants of the largest subfamily, Dipterocarpoideae, are the sources of resveratrol oligomers (oligostilbenoids), sesquiterpenes, and triterpenes [2]. Until now, the chemistry of Dipterocarpaceae is relatively less known. This is because the early research on Dipterocarpaceae was mainly focused on the chemical compounds of their resins such as terpenoid, sesquiterpenoid and triterpenoid. In the last two decades, the phytochemical research on Dipterocarpaceae has shifted rapidly. This is due to the fact that oligomeric resveratrol compounds have been found to be the main polyphenols. They include stilbene dimers, trimers, tetramers, hexamers, heptamers and octamers with various molecular framework resulting from different oxidative condensations of revesratrol monomers. These compound also show a variety of important bioactivities such as anti inflammatory, antibacterial, antifungal, cytotoxicity, chemopreventive and hepatoprotective. They also inibit topoisomerase II, gastic ATPase and 5α-reductase reaction [3].

Shorea bracteolate called white meranti is widely distributed in Sumatera, Peninsular Malaysia, Indonesia and Singapura. The tree grows up to 50 m in height and the timber is light hardwood. This paper reports the isolation and structure determination of a stilbene dimer, a stilbene trimer and a stilbene tetramer form the plant.

Materials and Methods

General experimental procedure

^{1}H and ^{13}C spectra were recorded in acetone-D on Bruker 300 Ultrashield NMR spectrometer measured at 300 and 125 MHz. IR spectrums and UV spectra were recorded on the Perkin Elmer spectrum on FT-IR spectrometer and Shimadzu UV-vis 160i instruments, respectively. Melting point was measured by Fisher Johns. Optical rotations were determined using a Perkin-Elmer 341 polarimeter in MeOH. Vacuum liquid chromatography (VLC) was carried out using Si-gel Merck 60 GF254 (230 – 400 mesh), while column chromatography (CC) was used Si-gel Merck 60 (200 – 400mesh) and TLC analysis on precoated Si-gel Merck Kieselgel 60 F254 0.25mm, 20 x 20 cm plates.

Plant material

The stem bark of *Shorea bracteolate* was collected in 2009 and a voucher specimen had been deposited at the UPM.

Extraction and isolation procedure

The stem bark of *S. bracteolate* was dried and cut into small pieces and ground to powder about 1mm mesh size using a grinder. The sample was extracted with acetone and the extract was evaporated in vacuo at 40 ^{0}C to yield a crude extract. The crude extract was fractionated using (VLC) to give 6 fractions. Fraction 3 (F3**)** was subjected to multiple radial chromatography (RC) to afford Compound 1**.** Fraction 4 (F4**)** was subjected to VLC using a series of increasing polarity solvent from 40% hexane/60% ethyl acetate to 90% ethyl acetate/10% methanol to give 5 fractions. Subfraction F43 was resubjected again to VLC to give 12 fractions. Similar TLC profile were pooled together to give 4 fractions. Subfraction F432 was then subjected to radial chromatography (RC) and CC to give Compound 2 [C: A: M (9:0.5:0.5)]. F44 was subjected to RC and PTLC to give Compound 3 [C: M (9:1)].

Results and Discussion

Investigation on the tree bark of *Shorea bracteolate* have resulted in the isolation of three oligostilbenoid compounds which successfully characterized as vaticanol A **(**1**)**, stepnophyllol C **(**2**)** and hopeaphenol A **(**3**).** Compound 1 was obtained as a yellow powder. The ^{1}H-NMR spectrum showed three sets of *ortho*- coupled aromatic protons. They were assignable to three 4-hydroxyphenyl groups at 7.28(2H, d, J=8.4, $H_{2a,6a}$), 6.83(2H ,dd, J=8.4, $H_{3a,5a}$), 7.07(2H, d, J=8.4, $H_{2b,6b}$), 6.60(2H, dd, J=8.7, $H_{3b,5b}$), 6.55(2H, dd, J=8.7, $H_{2c,6c}$) and 6.37(2H, dd, 8.4, $H_{3c,5c}$). It also showed a 3,5-dihydroxyphenyl group at 6.27 (1H, d, J=2.1, $H_{10c,14c}$), 6.21 (1H, 2.1, H_{12c}), a set of *meta*- coupled aromatic protons at 6.09(1H ,d, 2.4, H_{12a}), 6.48(1H, d, 2.4, H_{14a}), aromatic proton of a penta-substituted benzene ring at 6.22(br, s, H_{12b}), four unit of aliphatic methine protons coupled at 5.17(br, s, H_{7b}), 4.52 (br ,s ,H_{8b}), 3.64(1H, d, 7.8, H_{7c}), 4.19(br, s, H_{8c}), a set of aliphatic protons at 6.18(br, s, H7a) and 4.52 (br, s, H_{8a}). From these characteristics, it was suggested that the compound 1 is vaticanol A [4]. Figure 1 show the structure of vaticanol A.

Compound 2 was obtained as brownish powder. The ^{1}H NMR spectrum showed the presence of two sets of *ortho*-coupled aromatic proton at δ7.12 (2H, d, J=15Hz, $H_{2(6)a}$), 6.76(2H, d, J=15Hz, $H_{3(5)a}$), 6.76 (2H, d, J=15Hz, $H_{2(6)b}$), 6.58 (2H, d, J=15Hz, $H_{3(5)b}$), a 3,5-dihydroxyphenyl group δ6.29 (1H, br s, H_{10a}), 6.32 (1H, s, H_{12a}), a singlet aromatic proton 6.21 (1H, s, H_{12b}), two broad aliphatic protons δ4.30 (1H, br s ,H_{7b}), 3.98 (1H, br s, H_{8b}), two mutually coupled aromatic aliphatic hydrogens 5.32(1H,d,J=5Hz, H_{7a}) and 4.32 (1H,s,H_{8a}). From these characteristics, it was suggested that the compound 2 is stepnophyllols C [5]. Figure 2 shown the structure of stepnophyllols C.

Malaysian Journal of Analytical Sciences, Vol 20 No 6 (2016): 1535 - 1538
DOI: http://dx.doi.org/10.17576/mjas-2016-2006-36

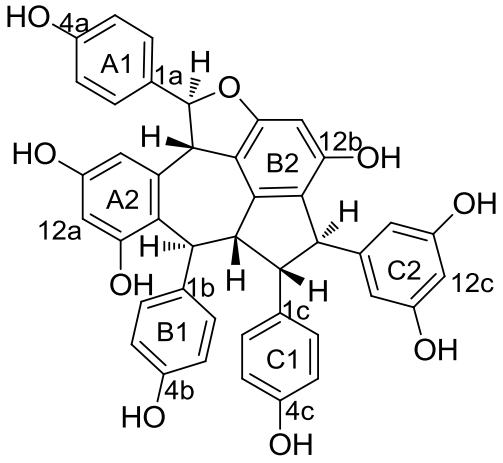

Figure 1. Structure of Vaticanol A

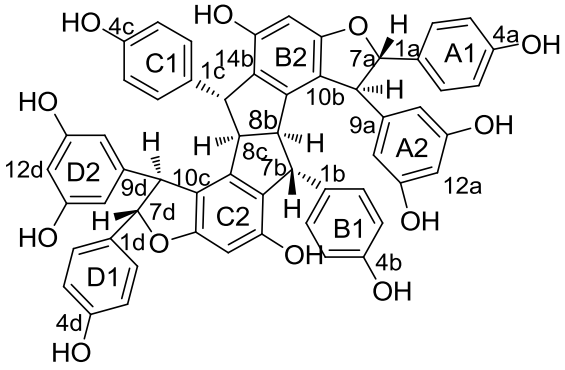

Figure 2. Structure of Stepnophyllols C

Compound 3 was obtained as a yellowish amorphous powder. The ^{1}H NMR spectrum showed the presence of eight *ortho*- coupled aromatic proton. They were assignable to four 1,4- disubstituted aromatic ring δ7.25 (2H, d, J=8.5Hz, $H_{2(6)a)}$), 6.84 (2H, d, J=8.5Hz, $H_{3(5)a}$), 7.52 (2H,d,J=8.5Hz, $H_{2(6)a'}$), 6.93 (2H, dd, J=8.5Hz, $H_{2(6)b}$, $_{3(5)a'}$), 6.56 (2H,d,J=8.5Hz, $H_{3(5)b}$), 6.32 (2H,m, $H_{2(6)b', 3(5)b'}$). Futher analysis of the ^{1}H NMR spectrum revealed a four set of 1,2,3,5 tetrasubstituted aromatic ring, 6.33 (1H,m, H_{12a}), 6.22 (1H,s, H_{14a}), 6.38 (1H,m,$H_{12a'}$), 6.40 (1H,s, $H_{14a'}$), 6.05 (1H, d, J=2.1Hz, H_{12b}), 5.90 (1H,m, $H_{14b,12b'}$), 5.01 (1H, d, J=2.1), a sequence of two vicinal methine doublets 5.83 (1H,d, J=13Hz, H7a), 4.41 (1H,d, J=13Hz,H8a), 5.73 (1H,d, J=8.5Hz, H7a'), 5.43 (1H,d,J=8.5Hz,H8a') and four contiguous methine multiplets 5.06 (1H,d, J=5.0Hz, H7b), 4.30 (1H,dd, J=5.0Hz, H8b), 4.73 (1H,d,J=4.5Hz, H7b'), 2.65 (1H,dd,J=5, H8b'). From these characteristics, it was suggested that the compound 3 is hopeaphenol A [6]. Figure 3 shown the structure of hopeaphenol A.

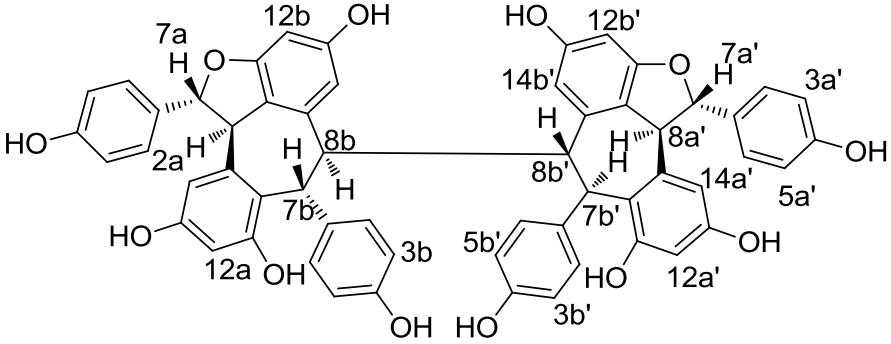

Figure 3. Structure of Hopeaphenol A

Conclusion

Three oligostilbenes, Vaticanol A **(**1**)**, Stepnophyllol C **(2)** and hopeaphenol A **(**3**),** were successfully isolated from the acetone extract of the stem bark of *Shorea bracelate.*
