**Abstract**

A screen-printed copper ion sensor with photocurable poly(n-butyl acrylate) (pBA) membrane based on ionophore o-xylylene bis(N,N-diisobutyldithiocarbamate) (o-xc) was successfully fabricated. Poly(2-hydroxylethyl methacrylate) (pHEMA)-modified Ag/AgCl screen-printed electrode was used in the development of the sensor and the sensor was characterized by potentiometric method. Optimization of pBA membrane for the electrode was carried out by varying the compositions of sodium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate (NaTFPB) and o-xc to determine the best analytical performance. The addition of NaTFPB and the increment of its ratio relative to o-xc showed super-Nernstian, small linear range, and high detection limit. For sensor fabricated based on o-xc without the addition of NaTFPB, the sensor showed Nernstian response. The best optimized sensor showed Nernstian slope with 31.29 mV/decade over a wide linear range of $1.0 \times 10^{-2} - 1.0 \times 10^{-6}$ M and low detection limit of $1.89 \times 10^{-7}$ M. The sensitivity of this sensor was also improved over the other copper ion sensors fabricated by similar photocuring technique. In addition, based on the separate solution method (SSM), this sensor exhibited good selectivity towards copper ion with low logarithm selectivity coefficient value for monovalent and divalent cations namely $K^+$, $Na^+$, $Ca^{2+}$, $Mg^{2+}$, $Ni^{2+}$ and $Co^{2+}$.

**Keywords:** screen-printed copper ion sensor, photocurable poly(n-butyl acrylate) membrane, ionophore o-xylylene bis(N,N-diisobutyldithiocarbamate), potentiometry

**Abstrak**

Sensor ion kuprum bercetak skrin yang berasaskan kepada ionofor o-xililen bis(N,N-diisobutilditiokarbamat) (o-xc) dalam membran terawatfoto poli(butil-akrilat) (pBA) telah dibangunkan. Sensor ion elektrod bercetak skrin Ag/AgCl terubahsuai poli(2-hidroksiletil metakrilat) (pHEMA) telah digunakan dalam pembangunan sensor dan pencirian sensor telah dijalankan melalui kaedah potensiometri. Pengoptimunan komposisi membran sensor ion pada elektrod telah dijalankan untuk menentukan prestasi analisis yang terbaik dengan mengubah komposisi sodium tetrakis[3,5-bis(trifluorometil)fenil]borat (NaTFPB) dan o-xc. Penambahan NaTFPB dan peningkatan nisbahnya terhadap o-xc dalam membran menunjukkan super-Nernstian, julat linear yang pendek dan had pengesanan yang tinggi. Sensor ion yang direka bentuk dengan menggunakan o-xc tanpa penambahan NaTFPB menunjukkan rangsangan Nernstian. Sensor ion yang terbaik menunjukkan kecerunan Nernstian iaitu 31.29mV/dekad, julat linear dari $1.0 \times 10^{-2} - 1.0 \times 10^{-6}$ M dan had pengesanan terendah $1.89 \times 10^{-7}$ M. Kepekaan sensor yang telah dibangunkan juga adalah lebih baik berbanding dengan sensor-sensor ion kuprum lain yang telah direka bentuk melalui kaedah rawatan foto yang sama. Nilai pekali keselektifan potensiometri ditentukan dengan kaedah larutan berasingan (SSM). Sensor tersebut juga memberikan keselektifan yang baik terhadap kation pengganggu dengan menunjukkan nilai pekali logaritma keselektifan yang rendah bagi kation monovalen dan divalen seperti $K^+$, $Na^+$,$Ca^{2+}$, $Mg^{2+}$, $Ni^{2+}$ dan $Co^{2+}$.

**Kata kunci**: sensor ion kuprum bercetak skrin, membran terawatfoto poli(n-butil akrilat), ionofor o-xililen bis(N,N-diisobutilditiokarbamat); potensiometri

## Introduction

Copper is one of the most widely spread heavy metals in the environment. It is extensively used for industrial, agricultural, and domestic purposes due to its high electrical conductivity, chemical stability, and potential to form alloy with other metals [1]. Copper is also an essential trace element to human health and involves in electron transfer process of various biological system [1,2]. However, copper as one of the heavy metal ions is considered toxic to many living organisms due to its non-biodegradable behavior [3]. Long term exposure to copper will cause irritation of the nose, mouth, eyes, headache, and stomach problems [4]. Intentionally high uptake of copper may exhibit toxicity and pose a threat to human health by causing Alzheimer's disease, Wilson's disease, hypoglycemia, liver and kidney damage, and gastrointestinal problem as the tolerance limit of copper in human body is 2 mg per day [5,6]. In addition, copper can act as a potential endocrine disrupter by modulating the estrogenic activity of endogenous hormones. By replacing zinc atom from the zinc fingers of estrogen receptor with copper, the binding of the receptor with DNA hormone responsive elements in the cell nucleus is prevented [7]. Therefore, in view of the widespread use of copper, its occurrence in the environment, and its adverse effects, its determination is important and highlights are needed for an efficient method of copper detection.

Application of ion sensor for the determination of metal ions has been widely developed because of its high selectivity, low detection limit, low cost analysis, require no sample pretreatment, and sensitive to electronics [8-10]. Among the ion sensors types, potentiometric detection method is the simplest method that offers various advantages such as fast and easy preparation procedures, simple instrumentation, fast response time, wide linear range, and may also suitable for online analysis [6,11]. The common ion sensor construction is normally based on polymeric membrane consisting the immobilized sensing material [12]. Hence, in the fabrication of an ion sensor, the ionophore as the electroactive and sensing material, should exhibits stronger affinity for a particular metal ion [13]. The copper ionophore o-xc used is shown in Figure 1.

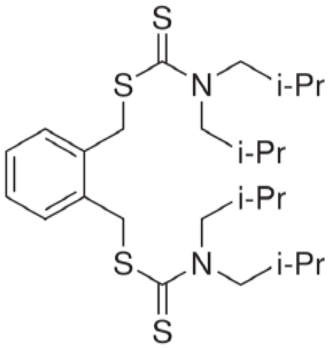

Figure 1. Structure of ionophore *o*-xylylene bis(N,N-diisobutyldithiocarbamate) (o-xc)

O-xc compound is a good ionophore as it shows a very good selectivity towards copper ion in copper ion sensors as reported by Kamata et al. [14], Woznica et al. [15], Birinci et al. [16], and Kisiel et al. [17]. O-xc is a non-cyclic compound, which consists of dithiocarbamate functional group. The sulfur atoms from the dithiocarbamate group pose σ orbital donor and n-back donation characteristic [18-19]. Thus, the sulfur atoms act as the active sites and able to coordinate with copper (II) ion to form a chelate with a four member ring [20].

Besides that, it is also crucial to select the right immobilization matrix for ionophore immobilization due to the nature of the ionophore. The selection will be affected by the types of immobilized matrix, and thus affect the performance of the sensor [21]. Most of the reported copper ion sensors utilized poly(vinyl chloride) (PVC)

membrane as polymer matrix because of its relatively low cost, high tensile strength, chemical inertness, and plasticizer compatibility [22-24]. A conventional copper ion sensor based on ionophore o-xc with PVC membrane was developed by Kamata et al. [14]. This sensor showed a Nernstian slope of 29 mV/decade within the linear range from $1.0 \times 10^{-6}$ to $1.0 \times 10^{-1}$ M, the detection limit of $1.4 \times 10^{-7}$ M and good selectivity over a wide variety of interference cations including alkali, alkaline earth, transition, and heavy metal ions. Another copper ion sensor with the same membrane components but used different conductive material, graphite, epoxy, and hardener mixture as the solid contact for the ion selective electrode reported by Birinci et al [16]. The sensor displayed a Nernstian response of 31.3 mV/decade over a linear range, $1.0 \times 10^{-6}$ to $1.0 \times 10^{-1}$ M, the detection limit of $4.9 \times 10^{-7}$ M and selective towards copper ions over common interference cations. PVC membrane is a hard polymer. A plasticizer is always needed to obtain a soft and elastic property for an optimum response. Therefore, both reported copper ion sensor used plasticizing solvent mediator, o-nitrophenyl octyl ether, in the membrane preparation in order to be functional as a copper ion sensor. However, plasticizer incorporation resulted in weakening the mechanical strength and adhesion of the polymer on the surface of electrode. Consequently, the polymer membrane tends to be peeled off easily from the transducer and causes a major shift of sensor response [25-27].

Alternatively, plasticizer-free acrylate polymer has become a choice of membrane material in this work. This polymer has various advantages. For instance, it is self-plasticizing, so it does not need any kind of external plasticizer. Acrylate polymer is also photocurable and can be formed by photopolymerization on an electrode surface [28-29]. Compared with PVC membrane deposition method such as solvent casting which needs at least one day of solvent evaporation [16], this photopolymerization method is fast and simple [28]. Moreover, this polymer also has lower glass transition temperature value, $T_g$, enable an excellent adhesion on solid surfaces. Therefore, it is suitable for application in solid state ion sensor [29]. Woznica et al. [15] have reported a solid-state copper ion sensor based ionophore o-xc with photocurable pBA membrane onto the surface of conducting layer, poly(3-octylthiophene-2,5-diyl) (POT) modified ion selective electrode. Without the addition of plasticizer, this sensor demonstrated a good selectivity towards various interference cations. However, lower Nernstian slope was observed with 26.3 mV/decade in the range of $1.0 \times 10^{-6}$ to $1.0 \times 10^{-1}$M with detection limit of $1.0 \times 10^{-6.3}$ M. A drop casting application for ionophore immobilization and entrapment method within pBA membrane in this sensor fabrication is said to be less efficient because this method causes an insufficient amount of ionophore o-xc presence in the membrane. Therefore, a more efficient immobilization method is also needed to render an improved performance of a sensor.

Furthermore, concerning solid state ion selective electrode coupled with potentiometric detection, screen-printed electrode represents a high interest when considering the technological aspects that offer low cost and simplicity of manufacturing, mass production, and long term stability [30,31]. High sensitivity, low detection limit, and no requirement of large volume of sample also other important advantages using screen-printed electrode [32]. Previously reported copper ion sensors based ionophore o-xc with PVC or pBA membranes are non-screen-printed solid-state sensors [15-17]. Therefore, the intention of this study is to explore a screen-printed copper ion sensor based ionophore o-xc with photocurable pBA membrane. Instead of drop cast immobilization method, the ionophore o-xc was immobilized within the pBA membrane during the photopolymerization. The optimization of the composition of the ion selective pBA membrane for preparing the best copper ion sensor was also detailed.

## Materials and Methods

### Reagents and chemicals

Chemicals used in this study included n-butyl acrylate (nBA), 2,2-dimethoxy-2-phenylacetophenone (DMPP), 1,6-hexanediol diacrylate (HDDA), 2-hydroxylethyl metacrylate (HEMA) from Sigma Aldrich; sodium tetrakis [3,5-bis(trifluoromethyl) phenyl] borate (NaTFPB), *o*-xylylene bis(N,N-diisobutyldithiocarbamate) (o-xc) from Fluka; copper (II) chloride dihydrate from S&M, sodium chloride from SYSTERM, potassium chloride from Sigma Aldrich, calcium chloride from HMBG, cobalt chloride hexahydrate from AJAX, and magnesium chloride and nickel chloride hexahydrate from Fluka. All chemicals are analytical grade and used as obtained. Deionized water was used for the standard solution preparation.

**Apparatus**

The electrochemical measurements were performed using an Orion Ion meter. A double junction Ag/AgCl was used as the reference electrode. The reference electrode was filled with 0.1 M Tris HCl buffer at pH 7.00 saturated with AgCl as internal reference solution and 0.1M lithium acetate as gel bridge electrolyte. The working electrode was an Ag/AgCl screen-printed electrode (Scrint Print Sdn. Bhd., Malaysia). An ultraviolet (UV) exposure unit (R.S.Ltd) installed with four light tubes transmitting UV light at the wavelength of 350 nm was used for photopolymerization of pBA membrane.

**Preparation of poly(2-hydroxylethyl methacrylate) (pHEMA) as inner layer**

A mixture of 913 µL HEMA monomers and 15.68 mg of photoinitiator, DMPP was drop-coated onto the Ag/AgCl screen printed electrode. The electrode was then placed in the UV-exposure unit for photopolymerization process. Before the irradiation of UV, the unit was purged with nitrogen gas for 2 minutes and then irradiated for 3 minutes under constant flow of nitrogen gas. The polymer film formed was then hydrated with 0.1 M of copper (II) chloride dihydrate solution for 30 minutes to form the inner layer of the sensor. This photocuring method was similar to the method reported by Lee & Hall [28] with minor modification.

**Preparation of ion selective poly(n-butyl acrylate) pBA membrane**

A mixture of nBA monomers, cross linker HDDA, photoinitiator DMPP, and required amounts of lipophilic salt, NaTFPB and ionophore o-xc was prepared as shown in Table 1. The mixture was then deposited on the top of the hydrated pHEMA inner layer and then photocured in a UV- exposure unit under a nitrogen gas atmosphere for 8 minutes to form the self-plasticizing and ion selective pBA membrane. The procedures to fabricate copper ion sensor with pHEMA-pBA membrane and the design of pHEMA modified-Ag/AgCl screen printed electrode with pBA membrane are shown in Figure 2 and Figure 3 which reported by Alva [33] with minor modification.

Table 1. Composition of ion selective pBA membrane

| Sensor No. | nBA (wt%) | HDDA (wt%) | DMPP (wt%) | o-xc (wt%) | NaTFPB (mol%) |

**Procedure to evaluate the copper ion sensor responses**

A complete electrochemical cell was setup which consisted of reference electrode and copper ion sensor. Both reference electrode and copper sensor were connected to an Orion ion meter and the potential differences or electromotive force (EMF) in mV unit were recorded when a stable reading was reached. Copper ion sensor with varying composition of pBA membrane was measured with the standard solution of copper (II) chloride dihydrate in the range of $10^{-1}$M to $10^{-8}$M. The graph of EMF versus logarithm of copper (II) chloride dihydrate concentration was plotted and the slope of the graph was determined [34].

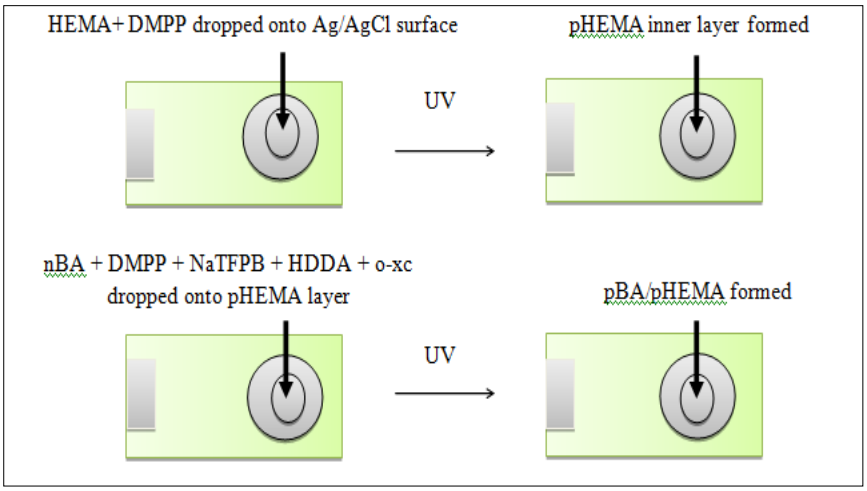

Figure 2. Steps to fabricate Ag/AgCl screen-printed copper ion sensor with pHEMA-pBA membrane

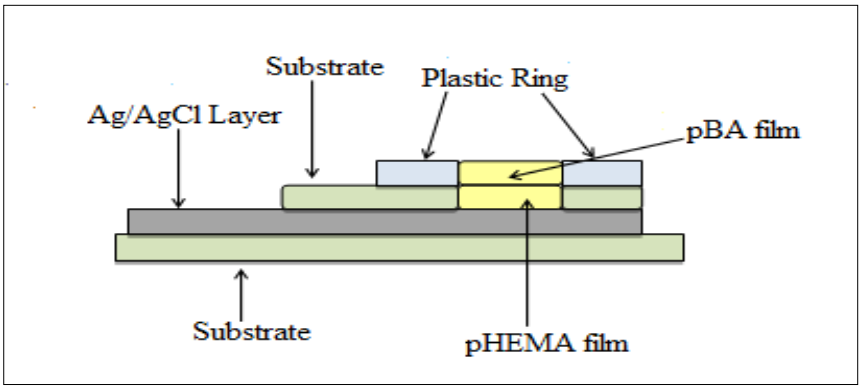

Figure 3. The design of Ag/AgCl screen printed electrode with pBA-pHEMA membrane

The selectivity behavior of the ion sensor is usually described in terms of selectivity coefficient. The selectivity coefficient of the proposed electrode was determined by separate solution method (SSM) with reference to Nicolsky-Eisenmann equation [35]. An amount of 0.01 M of interference ions NaCl, KCl, $CaCl_2$, $CoCl_2$, $MgCl_2$ and $NiCl_2$ were prepared and the potential differences were measured to evaluate the selectivity of the copper ion sensor. The measurements were done in triplicate for each interference ions and the average value was taken to determine the logarithm selectivity coefficient of the sensor.

## Results and Discussion

### Effect of lipophilic salt NaTFPB on copper ion sensor response

The presence of anionic sites has been known to be beneficial to cation selective sensor especially those sensors with neutral ionophore. It can increase the anionic property of the ion selectivity membrane by reducing the surface resistance, attracting more cations to the membrane surface, and enhancing the cation exchange process at the membrane-solution interface [36,37]. The lipophilic salt used in this study was NaTFPB as showed in Figure 4. The anionic site was created by NaTFPB in this work after entrapped together with ionophore into the membrane phase. Therefore, it is vital in determining the exact composition of lipophilic salt NaTFPB and ionophore o-xc inside the membrane as these two components will affect the sensitivity and selectivity of the ion sensor significantly [36].

Seven batches of copper ion sensor with different amounts of NaTFPB were fabricated to evaluate their performances.

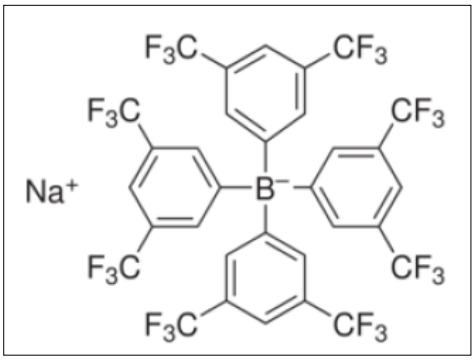

Figure 4. NaTFPB molecule with negatively charged B

Nernstian response is revealed when calibration graph of potential differences versus logarithm of ion activity is linear with a slope of 29.58 mV/decade for every 10 increment of divalent ion concentration at 298.15 K [38]. According to Figure 5 and Table 2, Sensor 1 to Sensor 5 with 80 mol%, 60 mol%, 40 mol%, 30 mol% and 20 mol% of NaTFPB showed super-Nernstian response while Sensor 6 and Sensor 7 with 1 mol% and 0 mol% of NaTFPB showed Nernstian response.

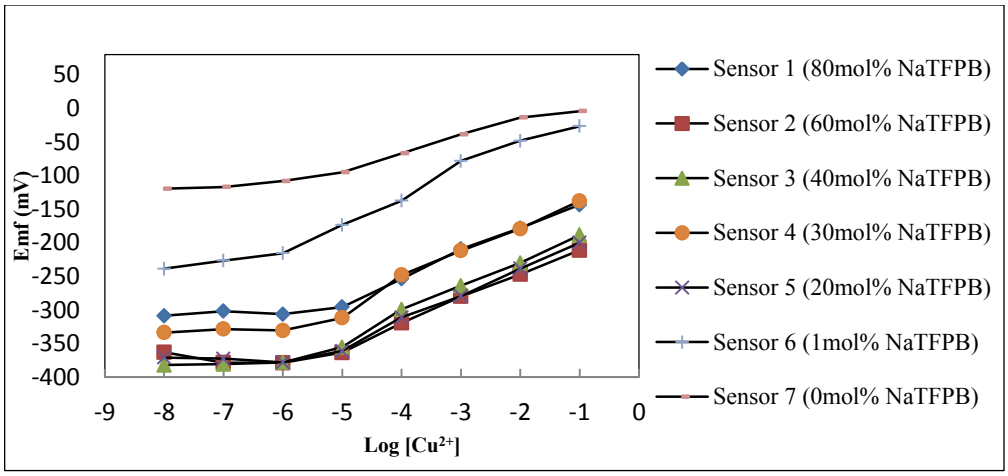

Figure 5. Potentiometric response of copper ion sensors based on 1 wt% of ionophore o-xc and different amounts of NaTFPB lipophilic salts.

NaTFPB lipophilic salt is known to reduce the membrane resistance and increase the anion site. With the aim of anion sites, the ion-transport process from aqueous phase to organic phase (pBA membrane) becomes faster because it induces the efficiency of cations attraction to the membrane surface [26]. Nevertheless, excessive amount of NaTFPB may cause the pBA membrane to become over polar and negatively charged. This will lead to a fast influx of copper (II) ions into the pBA membrane and a depletion zone of the copper (II) ions from the Nernst diffusion layer can be occurred. Therefore, a super-Nernstian response was observed in Sensor 1 to Sensor 5 [39].

Table 2. Performance of copper ion sensors based on 1 wt% ionophore o-xc and different amounts of NaTFPB lipophilic salts

| Sensor No. | Slope (mV/decade) | Linear Range (M) | Detection Limit (M) | ($R^2$) |
|---|---|---|---|---|
| 1 | 37.24 | $10^{-1} – 10^{-4}$ | $1.00 \times 10^{-5}$ | 0.999 |
| 2 | 37.06 | $10^{-1} – 10^{-4}$ | $8.70 \times 10^{-6}$ | 0.998 |
| 3 | 36.59 | $10^{-1} – 10^{-4}$ | $3.39 \times 10^{-6}$ | 0.998 |
| 4 | 36.32 | $10^{-1} – 10^{-4}$ | $1.83 \times 10^{-6}$ | 0.998 |
| 5 | 35.55 | $10^{-1} – 10^{-4}$ | $1.62 \times 10^{-6}$ | 0.997 |
| 6 | 28.71 | $10^{-1} – 10^{-4}$ | $1.23 \times 10^{-6}$ | 0.999 |
| 7 | 27.20 | $10^{-2} – 10^{-5}$ | $1.19 \times 10^{-6}$ | 0.999 |

Furthermore, *o*-xc is a neutral molecule, the non-symmetry arrangement of the dithiocarbamate group induces a polarity within the ionophore because the structure of ionophore o-xc consisted of two dithiocarbamate functional group at the ortho position of the benzene ring. Hence, with the addition of NaTFPB anionic salt, it further increases the polarity and negative charge of the pBA membrane and a super-Nernstian response is expected. Therefore, a super-Nernstian response was observed in Sensor 1 to Sensor 5 [39]. Super-Nernstian behavior is undesirable because such response is unstable and irreproducible. Excessive of NaTFPB will also lead to a loss of sensor selectivity towards copper (II) ions. Hence, when lower amounts of NaTFPB were used, e.g. 1 mol% and 0 mol% as in Sensor 6 and Sensor 7 in the pBA membrane, Nernstian response was observed due to lower ionic behavior. The low or non-requirement of the lipophilic anion such as TFPB in this sensor membrane for optimum response also indicated that the membrane itself might contain certain amount of anionic charge intrinsically.

In terms of detection limit, ion sensors which consisted of NaTFPB in the pBA membrane showed a higher detection limit. With the high polarity and anionic effect of the pBA membrane, an excessive influx of copper (II) ion from sample into the membrane induced and this cannot be balanced out by the ion exchange process of inner electrolyte at the membrane-inner electrolyte phase. Thus, the two sides of membrane are failed in achieving a thermodynamic equilibrium and higher detection limit was obtained. This is also parallel to previous study by Mi et al. [40] who reported that if the membrane is not at a steady stage, a higher influx of ion will lead to a higher detection limit.

Given that the pBA membrane without the addition of NaTFPB showed a better potentiometric response and the lowest detection limit, membrane composition of Sensor 7 was chosen for further optimization.

**Effect of ionophore o-xc on copper ion sensor response**

Figure 6 presents the calibration curves of four copper ion sensors with different amounts of ionophore o-xc. Their performances were evaluated and tabulated in Table 3.

According to Table 3, all four copper ion sensors showed Nernstian responses and explained a good response towards the sensitivity. The increment amount of ionophore o-xc also improved the performances of the copper ion sensor. This is because the polarity within the pBA membrane depends on the ionophore o-xc. Hence, higher amount of ionophore o-xc accelerates the ion transfer process from aqueous phase to pBA membrane phase. Besides, the movement of copper (II) ion through the pBA membrane is based on 'ion-jumping' or 'hopping' mechanism which mean passing an ion 'bucket' from one carrier to the other until it reaches the surface of Ag/AgCl electrode [41]. Therefore, with the higher amount of ionophore o-xc within the pBA membrane, the ion-transport process within the pBA membrane becomes better and faster. Thus, Sensor 10 with the highest amount of ionophore o-xc showed the best response.

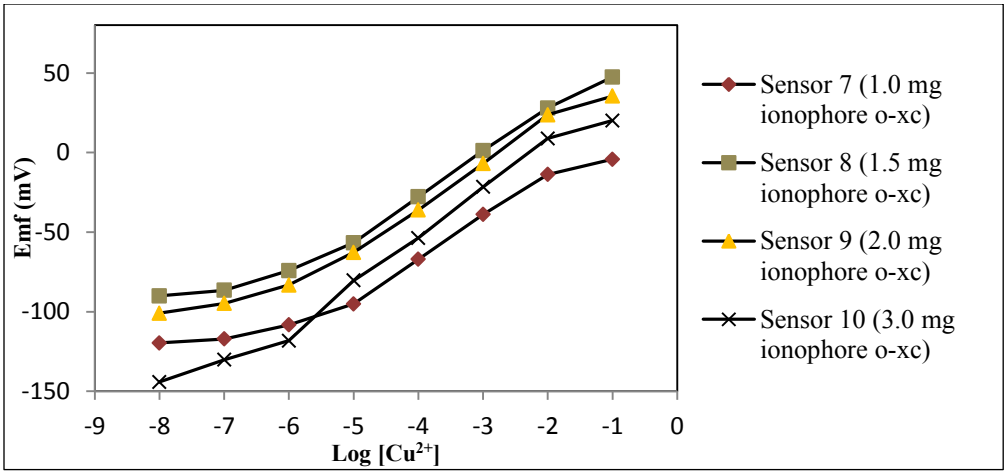

Figure 6. Potentiometric response of copper ion sensors based on 0 wt% of NaTFPB and different amounts of ionophore o-xc

Table 3. Performance of copper ion sensors based on 0 wt% of NaTFPB and different amounts of ionophore o-xc

| Sensor No. | Slope (mV/decade) | Linear Range (M) | Detection Limit (M) | ($R^2$) |
|---|---|---|---|---|
| 7 | 27.20 | $10^{-2} – 10^{-5}$ | $1.19 \times 10^{-6}$ | 0.999 |
| 8 | 28.31 | $10^{-2} – 10^{-5}$ | $8.49 \times 10^{-7}$ | 0.999 |
| 9 | 28.84 | $10^{-2} – 10^{-5}$ | $5.17 \times 10^{-7}$ | 0.999 |
| 10 | 31.29 | $10^{-2} – 10^{-6}$ | $1.89 \times 10^{-7}$ | 0.999 |

Sensor 10 showed the lowest detection limit of $1.89 \times 10^{-7}$ M and wider linear range, $10^{-2}$ - $10^{-6}$ M. This is due to a high amount of ionophore o-xc inside the pBA membrane. Higher amount of ionophore allowed more complexation to occur between copper (II) ion and ionophore o-xc. Thus more influx of copper (II) ion into the membrane was expected. The pBA membrane thus saturated with the copper (II) ion and this stabilized the copper (II) ion concentration at the interface of membrane-inner electrolyte. As a result, the sensitivity of the sensor towards copper (II) ion was increased and a wider linear range was obtained. A wider linear range subsequently lowers the detection limit [42].

**Selectivity on copper ion sensor**

Interference study was carried out for the best four copper ion sensors; Sensor 7 to Sensor 10 by the separate solution method (SSM). This selectivity method was used when the ion sensor showed Nernstian response within a linear range. In the SSM, the emf of an electrochemical cell between a reference electrode and the ion sensor was measured with each of the two separate solutions, namely one of the solution containing the ion analyte A with selected concentration. Meanwhile the other solution contained the interference ion B with the same concentration. If the measured values are $E_A$ and $E_B$, the logarithm selectivity coefficient can be calculated from the Nicolsky-Eisenman equation as shown in equation 1 below:

$$\log K_{A,B}^{pot} = \frac{(E_B - E_A)Z_A F}{2.303RT} + \left(1 - \frac{Z_A}{Z_B}\right)\log a_a \quad (1)$$

where R is the gas constant, T is the temperature in Kelvin unit, F is the Faraday constant, E is the potential difference of ion in mV, Z is the ion charge, A is the main ion, copper (II) ion in this work, B is the interference ion, and $a_a$ is concentration of 0.01 M used in this work.

From Table 4, it was found that the higher the amount of ionophore o-xc, the lower the value of logarithm selectivity coefficient was obtained. According to Alva [33], the lower the value of logarithm $K_{A,B}^{pot}$, the more selective the ion sensor. Selectivity of the membrane pBA was affected by the tendency of ionophore in forming a stable complex with the analyte ion and the selectivity coefficient can be also be explained and determined by the following equation 2:

$$K_{ij}^{pot} = \frac{\Sigma_n K_{j,n}}{\Sigma_n K_{i,n}} = \frac{\Sigma_n \beta_{js,n}^{w} k_{js,n} ({}^{c_s}/_{k_s})^n}{\Sigma_n \beta_{is,n}^{w} k_{is,n} ({}^{c_s}/_{k_s})^n} \quad (2)$$

where j is the interference ion and i is the main ion. $\beta_{js,n}^{w}$ and $\beta_{is,n}^{w}$ are complex stability constant, $k_{js,n}$ and $k_{is,n}$ is distribution constant, $k_s$ is distribution of free ligand constant, and $c_s$ is concentration of ligand S (ionophore). Selectivity is influenced by the saturation of ionophore o-xc-copper (II) complex within the pBA membrane. Hence, copper ion sensor with the highest amount of ionophore o-xc showed the lowest value of logarithm selectivity coefficient due to formation of more complexes. Besides, high distribution of ionophore o-xc-copper (II) complex could also prevent the influx of interference ion into the membrane; thus, further increase the selectivity of the copper ion sensor [42].

Table 4. Logarithm selectivity coefficient $Log(K_{Cu^{2+},M^{n+}}^{pot})$ for four ion sensors with different amounts of ionophore o-xc

| Sensor No. | Interference Ions | | | | | |
|---|---|---|---|---|---|---|
| | $K^+$ | $Na^+$ | $Mg^{2+}$ | $Ni^{2+}$ | $Co^{2+}$ | $Ca^{2+}$ |
| 7 | 0.44± 0.18 | 0.58±0.09 | -1.53±0.19 | -1.18±0.05 | -1.11±0.06 | -1.15±0.44 |
| 8 | -0.13±0.10 | -0.01±0.10 | -2.27±0.05 | -2.13±0.07 | -2.07±0.11 | -2.15±0.07 |
| 9 | -0.45±0.05 | -0.40±0.03 | -2.62±0.10 | -2.40±0.09 | -2.35±0.06 | -2.40±0.08 |
| 10 | -1.49±0.10 | -1.41±0.15 | -3.30±0.07 | -3.09±0.02 | -3.05±0.05 | -3.12±0.06 |

Among the four copper ion sensors, Sensor 10 showed the best selectivity towards copper (II) ion with the lowest logarithm selectivity coefficient for all the interference cations. From the four divalent interference cations, cobalt ion gave higher logarithm selectivity coefficient. This might be related to the radius of the interference cations [43] as cobalt (II) ion has a similar ionic radius with copper (II) ion. However, the logarithm selectivity coefficient of the ion sensor towards cobalt (II) ion was -3.05±0.05, which showed that interference effect from cobalt ion was insignificant. Monovalent interference cation such as potassium and sodium gave higher logarithm selectivity coefficient. Such larger value is aroused from the $(1 - \frac{2}{Z_B})$ in the Nicolsky-Eisenman equation. Hence, the smaller the charge of the interference ion, $Z_B$, the larger the value of logarithm selectivity coefficient [1]. Furthermore, potassium and sodium ions have larger ionic radius and different chemical properties from copper (II) ion as potassium and sodium ions belong to alkali metal ion whereas copper (II) ion is a heavy metal ion, the disturbance produced by these two ions is negligible. Therefore, the above results demonstrated that Sensor 10 showed a good selectivity towards copper (II) ion.

**Comparison with previous studies**

The performances of the screen-printed copper ion sensor in this work were compared with the previously reported copper ion sensor based ionophore o-xc (Table 5).

Table 5. Comparison between screen-printed copper ion sensor and reported potentiometric copper ion sensors with ionophore *o*-xylylene bis(N,N-diisobutyldithiocarbamate)

| **Ionophore Immobilization Matrix** | **Linear Range (M)** | **Detection Limit (M)** | **Slope (mV/decade)** | **$\mathbf{Log(K^{pot}_{Cu^{2+},M^{n+}})}$** | **Ref.** |
|---|---|---|---|---|---|
| Poly(n-butyl acrylate)-photocured membrane, non-plasticised | $1.0\times10^{-6}$ - $1.0\times10^{-2}$ | $1.89\times10^{-7}$ | 31.29 | $K^+$(-1.49), $Na^+$(-1.41), $Mg^{2+}$(-3.30), $Ca^{2+}$(-3.12), $Ni^{2+}$(3.09), $Co^{2+}$(-3.05) | This work |
| Poly(n-butyl acrylate) (drop cast membrane) | $1.0\times10^{-6}$ - $1.0\times10^{-1}$ | $1.00\times10^{-6.3}$ | 26.30 | $K^+$(-1.60), $Na^+$(-2.4), $Ca^{2+}$(-4.00), $Ni^{2+}$(-3.70) | [15] |
| Poly(lauryl acrylate-hexyl acrylate) | $1.0\times10^{-6}$ - $1.0\times10^{-2}$ | $1.00\times10^{-6.5}$ | 27.20 | $Na^+$(-1.8), $Mg^{2+}$(-6.1), $Ni^{2+}$(-5.7) | [17] |
| Poly(vinyl chloride)-Plasticised | $1.0\times10^{-6}$ - $1.0\times10^{-1}$ | $4.90\times10^{-7}$ | 31.30 | $K^+$(-2.42), $Na^+$(-4.71), $Ca^{2+}$(-3.50), $Ni^{2+}$(-2.30) | [16] |
| Poly(vinyl chloride) - Plasticised | $1.0\times10^{-6}$ - $1.0\times10^{-1}$ | $1.40\times10^{-7}$ | 29.0 | $K^+$(-2.35), $Na^+$(-2.65), $Mg^{2+}$(-3.60), $Ca^{2+}$(-3.60), $Ni^{2+}$(-3.20), $Co^{2+}$(-4.00) | [14] |

This copper ion sensor showed comparable selectivity with the reported copper ion sensors. When compared with previously reported solid stated copper ion sensor with acrylate membrane, this copper ion sensor gives a better performance in terms of sensitivity with higher Nernstian slope (31.29 mV/decade) and lower detection limit.

## Conclusion

A screen-printed copper ion sensor with photocurable pBA non-plasticised membrane based on ionophore o-xc via direct ionophore entrapment method had been fabricated and demonstrated good analytical performances. Besides, it is also shown that the composition of ionophore o-xc and anionic site (TFPB) within the pBA membrane has a strong influence on the response of the copper ion sensor. The introduction of NaTFPB inside the pBA membrane did not give good response whereas the membrane without the addition of NaTFPB showed a better performance. The membrane bearing the composition (w/w %) of 96.06:0.10:0.96:2.88 (nBA:HDDA:DMPP:o-xc) gives the best analytical performances. The sensitivity, detection limit and selectivity of the Cu(II) ion sensor obtained were comparable or slightly better than other reported copper ion sensors.

**Abstract**

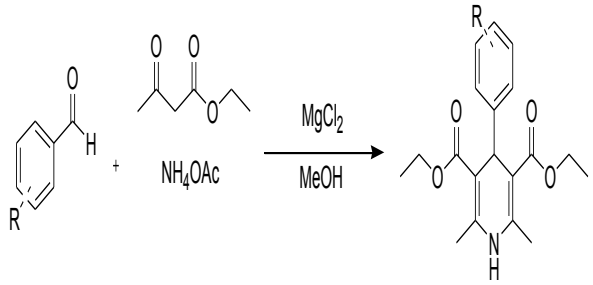
The synthesis of 1,4-dihydropyridine (1,4-DHP) derivatives in the presence of alkaline earth metal chlorides was reported. Specifically, the $MgCl_2$ catalyzed the synthesis of 1,4-DHP derivatives in good yields, ranging from 69 – 87%. The $Mg^{2+}$ serves as the Lewis acid catalyst in the formation of 1,4-DHP and the proposed mechanism of the formation of 1,4-DHP was elaborated in this manuscript. There are many advantages employing $MgCl_2$ as a catalyst in this study, including inexpensive, ubiquitous availability of this metal, simple filtration protocol, which has spark considerable interest in the use of this catalyst in promoting organic reactions.

**Keywords**: alkaline earth metal, magnesium chloride; 1,4-dihydropyridine

**Abstrak**

Sintesis terbitan 1,4-dihidropiridina (1,4-DHP) dalam kehadiran logam alkali bumi dibincangkan dalam artikel ini. Secara khususnya, sintesis terbitan 1,4-DHP melalui pemangkin $MgCl_2$ memberi peratusan hasil yang baik, dalam lingkungan 69 –87%. Ion $Mg^{2+}$ bertindak sebagai pemangkin asid Lewis dalam pembentukan 1,4-DHP dan cadangan mekanisma terhadap pembentukan 1,4-DHP telah dihuraikan dalam manuskrip ini. Terdapat banyak kelebihan menggunakan $MgCl_2$ sebagai pemangkin dalam kajian ini, termasuk kos yang murah, ketersediaan logam ini, protokol pengekstrakan yang mudah, yang mana ini telah mencetuskan minat yang besar dalam penggunaan pemangkin ini dalam pelbagai tindak balas organik.

**Kata kunci**: logam alkali bumi, magnesium klorida, 1,4-dihydropiridin



## Introduction

1,4-dihydropyrdines (1,4-DHPs) are important classes of pharmaceutical compounds that are usually prescribed clinically for the treatment of cardiovascular diseases, such as heart failure, angina pectoris and hypertension [1]. In the pharmaceutical pipeline today, there are more than twelve 1,4-DHPs drug candidates commercially available in the global market, such as the nifedipine [2], felodipine [3], nicardipine [4] and etc., which were used to treat cardiovascular diseases.

Due to the attractiveness of the 1,4-DHPs in pharmaceutical application, various synthetic approaches to produce 1,4-DHP derivatives have been reported, such as the use microwave irradiation [5], solar thermal energy [6], ultrasound irradiation [7], ionic liquids [8], and $AlCl_3$ as Lewis catalyst [9]. In spite of the above efforts to improve further on the 1,4-DHPs reactions, a number of drawbacks have been identified such as unsatisfactory yields, high reaction temperatures and long reaction hours [10].

Recently, there are a number of literatures reported on the use of alkaline earth metals for organic transformations. For instance, $MgCl_2$ has been successfully employed for the aldol synthesis of α-dimethylsilylesters [11]. An improved method on the Biginelli reaction by using alkaline earth metal chlorides such as $MgCl_2$, $CaCl_2$, $BaCl_2$ and $SrCl_2$ as homogenous catalysts in the presence of acetic acid as solvent had been reported [12]. The synthesis of dihydropyridine, acridine and xanthene derivatives with $Ca(OTf)_2$ in the presence of $Bu_4NPF_6$ as additive and water as solvent has also been disclosed recently [13]. The alkaline earth metals are the most abundant elements encountered in our daily lives in which most of it can be found buried in the earth crust and in the ocean [14]. On green chemistry perspective, the use of alkaline earth metals in organic reactions are favorable due to the fact that, metals such as calcium and magnesium are ubiquitously available in nature compared to other transition and lanthanide elements [15]. However, only limited organic reactions which employ alkaline earth metals as catalysts were reported as their applications are not being fully explored [16].

In the course of our research to synthesize bioactive heterocyclic compounds, herein we report the synthesis of 1,4-DHP derivatives catalyzed by $MgCl_2$ from the starting materials benzaldehydes, ethyl acetoacetate and ammonium acetate (as shown in Scheme 1). The advantages of this protocol include the exclusion of additional additive, for example $Bu_4NPF_6$ and the reaction could be accomplished within four hours. The synthesized products were obtained in good yield as described in this paper.

Scheme 1. The $MgCl_2$ catalyzed the synthesis of 1,4-DHP derivatives

## Materials and Methods

All the chemicals and solvents used without further purification in this study are supplied by Merck, Acros organic and HmbG® chemicals. These include benzaldehyde, 4-fluorobenzaldehyde, 4-chlorobenzaldehyde, 4-nitrobenzaldehyde, 4-bromobenzaldehyde, ethylacetoacetate, ammonium acetate, methanol, ethyl acetate, n-hexane and silica gel 60 (0.063-0.200mm). The FT-IR spectra were recorded on Perkin Elmer 100 FT-IR spectrometer, in spectral range of 4000 – 400 $cm^{-1}$. $^1H$ and $^{13}C$-NMR spectra were recorded using Bruker Avance III 400 spectrometer, with deuterated chloroform as solvent at room temperature at 400 MHz. GC-MS analyses were performed using Shimadzu QP2010SE.

**Synthesis of the 1,4-DHP derivatives**

To a mixture of benzaldehyde derivatives (1.47 mmol), ammonium acetate (1.47 mmol), and ethyl acetoacetate (1.47 mmol) in methanol (3 ml), $MgCl_2$ was added (0.15 mmol) and the mixture were heated under reflux for four hours. After the completion of the reaction, the solvent was evaporated under reduced pressure to obtain the crude product. The crude product was then purified over silica gel column chromatography (hexane: ethyl acetate = 7:3, v/v) to give the title compounds **1a-1k**.

## Results and Discussion

The optimized condition was determined using a model reaction that consisted of benzaldehyde, ethyl acetoacetate and ammonium acetate. The model reaction was first conducted without adding any catalysts, recorded only 30% yield after the reaction was heated under reflux for four hours in methanol. The use of catalytic amount of $MgCl_2$ greatly enhanced the yield of the desired product and the best yield was recorded with the use of 5 mmol of $MgCl_2$ which afforded 87% yield of the desired product. Next, the study of using various alkaline earth metals in different solvents was evaluated. Based on the optimization study (Table 1), the maximum yield of **1a** was recorded when the reaction was heated under reflux for four hours in the presence of 5 mmol of $MgCl_2$ as catalyst in MeOH.

Table 1. Synthesis of **1a** under different solvents and alkaline earth metals.

| Entry | Solvent | $MgCl_2$ Time/ Yield (%) | $CaCl_2$ Time/ Yield (%) | $SrCl_2$ Time/ Yield (%) | $BaCl_2$ Time/ Yield (%) |
|---|---|---|---|---|---|
| 1 | MeOH | 4h/ 87 | 4h/ 75 | 4h/ 79 | 4h/ 82 |
| 2 | AcOH | 4h/ 37 | 4h/ 33 | 4h/ 32 | 4h/ 35 |
| 3 | THF | 4h/ 70 | 4h/ 65 | 3h/ 72 | 4h/ 67 |
| 4 | DMSO | 5h/ 82 | 4h/ 80 | 4h/ 76 | 5h/ 78 |

The improved protocol was employed to synthesize different substituted 1,4-DHP derivatives by using a variety of benzaldehydes. As shown in Table 2, all the reactions proceeded smoothly in the presence of $MgCl_2$ and the desired products were isolated in moderate to good yields, ranging from 69 – 87%. The electronic effect of different substituted groups on benzaldehydes was also evaluated. Specifically, the benzaldehydes bearing the electron-withdrawing group gave a higher yield compared to benzaldehydes bearing electron-donating group (Table 2, 1b -1j vs 1k). This result was in agreement with a previous study on the synthesis of the 1,4-DHP derivatives using ultrasound method [17]. Among the investigated electron-withdrawing substituents, the *para*- position gave a higher yield compared to *ortho*- and *meta*- position (Table 2, 1b -1e vs 1f-1j). In the previous study, the side products (Figure 1) were usually yielded along with the desired products [17]. Gratifyingly, under this improved protocol which utilized $MgCl_2$ as catalyst, only one 1,4-DHP derivative was isolated for each reaction, with no side products isolated during the purification process in the column chromatography.

Table 2. The isolated yields and melting point obtained for compounds 1a – 1k

| Product | R | Time (h) | Isolated Yield (%) | M. P ($^oC$) | |
|---|---|---|---|---|---|
| | | | | Observed | Reported |
| 1a | Ph- | 4 | 87 | 155.7 | 158 – 160 [18] |
| 1b | 4-$NO_2$ | 4 | 83 | 130.3 | - |
| 1c | 4-Br | 4 | 80 | 168.1 | 165 – 167 [19] |
| 1d | 4-F | 4 | 81 | 157.9 | 155 – 157 [20] |
| 1e | 4-Cl | 4 | 80 | 147.9 | 147 – 148 [21] |
| 1f | 2-Cl | 4 | 73 | 121.3 | 122 – 123 [22] |
| 1g | 2-F | 4 | 72 | 150.5 | 148 – 152 [23] |
| 1h | 2-Br | 4 | 70 | 142.7 | 140 – 141 [19] |

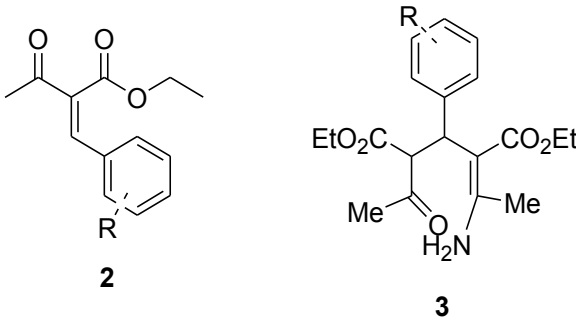
| 1k | 4-$CH(CH_3)_2$ | 4 | 69 | 95.7 | 97 [25] |



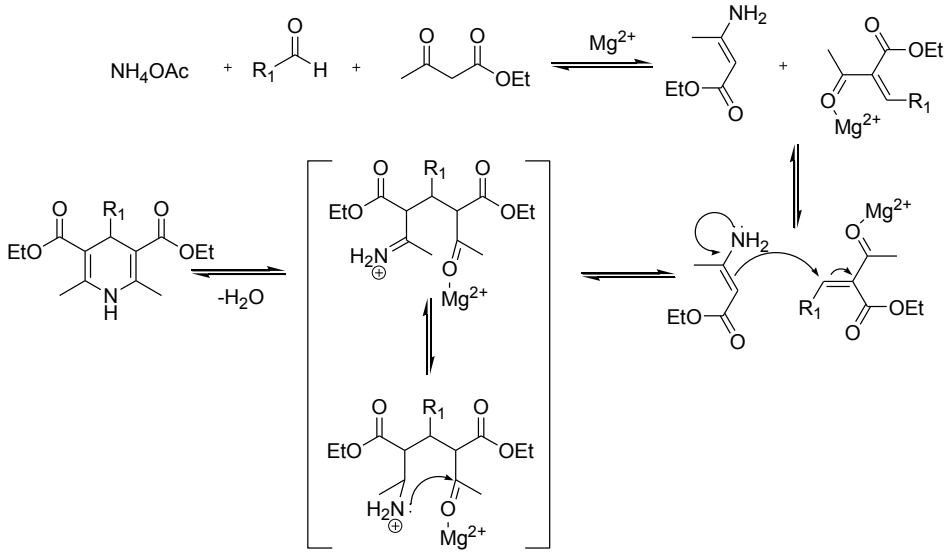


Figure 1. The side products, 2 and 3 were reported to be produced from the Hantzsch 1,4-dihydropyridine synthesis [17]

The proposed mechanism for the formation of 1,4-DHP catalyzed by $MgCl_2$ was elaborated in Scheme 2. Firstly, one equivalent of ethyl acetoacetate reacted with benzaldehyde to form the knoevenagel adduct and one equivalent of ammonium acetate reacted with ethyl acetoacetate to form ester enamine. Subsequently, the Michael-type addition and condensation occurred to yield 1,4-DHP derivative as the final product. The $Mg^{2+}$ serves as the Lewis acid catalyst in the formation of 1,4-DHP derivatives.

Scheme 2. The proposed mechanism for the formation of 1,4-DHP derivatives catalyzed by $MgCl_2$

**Physical and spectral data**

The spectroscopic data of the synthesized compounds **1a – 1k** is as follows:

**2,6-dimethyl-4-phenyl-1,4-dihydropyridine-3,5-dicarboxylic diethyl ester (1a)**

M.p: 98.4 $^{o}$C; IR (cm-1): v(N-H) 3343.60, v(C-H)sp$^2$ 3088.64, v(CH)sp$^3$ 2982.34, v(C=O) 1687.24, v(C=C) 1651.62, v(C-N) 1373.70; $^{1}$H- NMR (ppm): (t, 6H, CH3) 1.149, (s, 6H, CH3) 2.266, (m, 4H, CH2) 4.018, (s, 1H, CH) 4.917, (s, 1H, NH) 5.463, (t,2H, CH ) 7.150, (m, 1H, CH) 7.047, ( d, 2H, CH) 7.21; $^{13}$C- NMR (ppm): 19.2, 14.8,30.2, 130.8, 60.8, 128.2, 128.6, 126.2, 100.4, 165.4, 143.6. GC-MS: m/z 371 $[M+H]^+$.

There are many advantages of using of $MgCl_2$ in the Hantzsch dihydropyridine synthesis, including the simple separation process, mildness of this technique, no side products and good yields. The alkaline earth metals are inexpensive, especially $MgCl_2$ which can be found ubiquitously buried in the earth's crust. Although various literatures have been generated with respect to the synthesis of 1,4-DHP derivatives, most of these methods relied on the use of expensive chemicals, toxic chemicals or harsh condition.

## Conclusion

A simple, mild and high yielding protocol for the synthesis of 1,4-DHP derivatives catalyzed by $MgCl_2$, an alkaline earth metal has successfully developed. The mildness of this technique, experimental simplicity and the inexpensive of this catalyst have rendered this protocol an attractive way for the synthesis of 1,4-DHP derivatives. Furthermore, this heterogeneous catalyst can be easily removed with simple filtration technique. Further application using alkaline earth metals in other organic reactions are continuously been explored in our laboratory.

**Abstract**

Pre-treatment is a crucial step in biomass processing prior to the hydrolysis or fermentation to bioethanol. Herein, the potential of deep eutectic solvent (DES) in the pretreatment of oil palm biomass were described. The mechanism of swelling and dissolution of oil palm trunk (OPT) was studied under optical microscopy. The OPT fibres were stirred and heated at 100 °C in choline chloride:glycerol (ChCl:Gly), choline chloride:ethylene glycol (ChCl:EG), ethylammonium chloride:glycerol (EAC:Gly) and ethylammonium chloride:ethylene glycol (EAC:EG) with 1:2 molar ratio each. All DESs tested had showed homogenous swelling and disintegration of small fragments interaction mode with OPT. There were more small fragments observed in EAC-based DES compared to ChCl-based DES. This finding supports the result for the percentage of dissolution where OPT in EAC-based DES recorded higher dissolution with 55% and 50% in EAC:EG and EAC:Gly respectively whereas ChCl-based DES recorded only 33% and 29% in ChCl:EG and ChCl:Gly, respectively. In ChCl-based DESs the fragmentations were accompanied by large unswollen section of fibres. The formation of small fragments indicates that the fibres experienced a fast dissolution. Therefore, the EAC-based DESs proved to be a better swelling and dissolution media for oil palm biomass pretreatment compared to ChCl-based DES.

**Keywords:** deep eutectic solvent, oil palm biomass, dissolution, swelling, pre-treatment

**Abstrak**

Pra-rawat adalah satu langkah dalam pemprosesan biomas sebelum hidrolisis atau fermentasi kepada bioetanol. Disini, potensi pelarut eutektik (DES) dalam pra-rawat biomas kelapa sawit telah diterangkan. Mekanisma pembengkakan dan pemelarutan batang kelapa sawit (OPT) telah dikaji dengan mikroskop optik. Fiber OPT telah dikacau dan dipanaskan pada suhu 100 ºC dalam kolin klorida:gliserol (ChCl:Gly), kolin klorida:etilin glikol (ChCl:EG), etilammonium klorida: gliserol (EAC:Gly) dan etilammonium klorida: etilin glikol (EAC:EG) dengan kadar molar 1:2 setiap satu. Semua DES yang dikaji telah menunjukkan mod interaksi pembengkakan secara setara dan pecahan fragmen kecil dengan OPT. Lebih banyak fragmen kecil dapat dilihat dalam DES berasaskan EAC berbanding dengan DES berasaskan ChCl. Ini disokong oleh peratusan pelarutan dimana OPT dalam DES berasaskan EAC menunjukkan keputusan lebih tinggi dengan masing – masing 55% dan 50% dalam EAC:EG and EAC:Gly sementara DES berasaskan ChCl hanya menunjukkan masing – masing 33% dan 29% dalam ChCl:EG dan ChCl:Gly. Bagi DES berasaskan ChCl, fragmentasi adalah disertai dengan kehadiran fiber besar yang tiada pembengkakan. Pembentukkan fragmen kecil menunjukkan bahawa fiber mengalami pelarutan yang cepat. Oleh itu, DES berasaskan EAC terbukti lebih baik sebagai media pembengkakan dan pelarutan bagi OPT berbanding DES berasaskan ChCl.

**Kata kunci**: pelarut eutektik, biomas kelapa sawit, pelarutan, pembengkakan, prarawat

## Introduction

Deep eutectic solvent (DES) is a new class of solvent that emerged from ionic liquid (IL) family which is formed by the combination of ammonium salt and a hydrogen bond donor [1]. The two components that have a high melting point each, for example choline chloride (302 °C) and urea (133 °C), exhibit a freezing point depression of 12 °C, making it a liquid as a mixture at room temperature [2]. Various combinations of DES have been studied by changing the ammonium salt and the hydrogen bond donor. Examples of hydrogen bond donors used are alcohols, amides, carboxylic acids and amines [3]. Not only can the component be varied, the molar ratio of each component can also be varied. This widens the type of DES that can be formed. There are many advantages of DES including their biodegradability, thermal stability, low melting point and the fact that they are highly cost-efficient [1]. DES is easily prepared by simple mixing of the two selected substances, ammonium salt (e.g. choline chloride) and a hydrogen bond donor (e.g. glycerol), at 80 °C [4].

DES has shown considerably high potential in biocatalysis reactions such as hydrolysis, transesterification, and esterification. It was reported that choline chloride: glycerol (ChCl:Gly) as a co-solvent of aqueous reactions can enhance the reaction up to 20-fold [5]. The use of 10% (v/v) of ChCl:Gly as the reaction medium for the hydrolysis of *p*-nitrophenyl acetate led to a 3-fold increase for pig liver esterase (PLE) and *Rhizopusoryzae esterase* (ROE) [5]. The properties and performance of DES in biocatalysis has led to our interest in exploring its utilization in dissolving high crystalline compounds such as lignocellulosic biomass in view of progressing with the enzymatic hydrolysis of the treated biomass.

Pre-treatment of biomass is crucial in order to break down the highly crystalline cellulose. The process will ease the access of cellulase to the amorphous cellulose, where this can enhance the conversion of monosaccharides (e.g. glucose). Francisco et al. [6] explored the application of the novel DES solvent system on lignocellulosic biomass. They reported that the solubility of lignin increased by the addition of lactic acid in DES, while cellulose gave negative results. However, a malic acid-proline series enhanced the dissolution of starch and cellulose. This report proved that the DES system or low transition temperature mixtures (LTTMs) can dissolve some of the lignin, although the screened mixtures gave low solubility for cellulose and starch.

Observation of the swelling and dissolution of fibre in certain solvents is one of the methods used to characterise the quality of solvents in terms of its ability to dissolve and swell the fibres. Many studies have been carried out for the dissolution of cellulose and wood fibre in various types of solvents such as NaOH [7], *N*-methylmorpholine-*N*-oxide (NMMO) [8], lithium chloride/urea/water [9] and ionic liquids [10-13]. The swelling process of cellulosic materials can improve the reactivity and accessibility of the cellulose. This phenomenon can be used to introduce activation of the substrate [14]. Five different modes were proposed for wood and cotton fibre dissolution as a function of solvent quality by using an NMMO-water system with or without additives [8].

Similar interactions were observed by using NaOH-water and ionic liquids for various types of plant fibres and cellulosic materials. Cuissinat and Navard [8] had classified dissolution of wood and fibre into 5 different classes according to its degree of swelling or dissolution. The modes include fast dissolution by disintegration into fragments (Mode 1), swelling by ballooning with dissolution (Mode 2), swelling by ballooning without dissolution (Mode 3), homogenous swelling (Mode 4) and no swelling and no dissolution (Mode 5). In view of the advantages of DES over ionic liquid, an investigation of DES as a medium for biomass pre-treatment was conducted. This report is one of the earliest works on utilising DES for dissolving and pre-treatment of raw oil palm biomass. The properties of oil palm biomass fibre after pre-treament with DES were observed through optical microscopy.

## Materials and Methods

### Preparation of OPT fibre

OPT fibre was obtained from Biomass Technology Center (BTC) of Malaysian Palm Oil Board (MPOB). By using a thermo chemical refiner, the fibre was cleaned, shredded and refined into loose fibrous material. Prior to usage, the fibre was sieved to size 250 μm and dried to constant weight.

**Preparation of deep eutectic solvent**

DESs of 1:2 molar ratio (Table 1) were prepared by stirring the two components, ammonium salt and hydrogen bond donor (e.g.: 0.1 mol for ChCl and 0.2 mol for Gly), at a temperature of 80 °C. The mixture was stirred until a homogenous and colourless liquid was obtained [1].

Table 1. DESs used in the study

| DES | Ammonium Salt | Hydrogen Bond Donor |
|---|---|---|
| ChCl:Gly | Choline chloride | Glycerol |
| ChCl:EG | Choline chloride | Ethylene glycol |
| EAC:Gly | Ethylammonium chloride | Glycerol |
| EAC:EG | Ethylammonium chloride | Ethylene glycol |

**Dissolution of oil palm biomass**

The samples were prepared by adding 0.5 g of fibre (250 µm) into 9.5 g of DES in a screw capped vial. All mixtures were incubated in an oil bath at 100 °C with vigorous stirring. After 24 hours of incubation, a small amount of dissolution mixture was taken from each sample for observation. The swelling and dissolution mechanism was observed using an optical microscope with a Metallux 3 (Leitz) [(Nikon DS-Fil-42)]. A small portion of the dissolution mixture was placed on a glass plate and viewed at 20 times magnification.

**Percentage dissolution of oil palm trunk**

5% of fibre (250 µm) in DES was prepared by adding 0.5 g fibre in 9.5 g of DES. The mixture was incubated in oil bath at 100 °C with vigorous stirring. All dissolutions were carried out for 48 hours. After 48 hours, the mixture was centrifuged and filtered using crucible glass to separate the undissolved fibre. The filtration was washed with distilled water and dried in an oven at 50 °C overnight. Filtered sample was then cooled in desiccator and weighed to a constant weight. The percentage of fibre dissolved was calculated using equation 1:

$$\text{Fiber dissolved (\%)} = \frac{w_i - w_f}{w_i} \times 100 \quad (1)$$

where $w_i$ is the weight of initial fibre and $w_f$ is the weight of residue recovered.

## Results and Discussion

OPT was pre-treated in four different DESs (Table 1) in order to observe the type of interaction when the ammonium salt or hydrogen bond donor is varied. All data was taken within 24 hours for observation under optical microscopy. Figure 1 shows the shape of fibre observed in ChCl:Gly, ChCl:EG, EAC:Gly and EAC:EG after 24 hours of heating and stirring. Based on our observations, all DESs exhibited homogenous swelling and disintegration of small fragments for OPT fibres.

Homogenous swelling occurs when the solvent only swell the fibres and this does not lead to any dissolution of the fibres in the media. This type of interaction will make the fibre stay in the swollen state and thus leads to bad solvation for wood fibre as the swelling occurs very slowly. Cuissinat and Navard [8] suggested that in this type of behaviour, the solvent penetrates the fibre matrix at its loose regions such as pores and less dense disordered point, without making contact to the general part of the fibre. Unfortunately, this mode of interaction will not affect the cellulose crystal in dissolution or reformation to amorphous cellulose.

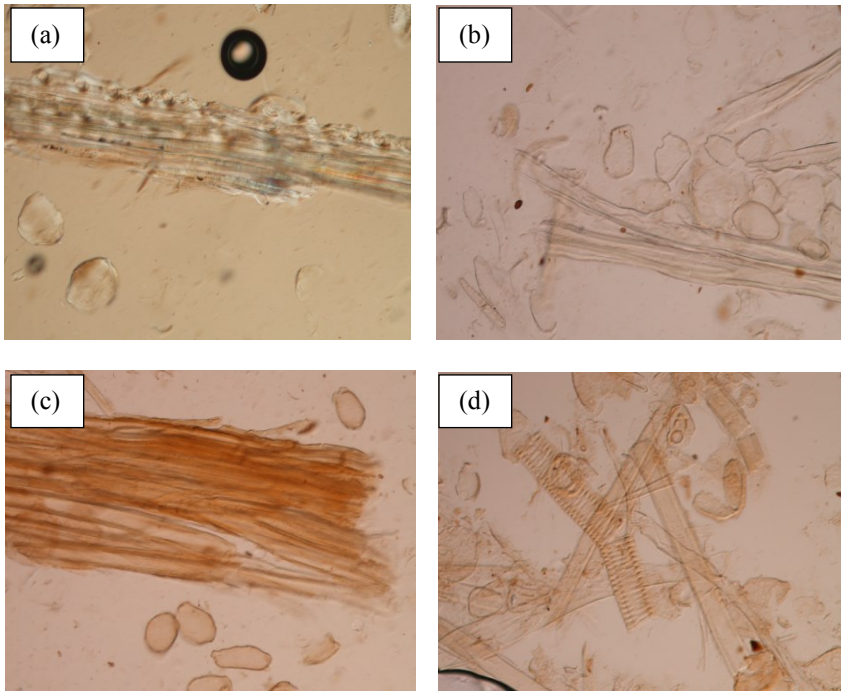

Figure 1. OPT in (a) ChCl:Gly, (b) ChCl:EG, (c) EAC:Gly and (d) EAC:EG after 24 hours at 100 °C

Disintegration of small fragments of the fibres was another type of interaction observed in the sampling. This indicates fast dissolution where the fibres were broken over all their length, giving large rod-like pieces [8]. These small fragments will then easily dissolve in the media. Based on our data, this interaction is rather low in ChCl-based DES but more frequent in EAC:Gly and EAC:EG (Figure 2). The presence of more small fragments in EAC-based DES media showed that the solvent can provide good dissolution and thus indicates that they are better solvent compared to ChCl:Gly and ChCl:EG (Figure 3).

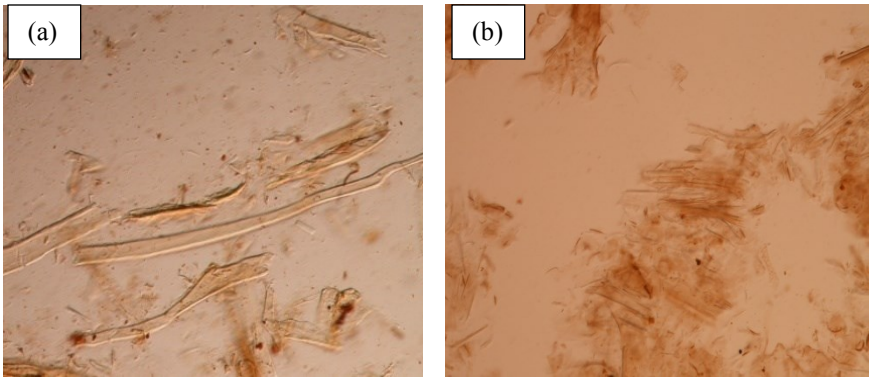

Figure 2. Fibre treated at t = 20 hours in (a) EAC:Gly and (b) EAC:EG. Small fragments were generated mainly by agitation provided

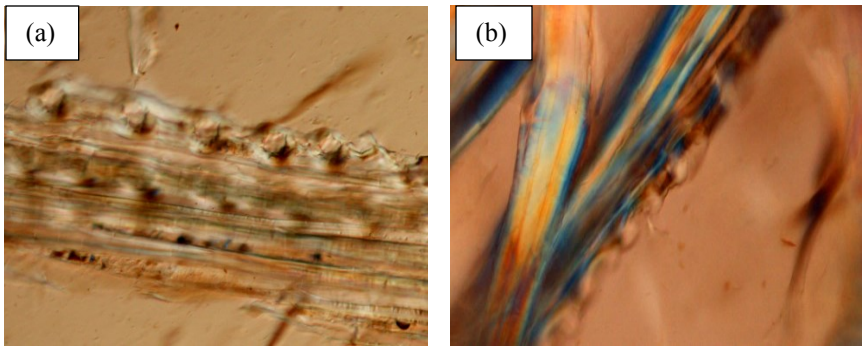

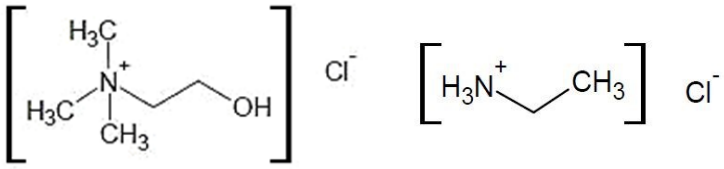

Figure 3. OPT fibre in (a) ChCl:Gly and (b) ChCl:EG at t = 24 hours

In addition, the dissolution of OPT in each solvent were calculated. ChCl-based DES showed lower percentage of solubility than EAC-based DES (Table 2). This result clearly supports the earlier findings that EAC-based DES has higher capability in terms of dissolution of oil palm biomass. Figure 4 shows the chemical structure for ChCl and EAC. EAC has simpler structure compared to ChCl where EAC has only one alkyl chain. ChCl has three methyl groups attached to the nitrogen atom. Thus, ChCl only has one H that can make hydrogen bond with cellulose. EAC salt has 3H and ethyl chain attached to the nitrogen atom. This may help EAC-based DES to dissolve lignocellulosic materials better than ChCl-based DES.

Table 2. Percentage of dissolution for OPT in DESs after 48 hrs of pre-treatment.

| **Solvent** | **Solubility (wt %)** |
|---|---|
| ChCl:Gly | 33.27 |
| ChCl:EG | 29.13 |
| EAC:Gly | 50.77 |
| EAC:EG | 55.60 |

(a) Choline chloride (b) Ethylammonium chloride

Figure 4. Chemical structure of (a) choline chloride and (b) ethylammonium chloride

There are several other solvents that have been tested for mechanism of swelling and dissolution on wood fibres and cellulose derivatives. The solvents are *N*-methylmorpholine-*N*-oxide (NMMO), sodium hydroxide (NaOH) and ionic liquids (ILs). NMMO and NaOH are well known as conventional cellulose solvents. NMMO with small percentage of water (17% and 35%) and NaOH showed excellent quality for wood and cellulose solvents [8]. Nitrocellulose in NMMO-water (17% and 35%) showed small fragmentation where the solvents give strong penetration and thus dissolves nitrocellulose in the media (Mode 1) [10].

ILs have been studied in order to offer alternative solvents for cellulose. The quality of ILs for wood and cellulose fibres can range from Mode 1 to Mode 4. 1-n-butyl-3-methylimidazolium chloride, $C_4$mimCl showed the best media for cotton and wood fibre with disintegration of small fragments and dissolves in $C_4$mimCl (Mode 1) [15]. 1-ethyl-3-methylimidazolium chloride, EmimCl and 1-butyl-3-methylimidazolium chloride, BmimCl shows swelling by ballooning with dissolution occurred for cellulose fibre (Mode 2) [16]. Whereas for OPT, OPF and EFB fibres, both ILs exhibited homogenous swelling without dissolution. In this paper, we carried out the swelling and dissolution of OPT in DESs with aim to provide alternative solvent for wood and cellulose fibres. Based on our findings, DESs exhibited type of mechanism in Mode 1-4.

Although ILs and DESs have similarity in terms of quality, DESs have advantage in terms of solvent properties. ILs are hazardous due to the halide anions and very poor biodegradability. It requires high purity since small amount of impurity can affect its physical properties. The synthesis of ILs can't be described as an environmental friendly process since it requires large amount of salts and solvents in order to achieve complete anion exchange [17]. In contrast to ILs, DESs are cheaper, easier to synthesize and biodegradable [1]. Drawbacks of ILs lead DESs to be the alternative solvent for ILs and other conventional cellulose solvents.

Swelling and dissolution of wood fibre in DESs can be the easiest and fastest method in determining quality of solvents based on the modes introduced by Cuissinat and Navard [8], using simple instrument (optical microscopy) with low cost and less toxic solvent (DESs).

## Conclusion

DESs were prepared and their effectiveness as pre-treatment media for oil palm biomass was studied under optical microscopy. DESs showed their potential as pre-treatment media for lignocellulosic biomass although currently its effectiveness has not surpassed some ILs. Based on our findings, DESs can provide homogeneous swelling and disintegration of small fragments for OPT fibres. The EAC-based DES showed better interaction than ChCl-based DES for dissolution of oil palm biomass. Currently, we are looking at the enzymatic hydrolysis of the DES pre-treated oil palm biomass and preparing other DESs for the pre-treatment.

**Abstract**

One standard chromatographic conditions of HPLC was developed for different Dipterocarpaceae plant extracts. The purpose of this study is to achieve an optimized chromatographic method that is able to produce a reasonably good separation and resolution of oligostilbenes in plant crude extracts. For this purpose, five model samples of Dipterocarpaceae extracts, *Shorea parvifolia, Shorea ovalis, Dipterocarpus crinitus, Dipterocarpus gracilis* and *Hopea* spp. were used. The parameters, which include types of chromatographic solvents, types of mobile phase elution, solvent composition and the injection volumes, were modified. The results showed that the optimum chromatographic conditions were achieved when a gradient elution was adopted, with the solvent composition of $H_2O$: ACN from 95:5 to 25:75 in 20 minutes. The injection volume of 5 µL is best for a 1 mg/ml sample concentration. The temperature was maintained at 35 °C and the flow rate was at 1.0 ml/min. Some compromises were taken into account such as having less accurate method if compared with a single method developed for single extract or sample. The method showed positive results when tested on 10 extracts of the same family from different plant parts and localities.

**Keywords**: dipterocarpaceae, *Shorea* spp., *Dipterocarpus* spp., chromatography, high performance liquid chromatography

**Abstrak**

Satu kaedah piawai untuk keadaan kromatografi KCPT telah dibina untuk ekstrak dari tumbuhan Dipterocarpaceae yang berlainan. Tujuan kajian ini ialah untuk mencapai satu kaedah kromatografi optimum yang dapat menghasilkan pemisahan komponen oligostilbene dari ekstrak tumbuhan dengan resolusi yang baik. Untuk tujuan ini, lima sampel ekstrak tumbuhan Dipterocarpaceae, *Shorea parvifolia, Shorea ovalis, Dipterocarpus crinitus, Dipterocarpus gracilis* dan *Hopea* spp. telah digunakan sebagai model. Parameter yang merangkumi jenis pelarut, jenis aliran fasa bergerak, komposisi pelarut dan isipadu suntikan sampel telah diubahsuai. Keputusan menunjukkan kaedah kromatografi yang sesuai berjaya dicapai apabila aliran bercerun digunakan dengan komposisi pelarut $H_2O$: ACN dari 95:5 kepada 25:75 di dalam masa 20 minit. Isipadu suntikan 5 µL adalah sesuai untuk larutan sampel berkepekatan 1 mg/ml. Suhu turus ditetapkan pada 35 °C dan kadar aliran fasa bergerak adalah pada 1.0 ml/min. Walaubagaimanapun, resolusi setiap kromatogram tidak sebaik dan sejitu apabila kaedah berlainan dibangunkan untuk setiap sampel secara individu. Kaedah ini telah telah menunjukkan keputusan yang positif apabila diuji ke atas sepuluh ekstrak lain dari famili tumbuhan yang sama. Sampel ujian tersebut adalah dari bahagian tumbuhan yang berlainan dan dari kawasan pensampelan yang berbeza.

**Kata kunci:** dipterocarpaceae, *Shorea* spp., *Dipterocarpus* spp., kromatografi, kromatografi cecair prestasi tinggi

## Introduction

Dipterocarpaceae family produces a high diversity of oligostilbene structures, ranging from dimeric to octameric stilbenes. Oligostilbenes are the most phytochemical components that were studied on this family due to their abundance in the plants which can be isolated from their leaves, bark, wood, heartwood and seeds. Oligostilbenes have attracted a major attention due to the bioactivities of crude extracts, fractions, as well as the isolated pure compounds including anti-inflammatory, cytotoxicity, antimicrobial and antioxidant activities [1-3]. As the isolation and characterization techniques for plant compounds developed, investigations of oligostilbenes became more abundant and more new compounds from various families were characterized. In our previous report, we have isolated 5 new oligostilbenes from *Neobalanocarpus heimii* [4].

Chromatographic technique is now being used beyond its original purpose, which is to separate and purify a mixture of compounds. It is also used to identify and quantify the individual components of mixtures in the phytochemical and analytical chemistry [5]. High performance liquid chromatography (HPLC) analysis plays a major role in phytochemical analysis including identification of crude plant extracts [6]. Method development for HPLC requires decisions regarding the choice of column, mobile phase, detectors, and method quantitation [7]. Optimization of HPLC conditions and other important perspectives during method development are conducted to provide a simple, precise, rapid and accurate analysis of plants.

The obvious challenge in chromatographic profiling of plant extracts is repetitive method development works whenever working with new samples. Usually, the chromatographic method differs for every sample. Thus, chromatographic method is developed for one particular sample only at one time. This leads to the increase consumption of money and time. We were suggesting a dereplication strategy to identify compounds as early as in a crude mixture in order to work faster [8,9].

The aim of analysis of each HPLC method may vary for each developmental area. In phytochemical studies, HPLC are frequently applied for quantitative and qualitative analysis of organic compounds in natural plant extracts, such as and alkaloids from *Nicotiana spp.*[10]. In a different field, a number of HPLC methods have been developed for the quantification of samples such as sildenafil in human plasma [11], acetazolamide, furosemide and phenytoin in suspensions [12].

Phytochemical studies of Dipterocarpaceae by using HPLC are conducted to determine the composition of the plant such as resveratrol dimer O-glucosides with enantiomeric aglycones [13], bergenin phenylpropanoates [14], oligostilbenoids and 3-ethyl-4-phenyl-3,4-dihydroisocoumarins [15].

In this study, one standard method of chromatographic conditions of HPLC is developed to analyze different samples of Dipterocarpaceae extracts. Optimization of developing method involves the changing of solvent conditions and injection volume only. Conditions, such as column temperature and types of solvents were selected based on the previous study [4], flow rate was calculated based on Van Deemter equation for mobile phase velocity, and the wavelengths were measured prior to the experiments.

## Materials and Methods

### Materials and reagents

The model samples, *Shorea parvifolia, Shorea ovalis, Dipterocarpus crinitus, Dipterocarpus gracilis* and *Hopea* spp. are available at Atta-ur-Rahman Institute for Natural Product Discovery repository. The test samples were collected from Malaysian National Parks, mainly in the area of Selai and Kuala Kerian. Organic solvents used for extraction were of analytical grade. Acetonitrile used for HPLC analyses were of chromatographic grade from RCI Labscan. Ultrapure water (18 MΩ $cm^{-1}$) was obtained from PURELAB® Option water purification system (ELGA).

### Instrumentation

The HPLC system is a Dionex Ultimate 3000 from Thermoscientific. The system is equipped with an ultra-pressure pump, a degasser, an auto sampler and a diode array detector (DAD). The chromatographic profiles and the integrated data were recorded using Chromeleon Chromatography software. The separations were achieved through a Phenomenex® Luna 5 µm C18 column (150 X 4.6 mm) equipped with a guard column of similar chemistry.

**Extraction of samples**
An amount 1 g of each sample was extracted in 10 ml of acetone. Extraction was carried out by maceration under sonication. For each sample, the extraction process was repeated 3 times. The extracts were filtered and reduced under vacuum. The samples were transferred into vials and dried over nitrogen gas.

**Sample preparation for HPLC analysis**
The samples were prepared by dissolving the extracts in acetonitrile to the concentration of 1000 ppm according to the weight. Then, the samples were filtered through 0.45 µm membrane filter into HPLC vials.

**HPLC analysis**
The HPLC analyses for Dipterocarpaceae crude extracts were established at the wavelengths of 215 nm, 254 nm and 283 nm. The column temperature was maintained at 35 °C, and the flow-rate was set at 1 ml/min. The injection volumes were 5 and 10 µl for each analysis. The mobile phase were acetonitrile: water (ACN:$H_2O$) at different compositions, for both isocratic and gradient elution mode.

The system was purged prior to initiation of analysis to ensure the line tubes are free from air bubbles. The column was conditioned for 30 minutes and the baseline was monitored for irregularities. The sample injections were performed automatically by an auto sampler. The column was flushed with 95% acetonitrile for 5 minute after each chromatographic run, followed by a 5-minute post-run at solvent composition of the next injection.

**Method development and validation**
A method development was initiated by a full-range gradient of ACN:$H_2O$ (5:90 to 95:5), enables the elution of all compounds in sample ranging from polar to non-polar compounds. By keeping the initial solvent composition of ACN:$H_2O$ at 5:90, the water component was gradually reduced at the end of chromatographic run, until the retention time of the last peak achieve maximum chromatographic run, and/or an isocratic gradient is achieved. The run-time was adjusted to accommodate the retention time of all compounds in the samples. Each chromatogram was analyzed and the best solvent composition was decided. The analyses were continued by keeping the end solvent composition of selected condition, while gradually increasing acetonitrile percentage in the initial composition. Using this strategy, the solvent compositions were adjusted until an isocratic gradient was achieved. An optimum condition was selected for the best separation of all model samples. The system is also enable to create a curve gradient (Figure 1), which were also tested for all samples. The injection volumes were also tested.

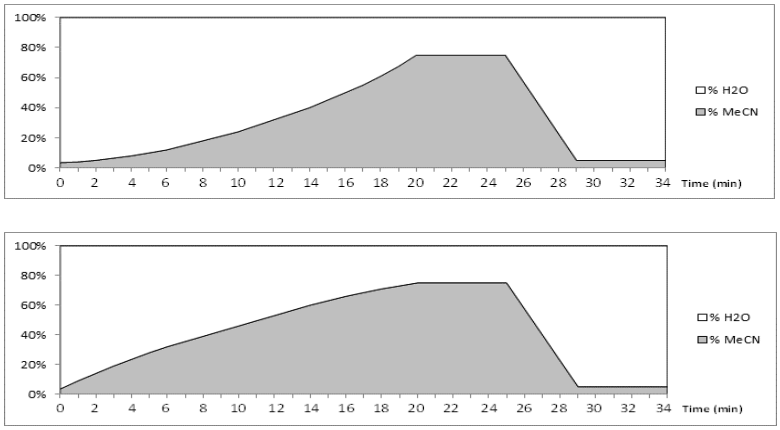

Figure 1. Curve gradient elution; concave (top) and convex (bottom) gradient elution, The graph represent the percentage of water and acetonitrile

## Results and Discussion

### Chromatographic conditions for model sample

All model samples had undergone a full-range gradient method to obtain the overall performance of their chromatographic profiles. The full-range gradient method is also a standard gradient elution scouting run to determine the best elution mode to be chosen in this study. Dolan [16] had suggested that the scouting run can be a guide tool to determine the best elution mode for a specific sample, column and eluent system. The chromatographic profiles samples using the full-range gradient method show that the samples occupied more than 40% of the separation space (Figure 2). This indicates that the separation should be done by the gradient elution.

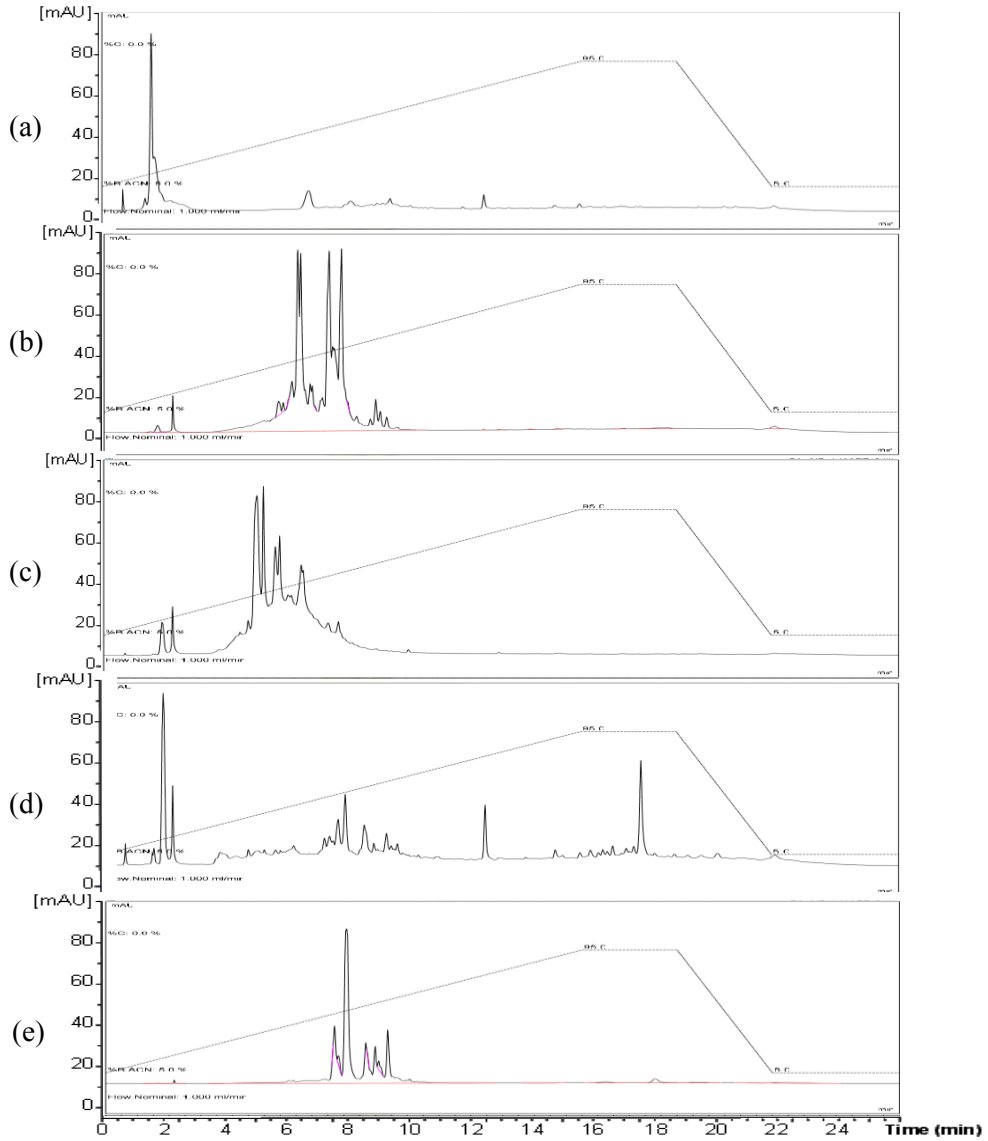

Figure 2. Chromatogram profiles of model samples using full-range gradient method of ACN:$H_2O$ (5:95 to 95:5 in 15 minutes); (a) *Shorea parvifolia*, (b) *Shorea ovalis*, (c) *Dipterocarpus crinitus*, (d) *Dipterocarpus gracilis*, and (e) *Hopea* spp

From the initial analysis of the chromatographic profile, we have decided to increase the chromatographic run from 15 to 20 minutes to accommodate the wide range of retention time for compounds in *Dipterocarpus gracilis.* The analyses were continued by changing the solvent composition of the initial and the end of a chromatographic run. All chromatographic profiles were analyzed and after some adjustment and modification, an isocratic mode of ACN:$H_2O$ (5:95 to 75:25 in 20 minutes) was considered performing a reasonably good separation for all samples. Figure 3 shows the chromatographic profiles of all model samples using the selected chromatographic conditions.

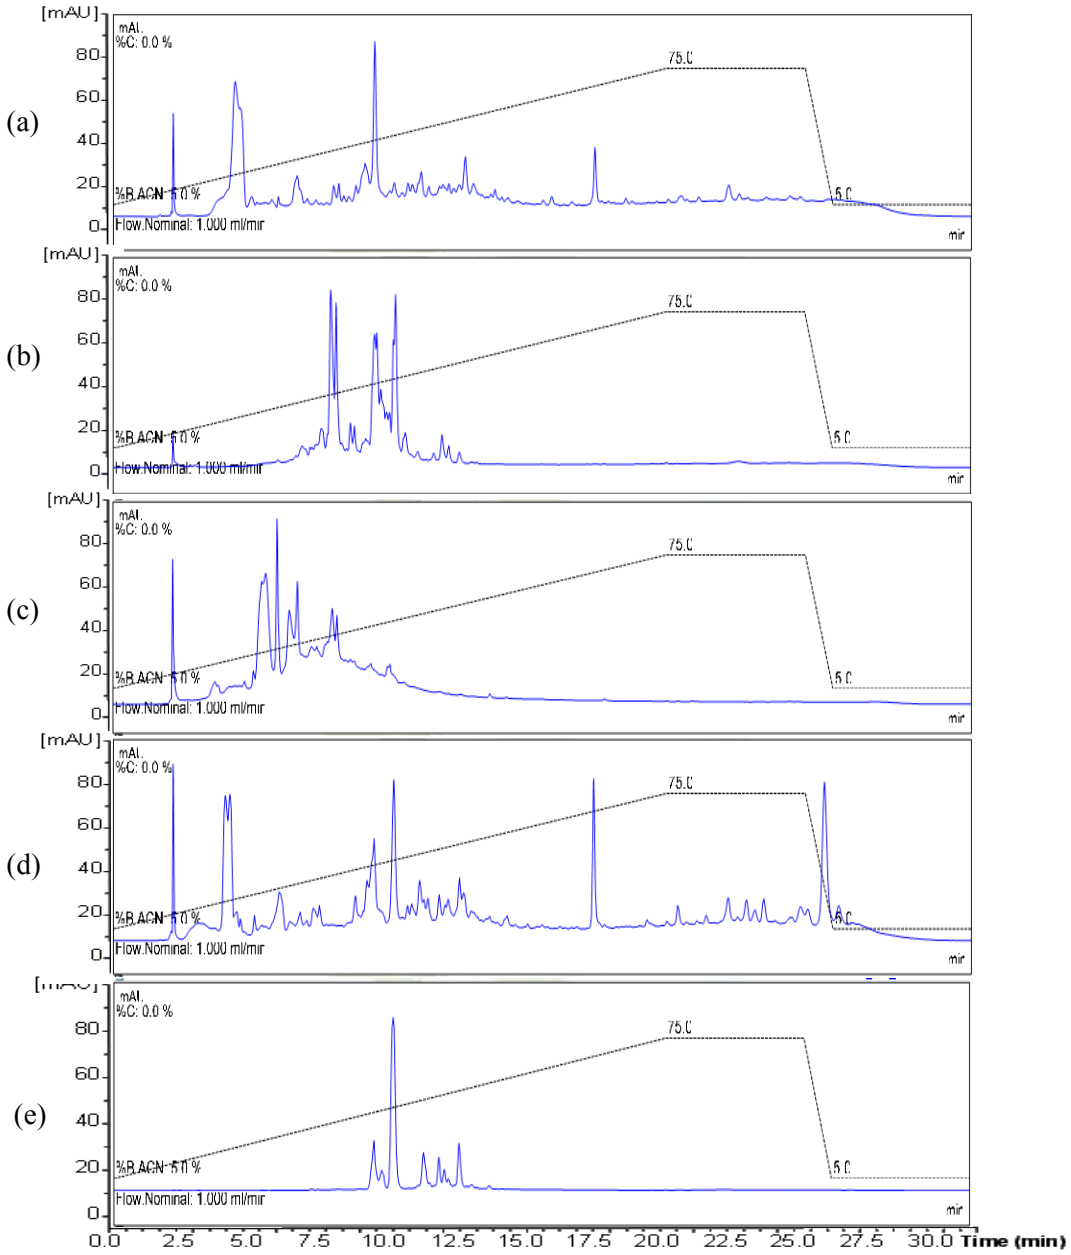

Figure 3. Chromatographic profiles of model samples using an isocratic mode of ACN:$H_2O$ (5:95 to 75:25 in 20 minutes); (a) *Shorea parvifolia,* (b) *Shorea ovalis,* (c) *Dipterocarpus crinitus,* (d) *Dipterocarpus gracilis,* and (e) *Hopea* spp

**Curved gradient method**

Basically, there are two types of curved gradient method; concave and convex gradients. These methods were tested to discover any improvements on the separation of samples. In a reverse phase chromatography, concave and convex gradients were used for analyzing multi-component samples which require the extra resolution either at the beginning or at the end of the gradient. The elution rate was maintained at $H_2O$:ACN (95:5 to 25:75 in 20 minutes) for both gradient method. The results, however, did not show any improvement in the resolution and failed to achieve optimal separation of model samples. Thus, it was not considered for further optimization of the chromatographic conditions for the model samples.

**Injection volume**

Injection volume is considered as one of the parameter that can be modified to achieve optimized method development for better separation of all samples. In this study, the gradient elution was fixed to be $H_2O$:ACN (95:5 to 25:75) and the run time was set up to be 20 minutes. The chromatograms showed that the injection volume had the significant effect on the chromatographic resolution. The shapes of peaks were improved, thus producing a better resolution. Previous studies [17,18] also showed that with the increase of injection volume, the resolution of separated compounds would be decreased. In this study, the injection volume of 5 µl per injection of samples is considered to be the best compromise.

**Method validation on test samples**

Ten plant samples were chosen to be tested with the optimized chromatographic conditions to ensure the reproducibility of the developed method. The tested samples are from the same family as the model samples but different parts of the plant that were studied. The tested samples were taken from the wood of the buttress and each species were from two places in Malaysia (Selai and Kuala Kerian). *Shorea parvifolia, Shorea leprosula, Shorea ovalis, Dipterocarpus crinitus* and *Hopea* spp. were chosen to test the method. Figures 4(a-e) show the chromatographic profiles of all tested samples.

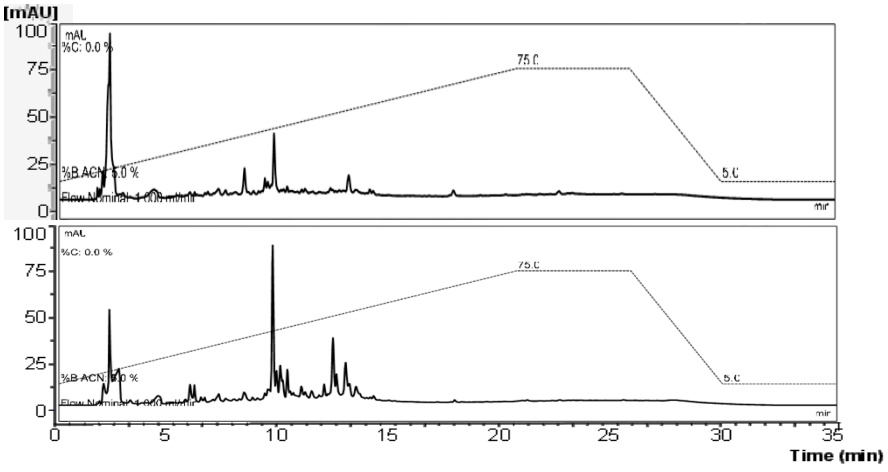

Figure 4(a). Chromatographic profiles of test samples using an isocratic mode of ACN:$H_2O$ (5:90 to 75:25 in 20 minutes) of *Shorea parvifolias.* The top chromatogram is for sample from Selai and the bottom is sample from Kuala Kerian

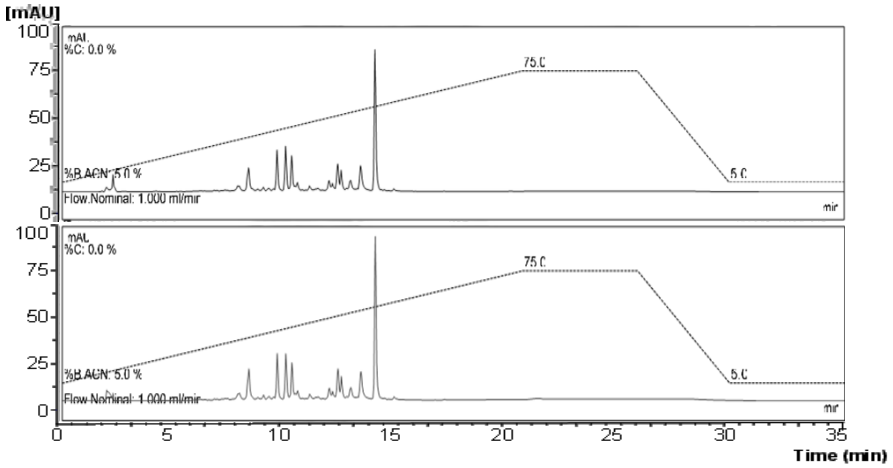

Figure 4(b). Chromatographic profiles of test samples using an isocratic mode of ACN:$H_2O$ (5:90 to 75:25 in 20 minutes) of *Shorea leprosula.* The top chromatogram is for sample from Selai and the bottom is sample from Kuala Kerian

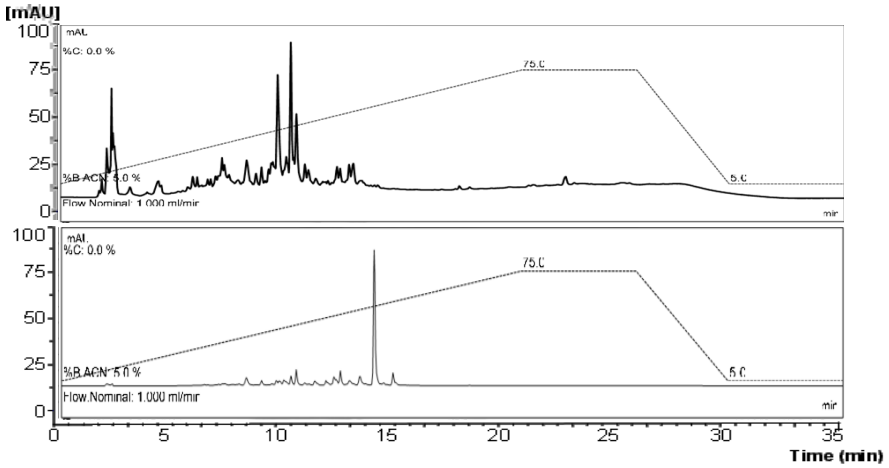

Figure 4(c). Chromatographic profiles of test samples using an isocratic mode of ACN:$H_2O$ (5:90 to 75:25 in 20 minutes) of *Shorea ovalis.* The top chromatogram is for sample from Selai and the bottom is sample from Kuala Kerian

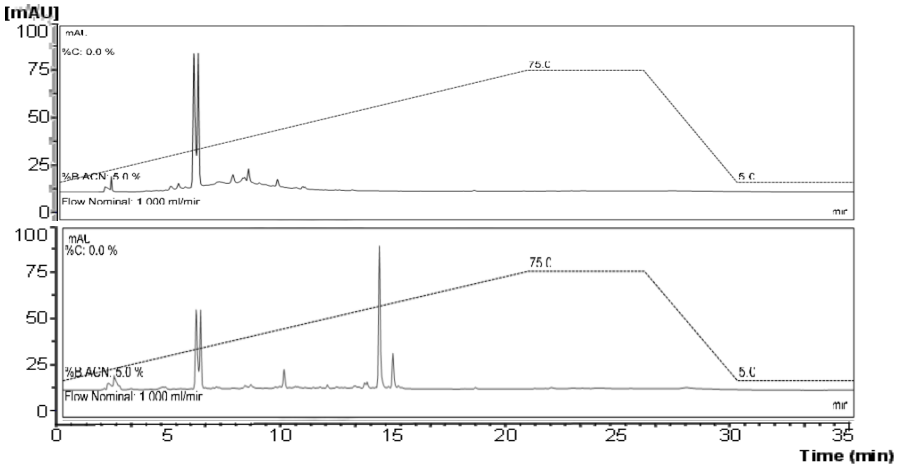

Figure 4(d). Chromatographic profiles of test samples using an isocratic mode of ACN:$H_2O$ (5:90 to 75:25 in 20 minutes) of *Dipterocarpus crinitus.* The top chromatogram is for sample from Selai and the bottom is sample from Kuala Kerian

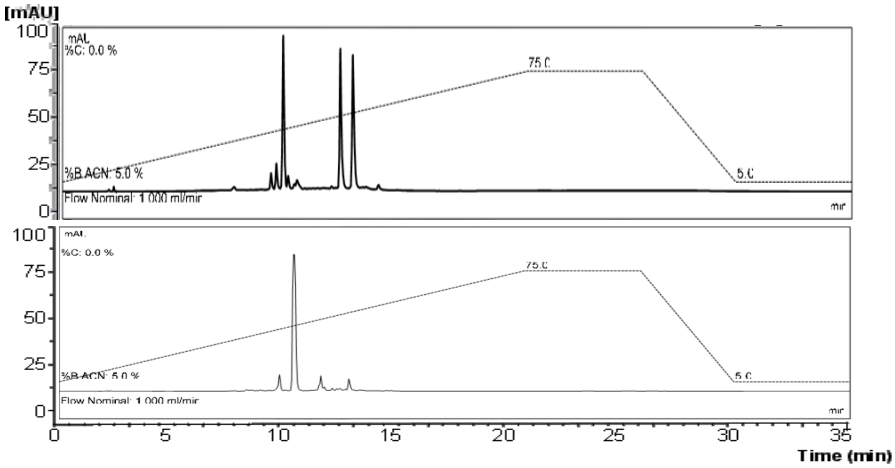

Figure 4(e): Chromatographic profiles of test samples using an isocratic mode of ACN:$H_2O$ (5:90 to 75:25 in 20 minutes) of *Hopea* spp. The top chromatogram is for sample from Selai and the bottom is sample from Kuala Kerian

The optimum chromatographic profiles for Dipterocarpaceae plant extracts were achieved by a gradient elution of water-acetonitrile from 95:5 to 25:75 in 20 minutes. A smaller injection volume is more favourable for a better resolution, in this case is 5 µL per injection. This standard method can reduce the overall assay development time for analysis of similar samples and provide essential information regarding the effects of chromatographic parameters on the separation. A longer gradient time will increase the retention of compounds in the column. Thus, the elution is slower and overlapping peaks for early-eluting compounds can be avoided. Nonetheless, longer gradient time up to a limit will cause overlapping peaks to the late-eluting compounds. Since the compounds were retained longer in the column, there is a chance that peaks will not eluted during the fixed run time and may be missing from the analyzed samples.

Though the tested samples can be separated by using the optimized method, it is best to individually alter the chromatographic conditions. This is to ensure better separation and resolution of samples and as well as a more accurate method can be achieved.

## Conclusion

The results show that a single chromatographic method for analyses of different plant samples is possible. A gradient elution method using water-acetonitrile (from 95:5 to 25:75) and injection volume of 5 µL was the chosen and optimized method. The run time was extended to 20 minutes to give sufficient time for the compounds to be eluted from the column and to avoid peak overlapping. Other parameters, the column temperature (35 °C) and the flow rate (1.0 ml/min) were kept constant.

As far as phytochemical studies are concerned, the ability of such a method to separate a set of plants samples using only one chromatographic condition provides a useful tool for more efficient natural compounds isolation. This eliminates the dependence on reproducing precise chromatographic data for every single plant sample, which has significantly influenced the energy and time consumptions. The strategy of having a single method for chromatographic condition can increase the productivity of phytochemical analysis of plant extracts, and avoid the replication of developing chromatographic conditions unnecessarily.

## Acknowledgement

The members of this project would like to thank Atta-ur-Rahman Institute for Natural Products Discovery, Research Management Institute (RMI), UiTM for supporting this project by providing laboratory space and administrative assistance. We are also grateful to The Ministry of Education (MOE) for the research funding under the Fundamental Research Grant Scheme (FRGS). We also want to thank Puan Marina Ismail, Akademi Pengajian Bahasa, UiTM for proofreading the manuscript.

**Abstract**

Virgin coconut oil (VCO) consists mainly of saturated medium chain fatty acids which are 48.8% lauric acid (C12:0) and 20.0% myristic acid (C14:0). Both medium chain fatty acids are essential in increasing metabolism and possess antibacterial properties. These fatty acids of VCO are in the form of triacylglycerols (TAGs). Hence, VCO has to be converted into a simpler form such as mono- and diacylglycerols (MAGs and DAGs) in order to increase its antibacterial functionality in metabolism. In this paper, VCO was chemically modified via enzymatic glycerolysis reaction conducted at a molar ratio of 1:1 (VCO:glycerol) and catalysed by lipase enzyme, *Candida antarctica* (Novozyme 435). The reaction was carried out in an incubator shaker at 50 °C and 250 rpm of reaction speed. Reaction parameters were reaction time (24 and 48 hours) and enzyme concentrations (3, 5 and 10%). The product comprises of 3.3% MAG, 3.6% DAG and 93.1% TAG has been obtained by preliminary optimum reaction condition at temperature of 50 °C with 5 %wt of enzyme concentration at 24 hours of reaction time. Chemical analysis techniques used were thin layer chromatography (TLC), fourier transformation infrared (FT-IR) spectroscopy and gas chromatography (GC). Products are potentially to be used as food emulsifier, pharmaceutical binders, antibacterial products as well as food additives.

**Keywords**: virgin coconut oil, glycerolysis, lipase enzyme, monoacylglycerol, diacylglycerol

**Abstrak**

Kandungan utama minyak kelapa dara (VCO) adalah asid lemak tepu berantai sederhana dengan 48.8% adalah asid laurik (C12:0) dan 20.0% asid miristik (C14:0). Asid lemak dengan rantaian sederhana adalah penting dalam meingkatkan kadar metabolisma dan mempunyai ciri-ciri anti-bakteria. Asid lemak dalam VCO adalah dalam bentuk triasilgliserol (TAG). Oleh itu, VCO perlu ditukarkan kepada bentuk yang lebih ringkas seperti mono dan diasilgliserol (MAG dan DAG) untuk meningkatkan fungsi anti-bakteria dalam metabolisma. Dalam kajian ini, VCO diubahsuai secara kimia melalui tindak balas gliserolisis berenzim yang dijalankan pada nisbah molar 1:1 (VCO:gliserol) dengan enzim lipase *Candida antarctica* (Novozyme 435) sebagai pemangkin. Tindak balas ini telah dijalankan dalam inkubator bergetar pada suhu 50 °C dengan kelajuan 250 rpm. Parameter tindak balas yang dilakukan adalah masa tindak balas (24 dan 48 jam) dan kepekatan enzim (3, 5 dan 10%). Hasil tindak balas terdiri daripada 3.3% MAG, 3.6% DAG dan 93.1% TAG telah diperolehi dengan kondisi tindak balas optimum awal pada suhu tindak balas 50 $^{o}$C dengan kepekatan enzim 5 %wt pada 24 jam tindak balas. Teknik analisis kimia yang digunakan adalah kromatografi lapisan nipis (TLC), spektroskopi transformasi fourier inframerah (FT-IR) dan kromatografi gas (GC). Produk berpotensi untuk digunakan sebagai pengemulsi makanan, pengikat dalam farmaseutikal, produk anti-bakteria dan bahan tambah dalam makanan.

**Kata kunci**: minyak kelapa dara, gliserolisis, enzim lipase, monoasilgliserol, diasilgliserol

## Introduction

Monoacylglycerol and diacylglycerol are chemical compounds which having one or two acyl groups attached to the glycerol backbone. A mixture of monoacylglyceol (MAG) and diacylglycerol (DAG) are commercially manufactured via glycerolysis reaction, in which fats and oils reacted with gycerol and undergo a transesterification reaction. MAG and DAG have both hydrophilic and hydrophobic portions which make them known as nonionic molecules. The molecular structure of MAG contains two free hydroxyl groups while DAG has one [1]. These molecules show excellent emulsifying properties due to their characteristics, and thus, being widely applied in the food, cosmetics, pharmaceuticals and chemical industries. Figure 1 shows the chemical structure of MAG and DAG.

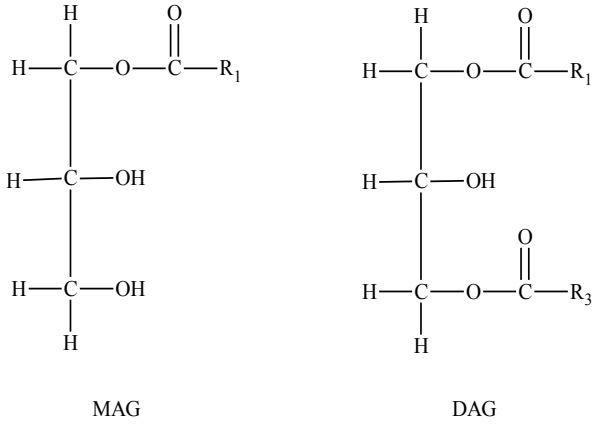

Figure 1. General chemical structure of MAG and DAG

Commercially, MAGs are used as binders in tablets and as emollients for transdermal slow-release drugs in the pharmaceutical industry. Furthermore, they are used as the most common food emulsifiers i.e. bakery products, margarines, dairy products, confectionery and sauces in the food industry. In cosmetics, they are often used as texturizing agents and for improving the consistency of creams and lotions [2]. In addition, MAGs are used in plastic production, textile processing and oil formulation for different types of machinery due to their excellent lubricating and plasticizing properties [3].

Meanwhile, DAGs are used as additives or carriers in the food, medicinal and cosmetic industry. A published literature proposed mechanisms for dietary DAG as it exhibits anti-obesity activity and can prevent postprandial hypertriacylglycerolemia in experimental animals and humans [4]. DAG oil has plentiful applications in edible products such as cooking oil, frying oil, salad oil and dressing, mayonnaise, shortening, margarine, chocolate and ice cream [5].

A previous work has attempted to manufacture MAGs and DAGs on an industrial scale by continuous chemical glycerolysis of fats and oils at high temperature (220 – 250 °C) employing inorganic alkaline catalysts under nitrogen gas atmosphere [6]. Unfortunately, the products suffered a few discrepancies with several disadvantages in the process itself [7]. The products were unattractively dark-coloured and have a burnt taste due to the high reaction temperature involved. Nonetheless, the chemical catalysis process was energy intensive, thus low yields were produced (30 – 40%) which acquired product purification by molecular distillation [8].

The use of enzymes as catalyst to modify the structure and composition of oils and fats has recently gained considerable attention, resulting in important advances in this specific field of biotransformation. Recently, enzymatic reactions have been considered as an alternative for chemical methods in large-scale productions [9]. Lipases are enzymes that hydrolyze fatty acids from lipid species such as triacylglycerols. Lipases catalyze the whole range of ester exchange reactions (alcoholysis, acidolysis, esterification, glycerolysis) and hydrolysis. The mild reaction condition and high purity MAG are the desirable advantages of enzymatic processes compared to chemical methods [10]. In parallel to green chemistry concept, enzyme reactions require less solvent which generated cleaner products. Figure 2 shows the X-ray structure of *Candida antarctica* lipase A. The enzyme is classified as hydrolase [11].

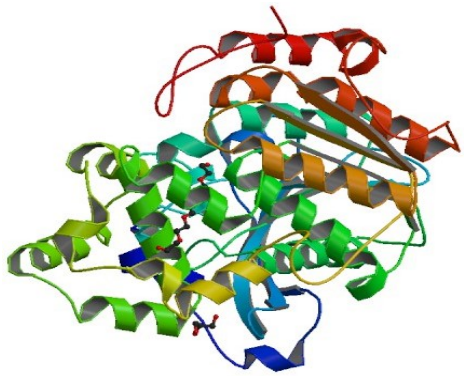

Figure 2. X-ray structure of *Candida antarctica lipase A*

Virgin coconut oil (VCO) is obtained from the fresh and mature kernel of the coconut (*Cocos nucifera* L.) through mechanical and natural means. The selection methods could involve heat provided that it does not lead to alteration or transformation of the oil. Approximately 60% of the total oil of coconut oil being medium chain triglycerides (MCTs) and thus it is considered as a natural source of MCTs. The term MCT refers to triacylglycerol which is composed of a glycerol backbone and three saturated fatty acids with chain length of 6 – 12 carbons. MCTs have been reported to be beneficial to human health. MCTs are mainly used as a nutritional supplement for patients suffering from absorbtion disability caused by intestinal resection and also as a component of infant feeding formulas [12]. A study had reported that MCTs have beneficial effects on weight control and glucose, as well as lipid metabolism [13]. Compared with other triglycerides that mainly contain saturated long chain fatty acids, MCTs have a lower melting point, smaller molecular size, lower solidification temperature and lower energy density. These distinct chemical properties affect the ways in which MCTs are absorbed and metabolized [14].

This preliminary study on enzymatic glycerolysis of VCO using a commercial immobilized *Candida antarctica* lipase (Novozyme 435) was performed to evaluate potential chemical modification method to produce MAGs and DAGs for various applications.

## Materials and Methods

### Materials

Virgin coconut oil (produced by Country Farm Sdn. Bhd.) was directly purchased from a local market and used without any pre-treatments. Lipase *Candida antarctica* (Novozyme 435) were purchased from Sigma-Aldrich and glycerol (99.5%) were obtained from Systerm.

### Physicochemicals analysis of VCO

#### *Saponification value (SV)*

Saponification values (SV) were determined using the International Union of Pure and Applied Chemistry (IUPAC) method II.D.2 [15]. In a reflux condenser, 2.0 g of oil samples were added with Ethanolic KOH 0.5 N and boiled for

60 minutes. The mixtures were cooled and subsequently titrated with 0.5 N HCl until the pink colour disappear and changed to colourless. All SV determinations were carried out in triplicates.

***Iodine value (IV)***

The determination of iodine value (IV) of oil was carried out according to the IUPAC method II.D.7 [15]. A reaction was held in the dark between 0.5 g of oil samples with the Wij's solution for 1 hour. The mixture was consequently titrated with sodium thiosulphate solution. IV values were determined in triplicates and expressed as gram of iodine absorbed by 100 g of the fats (g $I_2$/ 100 g).

***Free fatty acids value (FFA)***

Free fatty acid (FFA) value was ascertained using the IUPAC method II.D.1 [15]. An amount 5.0 g of oil samples were added with 50 mL of neutralized diethyl ether: ethanol (1:1; v/v) and 1 – 2 mL of phenolphthalein indicator. The mixture was heated on a hot plate with controlled temperature around 40 °C. It was then titrated with a standard NaOH until a constant pink colour was obtained. All FFA value determinations were conducted in triplicates and expressed as mg of KOH required to neutralize the free fatty acids in 1 g of VCO (mg KOH/g oil).

***Peroxide value (PV)***

The determination of Peroxide Value (PV) was carried out according to AOCS Cd 8b-90 [16]. An amount 5.0 g of samples were added with 30 mL of mixture of acetic acid and chloroform in a conical flask and mixed well. Then, 0.5 mL of concentrated potassium iodide (KI) was pipetted into the mixture and the flask was manually shaken for a minute. After shaking, 30 mL of distilled water and few drops of starch were added and the mixture was titrated gradually with 0.01 N sodium thiosulphate until the blue colour has disappeared.

***Moisture content***

Determination of moisture content was based on the AOAC method [17] with slight alteration. Sample was weighed and heated at 105 °C in a crucible for at least 7 hours and then, cooled to room temperature. The crucible was re-weighed with the sample inside until constant readings were gathered. Moisture content was calculated based on weight difference obtained.

**Fatty acids methyl ester (FAME) analysis**

Exactly 0.2 ml oil samples were prepared by dissolving in hexane and later added with 0.2 mL of 1 M sodium methoxide. The mixture was vortexed and FAME solution in the upper layer was collected for GC-FID analysis. The analysis of FAME was conducted with Shimadzu GC-17A gas chromatography equipped with a flame ionization detector (FID). BPX-70 column was used in this experiment (0.25 mm internal diameter, 30 m length and 0.25 µm film thickness). The column was initially set at 100 $^{o}$C and held for 3 minutes, then increased to 245 $^{o}$C and held for another 10 min at a rate of 4 $^{o}$C/min. The temperature of injector and detector port were 250 °C and 280 °C respectively. Helium gas with purity level 99.99% is used as carrier gas.

**Enzymatic glycerolysis reaction**

Glycerolysis reaction was modified based on a research conducted by Pinyahpong et al. [18]. The molar ratio used for VCO:glycerol was 1:1. An approximately 2.8% (w/v) of distilled water was added based on the volume of oil used and 3 %wt of lipase enzyme was added based on the weight of glycerol. The reaction was carried out at 50 $^{o}$C in a shaking incubator with 250 rpm for 24 hours.

After 24 hours, the reaction stopped and the enzyme was then separated from the mixture using filter paper in a present of vacuum condition. The filtrate was placed into a separating funnel and followed by 50 mL of chloroform, 50 mL of ethanol and 30 mL of diethyl ether were added to separate excess glycerol. The mixture was then washed with 100 mL of sodium chloride (4 times) and 100 ml of sodium hydroxide (4 times). This is to remove the free fatty acids from the glycerolysis reaction. Finally, the product was obtained after using rotary evaporator. This paper will discuss some factors that affected lipase-catalysed glycerolysis such as time of reaction (24 hours and 48 hours) and enzyme concentration used; 3%, 5% and 10% of glycerol (w/w).

**Chemical compositions analysis**

Product identification was analysed using Thin Layer Chromatography (TLC). An aliquots of the reaction mixtures were applied on a silica gel 60 plate (Merck) in developing solvent mixture of n-hexane:diethyl ether:acetic acid (70:30:1; v/v). The spots of each product were visualized by immersing the plate in $KmNO_4$ solution.

The composition of products were analysed by using gas chromatography (Shimadzu GC-17A) fitted with a capillary column (DB-5ht, 30 m × 0.320 mm, 0.25 μm thickness) and equipped with a flame ionization detector (FID). The separation of compounds was performed using the following oven temperature profile: initial temperature 80 $^{o}$C, programmed to 350 $^{o}$C at 10 $^{o}$C/min, and final temperature held for 10 min. The sample was prepared by adding 0.03 mL of sample in 1 mL of ethyl acetate in a vial. Only 0.1 μL of the prepared sample was injected into GC.

The functional groups analysis of product was determined using FT-IR spectroscopy. In this study, FT-IR with the model of Perkin Elmer Spectrum BX was used. The sample was smeared thinly on the NaCl plate and FT-IR spectrum was recorded.

## Results and Discussion

**Physicochemicals properties of VCO**

The results obtained were within accepted levels according to Asian Pacific Coconut Community (APCC) specifications [19] as shown in Table 1. The molecular mass determined for VCO is 651.57 g/mol. VCO was converted to fatty acids methyl ester (FAME) and its composition was determined by using gas chromatography. A standards of FAME was calibrated and established for each peak of compound prior sample analysis. The chromatogram of methyl esters of VCO is shown in Figure 3.

Table 1. Physicochemical Properties of VCO

| Tests | Value | APCC Standard |
|---|---|---|
| Saponification Value (mg KOH / g) | 258.30 | 250 – 260 |
| Free Faty Acids (mg KOH / g) | 0.225 | 0.5 max |
| Iodine Value (g $I_2$ / 100 g) | 4.13 | 4.1 – 11.0 |
| Peroxide Value (meq / kg) | 0.2 | 3.0 mas |
| Moisture Content (% weight) | 0.11 | 0.1 – 0.5 |

Retention time is the time taken by certain compounds to move along the column towards the detector. This period depends on the boiling point of each compound. Compounds with higher boiling points have longer retention period. In general, the boiling point of the compound was influenced by several molecular factors such as the number of carbon (carbon chain length) and the number of double bonds that exist in the compound. The number of carbon is in conjunction with the molecular weight of these compounds. Heavier molecules (high molecular weight) have higher boiling points. This caused the molecule to be less volatile and therefore will be detected slower, thus prolonged its detention time. Similarly, compounds with more double bonds have longer period of detention [20].

The peaks composition of product were compared with the retention times of calibrated methyl esters standards as followed, mehyl caprilate (3.375 min); methyl caprate (5.581 min); methyl laurate (9.071 min); methyl myristate (12.913 min); methyl palmitate (16.708 min); methyl stearate (20.283 min); methyl oleate (20.853 min) and methyl linolate (22.022 min). From the observation on the GC result, methyl caprylate that has 6 carbons had the shortest retention time and was detected the earliest. Methyl stearate has 18 carbons which produced longer detention period. Meanwhile, methyl stearate, oleate and linolate have the same carbon number of 18. However, linolate has 2 double bonds and thus, produced the longest detention period.

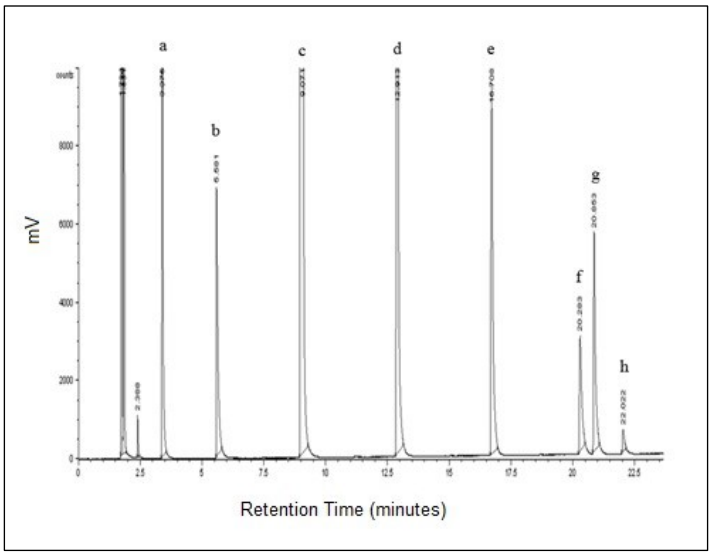

Figure 3. GC chromatogram of VCO (a: methyl caprilate, b: methyl caprate, c: methyl laurate, d: methyl myristate, e: methyl palmitate, f: methyl stearate, g: methyl oleate, h: methyl linolate)

The carbon chain composition of VCO was tabulated in Table 2 and compared to APCC standard [19]. The results showed that VCO sample consists of caprylic (C8:0), capric (C10:0), lauric (C12:0), myristic (C14:0), palmitic (C16:0), stearic (C18:0), oleic (C18:1) and linoleic (C18:2). It was found that VCO contains high saturated fatty acids (SFA) which was 93.9% and low unsaturated fatty acids which was 6.0%. These findings were in agreement with Mansor et al [12].

Table 2. Fatty acids composition of VCO

| Fatty Acid Composition | Percentage (%) | APCC Standard (%) |
|---|---|---|
| Caprylic acid | 6.3 | 4.6 – 10.0 |
| Capric acid | 5.4 | 5.0 – 8.0 |
| Lauric acid | 48.8 | 45.1 – 53.2 |
| Myristic acid | 20.0 | 16.8 – 21.0 |
| Palmitic acid | 9.8 | 7.5 – 10.2 |
| Stearic acid | 3.6 | 2.0 – 4.0 |
| Oleic acid | 5.4 | 5.0 – 10.0 |
| Linoleic acid | 0.6 | 1.0 – 2.5 |

**Product compositions**

TLC was used to validate the products after the reaction. Based on the results, TLC plate confirmed the product formation. MAG (i) was detected first, followed by 1,2-DAG (ii), 1,3-DAG (iii) and TAG (iv) respectively (Figure 4). The components were detected based on their polarity. No fatty acids were detected on the TLC plate.

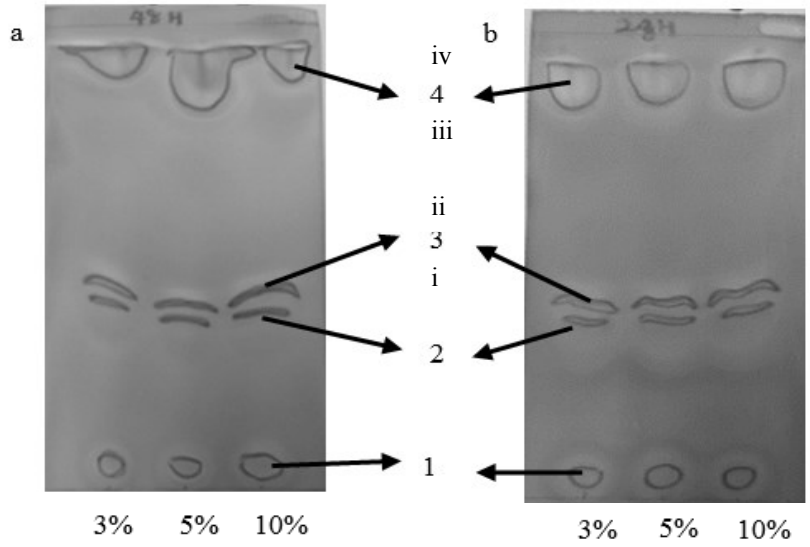

Figure 4. TLC plate of glycerolysis reaction (a: Reaction time for 48 hours; b: Reaction time for 24 hours)

In this study, glycerolysis between VCO and glycerol (molar ratio 1:1) with 3, 5 and 10 %wt of ezyme concentration at 50 $^{o}$C for 24 and 48 hours were investigated. The results showed that 3 %wt of enzyme at 24 hours of reaction gave 1.4% MAG, 2.2% DAG and 96.4% of unreacted TAG. It was observed that 5% of enzyme at 24 hours of reaction yielded increment on MAG and DAG contents. However, there were no increment observed for conversion of MAG and DAG if increase the enzyme concentration to 10 %wt. The reaction was continued with pro-long the reaction time. It was reported that no significant increment of MAG and DAG content for 48 hours at any enzyme concentrations. The percentage of conversions are still low and not fully optimized. But, this findings proved that the conversion of VCO in TAG form into simpler compounds (MAG and DAG) is possible to be done through enzymatic glicerolysis with further investigations. Some parameters have to optimized and different types of lipase enzymes have to be considered for this reaction. In order to push forward the reaction, selected factors that may favour the reaction have been studied such as time of reaction (RT) and percentage of enzyme concentrations. Based on the results (Table 3), glycerolysis with 5 % of enzyme loading and 24 hours of reaction time gave the highest composition of MAG and DAG.

Table 3. Compositions of products

| **Enzyme Concentration (%)** | **Reaction Time (hours)** | **Product Compositions (%)** | | |
|---|---|---|---|---|
| | | **MAG** | **DAG** | **TAG** |
| 3 | 24 | 1.4 | 2.2 | 96.4 |
| 5 | 24 | 3.3 | 3.6 | 93.1 |
| 10 | 24 | 1.5 | 3.2 | 95.3 |
| 3 | 48 | 0.5 | 1.5 | 98.0 |
| 5 | 48 | 0.6 | 1.2 | 98.2 |
| 10 | 48 | 1.6 | 2.4 | 96.0 |

## Conclusion

Preliminary findings conclude that glycerolysis reaction of VCO as the starting material was successfully performed. The optimum condition for the reaction was 5% enzyme loading at 50 °C for 24 hours of reaction time. Based on GC analysis results, the product comprises 3.3% MAG, 3.6% DAG and 93.1% TAG. The product identification was further confirmed through TLC plate analysis technique.

**Abstract**

The study was conducted to evaluate the molluscicidal activity of *E. rheedii* methanol bark extract against *P. canaliculata* and to screen for phytochemical compounds of *E. rheedii* bark extracts. The golden apple snails with size range of 20 – 40 mm were treated with four different concentrations of *E. rheedii* (1000, 5000, 10000 and 20000 ppm) and paddy-field water mix with 50% methanol serving as the control treatment. The molluscicidal effects of the extract were evaluated after 24, 48 and 72 hours. The results of the study showed that high treatment concentrations (10000 and 20000 ppm) recorded the highest mortality rate (100%) while low concentrations (1000 ppm) showed the lowest mortality rate (27%). However, no mortality was recorded in the control treatment. The molluscicides activity with $LC_{50}$ is 1,611 ppm and $LC_{90}$ is 4,266 ppm and could be attributed to the presence of saponin in the bark extracts. *E. rheedii* bark extract provides a great potential for developing green pesticides to control *P. canaliculata*. Nevertheless, further research is needed to determine its biochemical mechanism.

**Keywords**: golden apple snail, *Entada rheedii*, molluscicidal activity, phytochemical content

**Abstrak**

Kajian ini dijalankan untuk menilai aktiviti moluskisida oleh ekstrak metanol kulit kayu *E. rheedii* terhadap *P. canaliculata* dan untuk menyaring sebatian fitokimia yang terkandung di dalam ekstrak kulit kayu *E. rheedii.* Siput gondang emas bersaiz antara 20 – 40 mm telah dirawat dengan empat kepekatan *E. rheedii* yang berbeza (1000, 5000, 10000 dan 20000 ppm) dan campuran air sawah padi dengan 50% metanol menjadi rawatan kawalan. Kesan moluskisida oleh ekstrak dinilai selepas 24, 48 dan 72 jam. Keputusan kajian menunjukkan bahawa kepekatan rawatan tinggi (10000 dan 20000 ppm) mencatatkan kadar kematian tertinggi (100%) manakala kepekatan yang rendah (1000 ppm) menunjukkan kadar kematian yang paling rendah (27%). Walau bagaimanapun, tiada kematian direkodkan dalam rawatan kawalan. Aktiviti moluskisida dengan $LC_{50}$ adalah 1611 ppm dan $LC_{90}$ adalah 4266 ppm boleh dikaitkan dengan kehadiran saponin dalam ekstrak kulit kayu. Ekstrak kulit kayu *E. rheedii* mempunyai potensi yang besar dalam membangunkan racun perosak yang selamat terhadap alam sekitar untuk mengawal *P. canaliculata.* Walau bagaimanapun, penyelidikan lanjut perlu dilakukan untuk menentukan mekanisme biokimianya.

**Kata kunci**: siput gondang emas, *Entada rheedi*i, aktiviti moluskisida, kandungan fitokimia

## Introduction

The golden apple snail, *Pomacea canaliculata* (*P. canaliculata*) is native to South America [1] and has been introduced from Argentina to Taiwan in the 1980's for the purpose of food commercialization. Nevertheless, due to the low response of consumers towards snails as food, it has affected the marketing and farming activities of golden apple snail and caused producers to close their farms. Hence, it was contributed to the establishment and distribution of the snail populations that became a major invasive rice pest in South-East Asia [2]. In Malaysia, *P. canaliculata* was first found in abandoned mines; Puchong, Selangor in 1991 [3] and then was introduced in Keningau, Sabah in 1992. Then, it was spread throughout Peninsular Malaysia and caused extensive damage to paddy field areas in the Northern parts of Malaysia especially in the state of Perlis and Kedah. The problem became more serious due to the climatic change, which influences the rapid distribution and spread of snails throughout irrigation areas [4].

*P. canaliculata* was known as the most destructive invasive species that attacked and destroyed the young stems and paddy leaves. It has been reported that the snails could eat about 7-24 rice seedlings per day. Although farmers can control the snail populations in their paddy field plots through the application of various types of chemical fertilizers, but the problem is ever increasing because of the continuous supply and snail distribution through the water irrigation system [4]. Many approaches including chemical, mechanical or biological methods have been applied to control the widespread of golden apple snails in the field plantation area but the practice may have positive and negative impacts to humans, the environment and the ecosystem. Previous studies reported that the usage of chemical fertilizers such as metaldehyde and niclosamide can cause water pollution and thus affect the ecosystem or water sources [5]. The uses of mechanical techniques such as rice-duck mutualism [2] and attractant bite using jackfruit, papaya, spinach, cassava leaves and banana leaves are also effective. Badrulhadza and Yahya [6] found that snails are more attracted to jackfruit and papayas, thus this method is also important as it could contribute to the integrated management of golden apple snails in field plantation areas. Besides that, the application of biological control and pesticides derived from extracts of seed, leaves, fruit or other plant parts also give significant impacts in the management of the snails. Leaves extracts of *Solanum* species [7], *Barringtonia racemosa* L. kernel extract [5], and extracts of *Agave filifera*, *Ammi majua* and *Canna indica* leaves and flowers [8] have been reported as effective in controlling snails in their plantation areas. The effectiveness of the plant extracts in controlling snails may be due to the presence of bio-active compounds such as saponins, flavanoids, and terpenoids that react with pest body system.

*Entada rheedii* (*E. rheedii*) Spreng or known as African Dream Herb is a woody climber of the legume family. This plant is found in Africa and South-East Asia [9,10]. Some chemical contents of *E. rheedii* are antigenic acids, fatty acids, entadamide A, B, and C, phaseoloidine, echynosystic type sapogenin, saponin, saponin III, triglycerides, triterpenes and triterpenoids can be found in all parts of *E. rheedii.* Saponins and heterosides can be found in the bark and seed parts. Besides that, *E. rheedii* gives antitumor effects and is toxic to molluscs. This may be due to the presence of saponin that could break the red blood cells and disrupt the haemolysis system in molluscs [11]. Hence, the present study was carried out to evaluate the potential use of *E. rheedii* stem bark extracts on *P. canaliculata.* The information generated from this research could be beneficial for further studies on the specific compounds that lead to the mortality of *P. canaliculata.*

## Materials and Methods

### Plant material

The selection of *E. rheedii* as tested plant in this study was based on the presence of phytochemical constituents such as saponin, which reportedly could lower the surface tension of water and restrict the breathing process of *P. canaliculata*. The plant species *E. rheedii* was collected from Kota Bharu, Kelantan. The effectiveness of the stem bark extract against *P. canaliculata* was assessed to determine the toxicity effects.

### Preparation of *Entada rheedii* stem bark extracts

About 500 mg of *E. rheedii* stem bark was grounded into fine powder and then macerated with 2.3 L of methanol (MeOH) in a 3000-mL beaker at room temperature for 24 hours. The extract was filtered with filter paper, and then concentrated to dryness under reduced pressure in a rotary evaporator. The crude extract was stored in a labelled specimen jar.

**Preparation of treatment concentrations**
Four treatment concentrations consisting of 1000, 5000, 10000 and 20000 ppm were prepared from the crude extract of *E. rheedii* using methanol 50% (v/v) to determine the lethal death at 50% ($LD_{50}$) and lethal death at 90% ($LD_{90}$) values. Paddy-field water with 50% methanol served as the control treatment.

**Sampling of tested golden apple snail**
The golden apple snails with size range of 20 – 40 mm were collected from Pahang Tua Paddy Field in the Integrated Agriculture Development Area (IADA) Pekan, Pahang. The shell height was used for size determination in order to get a uniform size for the toxicity test in laboratory conditions [12]. Tested snails were acclimatized in the laboratory in four different plastic aquariums and fed with papaya leaves for seven days.

**Molluscicidal activity**
The molluscicidal activity was performed using the methods described by Reish and Oshida [13] with some modifications. Each treatment was triplicated. Paddy-field water with pH 6.78 taken from the location of the collected snails was filled in four plastic containers to a depth of seven centimetres measured from the bottom of the container. Ten test snails were placed in the plastic containers and were then covered with netting cloth to prevent them from crawling out during experiments. The test snails were allowed to move freely for about 30 minutes and 100 ml of the treatment concentration were then poured into plastic containers. The mortality of the golden apple snails was assessed every 24 hours of exposure for 3 days. The death of the snails and the toxicity effects were determined by mucus secretion through the operculum gap [5] and the lack of mobility or if the body is retracted well into or hanging out of the shell [14].

**Phytochemical screening**
Phytochemical screening was performed using the methods described by Rauf et al. [15] to determine the presence of glycoside, alkaloids, saponins, tannins, flavanoids and terpenoids.

**Test for glycosides**
The extract was hydrolyzed with hydrochloric acid (HCl) and neutralized with sodium hydroxide (NaOH) solution. A few drops of Fehling's A and B solutions were added and the formation of a red precipitate indicates the presence of glycoside compounds.

**Test for alkaloids**
An amount 0.2g of extract was added with 2% $H_2SO_4$ and warmed for two minutes. The solution was filtered and then added with few drops of Dragendorff's reagent. The appearance of orange red precipitation indicates the presence of alkaloids.

**Test for saponins**
An amount 0.2g of extract was added with 5ml distilled water and heated to boiling point. The appearance of creamy mist with small bubbles indicates the presence of saponins.

**Test for tannins**
A small amount of extract was mixed with distilled water, heated to boiling point on water bath and then filtered. A few drops of ferric chloride were added and the appearance of a dark green colour indicates the presence of tannins.

**Test for flavonoids**
An amount 0.2g of extract was dissolved in diluted NaOH, and added with few drops of HCl. The turn of a yellowish colour to colourless indicated the presence of flavanoids.

**Test for terpenoids**
An amount 0.2g of extract was mixed with 2 mL of chloroform ($CHCl_3$) then 3 mL of concentrated $H_2SO_4$ was added to form a layer. The layer with reddish brown colour shows the presence of terpenoids in extract.

**Statistical analysis**

The mean and standard errors were analyzed using analysis of variance (ANOVA) and Least Significant Difference (LSD) for pairwise comparison to determine the significant differences among each treatment. The concentration that could kill 50% ($LC_{50}$) and 90% ($LC_{90}$) of tested snails were determined from Finney's Table [16].

## Results and Discussion

**Mortality of *P.canaliculata* against *E.rheedii stem* bark methanolic extracts**

The results of the study revealed that no mortality was found in the control treatment of the tested *P. canaliculata* after 72 hours of exposure. (Figure 1). The 100% mortality rate of *P. canaliculata* was observed in 20, 000 ppm MeOH extracts after 48 hours exposure to such conditions. A 100% mortality rate was also recorded in high concentrations of 10, 000 and 20, 000 ppm respectively after 72 hours exposure (Table 1). The response of the snails to the treatments was determined through mucus production (Figure 2). Brain et al. [17] stated that *P. canaliculata* response to the pesticides through secretion of mucus by means to reduce their contact to the molluscicides. In addition, the presence of saponins cause toxicity to snails and affect cell membrane and lower the surface tension.

Table 1. Response of *P. canaliculata* against different concentrations of *E. rheedii* stem bark methanolic extract after 24, 48 and 72 hours

| Treatment Concentration (ppm) | Percentage of Mortality (%) | | |
|---|---|---|---|
| | 24 hours | 48 hours | 72 hours |
| 0(Control) | 0 | 0 | 0 |
| 1000 | 7 | 17 | 27 |
| 5000 | 27 | 87 | 93 |
| 10000 | 40 | 97 | 100 |
| 20000 | 47 | 100 | 100 |

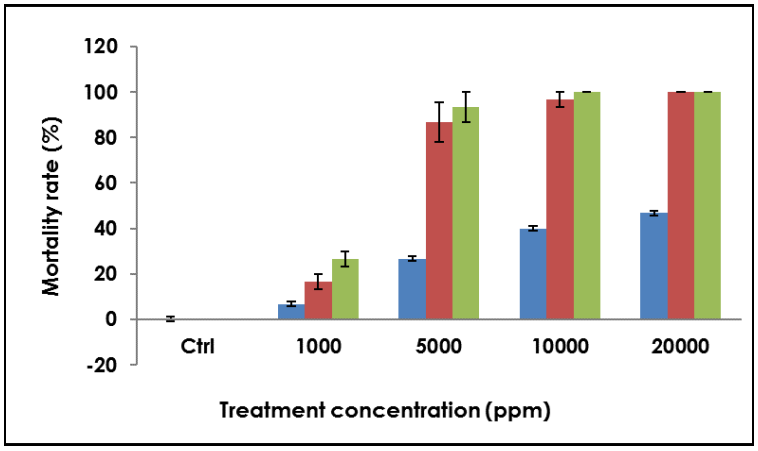

Figure 1. Mortality rate of *P. canaliculata* in control treatment and different concentrations of MeOH

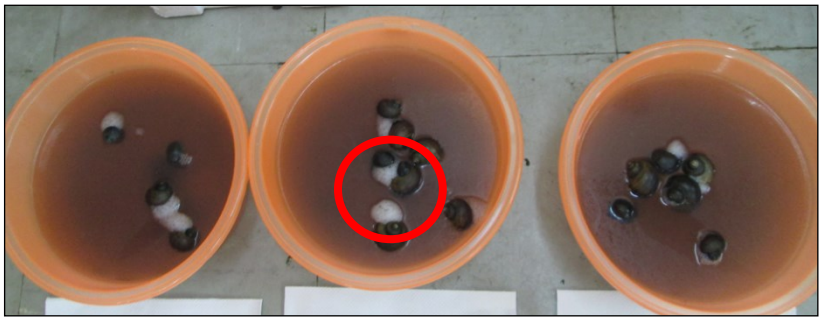

Figure 2. Mucus secretions in *P. canaliculata* during application of *E. rheedii* stem barks extract treatments

Phytochemical screening test (Table 2) showed the presence of bioactive compounds such as alkaloids, flavanoids, glycosides, saponins, tannins and terpenoids in the bark extract of *E. rheedii*. Previous studies reported that flavanoids and saponins both could block the process of breathing probably due to diffusion of oxygen through the gills of the golden apple snails which is then obstructed by the secretion of mucus [5]. Several plants with molluscicidal activity had been identified such as *Chenopodium ambrosioides* and *Ruta chalepensis* with secondary metabolites of flavanoids, triterpenes, saponins, and alkaloids [18]. Based on the probit analysis of $LD_{50}$ and $LD_{90}$, in order to control 50% and 90% of the golden apple snail population, about 1611 ppm and 4266 ppm of *E. rheedii* bark crude extract concentration could be applied respectively.

Table 2. Phytochemical screening test of *E. rheedii* stem bark extract

| **Phytochemical Content** | **Presence of Bioactives Compound in Methanolic Extract** |
|---|---|
| Alkaloids | - |
| Flavonoids | + |
| Glycosides | + |
| Saponins | + |
| Tannins | + |
| Terpenoids | + |

## Conclusion

The results of the study revealed that high concentrations of methanolic bark extracts of *E. rheedii* (10000 ppm and 20000 ppm) are able to kill 100% of tested *P. canaliculata* after 72 hours exposure. Phytochemical screening test also showed the presence of bioactive compounds such as saponins, tannins and terpenoids in the bark extract, which demonstrated the potential use of *E. rheedii* as a new source of green pesticides in controlling the population of golden apple snail in paddy field plantation areas. In addition, it is suggested to test the effectiveness of *E. rheedii* bark extract against juvenile stages of the golden apple snail. However, further studies are needed to develop its potential as green molluscicides.

# THE COMMON PITFALL OF USING ENRICHMENT FACTOR IN ASSESSING SOIL HEAVY METAL POLLUTION

## (Kepincangan Penggunaan Faktor Pengkayaan dalam Menilai Pencemaran Logam Berat di dalam Tanah)

**Abstract**

A soil pollution assessment of heavy metal Zn, Cu, Cr, Cd, Ni and Pb was carried out in Kuala Terengganu, Malaysia. A total of 245 surface soil samples were sampled and have been subjected to a total digestion and analyzed by inductive couple plasma-optical emission spectrometry (ICP-OES). The contamination of the soils was assessed on the basis of enrichment factors (EFs). Large discrepancies in results of enrichment factor associated with the choices of reference elements in the EFs' calculation have been observed. Our study show that the choice of four commonly-used reference elements (Al, Fe, Ca and Mn) in enrichment calculation could easily alter the enrichment factor values of element of interest by more than 4-folds although the results were supposed to be similar regardless of which reference elements being used. This could lead to serious misinterpretation of soil quality assessment result.

**Keywords**: soil quality assessment, Malaysia soil, elemental analysis, acid digestion

**Abstrak**

Satu penilaian pencemaran logam berat Zn, Cu, Cr, Cd, Ni dan Pb dalam tanah telah dijalankan di Kuala Terengganu, Malaysia. Sebanyak 245 sampel tanah telah diambil, diproses berdasarkan kaedah penghadaman asid dan kepekatan logam berat telah dianalisa dengan menggunakan spektrofotometer pancaran plasma gandingan aruhan (ICP-OES). Pencemaran tanah telah dinilai menggunakan pendekatan faktor pengkayaan. Kajian ini menunjukan nilai-nilai faktor pengkayaan boleh berbeza dengan ketara apabila pengiraan faktor pengkayaan dirujukkan kepada elemen rujukan yang berbeza. Kajian kami mendapati nilai-nilai faktor pengkayaan boleh berbeza sebanyak empat kali ganda apabila pengiraan faktor pengkayaan merujuk kepada Al, Fe, Ca dan Mn dan perbezaan nilai-nilai faktor pengkayaan boleh membawa wujudnya kesilapan dalam mentafsir kualiti tanah yang dikaji.

**Kata kunci**: kajian kualiti tanah, tanah Malaysia, analisa unsur, penghadaman asid

## Introduction

Heavy metals like Cd, Pb, Zn, Cu, Cr and Ni in soil have received wide attention due to their potential toxic impact on the environment if present in excessive concentrations. It is critically important to carry out soil quality monitoring program on a regular basis, particularly in urban watershed to support sustainable planning and development for better livelihood. There are three common approaches of assessing soil quality: (1) take measurements periodically over the time to monitor changes or trends in soil quality; (2) compare measured values to a standard or reference soil condition (i.e. Netherlands' Dutch Target, Australia's Soil Investigation Level,

USEPA Ecological Screening Levels, British Soil Guideline and Japanese Environmental Quality Standards). The former method is commonly used by stakeholders to identify areas where problems occur, to identify areas of special interest, or to compare fields under different management systems over time and latter generally adopted by law enforcement authorities for soil pollution control and mitigation. Finally, the third approach is based on calculation of enrichment factors (EFs) to evaluate anthropogenic influences on soil quality.

Enrichment factor is an index used as a proxy to assess the heavy metals contamination level in soil by estimating the differential of heavy metal concentrations against uncontaminated background or reference levels [1,2]. An enrichment factor can be defined as in equation 1:

$$\mathrm{EF}_i = \frac{(\mathrm{y/x})_{\mathrm{sample}}}{(\mathrm{y/x})_{\mathrm{background}}} \quad (2)$$

where, $y$ is concentration of target metal, $x$ is concentration of reference element or normalizer in soil and in background or baseline reference material. In soil quality study, the interpretation of enrichment factor is based on the deviation of the ratio between a metal of interest and a reference element that exhibit conservative and immobile behavior in environment in a sample to the equivalent ratio in a reference material from unity (Efs = 1). Enrichment factor equal to one is generally taken to mean that there has been no net gain or loss of a metal in the sampled soil respective to the reference material. Enrichment factor ratio should increase (Efs > 1) if there has been a net gain of metal concentration due to extra input (e.g. anthropogenic sources), and a net loss of metal concentration in the system (e.g. due to weathering, biological assimilation) should decrease the ratio value (Efs < 1).

Enrichment factor is practice widely in environmental studies. Nevertheless, the assumption of enrichment factor as pollution detection tool inherits many theoretical shortcomings [3,4]. The work done by Reimann and de Caritat [3,4] concluded that EFs calculation is strongly influenced by the natural variable composition of the reference material, biogeochemical processes and physico-chemical alteration of elements in crust materials. The authors regarded using EFs to interpret pollution event in any environmental sudies as doubtful. The primary objective of this study is to determine the metal concentrations in soil of Kuala Terengganu. Fortuitously, this study will allow to test the reliability of enrichment factor as a pollution proxy for soil quality assessment.

## Materials and Methods

### Soil sampling

The soil quality assessment was carried out in Kuala Terengganu district, Malaysia (5.33°N, 103.1°E, Figure 1). Sampling of soil had been accomplished on 245 cells of 1 km x 1 km square grid using the topographic maps. About 1 kg of soil sample was collected from the first 10-15cm of the upper soil horizon using a plastic spade at each grid. The collected samples were air-dried, ground, and passed through sieve of a 0.6 mm mesh size for subsequent acid digestion.

### Soil digestion and chemical analysis

All soil digestion and element analysis was performed in analytical chemistry laboratory of Universiti Malaysia Terengganu (UMT). All apparatus used in this experiment were acid-cleaned with 10% $HNO_3$. The soil digestion procedure for heavy metal analysis was carried out using USEPA method 3052. In general, an acid mixture of $HNO_3$:HCl:HF (9:4:1) ml ratio was added to 0.5 g of soil sample inside a Teflon vessel. Later, digestions of soils were performed in a microwave-heated oven (Ethos Plus Milestone, USA) at 210 °C for 20 minutes. After digestion, small amount of saturated $H_3BO_3$ acid was added into solution to neutralize remaining active HF in solution. The digested solution then makes up to 25 ml of final volume with ultrapure deionized water. A complete digested soil sample will normally yield a clear solution. Quality control and quality assurance also carried out by using two standard reference materials *SRM-2709* and *SRM-2711* obtained from the National Institute of Standards and Technology (NIST, USA). The SRMs were subjected to similar sample treatment procedures as described above. All samples and SRMs were analyzed for Al, Fe, Mn, Ca, Zn, Cu, Cr, Cd, Ni and Pb by inductive couple plasma optical emission spectrometer (Varian Vista Pro, Australia). SRMs recovery result shows that the analytical accuracy for all measured metals in SRM (n = 12) was within 5-15% error for all metals, expect for Cr which was 10-25% error.

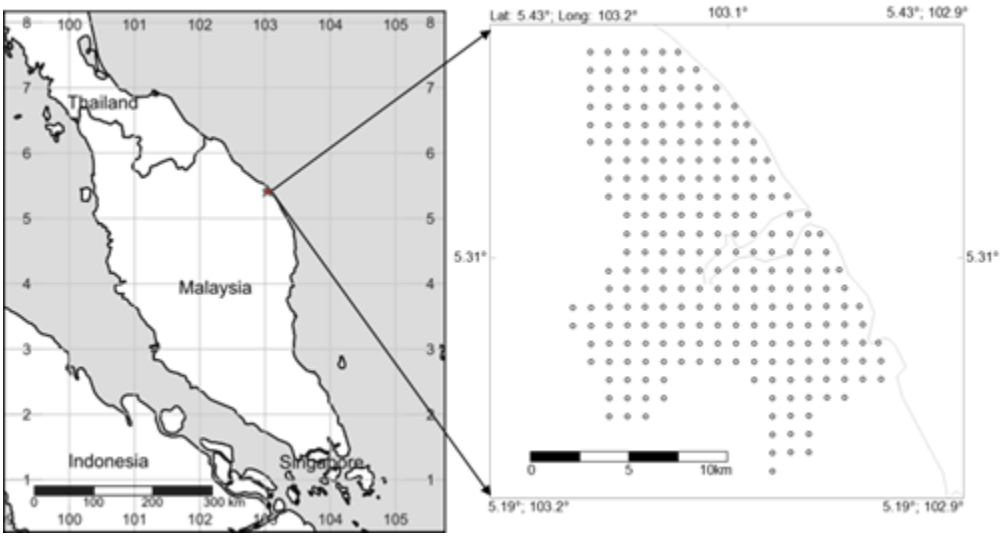

Figure 1. The sampling site in Kuala Terengganu district

**Enrichment factor calculation and geochemical mapping**

The calculation of a normalized enrichment factor for a given metal for this study is represented by equation 1. Where, $EF_i$ is the enrichment factor of target metal *i*, $(y/x)_{sample}$ is the target metal to reference (conservative) element' ratio in the samples of interest; while $(y/x)_{background}$ is the target metal to reference metal ratio in world soil baseline reference taken from Ure and Berrow [5].

## Results and Discussion

**Heavy metals concentration in Kuala Terengganu soil**

The concentration range of metals in Kuala Terengganu soils and their mean values are given in Table 1. The mean concentration values of all metals, except Cd in surface soil of Kuala Terengganu were lower than those reported in worldwide average values [5].

Level of Al (0.45%), Ca (0.14%), Mn (82.9 mg/kg) in the soil samples studied was found much lower (10 fold) than those reported by Ure and Berrow [5] for world average values 6.65%, 1.96% and 760 mg/kg, respectively. The studied soil samples were relatively poor in Fe, Cu, Cr, Zn and Ni. The mean values of these metals were lower than those reported by Zarcinas et al. [7] for Malaysian agricultural soils (Table 2) and for world average value [5]. Level of Pb (23.6 mg/kg) detected in the soil samples were similar to those found in Zarcinas et al. [7] (26.4 mg/kg) and worldwide average value (29.2 mg/kg). Conversely, the content of Cd in studied soil ranged between 0.38 and 6.78 mg/kg with the median concentration of 1.28 mg/kg and was found to be two times greater than the mean concentration of world average (0.62 mg/kg).

The *Baging, Rhutapai, Rusila* and *Rudua* soil series associated to BRIS (Beach Ridges Interspersed with Swales) were reported as dominant soils in these areas [6]. The low heavy metal concentrations in Kuala Terengganu soil indicates the sampled soils are mainly originated from highly weathered BRIS soils. The decreasing order of concentration on the different metals Fe>Al>Ca>Mn>Zn>Pb>Cr>Cu>Ni>Cd reflects their abundance in BRIS soil are associated with low cation exchange capacity, low organic matter content, and excessively-drained sandy soil properties promote leaching losses.

Table 1. The range, median, mean of selected metals in surface soil of Kuala Terengganu (in mg $kg^{-1}$, n=245)

| Metal | Range | Median | Mean | Worldwide Average [5] |
|---|---|---|---|---|
| Al* | 0.14-1.44 | 0.42 | 0.45 | 6.65 |
| Fe* | 0.22-7.70 | 1.54 | 1.57 | 3.20 |
| Mn | 2.53-356 | 51.3 | 82.9 | 760 |
| Ca* | 0.01-1.17 | 0.08 | 0.14 | 1.96 |
| Zn | 4.61-204 | 31.4 | 38.3 | 59.8 |
| Cu | 0.82-148 | 9.39 | 10.9 | 25.8 |
| Cr | 3.05-50.1 | 21.6 | 20.5 | 84.0 |
| Cd | 0.38-6.78 | 1.21 | 1.28 | 0.62 |
| Ni | 1.91-16.7 | 7.18 | 7.02 | 33.7 |
| Pb | 2.54-160 | 21.9 | 23.6 | 29.2 |

*values reported in weight percent, wt.%

**Soil pollution assessment of heavy metals using enrichment factor**

To allow quantitative comparisons between degrees of metals enrichment in the soil pollution assessment, Sutherland [8] and Loska et al [9] had distinguished five contamination categories of the enrichment factor. An EF < 2 is deficiency of minimal enrichment, suggestive of no or minimal pollution; EF 2 - 5 is moderate enrichment; EF 5 - 20 is significant enrichment; EF 20 - 40 is very high enrichment and EF > 40 is extremely high enrichment, indicating an extreme pollution signal. Several elements are utilized as normalizer in enrichment factor, in particular element that have been associated with rock-forming minerals (see summary in Table 2).

Table 2. Selection and justification of reference element for enrichment factor calculation in relation to assess anthropogenic impact

| Normalizer | Justification | Reference |
|---|---|---|
| Al | Al has no significant anthropogenic input compared to the large of geogenic element; Ion potential of Al is close to target elements, reduce variation in comparison | [10] |
| Mn | Mn is one of largest components of soil | [11] |
| Fe | Fe is abundant in soils; considered to be free from anthropogenic contribution | [1, 12] |
| Ca | Ca is one of the main components of the Earth's Crust, concentration in soil is connected with the matrix, lower mining interference factor (MIF) compared to Al and Zr | [9] |
| Zr | Zr has no significant anthropogenic source and resides primarily in the weathering-resistant heavy mineral Zircon | [13] |
| Sc | Sc is stable to supergene processes associated with oxidation and chemical weathering | [14] |
| Sr | Sr is one of the main components of the Earth's Crust, concentration in soil is connected with the matrix | [15] |
| Ti | Ti is a common rock-forming element and very resistant to weathering in the soil. | [16] |

The scatter plot in Figure 2 illustrates a comparison study of selected elements EF against different normalizers (Fe, Al, Ca and Mn) and the obtained results showed that EF values of metal were different corresponding to the

normalizers used. For better interpretation, four different colour lines representing the contamination categories scale suggested by Sutherland [8] and Loska et al. [9] were plotted (Figure 2). For example, if a sample fall within green and yellow line, then the sample was classified as being moderate enriched (EF = 2-5). If it falls between the yellow and orange line, then the sample was classified as significant enrichment (EF = 5-20). If a sample surpassed the orange line but was within the red line, then the sample was classified as being very highly enriched (EF = 20-40). Samples with the enrichment factor greater than 40 that were found to have surpassed the red line were classified as samples with severe pollution. If samples fall below green line (EF < 2), then samples were classified as depletion to minimal enrichment suggestive of no or minimal pollution.

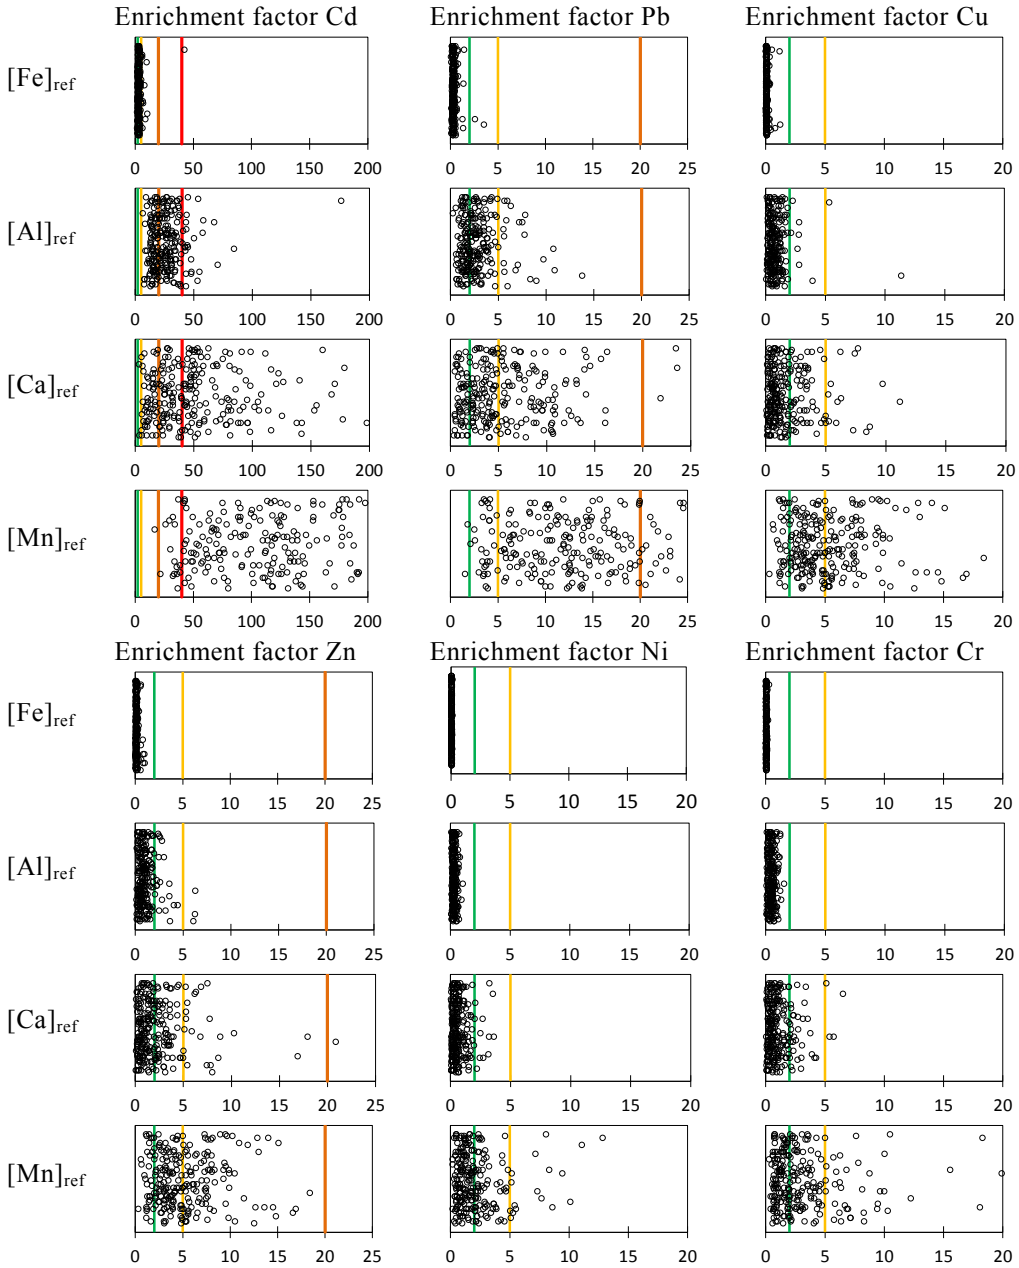

Figure 2. Comparison of enrichment factor for target metals using different notmaliser; green, yellow, orange and red colour lines representing contamination categoresis scale proposed by Loska et al. [9] and Sutherland [8]

Theoretically, the selection of reference element used in EFs calculation should hardly be affected by weathering processes and should show little variability of occurrence [3]. If different reference elements are selected to calculate EFs, they should all show similar pollution signals regardless of which normalizers were being used. In this study, however, all four sets of EFs calculation (refer Figure 2) bear no relationship to each other.

Figure 2 show EFs values for all metals derived from all four normalizers differ in the range from 1 to 4-folds. EFs derived from Ca and Mn normalizer generally had overestimated amount compared to Al and Fe. We found that 93% and 6% of the Cd samples were classified as extremely high polluted and very high polluted respectively when Mn was used as reference element. These outcomes are very different to the other reference elements, in particular to Fe normalizer. For Fe reference-EFs, 95% of Cd samples were classified as moderate enriched or lower. Al and Ca normalizer also produced a wide range of EFs for Cd samples and these values ranged between Fe and Mn references derived EFs. These discrepancies reflect that EFs do not provide a simple technique to differentiate particular suite of metals was whether of anthropogenic origin or vice versa.

The color contour maps of Pb concentration and EFs in Figure 3 were created using the inverse distance weighting (IDW) spatial interpolation technique in ESRI ArcMap 9.2. In Figure 3, the Pb hotspots in Kuala Terengganu soils are marked in red colors. The Pb concentration for Kuala Terengganu soils were also compared to Dutch environmental pollutant reference values, also known as "Dutch target" used in environmental remediation, investigation and cleanup purposes. For Kuala Terengganu, three out of 245 samples had exceeded the Dutch recommendation value of 85 mg/kg. The spatial variations for each metal for Kuala Terengganu soil in this study can be found in Poh [17].

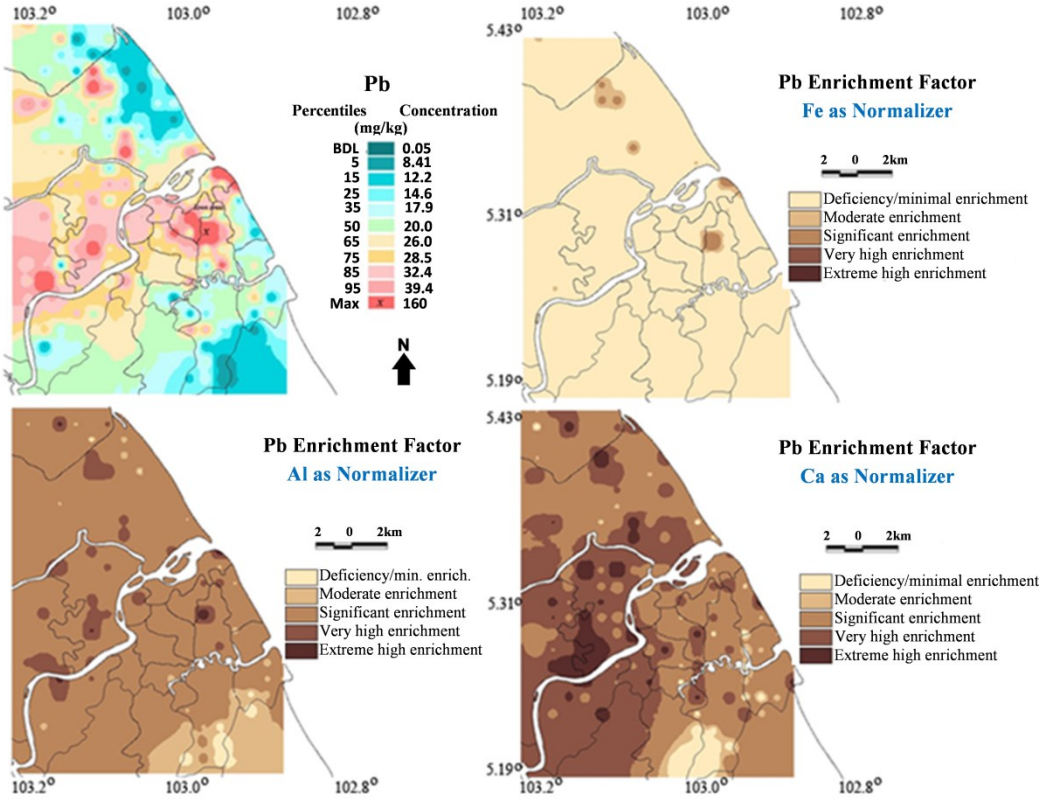

Figure 3. Comparison of the calculated EFs for Pb in Kuala Terengganu soils

Three striking features of the EFs pattern of Pb are evident in Figure 3. First, the EFs for Pb show great spatial variation compared to Pb distribution pattern in Kuala Terengganu soil. Second, this variation is multidimensional; that is three different set of reference element show mainly independent of EFs variation. For example, when EFs was calculated relative to the Pb/Al ratio, the pattern of high Pb enrichment was recorded at the same areas in the Pb concentration map. However, when the EFs Pb/Fe ratio distribution was compared to Pb concentration map, it turns out, several high enrichment values near the central part of the map disappeared. Furthermore, when EFs Pb/Ca ratio distribution was compared, the high anomaly near to river mouth was no longer present in the map. Meanwhile, an unexpected extremely high EFs had appeared scattered in the central part of the map. Third, these EFs patterns have a pervasive missed-interpretation of pollution signal. In this case, EFs Pb/Al ratio distribution showed 50% of Kuala Terengganu soils were significantly enriched by Pb but EFs Pb/Fe ratio distribution, on the other hand illustrated that 99% of areas were still less contaminated by Pb. The results could overestimate, underestimate, or simply incorrectly estimate the environmental pollution.

The potential sources of errors for EFs technique mentioned above can be explained in a number of ways. First, a huge natural variation in concentration of the different elements in reference materials (i.e. continental crust value, world soil average) exist and using single mean value from a skewed distribution dataset (i.e. Ure and Berrow [5]) does not permit a reasonable EFs assessment. Ure and Berrow [5] reported Pb concentration in world soil is ranges from 1 – 888 mg/kg with average value of 29.2 mg/kg, obviously the given mean value does not reflect the true average Pb concentration for world average soil. This is one of a very good example to show that using the mean world soil value as a proxy of "natural background values" in enrichment factor inherent a serious flaw to estimate pollution signal in environment.

Second, an inhomogeneous distribution of reference elements in the study area could also lead to misinterpretation in EFs. Overestimation of EFs occurs when the chosen reference elements (normalizer) showed a natural spatial variation that was as large as, or larger than, that of the target metal of interest [4]. In this study, we used quartile coefficient of dispersion (cqv) statistical analysis to compare the dispersion of the maximum concentration differences between Pb and other reference elements. The calculated cqv for Ca, Fe and Al against Pb was 2.2, 1.1 and 0.7 respectively, indicated that the natural spatial variation of Ca was found 2 times greater than Pb. We found that the large dispersion of Ca concentration has attributed greater EFs value of Pb in Kuala Terengganu and the Pb/Ca ratio EFs was found greater than Pb/Al and Pb/Fe ratio EFs by order of two magnitudes (Figure 3).

The large discrepancies in EFs value could be due to two other factors: (i) the differential solubility of refractory minerals in acid digestion protocols as well as grain size fractionation effect resulted different concentration of metal elements in Earth materials and; (ii) the significance of biogeochemical and weathering processes that control element concentration in Earth surface are not considered in EFs assessment on pollution studies. Reimann and de Caritat [3,4] and Desaules [18] have provide a detailed explanation and references in conceptual shortcomings of EFs in environmental studies.

## Conclusion

Our work demonstrated that application of enrichment factor in the assessment of soil pollution level in Kuala Terengganu inherent a major weakness. One unanticipated finding was that the choice of four commonly-used reference elements (Al, Fe, Ca and Mn) for enrichment calculation could easily alter the enrichment factor values of Pb by more than 4-folds although the results were supposed to be similar regardless of which reference elements being used. This bias can be attributed to the absent of a reliable "natural background value" or references. Another shortcoming of EFs approach in assessing the level of anthropogenic sources to environment is EFs did not take into account the natural variation of element concentration in environmental samples in relation to biogeochemical and localized lithogenic processes as mentioned in Reimann and de Caritat [3,4] and Desaules [18]. Therefore, application of enrichment factor as a way to fingerprint the anthropogenic source of heavy metals in soils requires extra caution in future study.

**Abstract**

Derivatives of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea were successfully synthesized from the reaction of 1,10-phenanthroline with *x*-bromobenzoylisothiocyanate (*x* = *ortho*, *meta* and *para*) to give phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT, respectively. The molecular structures of the derivatives compounds were elucidated based on the crystal structure of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea, CHNS elemental analysis, mass spectrometry, spectroscopic data (infrared, ultraviolet-visible, nuclear magnetic resonance and luminescence) and cyclic voltammetry.The mass spectrum show similar *m/z* values at 460.9 and 260.0, which represent the molecular ions for $[(\text{phen-}x\text{-BrBT})\text{-Na}]^+$ and $[\text{BrBT}]^+$, respectively. The presence of a $\nu$(NH) (3389-3599 $cm^{-1}$) and the disappearance of $\nu(NH_2)$ bands from 1,10-phenanthroline-5-amine indicate the formation of the *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea. Attachment of a Br atom to the benzoyl moiety reduced the stretching frequency of C=O group by >20 $cm^{-1}$ compared with phen-BT ligand. The compounds exhibit two $\pi\rightarrow\pi^*$ bands at 231 and 269-270 nm for the phenanthroline and benzoyl moieties, respectively. The resonance for N-H proton appeared at $\delta$ = 11.53-12.49 ppm. In addition, $^{13}C$ resonance signals for C=S and C=O groups were recorded at around 182 and 167.39-169.08 ppm, respectively. The synthesis and effect of a Br substitution on the structural and luminescence properties of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives are presented and discussed in this study.

**Keywords**: benzoylthiourea, 1,10-phenanthroline, thiocyanate, infrared, luminescence

**Abstrak**

Terbitan *N*-bromobenzoil-*N*'-(1,10-fenantrolin-5-il)tiourea telah disintesis melalui tindak balas di antara 1,10-fenantrolina dengan *x*-bromobenzoilisotiosianat (*x* = *orto*, *meta* and *para*) masing-masing menghasilkan sebatian phen-*o*-BrBT, phen-*m*-BrBT dan phen-*p*-BrBT. Struktur sebatian ditentukan berdasarkan struktur kristal *N*-benzoil-*N*'-(1,10-fenantrolin-5-il)tiourea, analisis unsur CHNS, spektrometri jisim, data spektroskopi (inframerah, ultralembayung-boleh nampak, pendarcahaya dan resonans magnetik nuklear) dan voltammetri kitaran. Spektrum jisim bagi ketiga-tiga sebatian ini menunjukkan nilai *m/z* yang sama pada 460.9 dan 260.0 masing-masing mewakili ion molekul $[(\text{phen-}x\text{-BrBT})\text{-Na}]^+$ dan $[\text{BrBT}]^+$. Kemunculan isyarat $\nu$(NH) pada 3389-3599 $cm^{-1}$ dan kehilangan frekuensi regangan $\nu(NH_2)$ bagi sebatian 1,10-fenantrolin-5-amina menunjukkan pembentukan molekul *N*-bromobenzoil-*N*'-(1,10-fenantrolin-5-il)tiourea. Kehadiran atom bromo pada gelang benzoil telah merendahkan frekuensi regangan $\nu$(CO) sebanyak >20 $cm^{-1}$ berbanding *N*-bromobenzoil-*N*'-(1,10-fenantrolin-5-il)tiourea. Spektrum elektronik sebatian memapar dua jalur serapan bagi peralihan $\pi\rightarrow\pi^*$ pada 231 dan 269-270 nm masing-masing berpunca daripada moieti fenantrolina dan benzoil. Isyarat resonan $^1H$ (N-H) hadir pada $\delta$ = 11.53-12.49 ppm manakala, isyarat $^{13}C$ bagi kumpulan berfungsi utama C=S dan C=O telah dikenal pasti masing-masing pada 182 dan 167.39-169.08 ppm. Sintesis dan kesan

kehadiran Br pada posisi *orto*, *meta* dan *para* terhadap struktur serta sifat pendarcahaya sebatian dilapor dan dibincang di dalam kajian ini.

**Kata kunci:** benzoilthiourea, 1,10-fenantrolina, tiosianat, inframerah, pendarcahaya

## Introduction

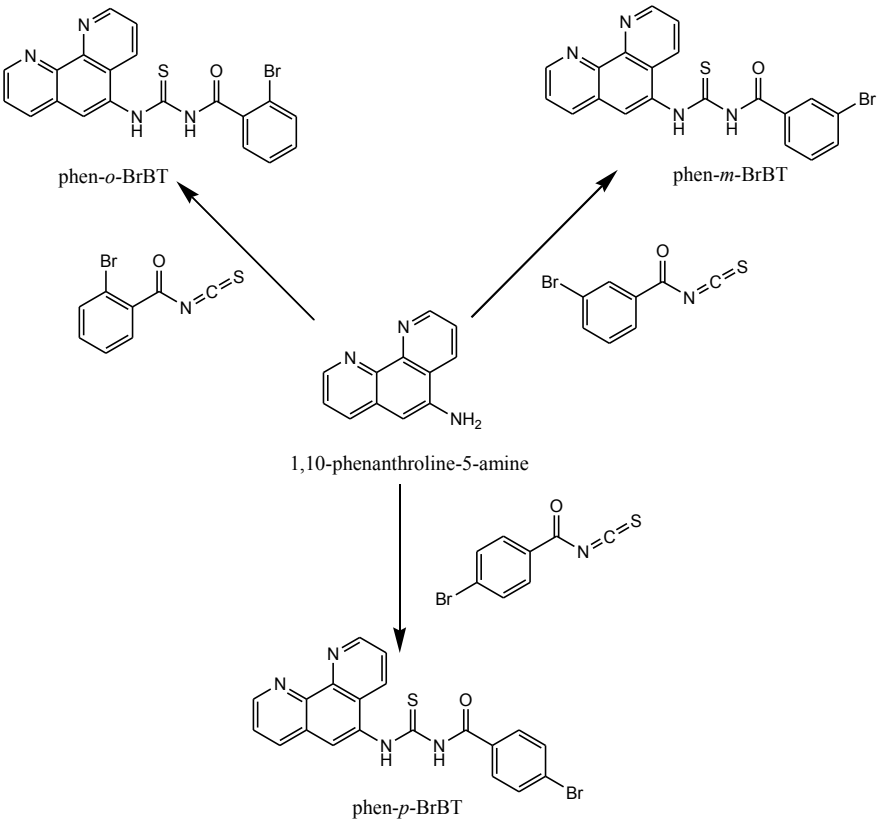
Polypyridine compounds such as 1,10-phenanthroline (phen) are one of the most widely used chelating ligands in modern coordination chemistry [1,2]. The shape of the phen favors the formation of metal complexes via chelation and hence, phen and its derivatives are widely used ligands in metal complexes. The metal complexes of phen derivatives have many applications in various fields such as molecular catalysis, solar energy conversion, herbicides and nucleic acid probes. Besides, metal-phen compound has also been used in the development of luminescence-based sensors for pH, anions and cations [3].

Thiourea compounds are essential as building blocks in the synthesis of heterocyclic compounds [4]. Substituted thioureas have gained great attention in the preparation of wide variety of biologically active compounds [5,6]. Thioureas are also an important class of organic compounds, which showed high biological activity, used as corrosion inhibitors and antioxidant, and were also widely used as polymer components [7]. The synthesis of thiourea derivatives can be easily done with a good yield [8]. One of the thiourea derivatives that have gained a lot of attention is benzoylthiourea, which has shown a wide range of biological activities including antiviral [9], antibacterial [10,11], antifungal [12], herbicidal [13] and acting as chelating agents [14,15].

Phenanthroline derivatives and bromobenzoylthiourea compounds are widely used chelating agents in the coordination chemistry [1,4]. This study attempts to combine both classes of the compounds to form a multi-dentate benzoylthiourea ligand that contains both moieties. Subsequently, this new multi-dentate chelating ligand can be used to form stable complexes with metal ions. The derivatives of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea compounds are expected to be a more effective class of the organic compounds to coordinate with metal ions due to the presence of lone pair electrons on nitrogen, sulphur and oxygen atoms. In addition, the $\pi$-electron cloud in the phen and benzoylthiourea moieties will also add to the stability of the coordination complexes through delocalization of electrons across the coordination sphere.

In this paper, we present the synthetic method, structural and electronic properties of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives. In addition we also discussed the effects of the Br substitution on the structural and luminescence properties of the compounds.

## Materials and Methods



### Chemicals and instrumentation

Benzoyl chloride, 1,10-phenanthroline-5-amine, *o*-bromobenzoyl chloride, *m*-bromobenzoyl chloride and *p*-bromobenzoyl chloride were purchased from Fluka (Malaysia). All solvents were of reagent grade quality and were obtained from commercial suppliers and used without further purification.

Melting points were determined on an Electrothermal 9100. Elemental (C, H, N and S) analyses were performed on Leco 932 analyzer. The mass spectra were recorded on a Bruker micrOTOF-Q 86 spectrometer equipped with an electrospray ionization (ESI) module. The source temperature was maintained at 180 ˚C at an approximately 0.4 bar pressure. Infrared measurements of the complexes were recorded by using Agilent Cary 630 spectrophotometer in the range of 4000-400 $cm^{-1}$ in the ATR Diamond mode, whereas the UV-Vis absorption spectra were obtained by using a 1 cm path length quartz cell on a Perkin-Elmer Lambda 35 spectrometer. The $^{1}H$ NMR and $^{13}C$ NMR spectra were collected on a ECP 400 (Delta-NMR) spectrophotometer as deuterated DMSO solution. The chemical shifts were scaled to parts per million (ppm) with reference to TMS. The electrochemical measurements were carried out with a Voltalab PGZ402, AmetekVersastat 4 system. Steady state emission spectra were recorded on an Edinburgh FLS920 time resolved fluorescence spectrometer at 298 K in $CH_3CN$, using 1 cm path length quartz cell.

**Synthesis of *N*-(x-bromobenzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea**

Firstly, *ortho*-, *meta*- and *para*-bromobenzoyl chloride derivatives (1.5 mmol) were reacted with ammonium thiocyanate (1.15 mmol) in acetone (30 ml) to give the corresponding bromobenzoylisothiocyanate derivatives followed by a condensation with 1,10-phenanthroline-5-amine in ethanol (20 ml) to give *o*-bromobenzoyl-(1,10-phenanthrolin-5-yl)thiourea [phen-*o*-BrBT], *m*-bromobenzoyl-(1,10-phenanthrolin-5-yl)thiourea [phen-*m*-BrBT] and *p*-bromobenzoyl-(1,10-phenanthrolin-5-yl)thiourea [phen-*p*-BrBT] compounds, respectively (Scheme 1). The reaction mixtures were left to stir for 5 hours at 80˚C. The products were collected as yellow precipitates and the solvents were removed under reduced pressure. The precipitates were then rinsed with cold acetone to give the desired products. Recrystallization in a suitable solvent gave a pure yellowish crystalline product.

Scheme 1. Schematic diagram for the synthesis of *N*-(*x*-bromobenzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives from *x*-bromobenzoylisothiocyanate and 1,10-phenanthroline-5-amine

## Results and Discussion

The phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds were characterized on the basis of the mass spectrometry, CHNS elemental analysis and the spectroscopic data from infrared, ultraviolet-visible, nuclear magnetic resonance ($^{1}$H and $^{13}$C) spectroscopy. Besides, the cyclic voltammetry and luminescence properties of these compounds also were recorded to provide more information on the electronic states and structures. Overall, the reactions gave a reasonable to good yield (58-68%) as summarized in Table 1.

Table 1. The yield and melting point of *N*-(bromobenzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives

| Compound | Yield (%) | Melting point (°C) |
|---|---|---|
| phen-BT | 65.0 | - |
| phen-*o*-BrBT | 63.5 | 197.5 – 198.3 |
| phen-*m*-BrBT | 57.9 | 146.3 – 151.3 |
| phen-*p*-BrBT | 68.0 | 175.2 – 176.5 |

**Elemental analysis of C, H, N and S**

There was some deviation from the theoretical value for C, H, N and S contents in the phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds. These differences are within the experimental errors and may be due to a contamination from the recrystallization solvent and atmospheric water. This is not uncommon as the solvent is quite polar and the compound contains Br atom that can also induce polarity in the molecule. We proposed a new chemical formula for each compound taking into consideration that the samples might be contaminated as shown in Table 2. The calculation revealed that the highest deviation (0.86) was for carbon content in the phen-*p*-BrBT sample.

Table 2. The elemental CHNS contents in phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT and the proposed new chemical formula to account for an acetone and water content

| Compound | Experiment (theory), % | | | | Proposed Chemical Formula | Largest Deviation (Element) |
|---|---|---|---|---|---|---|
| | C | H | N | S | | |
| phen-BT | 66.61 (67.02) | 4.83 (3.94) | 15.78 (15.63) | 8.73 (8.95) | $C_{20}H_{14}N_4OS \cdot 0.2H_2O \cdot 0.15C_3H_6O$ | 0.67 (H) |
| phen-*o*-BrBT | 53.54 (54.93) | 4.47 (3.00) | 11.72 (12.81) | 7.22 (7.33) | $C_{20}H_{13}BrN_4OS \cdot 1.1H2O \cdot 0.55 C_3H_6O$ | 0.66 (H) |
| phen-*m*-BrBT | 53.59 (54.93) | 4.12 (3.00) | 12.03 (12.81) | 7.17 (7.33) | $C_{20}H_{13}BrN_4OS \cdot 0.95H_2O \cdot 0.4C_3H_6O$ | 0.47 (H) |
| phen-*p*-BrBT | 56.55 (54.93) | 4.05 (3.00) | 12.14 (12.81) | 7.37 (7.33) | $C_{20}H_{13}BrN_4OS \cdot 0.9C_3H_6O$ | 0.86 (C) |

**Mass spectrometry**

The electron impact mass-spectrum of a representative compound namely phen-*p*-BrBT (Figure 1) shows the corresponding *m/z* value of the parent molecule with one mole of associated sodium ion, [phen-*x*-BrBT)-Na]$^+$ at 460.9 (459.0 *theory*). A fragmentation with *m/z* value corresponding to [BrBT]$^+$ was observed at 260.0 (258.9 *theory*). Similarly, the mass spectrum and the fragmentation masses of other derivatives agreed with the structures as shown in Figure 1.

**X-ray crystal structures**

The structure of *N*-(benzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea [phen-BT] [16] (Figure 2) was used as a reference to provide additional information in the determination of the molecular structure of the bromo-substituted analogues.

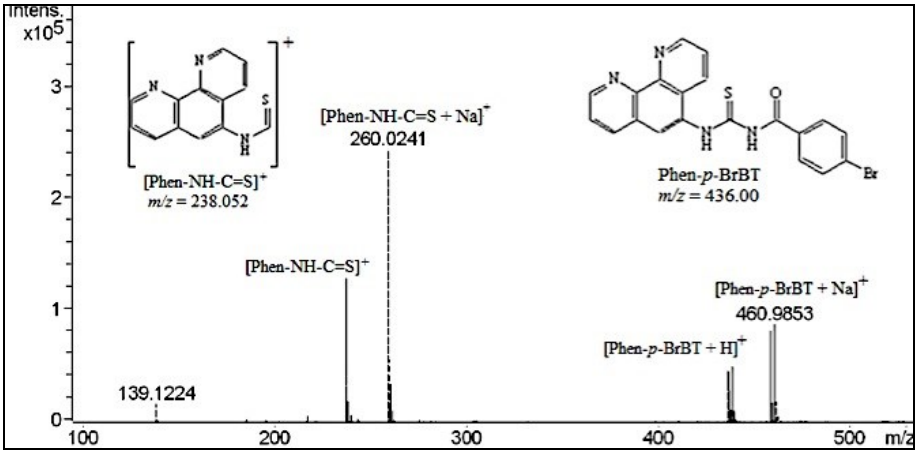


Figure 1. The mass-spectrum showing the molecular ion of phen-*p*-BrBT and its fragmentations as a representative compound.

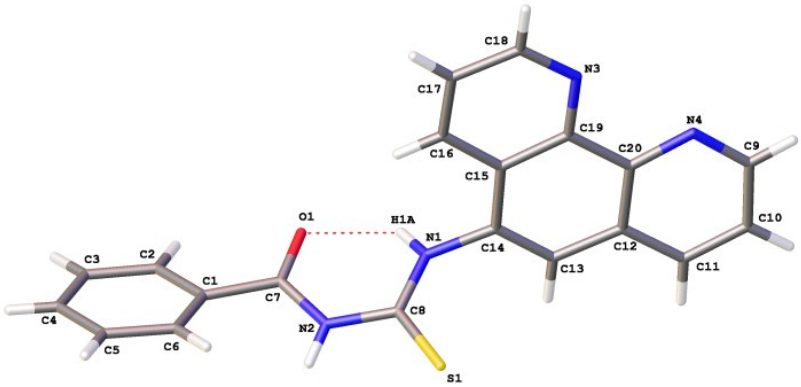

Figure 2. The molecular structure of the phen-BT with a dashed line indicates the intramolecular hydrogen bond that forms a pseudo-six membered ring

In the structure of phen-BT, the benzoyl and 1,10-phenanthroline moieties were attached to the terminal nitrogen atoms of the thiourea moiety at *cisoid* and *transoid* position relative to the thiono N2—C8 and N1—C8 bonds. The phenyl and phenanthroline rings are twisted relative to the central thiourea fragment with dihedral angles of 29.46(12)˚ and 74.06(8)˚, respectively. The phenyl and phenanthroline rings are almost perpendicular to each other with dihedral angle of 83.15(10)˚.

The S1—C8 and O1—C7 in the compound showed a typical double bond character with bond lengths of 1.651(2) and 1.222(3) Å respectively, and are comparable to other thiourea derivatives [17,18]. All C-N bonds (N2—C7, N2—C8, N1—C8 and N2—C14) in the thiourea fragments were in the range of 1.431(3) to 1.329(3) Å, which are an intermediate distance between those expected for single and double CN bonds (1.47 and 1.27 Å, respectively). Among these CN bonds, we noticed that N2—C14 was the longest bond, which indicated a $C_{sp}^{2}$-$N_{sp}^{2}$ single bond while N1—C8 bond was the shortest bond with more double bond character.

In the crystal structure of phen-BT compound, there was an intramolecular hydrogen bond, N1—H1A···O1 resulting in the formation of a pseudo six-membered ring (N1/H1A/O1/C7/N2/C8) in the molecule. The present of the

intramolecular hydrogen bond may contributed to the shift in the infrared signal of the C=O group and to a lesser extend to the $^{1}H$ and $^{13}C$ signals of the compounds since the spectrum were collected in a solution phase.

**Infrared spectra**

The infrared spectrum of phen-BT is shown in Figure 3 and the characteristic functional groups are listed in Table 3. Generally, the IR spectrum of 1,10-phenanthroline moiety shows strong bands in the 1400-1650 $cm^{-1}$ regions [19]. A band at around 1420 $cm^{-1}$ exhibits the stretching frequency of $\nu(C\text{-}N_{phen})$, which indicates a highly delocalized electronic distribution in the thiourea moiety.

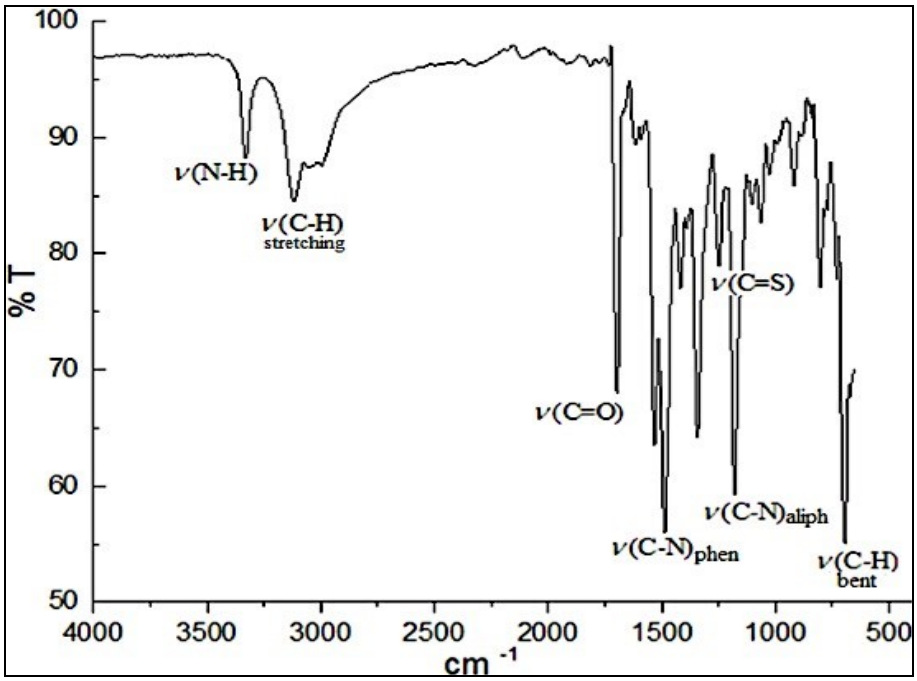

Figure 3. The infrared spectrum of phen-BT

Table 3. The stretching frequencies of characteristic functional groups for phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds

| Compound | IR spectrum ($cm^{-1}$) | | | |
|---|---|---|---|---|
| | $\nu$(NH) | $\nu(C\text{-}N_{phen})$ | $\nu$(C=O) | $\nu$(C=S) |
| phen-BT | 3332 | 1420 | 1700 | 1254 |
| phen-*o*-BrBT | 3513 | 1422 | 1672 | 1258 |
| phen-*m*-BrBT | 3513 | 1422 | 1673 | 1251 |
| phen-*p*-BrBT | 3596 | 1420 | 1676 | 1259 |

It is important to note the disappearance of $\nu(NH_2)$ stretching frequency of the amine group and the appearance of $\nu$(NH) stretching band at 3332, 3513, 3513 and 3596 $cm^{-1}$ in the spectra of phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT, respectively. The later band is an important indicator for the formation of the *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea molecules. In addition, bands at 3521-3599 $cm^{-1}$ regions indicate the asymmetric and symmetric vibrations frequencies for (N-H) of the secondary thioamide group.

A strong band at 1672-1700 $cm^{-1}$ was ascribed to the stretching vibration of the C=O group. The frequency for the C=O band decreases by >20 $cm^{-1}$ due to a more delocalised electronic distribution across the structural geometry and the presence of an intramolecular hydrogen bonding between the O atom of the C=O group with N-H as suggested by the X-ray crystal structure [20]. Furthermore, the presence of bromo atom as an electron-withdrawing group at the benzoyl moiety has weakened the C=O bond. Halogen atom with high electronegativity such as bromine is capable of reducing the electron density of the benzene ring and hence, has indirectly affected the neighbouring C=O group.

**Ultraviolet-visible spectra**

The UV absorption spectra of the phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds are shown in Figure 4 and the data is collected in Table 4. The ligands display two strong absorption bands in the ultra-violent region with absorption maxima at 231 (ε= 54,795-61,870 $Lmol^{-1}cm^{-1}$) and 269-270 nm (ε= 36,711-57,513 $Lmol^{-1}cm^{-1}$) that can be attributed to the π→π* ligand-centred (LC) transitions.

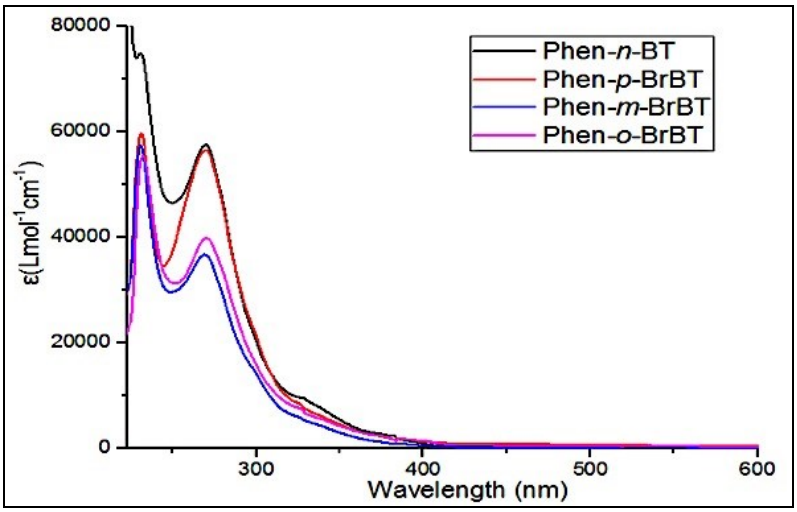

Figure 4. The electronic absorption spectra of *N*-bromobenzoyl-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives in acetonitrile

The intensity of phen-*p*-BrBT absorption band appears the highest compared to phen-*m*-BrBT and phen-*o*-BrBT. In addition, there is no significant change in the energy of the electronic absorption bands compared with the substituted phen-BT. However, the bromo-substituent in the phen-*o*-BrBT molecule has a restricted structural conformation and appeared to impede the electron transfer slightly for the higher energy transitions.

Table 4. Molar absorptivity and $\lambda_{max}$ of phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds

| **Compound** | **UV-Vis ($CH_2Cl_2$)** |
|---|---|
| | **λ(nm) / ε($Lmol^{-1}cm^{-1}$)** |
| phen-BT | 270 (57,513), 231 (61,870) |
| phen-*o*-BrBT | 269 (39,828), 231 (54,795) |
| phen-*m*-BrBT | 269 (36,711), 231 (57,405) |
| phen-*p*-BrBT | 270 (56,517) , 231 (59,724) |

**Nuclear magnetic resonance spectroscopy**

The structures of all compounds with the atomic numbering scheme are shown in Figure 5. The data are compiled in Table 5 and Table 6, respectively. In accordance with the IR spectra, the chemical shift of $H(N_1)$ were observed at 12.36, 12.49 and 12.53 ppm for phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT, respectively. The signal for the amine proton $\delta H(N_1)$ appears as the most deshielded proton signals since the proton was influenced by two electronegative groups (C=O and C=S) in the proximate distances. The signals of $\delta H(N_2)$ were slightly shielded and were observed in the downfield region at 12.26, 12.01 and 11.97 ppm for phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT, respectively. The signals for the phenanthroline protons were observed in the downfield region at δ=7.46-9.15 ppm.

Table 6 (cont'd). The $^{13}$C NMR signals of the *N*-(bromobenzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives

| Carbon | δ, ppm | | | |
|---|---|---|---|---|
| | **Phen-BT** | **Phen-*o*-BrBT** | **Phen-*m*-BrBT** | **Phen-*p*-BrBT** |
| C10, C15 | 125.37 | 128.34 | 128.46 | 125.43 |
| | | 128.18 | 128.33 | 126.23 |
| C11 | 137.37 | 133.68 | 136.27 | 132.60 |
| C12 | 126.32 | 129.86 | 125.46 | 127.72 |
| C14 | 128.39 | 133.24 | 132.67 | 131.46 |
| C17, C20 | 150.54 | 150.90 | 150.87 | 150.88 |
| | 150.48 | 150.66 | 150.66 | 150.66 |
| C18, C19 | 129.33 | 132.76 | 126.24 | 128.32 |
| | 128.99 | 132.46 | | |
| C1, C13 | 133.85 | 137.12 | 125.05 | 132.08 |
| | 133.71 | 136.95 | 133.77 | 132.00 |
| C2 | 124.01 | 126.23 | 124.22 | 123.84 |
| C3 | 124.29 | 125.57 | 136.97 | 124.19 |
| C4 | 123.77 | 125.57 | 123.86 | 133.75 |
| C5 | 124.29 | 123.88 | 131.23 | 123.19 |
| C6 | 124.01 | 119.44 | 122.07 | 123.84 |

As for the $^{13}$C NMR spectra, the most downfield signals were attributed to the resonances of C=S and C=O groups. The carbon atoms of the thiocarbonyl group appeared at 182.04, 182.39 and 182.04 ppm for phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT, respectively. The results revealed that the C=S signal was shifted downfield compared to that of C=O (167.39-169.08 ppm), which is partly due to the resonance effects of the CO and -NH- groups. These features and chemical shifts of the $^{1}$H and $^{13}$C NMR spectra are in agreement with the crystal structure of phen-BT as depicted in Figure 5.

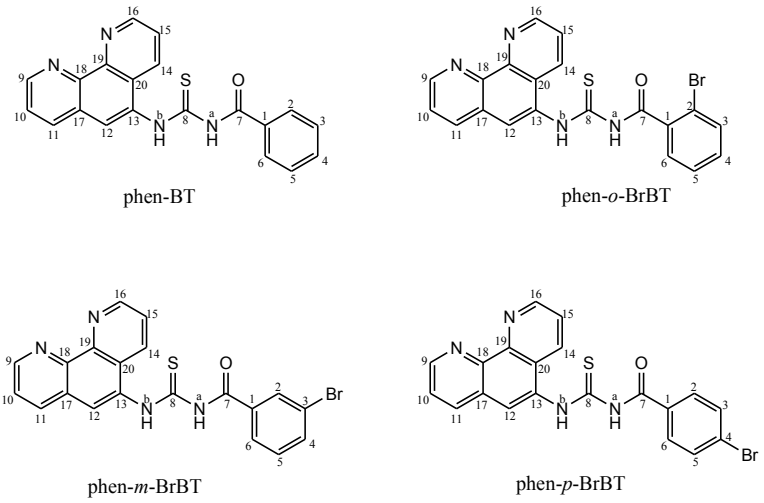

Figure 5. The structure of *N*-(bromobenzoyl)-*N*'-(1,10-phenanthrolin-5-yl)thiourea derivatives with the atomic numbering scheme for NMR structure elucidation

**Cyclic voltammetry**

Cyclic voltammetry is an important technique in electrochemistry analysis because it provides useful information on electron transfer process. The electrochemical cell consist of three electrodes - a platinum disk working electrode (2 mm, diameter), $Ag/Ag^+$ reference electrode (0.01 M $AgNO_3$; 0.1 M tetrabutylammonium perchlorate in $CH_2Cl_2$) and a platinum counter electrode. The potentials (1 mM) were recorded in $CH_2Cl_2$ with 0.1 M $[(n\text{-}C_4H_9)_4N]PF_6$. All compounds exhibit an irreversible oxidation and reduction redox couples. The redox potentials are listed in Table 7.

Table 7. The redox potentials for oxidation and reduction processes of phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT

| Compound | Irreversible processes | |
|---|---|---|
| | $E_p^{ox}$ | $E_p^{red}$ |
| Phen-BT | +1.68 | -1.43 |
| Phen-*o*-BrBT | +1.70 | -1.50 |
| Phen-*m*-BrBT | +1.42 | -1.60 |
| Phen-*p*-BrBT | +1.60 | -1.21 |

All derivatives showed irreversible redox potentials at (1.42 – 1.70) V and –(1.21 – 1.60) V for oxidation and reduction processes, respectively. Bromine atom has an overall destabilizing influence on the phenyl ring with the *o*- and *p*-bromo substituents exert higher stabilization to the phenyl ring. Thus, phen-*m*-BrBT was relatively easier to be oxidized compared with the phen-*o*-BrBT and phen-*p*-BrBT derivatives. Likewise, phen-*o*-BrBT and phen-*p*-BrBT derivatives would be much easier to be reduced, i.e. accept electron. However, only phen-*p*-BrBT derivative behaves as expected. Other factors such as solvent interactions might influence the redox behaviours of the molecules.

**Luminescence properties**

The concentration of the compounds is 9 x $10^{-6}$ mol $dm^{-3}$ and the luminescence quantum yields were calculated by using 2-aminopyridine ligand as a standard with $\phi_{std}$= 0.37 in $CH_3CH_2OH$ [19]. Figure 6 shows the emission spectra of the compounds. The excitation wavelength ($\lambda_{ex}$) for each sample was selected according to their absorption wavelength ($\lambda_{max}$) and listed in Table 8. Phen-*m*-BrBT, shows a relatively high fluorescence quantum yield ($\phi_s$ = 5.40 x $10^{-2}$ s) compared with that of *para* and *ortho* substituted analogues.

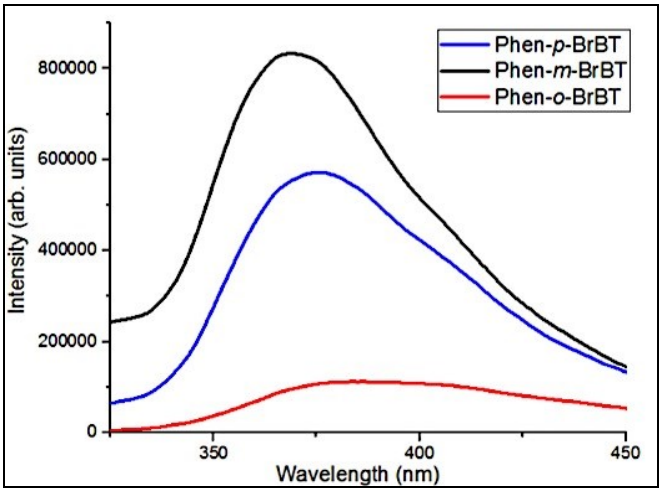

Figure 6. The steady-state fluorescence spectra of Br-substituted Phen-BT compounds measured in $CH_2Cl_2$

Table 8. The emission spectra, $\lambda_{em}$ of phen-BT, phen-*o*-BrBT, phen-*m*-BrBT and phen-*p*-BrBT compounds

| **Ligands** | $\lambda_{ex}$ **(nm)** | $\lambda_{em}$ **(nm)** | **Quantum Yield,** $\varphi_s$ **in** $CH_2Cl_2$ |
|---|---|---|---|
| Phen-BT | 270 | 365 | $7.27 \times 10^{-2}$ |
| Phen-*o*-BrBT | 269 | 379 | $5.61 \times 10^{-3}$ |
| Phen-*m*-BrBT | 269 | 369 | $5.40 \times 10^{-2}$ |
| Phen-*p*-BrBT | 270 | 375 | $2.29 \times 10^{-2}$ |

## Conclusion

The phen-*o*-BrBT, phen-*m*-BrBTand phen-*p*-BrBT compounds were successfully synthesized and characterized by analytical and spectroscopic techniques. The molecular structural properties are in agreement with the previously reported phen-BT crystal structure. The bromo atom at the *orto*, *meta* and *para* positions of the phenyl ring in the benzoyl moiety has weakened the C=O bond by reducing the electron density of the phenyl ring. In addition, the luminescence quantum yield appears to the affected by the Br substituent with the phen-*m*-BrBT derivative showing the highest quantum yield.

**Abstract**

Solidified floating organic drop microextraction (SFODME) was utilized as a separation or pre-concentration step prior to electrothermal atomic absorption spectrometric (ETAAS) determination of ultra-trace amounts of lead. The method was based on the formation of an extractable complex between Pb(II) and 1-(2-pyridylazo)-2-naphathol (PAN) as a chelating agent. The main parameters affecting the performance of SFODME, namely, type and volume of organic solvent, pH, concentration of the chelating agent, extraction time, stirring rate, extraction temperature, disperser solvent, ionic strength, and interference effect were investigated and optimized. Under optimized experimental conditions a pre-concentration factor of 22.03 and a detection limit of 0.064 μg $L^{-1}$ for the pre-concentration from 13.0 mL water sample was achieved. The relative standard deviation of the measurements in the range of 1.3 – 2.5% (n = 6). The proposed method was assessed through the analysis of certified reference water and recovery experiment with satisfactory results.

**Keywords:** solidified floating organic drop microextraction, lead, electrothermal atomic absorption spectrometry, water samples

**Abstract**

Pengekstrakan mikro pemejalan titisan organik terapung (SFODME) digunakan sebagai langkah pemisahan atau pemekatan sebelum penentuan jumlah surih plumbum ditentukan menngunakan spektrometri serapan atom elektrotermal (ETAAS). Kaedah ini berasaskan kepada pembentukkan kompleks yang boleh diekstrak di antara Pb(II) dan 1-(2p-piridilazo)-2-naphol (PAN) sebagai agen pengkelat. Parameter utama yang memberi kesan kepada prestasi SFODME iaitu jenis dan isipadu pelarut organik, pH, kepekatan agen pengkelat, masa pengekstrakan, kesan pengacauan, suhu pengesktrakan, pelarut serakan, kekuatan ionik dan kesan gangguan telah dikaji dan dioptimumkan. Keadaan optimum bagi eksperimen diperolehi dengan faktor pemekatan pada 22.03 dan had pengesanan dicapai pada 0.064 μg $L^{-1}$ bagi pemekatan 13.0 mL sampel air. Pengukuran sisihan piawai relatif berada pada julat 1.3 – 2.5% (n = 6). Kaedah yang dicadangkan juga dinilai melalui analisis sampel air rujukan yang disahkan dan ujian perolehan semula yang mencapai keputusan memuaskan.

**Kata kunci:** pengekstrakan mikro pemejalan titisan organik terapung, plumbum, spektrometri serapan atom elektrotermal, sampel air

## Introduction

Nowadays, increasing global environmental pollution is great concern. Heavy metals belong to a class of pollutants that can produce undesirable effects, even if they are present in minuscule amounts. Among the different heavy metals, lead is one of the most common and most toxic pollutants released into the environment from various industrial activities [1]. The accumulation of heavy metals in adults, is associated with heart disease, cancer, and may cause many serious disorders like anemia, kidney diseases, nervous disorder, and even death [2].

The important sources of lead are industrial processes such as smelting of lead, recycling of lead batteries, manufacturing of lead paints, etc. [3], and automobile exhausts. Water quality has become an issue of vital importance as it is an essential resource that is threatened by pollution. Maximum allowable limit of total Pb in drinking water considered safe by the United States Environmental Protection Agency (EPA) and Ministry of public health, Thailand is 10 μg $L^{-1}$ [4]. The tap water intended for human consumption is controlled regularly for an extensive array of potential contaminants by certified authorities.

Modern instrumental methods including spectrometry, namely, inductively coupled plasma mass spectrometry, inductively coupled plasma atomic emission spectrometry, and atomic absorption spectrometry, etc. [5-7] have been used for the determination of traces of metal ions in various media. However, because of the low concentration of Pb and the complexity of the environmental samples, direct analysis using the instruments is often impeded by matrix interferences. Several methods have been proposed for separation and pre-concentration of trace Pb, such as, liquid-liquid extraction (LLE) [8, 9], solid-phase extraction (SPE) [10-12], coprecipitation [13], cloud point extraction (CPE) [14, 15], and ion exchange [16]. Although these are the most commonly used sample pre-treatment methods, they have some drawbacks such as large consumption of reagents, low enrichment factors, multistage operation, and lengthy separation.

The miniaturized pre-concentration method based on LLE including, single drop microextraction (SDME) [17], hollow fiber liquid phase microextraction (HF-LPME) [18], homogeneous liquid-liquid extraction [19], and dispersive liquid-liquid microextraction (DLLME) [20, 21]. Solidified floating organic drop microextraction (SFODME) was introduced as one of these by Khalili Zanjini et al. [22]. In this method, a small volume of an organic solvent with a melting point near room temperature (in the range of 10-30 °C), which is immiscible with water, is delivered to the surface of an aqueous sample containing the analytes. When the equilibrium is reached, the sample vial is placed in an ice bath to solidify the microdrop which is easily removed and allowed to melt for the quantification of analytes [23].

In the present work, trace analysis of lead was developed based on SFODME technique and determination by electrothermal atomic absorption spectrometry (ETASS). 1-(2-pyridylazo)-2-naphthol (PAN), a chelating reagent widely used for many metals and that permits the pre-concentration of trace metals from solution [24], is used to extract Pb into the organic phase. This method was applied for the determination of lead in mineral bottled and tap water samples.

## Materials and Methods

### Instrumentation

The experiments were performed with a Varian Model SpectrAA 220Z atomic absorption spectrometer equipped with Zeeman background correction. A lead hollow cathode lamp was used as the radiation source. The analytical wavelength (283.3 nm), spectral bandwidth (0.5 nm) and lamp current (10.0 mA) were used as recommended by manufacturer. The graphite furnace temperature program was optimized and are showed in Table 1. The pH measurements were carried out with a Metrohm pH meter model 827 pH lab equipped with a combined glass electrode.

### Reagents and solutions

All reagents used in this study were of analytical grade. The stock solution of Pb(II) was obtained from AVS Titrinorm (VWR inter-national, Belgium). Working standard solutions were prepared daily by appropriate dilution from the stock solution with deionized water. The stock solutions of the chelating agent, 1-(2-pyridylazo)-2-

naphthol; PAN, (Acros organics, USA) were prepared by dissolving appropriate amounts in ethanol (ITALMAR, Thailand). The extraction solvent, 1-undecanol, was purchased from Merck, Germany. Buffer solutions of ammonium acetate (pH 4, 0.2 mol $L^{-1}$), phosphate (pH 7.0, 0.2 mol $L^{-1}$), and ammonium chloride (pH 9, 0.2 mol $L^{-1}$) were used to adjust the pH in the range of 2.0-12.0. The laboratory glassware was kept overnight in a 10% $HNO_3$ solution. The glassware was washed with deionized water and dried prior to use.

Table 1. Temperature program of ETAAS for determination of Pb

| Step | Temperature (°C) | Time (s) | Argon flow rate (L/min) |
|---|---|---|---|
| 1 | 95 | 15.0 | 0.3 |
| 2 | 120 | 5.0 | 0.3 |
| 3 | 400 | 14.0 | 0.3 |
| 4 | 2100 | 2.9 | 0 |
| 5 | 2100 | 2.0 | 0.3 |

**Extraction procedure**
An amount of 13 mL aliquot, either 15 μg $L^{-1}$ standard or water sample, was placed in a 15-mL screw cap glass vial with flat bottom containing a magnetic stirrer bar. The pH of the solution was adjusted to 6 using phosphate buffer and 0.5 mL of a solution of PAN chelating agent (3.0 mmol $L^{-1}$) was added. After the solution was mixed thoroughly, 90 μL of 1-undecanol was spiked into the stirring solution and was mixed for 20 min at 625 rpm, after that, the vial was cooled in an ice bath. The solidified drop of 1-undecanol was obtained rapidly. The solidified solvent was transferred into a vial and where it melted immediately. Therefore, the extract was diluted with ethanol (500 μL) and Pb(II) concentration was determined by electrothermal atomic absorption spectrometer.

**Water samples**
In order to validate the method, various water samples, including tap and mineral bottled water (Phitsanulok, Thailand) were selected. A water samples were filtered through a 0.45 μm Whatman filter membrane to remove any suspended material prior to the analysis.

## Results and Discussion

**Optimization of extraction conditions**
In order to obtain high pre-concentration factor (PF) [25] and good extraction recovery (ER), the effect of different parameters that affect extraction conditions such as type and volume of extraction solvent, pH, amount of chelating agent, stirring rate, extraction time and extraction temperature were optimized.

**Effect of type and volume of the extraction solvent**
To obtain optimal results, an appropriate extraction solvent must be chosen. It should have low volatility, density lower than water, low toxicity, and a melting point near room temperature (10 – 30 °C). In this paper, 1-undecanol (m.p. 13–15 °C) and 1-dodecanol (m.p. 22–24 °C), were used for the initial investigation. When the extraction was done, the analytical absorbances were about 0.071 and 0.034, respectively. Therefore, 1-undecanol was selected as the extraction solvent for further experiment in this study.

To evaluate the effect of the extraction solvent volume, different volumes of 1-undecanol were added in the range of 20 – 150 μL. The results of this experiment are shown in Figure 1. It can be seen that relative absorbance increased with increasing 1-undecanol volume in the range of 20 – 90 μL, and then decreased with further volume increases. Therefore, 90 μL was chosen as the optimum volume of the extraction solvent for further experiments. After the extraction procedure, the obtained of PF was 22.03.

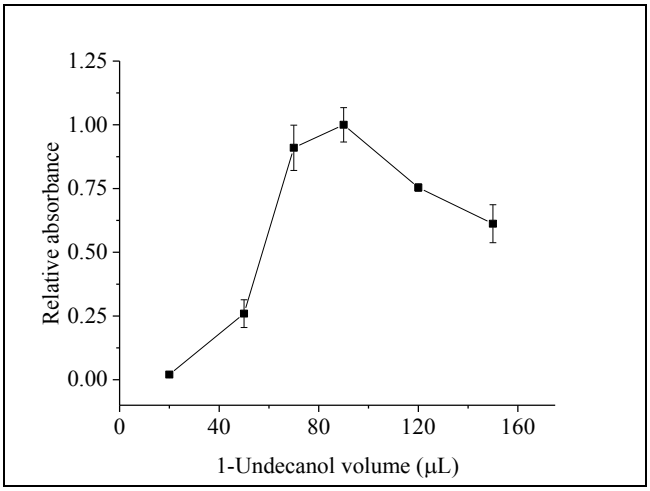

Figure 1. Effect of 1-undecanol volume on the extraction efficiency of lead. Utilized conditions: concentration of Pb(II), 15 μg $L^{-1}$; aqueous volume, 13 mL; pH 6; chelating agent, PAN, 3.0 mmol $L^{-1}$, 0.5 mL; extraction time, 3 min; stirring rate, 625 rpm; room temperature

**Effect of the sample pH**

The pH of the sample has an effect on metal complex formation. Furthermore, pH also has influences toward the extraction efficiency of Pb(II). Therefore, the effect of pH on the procedure was investigated in the range of 3.0-12.0. As shown in Figure 2, an absorbance maximum was observed pH equal to 9.0. Accordingly, a pH 9, obtained with ammonium chloride buffer, was selected for the optimization studies and real sample analysis.

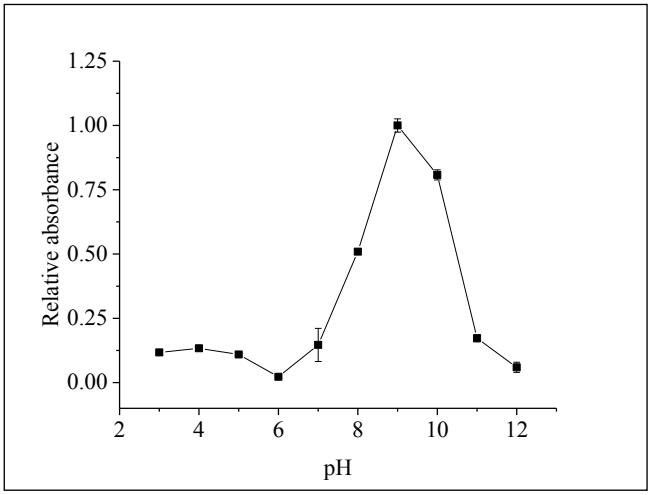

Figure 2. Effect of pH on the extraction efficiency of lead. Conditions are the same as in Figure 1 except pH, and 1-undecanol volume, 90 μL

**Effect of the PAN concentration**

The effect of PAN concentration, as chelating reagent, on the extraction efficiency was studied using various amounts of ligand ranging from 0.1 to 10.0 mmol $L^{-1}$ (equal 0.0038 to 0.38 mmol $L^{-1}$ in final volume of sample, 13

mL). The absorbance was stable when the concentration of ligand was higher than 3.0 mmol $L^{-1}$, indicating the complete complexation. Therefore, 3.0 mmol $L^{-1}$ (equal 0.115 mmol $L^{-1}$ in final solution) was chosen as the optimum concentration for the lead extraction.

**Extraction time**

Another important factor that affects the extraction is the extraction time, because of the mass transfer phenomena governing the extraction efficiency of the analyte in SFODME. The effect of the extraction time was studied by varying it in the range of 10 – 120 min under constant experimental conditions. The results are shown in Figure 3. It was found that with increasing extraction time, up to 40 min, the analytical signal increased, and remained constant at a longer extraction times. Thus, 40-min extraction was chosen as the optimum extraction time.

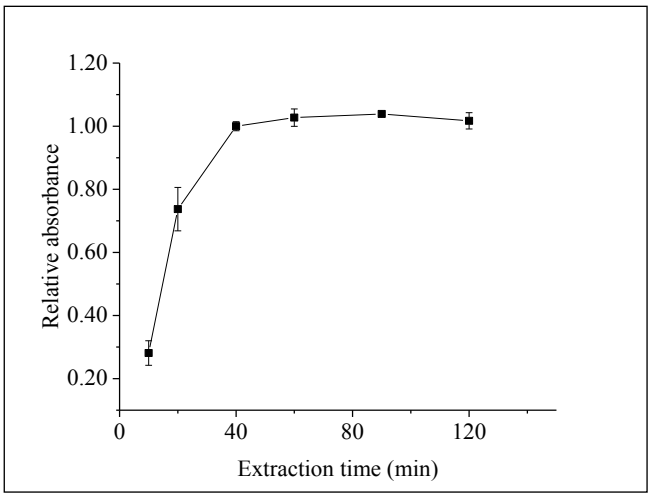

Figure 3. Effect of extraction time on the extraction efficiency of lead. Conditions are the same as in Figure 2 except extraction time. Performed at pH 9

**Stirring rate**

To enhance the extraction efficiency, sample stirring during the extraction procedure was applied. Based on the film theory of convective-diffusive mass transfer, increasing the stirring rate can decreased the thickness of the dilution film in the aqueous phase, so the mass-transfer will be increased. The effect of stirring rate on extraction efficiency was studied in the range of 100 – 1,200 rpm. The experimental results show that the analytical signal increases rapidly with increasing stirring rate from 375 to 750 rpm, and then remains constant upon further increases up to 1200 rpm. Therefore, a stirring rate of 750 rpm was employed for analysis.

**Extraction temperature**

Temperature affects the solubility of the organic solvent in water as well as the emulsification and therefore influences the extraction efficiency. This effect was performed by varying the extraction temperature between 20 °C and 80 °C. The results in Figure 4 showed that the relative absorbance increases with increasing extraction temperature up to 50 °C. At temperatures higher than 50 °C, 1-undecanol was slightly dissolved into the aqueous sample, affecting the analytical signal. Consequently, the extraction temperature at 50 °C was chosen for further study.

**Effect of salts**

The influence of ionic strength on the SFODME method was investigated by adding various amounts of sodium chloride (NaCl) and potassium chloride (KCl) in the range 0 – 5.0% (m/v) to the sample. The obtained results indicate that increasing the salt concentration from 0% to 5.0% does not significantly increase the extraction efficiency. Therefore, salts were not added to the aqueous samples studied in this work.

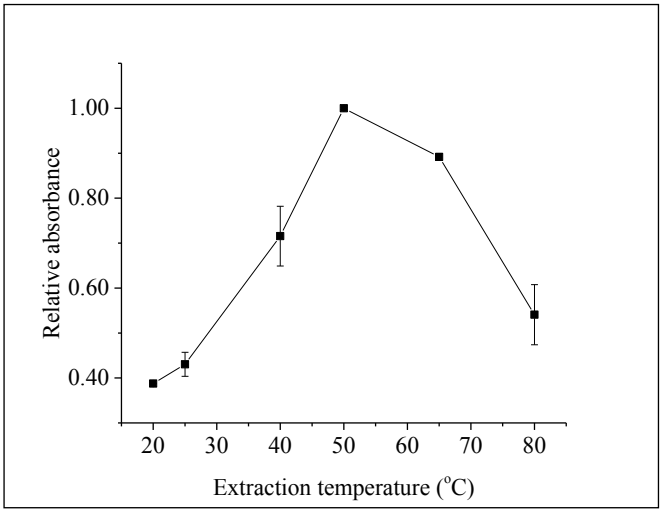

Figure 4. Effect of extraction temperature on the extraction efficiency of lead. Conditions are the same as in Figure 3 except extraction temperature. Performed with extraction time of 40 min

A summary of optimal conditions obtained for the SFODME method for pre-concentration and determination of lead is illustrated in Table 2.

Table 2. Optimal conditions for SFODME of lead ions

| **Optimal Conditions for SFODME of Pb(II)** | |
|---|---|
| Extraction solvent | 1-undecanol |
| Diluent | ethanol |
| pH | 9 |
| PAN concentration (mmol $L^{-1}$) | 3.0 |
| Extraction time (min) | 40 |
| Stirring rate (rpm) | 750 |
| Sample volume (mL) | 13 |
| Extraction phase volume (mL) | 0.090 |
| Extraction temperature (˚C) | 50 |

**Interference study**

The selectivity of the proposed method in the extraction and determination of the analyte was investigated as well. In these experiments, solutions of 10 μg $L^{-1}$ of Pb(II) containing interfering ions were treated using the optimized procedure. The tolerance limit was set as the amount of ion required to cause an error of ±5% in the determination of lead. The maximum tolerance limits of the investigated cations and anions are given in Table 3. The extraction by SFODME method is based on the fact that the target ions can form hydrophobic metal–PAN complex and them can be extracted to the extraction solvent (1-undecanol). Nonetheless, the tolerance limits of $Mg^{2+}$ and $Fe^{3+}$ were not as high as other ions, the concentration of $Mg^{2+}$ and $Fe^{3+}$ were at trace levels in several water samples. Therefore, these results indicate that the developed method can be applied to analysis of Pb in various water samples.

Table 3. Tolerance limits of interfering ions in the determination of 10 μg $L^{-1}$ Pb(II)

| Ions | Interfering Ratio (ion/Pb) | Pb(II) Recovery (% ± SD) |
|---|---|---|
| $Na^+$ | 1000 | 103.0 ± 0.1 |
| $K^+$ | 1000 | 94.9 ± 0.2 |
| $Cd^{2+}$ | 100 | 94.2 ± 0.3 |
| $Cr^{3+}$ | 1000 | 97.9 ± 0.1 |
| $As^{3+}$ | 100 | 92.4 ± 0.1 |
| $NO_3^-$ | 100 | 101.8 ± 0.1 |
| $SO_4^{2-}$ | 100 | 100.5 ± 0.2 |
| $PO_4^{3-}$ | 100 | 102.5 ± 0.1 |

**Analytical performance**

The analytical characteristics such as the linear range, precision, detection limit, and pre-concentration factor were obtained by processing standard solution of Pb. The calibration curve was obtained using the optimized conditions for the SFODME procedure followed by lead concentration determination by ETAAS. Linearity was obtained with lead concentration in the range up to 30.0 μg $L^{-1}$. The regression equation for lead determination is express as below

$$A = 0.0131C + 0.0100 \quad (1)$$

where A is the absorbance and C is the lead concentration in solution (μg $L^{-1}$). The correlation coefficient of the calibration curve equation was higher than 0.99. The pre-concentration factor was calculated as the ratio of the volume of the sample prior pre-concentration divided by the volume after pre-concentration. It was found to have a value of 22.03. The LOD and LOQ defined as $3S_b/m$ and $10S_b/m$ (where $S_b$ is standard deviation of the blank and $m$ is the slope of the calibration graph) were found to be 0.064 and 0.214 μg/L, respectively. The relative standard deviation (%RSD) for 6 replicate determinations at 15 μg $L^{-1}$ of Pb(II) is ±2.5%.

**Sample analysis**

To examine the reliability of this procedure, the method was applied for the determination of lead in mineral bottled and tap water samples. The accuracy of the proposed method was verified by spiking experiments at two concentration levels. As tabulated in Table 4, the recoveries of the added lead were always higher than 91%. To verify the accuracy of the proposed procedure, the method was used for the determination of lead in a sample of NRC-CNRC, National Research Council of Canada (SLRS-4). The results of this test are presented in Table 4, good agreement between the determined and certified values was obtained. Furthermore, these results indicate that the matrices of the mineral bottled and tap water samples had little effect on the SFODME–ETAAS method for the determination of lead. Comparison of pre-concentration techniques used for lead determination with ETAAS was showed in Table 5.

Table 4. Determination of lead(II) in several water samples. (n=2)

| Sample | Certified (μg $L^{-1}$) | Added (μg $L^{-1}$) | Found (μg $L^{-1}$) | Recovery (%) |

PF: pre-concentration factor

## Conclusion

It has been shown that solidified floating organic drop microextraction (SFODME) combined with ETAAS, can be used for the separation or pre-concentration of ultra-trace amount of lead in mineral bottled and tap water samples. A comparison of the represented method with the other liquid–liquid microextraction methods using different detection techniques for lead extraction and determination was successfully identified. It can be seen that the working range of SFODME-ETAAS is wider than that of the other reported methods. The main advantages of this methodology are simplicity, low cost, high enrichment factor, rejection of matrix constituents, and minimum use of organic solvents. Additional studies are in progress to evaluate the parameters of the SFODME method for pre-concentration and determination of other metals using various ligands and complexing agents in different matrices.

**Abstract**

Discharging waste without removing harmful compounds can lead to serious environmental and health issues. Despite of the high content of pollutants, wastewater environment can become an ideal condition for the growth of several microorganisms. Some species of microalgae have been found living in palm oil mill effluent (POME), making it suitable to be used in biological treatment. However, the ability of microalgae to grow and its composition characteristics in synthetic media are unknown. Therefore, this study evaluated the growth characteristics and biochemical productivity of *Chlorella sorokiniana* UKM3, *Coelastrella sp.* UKM4 and *Chlorella sp.* UMACC324, which had been previously isolated from POME. Bold's Basal Media (BBM) was used as the medium for cultivation. The experimental works were performed in a lab-scale photobioreactor at room temperature under continuous illumination for 14 days. From this study, *Coelastrella sp.* UKM4 showed the highest value of growth rates (0.52±0.03 $d^{-1}$), biomass productivity (0.07±0.02 $g.L^{-1}.d^{-1}$), lipid content (66.42±2.87 $mg.L^{-1}$, 7.26%) and lipid productivity (452.42 $mg.L^{-1}.d^{-1}$), whereas the highest chlorophyll content was observed in *Chlorella sorokiniana* UKM3 (26.84±1.76 $mg.L^{-1}$).

**Abstrak**

Pembuangan sisa yang tidak dirawat terlebih dahulu boleh menyebabkan isu yang serius terhadap alam sekitar dan kesihatan. Walaupun kandungan bahan pencemar adalah tinggi, air sisa boleh menjadi habitat yang ideal bagi pertumbuhan sesetengah spesis mikroorganisma. Beberapa spesies mikroalga telah dijumpai hidup dalam effluen kilang minyak sawit (POME). Ini menjadikan spesis mikroalga tersebut sesuai digunakan dalam proses rawatan sisa secara biologikal. Walau bagaimanapun, keupayaan mikroalga untuk bertumbuh dan ciri-ciri komposisinya didalam media sintetik adalah tidak diketahui. Oleh itu, kajian ini dijalankan untuk menilai ciri-ciri pertumbuhan dan produktiviti biokimia bagi *Chlorella sorokiniana* UKM3, *Coelastrella sp.* UKM4 dan *Chlorella sp.* UMACC324, yang sebelum ini telah dipencil dari POME. Media Bold's Basal (BBM) telah digunakan sebagai medium pertumbuhan. Kajian ini telah dilakukan dalam fotobioreaktor berskala-makmal pada suhu bilik dan dibawah pencahayaan yang berterusan selama 14 hari. Daripada hasil kajian ini, *Coelastrella sp.* UKM4 telah menunjukkan nilai yang tertinggi dalam kadar pertumbuhan (0.52±0.03 $hari^{-1}$), produktiviti biojisim (0.07±0.02 $g.L^{-1}$ $hari^{-1}$), kandungan lipid (66.42±2.87 $mg.L^{-1}$, 7.26%) dan produktiviti lipid (452.42 $mg.L^{-1}.hari^{-1}$). Kandungan klorofil yang paling tinggi pula dapat dilihat pada *Chlorella sorokiniana* UKM3 (26.84±1.76 $mg.L^{-1}$).

**Kata kunci:** mikroalga, pertumbuhan, biojisim, kandungan klorofil, kandungan lipid

## Introduction

Algae represent diverse groups of photosynthetic organisms with various sizes and shapes. There are two major types of algae, (a) Microalgae: unicellular and microscopic form of algae with the size of 3-10 μm, and (b) macroalgae (giant kelps or seaweeds): multicellular organisms and the most complex form of algae with the size reaching up to 70 m long [1,2]. These primitive chlorophyll-containing organisms are unique and can be found in various habitats on earth where light is available with little moisture, even in unusual and extreme conditions. Interestingly, algae have different ecological roles, where some algae are attached to other aquatic plants or submerged rocks, while others are found floating in the water. All aquatic animals are dependent directly or indirectly on algae since algae act as the base of the food chain, converting several nutrients into organic matter and oxygenating the water. For instance, aquatic life such as fishes depends on the number of algae. There would be no fish if there are no algae in the lake. Furthermore, the growth of algae is heavily influenced by a number of environmental factors, such as the amount of light penetrating the water, nutrients concentrations, temperature, parasitic relationships (bacteria or fungi), and also salinity of the medium growth [3–7].

On top of that, algae are able to manufacture their own food through photosynthesis like any other terrestrial plants. However, algae lack complex tissues and organs, such as stems and roots, which characterise the complex green plants [8]. These simple structures give them the ability to grow rapidly, doubling their growth within a short period of time. Other than that, algae are efficient in capturing solar energy and utilising carbon dioxide ($CO_2$) from their surrounding compared to trees and other green plants [1,9,10]. $CO_2$ plays an important role in microalgae cellular activities. In fact, approximately 50% of carbon is present in microalgae biomass and this carbon is obtained from the utilisation of $CO_2$ [8]. Furthermore, important biochemical, such as polyunsaturated fatty acids, pigments, lipids, proteins, carbohydrates, and vitamins, can be extracted from algae to be used in the production of high-value products such as fertilisers, cosmetics, and drugs [11–15]. Moreover, several different systems are available to grow algae in industrial sectors, namely open ponds, covered ponds, raceways, and engineered systems (photobioreactors) [13,16]. The comparisons of open and closed systems [17,18] are shown in Table 1.

Table 1. Comparisons of open and closed systems

| | **Open Systems** | **Closed Systems** |
|---|---|---|
| Contamination | High risk | Low risk |
| $CO_2$ | High $CO_2$ losses | Lower $CO_2$ losses |
| Evaporation | High evaporation losses | Low evaporation losses |
| Light | Poor light penetration | Excellent light used |
| Scale up | Easy to scale up | Difficult to scale up |
| Process | Difficult to control the process | Easy to control the process |
| Biomass | Low biomass productivity | High biomass productivity |
| Area | Required large area | Low area requirement |
| Harvesting | High cost | Relatively low cost |
| Investment | Low cost | High cost |
| Operation | Low cost | High cost |

As the world energy demand still depends heavily on fossil fuels, the global oil reserves would eventually become exhausted. The escalating price of oil also has caused dilemma among industrial activities, transportation sectors, and residential needs [19]. Furthermore, the search for suitable biomass from available food crops for biofuel production has indeed generated a lot of controversies. The use of agricultural land solely for biofuels production causes limited land available for food production. Thus, food supply becomes limited and eventually sparks hunger issues, food arguments, and sustainability issues. However, the ability of algae to have high productivities, grow

easily in the brackish or marine environment, does not need agricultural land and does not compete with edible oil crops makes it suitable to be the new source of biofuels. The land quality and soil fertility is not an issue in cultivating algae because algae grow in water, not soil [20]. Microalgae lipid in the form of triacylglycerides (TAGs) can be transformed into biofuel products, such as methyl ester, biodiesel, and gasoline substitute. Seaweeds biomass also has been considered as a new source of biofuels in the form of biomethane and bioethanol [21,22].

The release of untreated wastewater into the water bodies and high concentration of greenhouse gases in the atmosphere have caused climate change, threatened the global environment, and sparked health issues. Various methods (physical, chemical and biological) have been applied and compared to treat the wastes produced. Previous studies have asserted that the most effective and environmental friendly method is by using the biological approach. Biological treatments rely on microorganisms, such as bacteria, to break down organic wastes by using cellular processes. Apart from using bacteria, microalgae are one of the options to be used in biological treatment. The use of microalgae for the removal of pollutants and $CO_2$ in the wastewater is known as phycoremediation [23–25].

In Malaysia, the increasing demand for palm oil has directly increased the amount of palm oil wastes, such as empty fruit bunches (EFB), palm oil mill effluent (POME), and fibres. POME is a viscous and acidic brown liquid that releases highly unpleasant odour. It is the most expensive and difficult waste to manage compared to the rest. Typically, POME contains high concentration of total solids, organic and inorganic matters, oil, and also heavy metals. The high amount of organic matter causes high level of chemical oxygen demand (COD) and biochemical oxygen demand (BOD). However, some species of microalgae have been found living in the POME environment despite of the high content of pollutants. These microalgae use the organic matter in POME as nutrient for growth. The ability of microalgae to adapt and assimilate nutrient, as well as grow successfully in POME have made them suitable to be used in wastewater treatment. According to Ding et al. [25], POME-isolated microalgae, namely *Chlamydomonas sp.* UKM6 was able to reduce 29.1% of COD, 73% of total nitrogen content, and 63.5% of total phosphorus content in wastewater. Meanwhile, Tamil Selvam et al. [26] reported that *Characium sp.* isolated from POME was able to reduce 88.6% of total nitrogen content and 98% of phosphorus content in anaerobic POME. Besides functioning as nutrient removal, the biomass produced from microalgae in wastewater treatment can be used to produce multiple useable products [27–30].

Although these microalgae are able to thrive in POME, the adaptation ability of each microalga is varied from one species to another. Different environment or growth conditions can affect the ability of microalgae to grow and produce biomass. Thus, the main focus of this research is to determine the capability of POME-isolated microalgae to grow in synthetic media, as well as to compare their potential in producing biomass and biochemical products.

## Materials and Methods

### Algae strain

Three species of microalgae, namely *Chlorella sorokiniana* UKM3, *Coelastrella sp.* UKM4, and *Chlorella sp.* UMACC324 were obtained from Algae Culture Room, Faculty of Engineering and Built Environment, University Kebangsaan Malaysia (UKM), Bangi, Selangor, Malaysia. All the species were previously isolated from palm oil mill effluent.

### Preparation of media

Bold's Basal Media (BBM) is a freshwater algae medium that has been used to grow a variety of algal cultures. It was prepared by adding and mixing ten different components. BBM stock solutions (per litre) contain 25 g sodium nitrate ($NaNO_3$); 2.5 g calcium chloride dehydrate, ($CaCl_2.2H_2O$); 7.5 g magnesium sulfate heptahydrate ($MgSO_4.7H_2O$); 7.5 g potassium phosphate ($K_2HPO_4$); 17.5 g monopotassium phosphate ($KH_2PO_4$); 2.5 g sodium chloride (NaCl); 11.42 g boric acid ($H_3BO_3$); Alkaline EDTA solution containing 50 g ethylenediaminetetraacetic acid (EDTA); and 31 g potassium hydroxide (KOH); Acidified iron solution containing 4.98 g iron (II) sulfate heptahydrate ($FeSO_4.7H_2O$); and 1 ml concentrated sulfuric acid ($H_2SO_4$); Trace Metal solution containing 8.82 g zinc sulfate heptahydrate ($ZnSO_4.7H_2O$); 1.44 g manganese (II) chloride tetrahydrate ($MnCl_2.4H_2O$); 0.71 g molybdenum trioxide ($MoO_3$); 1.57 g copper (II) sulfate pentahydrate ($CuSO_4.5H_2O$); and 0.49 g cobalt (II) Nitrate Hexahydrate ($Co(NO_3)_2.6H_2O$) [31,32].

**Preparation of inoculums**

The POME-isolated microalgae stock cultures (10% v/v) were grown in Erlenmeyer flask (250 ml) containing 100 ml of synthetic media. Erlenmeyer flask opening was closed with sterile non-absorbance cotton wool. The culture was then incubated at constant room temperature (25±1 $^{o}$C), shaken at 100 rpm using an orbital shaker with 24 hours illuminations. After 10 days, the cultures were ready to be used as inoculums when the OD reading reached 1.0 at a wavelength of 750nm. Sub-culturing the microalgae culture has to be done every month in order to ensure the viability of the culture.

**Experimental procedure**

The experimental vessels were made by converting 1 litre Erlenmeyer flasks into lab-scale photobioreactors. Microalgae cultures were sparged with ambient air that was supplied by the gas compressor. The opening flasks were closed using silicone stopper. The air was introduced into all the flasks through sterilised silicon tube at 0.5 vvm (gas volume flow per unit of liquid volume per minute), constantly. Cool white fluorescent lamps were uniformly aligned behind the photobioreactors. These artificial lights were continuously supplied at an intensity of 54 µmol $m^{-2}$ $s^{-1}$. All sets of experiments were undertaken at room temperature (25±1 $^{o}$C) in batch mode and each experimental condition was conducted in duplicate. The pH of growth medium was not maintained throughout the experiment period. The samples were taken every 24 hours for 14 days. Figure 1 illustrates the experimental set up of the three strains of POME-isolated microalgae.

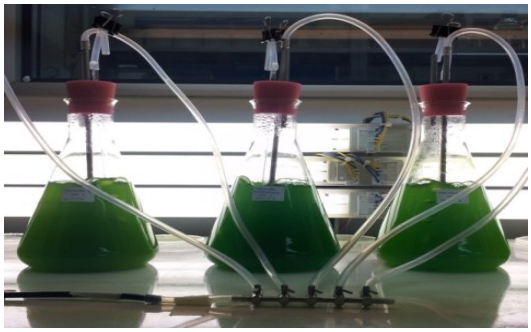

Figure 1. Experimental set-up

**Optical density (OD)**

The optical densities of growing cultures were measured by using portable spectrophotometer (HACH DR 2800, USA) at a wavelength of 750 nm [33,34]. The specific growth rate, $\mu$ ($day^{-1}$) of microalgae was calculated by using Equation (1) below:

$$\mu = \frac{\ln x_2 - \ln x_1}{t_2 - t_1} \quad (1)$$

where, $x_1$ and $x_2$ represent OD readings at 750 nm, while $t_1$ and $t_2$ are the time interval [35,36].

The maximum specific growth rate, $\mu_{max}$ ($day^{-1}$) was determined by using Logistic equation based on the optical density results. The rate of microalgae growth ($dx/dt$) is shown below [37,38].

$$\frac{dX}{dt} = \mu_{max} \left(1 - \frac{X}{X_{max}}\right) X \quad (2)$$

At the beginning of growth where $t = t_o$, the microalgae concentration was given by the initial concentration value ($X = X_o$). After integration, Equation (2) becomes:

$$X = \frac{X_o\, X_{max}\, e^{\mu_{max} t}}{X_{max} - X_o + X_o e^{\mu_{max} t}} \quad (3)$$

where, $X$ is the concentration of microalgae, $X_o$ is the initial concentration of microalgae, $X_{max}$ *is* the maximum value of the microalgae concentration, and $t$ is the time during cultivation. The calculations were carried out using MATLAB R2013a programme.

**Cell dry weight (CDW)**

The microalgae biomass was determined based on cell dry weight method. The microalgae samples were taken and filtered using vacuum filter accompanied with Whatman GF/C filter paper (1.2 µm pore sizes). Then, these filter papers were allowed to be dried in the oven (DHG 9146-A, China) overnight at 105°C until a constant weight was achieved. The cell weight was measured using an analytical balance (XB 220A, Switzerland) and calculated using Equation (4). Besides, the biomass productivity of microalgae was calculated using Equation (5) below [11].

$$\text{Cell dry weight, } (g.L^{-1}) = \frac{X_f - X_o}{V} \quad (4)$$

$$\text{Biomass productivity } (g.L^{-1}.d^{-1}) = \frac{\Delta X}{\Delta t} = \frac{(X_t - X_o)}{(t - t_o)} \quad (5)$$

where, $X_o$ is initial weight of filter paper (g), $X_f$ is filter paper weight after filtration (g), $V$ is the volume of microalga culture (L), while $X_t$ and $X_o$ are dry weights ($g.L^{-1}$) at time $t$ and $t_o$ respectively.

The efficiency of $CO_2$ fixation was calculated in terms of $CO_2$ consumed by microalgae. The $CO_2$ consumption rate was calculated by using Equation (6). It was derived from the typical molecular formula of microalgae biomass, $CO_{0.48}H_{1.83}N_{0.11}P_{0.01}$ [39,40].

$$CO_2 \text{ consumption rate, } P_{CO2} \ (g\ CO_2.L^{-1}d^{-1}) = 1.88 \text{ x biomass productivity} \quad (6)$$

**Chlorophyll content**

The cultures were harvested and centrifuged at 5000 rpm for 10 minutes. The supernatant was discarded. Furthermore, in order to extract the pigments, the collected samples were re-suspended with 90% methanol until the biomass appeared colourless. The cell debris was then removed via centrifugation. The absorbance of the extracted solvent was measured against a blank solvent at the given wavelengths using a portable spectrophotometer (HACH DR 2800, USA). The chlorophyll content was estimated using the following equations [41].

$$\text{Chlorophyll } a\ (mg.L^{-1}) = (16.5 \times A_{665}) - (8.3 \times A_{650}) \quad (7)$$

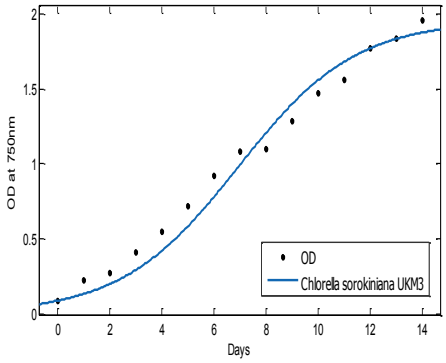
$$\text{Chlorophyll } b\ (mg.L^{-1}) = (33.8 \times A_{650}) - (12.5 \times A_{665}) \quad (8)$$

$$\text{Chlorophyll } a{+}b\ (mg.L^{-1}) = (4.0 \times A_{665}) + (25.2 \times A_{650}) \quad (9)$$

**Lipid content**

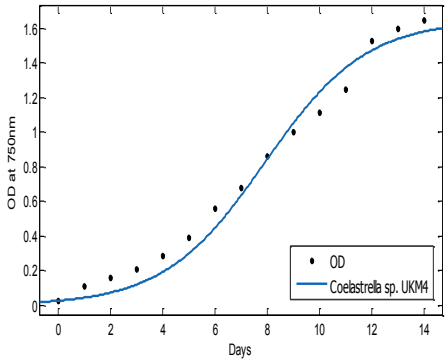
The cultures were collected via centrifugation at 5000 rpm for 10 minutes. The supernatant was discarded. The lipid in microalgae cells was extracted using Folch method [42]. The collected cells after centrifugation were mixed with chloroform-methanol (2:1 v/v) and sonicated. An amount of 0.9% sodium chloride (NaCl) was added to the mixture and left overnight. Next, the lower phase was collected and allowed to evaporate to remove the organic solvent. Moreover, sulfuric acid was added to the samples and incubated in boiling water for 10 minutes. Then, 5 ml of sulfophospho-vanillin [43] was added and the samples were measured at 520nm. The lipid standard curve was established by using cholesterol. The values of lipid content (%) and productivity were calculated using the equations below [11].

$$\text{Lipid content } (\%) = \frac{W_2}{W_1} \times 100\% \quad (10)$$



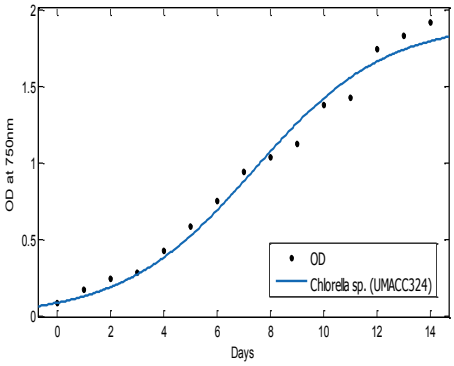
$$\text{Lipid productivity, } Y\ (mg.L^{-1}day^{-1}) = \frac{L \times \Delta W_1}{\Delta t} \quad (11)$$

where, $W_1$ is total biomass produced in day (mg.L$^{-1}$), $W_2$ is total lipid content (mg.L$^{-1}$), $L$ is lipid content (%), $\Delta t$ is duration of cultivation (day) and $\Delta W_1$ is variation of biomass concentration (mg.L$^{-1}$).



## Results and Discussion

### Microalgae growth evaluation



Synthetic media are artificial and simplified media that are designed to provide nutrients for growth of freshwater algae, as well as for maintaining algal strains. In microbial cell suspensions, cell turbidity can be determined easily by using the optical density method [44]. However, inaccuracies can occur due to the existence of pigments (chlorophyll *a* and *b*) content. Thus, the suitable wavelength that minimises the pigment absorbance should be carefully selected. For algal suspensions, the error can be minimised by measuring the cell density at a wavelength beyond the range of chlorophyll contents, such as at 750 nm. In this experiment, all three isolated microalgae were cultured in batch mode for 14 days without any optimisation factor that might affect the growth and biochemical composition. The results indicated that each species showed similar trends and adhered to the standard growth curve for microalgae. The algal growth curves based on OD 750nm are shown in Figure 2. All the microalgae underwent lag, exponential, and stationary phases when growing in synthetic media. Based on the graph, the lag phase of all the species was consistent from day 0 to day 4, followed by exponential phase (day 4 to day 10), and stationary phase (day 10 to day 14). However, the decline (death) phase was not achieved by day 14. The initial pH of BBM medium was around 6.9 to 7.1 and this value was observed to increase (up to pH 8.0) as the culture grew. The rise of pH levels is a good indicator as it shows that the microalgae are indeed growing in the culture medium. According to Borowitzka [45] and Goldman et al. [46], the pH value usually increases due to the photosynthetic activity of microalgae.

(a) *Chlorella sorokiniana* UKM3

(b) *Coelastrella sp.* UKM4

(c) *Chlorella sp.* UMACC324

Figure 2. Growth curves of POME-isolated microalgae at $OD_{750nm}$

According to Dailey and Reish [47], some algae species grow by increasing their cell number (cell division), rather than in size. The rate of cell division was varied according to the species and their living conditions. The increasing of algal biomass over a period of time is known as the new production or growth rate. Specific growth rate refers to the cell regeneration, which is the way of how fast the cells are dividing in a culture. Most of microalgae growth process can be explained by using the Logistic model. It is a common model of population growth with sigmoid profiles independent of substrate concentration [37]. The growth rates of each microalga species were calculated based on Equations (1) and (3). The results for growth rates are shown in Table 2.

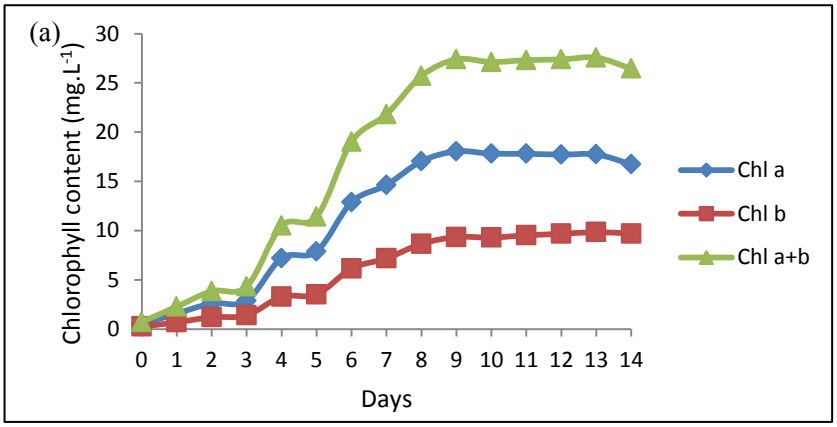
Table 2. Growth rates of POME-isolated microalgae in synthetic media

| **Microalgae sp.** | **Specific Growth Rate, μ ($d^{-1}$)** | **Maximum Specific Growth Rate, $\mu_{max}$ ($d^{-1}$)** | **Logistic Equation** |
|---|---|---|---|
| *Chlorella sorokiniana* UKM3 | 0.20 ± 0.05 | 0.44 ± 0.02 | $X = \frac{0.17\, e^{0.44t}}{1.87 + 0.09e^{0.44t}}$ |
| *Coelastrella sp.* UKM4 | 0.22 ± 0.03 | 0.52 ± 0.03 | $X = \frac{0.05\, e^{0.52t}}{1.62 + 0.03e^{0.52t}}$ |
| *Chlorella sp.* UMACC324 | 0.19 ± 0.04 | 0.41 ± 0.01 | $X = \frac{0.18\, e^{0.41t}}{1.83 + 0.09e^{0.41t}}$ |

The growth rate of microalgae can be altered by optimising and modifying the growth conditions. Besides that, the increase of inoculum density also can affect the algal growth. A study conducted by Griffith and Harrison et al. [48] stated that the growth rate, μ, decreased when the concentrations of inoculum increased. Thus, in this study, only one inoculum density at OD reading of 1.0 was used in all runs. Based on the results shown in Table 2, *Coelastrella sp.* UKM4 achieved the highest growth rate, followed by *Chlorella sorokiniana* UKM3 and *Chlorella sp.* UMACC324. In addition, Tamil Selvam [49] discovered that the specific growth rate for *Chlorella sorokiniana* in BBM medium was 0.18±0.01 $d^{-1}$. This value is slightly lower than the result obtained in this study, whereby μ attained by *Chlorella sorokiniana* UKM3 was 0.20±0.05 $d^{-1}$. Meanwhile, according to Vello et al. [50], the specific growth rates for *Chlorella sp.* UMACC322 and UMACC325 were 0.49±0.02 $d^{-1}$ and 0.51±0.1 $d^{-1}$, respectively. The values are higher compared to the growth rate displayed by the *Chlorella* strain in this study. The variation of algal growth rates usually related to the growth conditions and algal requirements [5–7].

Moreover, primary productivity was obtained by measuring the increase in biomass over a period of time. Productivity or called yield in mass algal culture differs from standing crop biomass. A standing crop can be described as the total dried biomass of the living organisms present in a given environment. The total biomass of standing crop may be high, but the productivity would be low. Occasionally, low biomass content shows high productivity and specific growth rates, or possibly the other way around. Maximum yield or productivity is usually obtained at intermediate densities and growth rates, while maximum growth rates usually occur at lower density. High densities cause slower growth rates due to several limiting factors, which alter the biochemical aspect within the cells. Besides, algal biomass would continue to increase until a factor limits its generation [51]. The shadowing effect also can cause a decrease in specific growth rates but higher biomass concentrations can be achieved. Furthermore, in a condition where light or nutrients are limited, low biomass concentration and high specific growth rates are expected to occur in the cultivation systems [52–54].

In this experiment, *Coelastrella* strain attained higher biomass productivity (0.07±0.02 $g.L^{-1}.d^{-1}$) in comparison to *Chlorella sorokiniana* and *Chlorella sp*. The productivity results are comparable with the microalgae growth rate. The higher productivity and growth rate achieved by *Coelastrella sp.* UKM4 showed that this microalga has the potential to be cultivated in a large-scale production to generate biomass for fertilisers, animal feed, and other



products. However, Minhat et al. [55] reported that the biomass concentration of *Chlorella sorokiniana* UKM3 in BBM was 2.52 $g.L^{-1}$, which is higher than the result obtained in this study. The results of biomass concentration, productivity, and $CO_2$ consumption rates are presented in Table 3. The consumption of $CO_2$ is related directly to the biomass production. As the biomass increases, the consumption rate also increases. Therefore, *Coelastrella sp*. has the potential to be used in carbon sequestration process compared to other strains.

Table 3. Biomass concentration, productivity, and $CO_2$ consumption rates of POME-isolated microalgae

| **Microalgae sp.** | **Biomass Concentration ($g.L^{-1}$)** | **Biomass Productivity ($g.L^{-1}.d^{-1}$)** | **$CO_2$ Consumption Rate ($g\ CO_2.L^{-1}d^{-1}$)** |
|---|---|---|---|
| *Chlorella sorokiniana* UKM3 | 0.86 | 0.06 ± 0.02 | 0.11 ± 0.03 |
| *Coelastrella sp.* UKM4 | 0.95 | 0.07 ± 0.02 | 0.13 ± 0.04 |
| *Chlorella sp.* UMACC324 | 0.78 | 0.05 ± 0.01 | 0.09 ± 0.01 |

**Biochemical content evaluation**

Pigmentation and storage product are important criteria in the classification of algae. Different groups of algae exhibit various colours due to the differences found in pigmentation. All the microalgae species used in this study are members of the division *Chlorophyta* or green algae. The pigments of green algae are chlorophyll *a* and *b*, whereas their accessory pigments are carotenoids and xanthophylls. Chlorophyll (green pigment) is an extremely important biomolecule for photosynthesis and growth. Furthermore, microalgae with high pigment content have the potential to be used as sources of dyes [6,7]. In this experiment, microalgae were treated using methanol to extract the chlorophyll content. Figure 3 illustrates the amount of chlorophyll content in each species. Based on the graphs, *Chlorella sorokiniana* UKM3 showed the highest chlorophyll content (Chl *a*+*b*) which is 26.84±1.76 $mg.L^{-1}$ at day 13. This value is higher compared to the result obtained by Tamil Selvam [49], which is 12.24±0.48 $mg.L^{-1}$. As for *Coelastrella sp*. UKM4, the chlorophyll content was the highest (26.47±6.14 $mg.L^{-1}$) at day 10, while *Chlorella sp.* UMACC324 was at day 13 (26.21±0.49 $mg.L^{-1}$). The chlorophyll content for all the species began to increase drastically from day 3 until day 8 before reaching stationary state. After day 11, the chlorophyll content in *Coelastrella sp.* showed a reduction (19.63 $mg.L^{-1}$). The reduction of chlorophyll content is directly related to the reduction of photosynthesis activity [56]. Besides, both *Chlorella* strains showed better performance in terms of chlorophyll availability compared to *Coelastrella sp.* at the end of cultivation. Although the microalgae used in this study are from the same division, the chlorophyll content presented in each species differed slightly. However, the amounts have been comparable with each other.

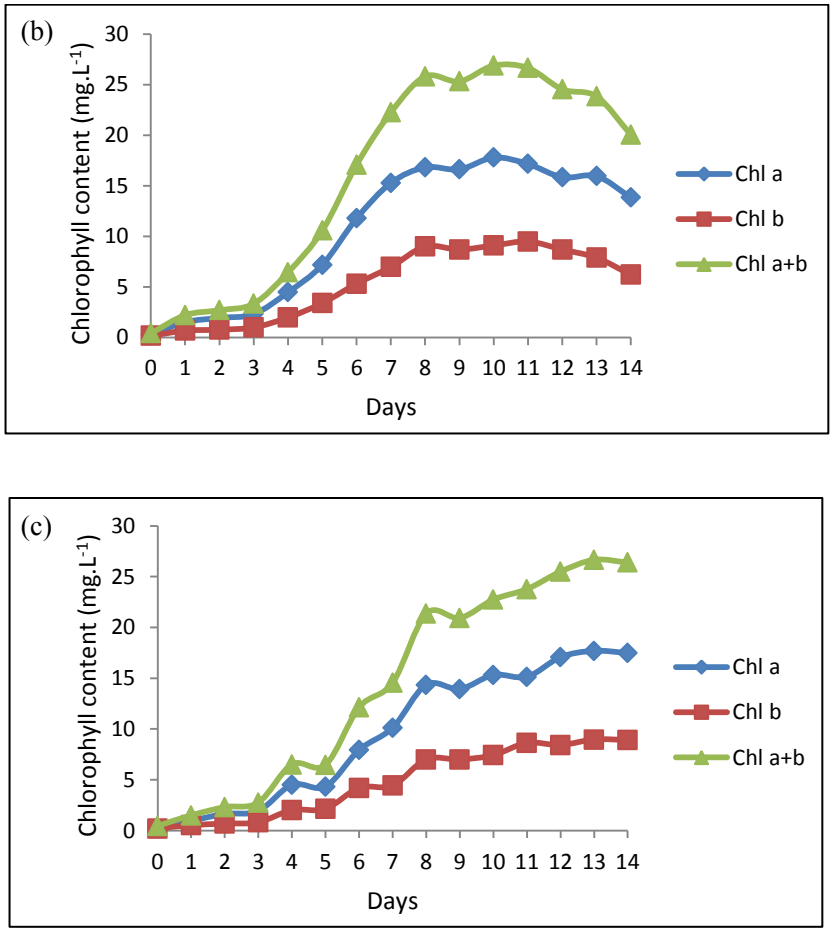


Figure 3. Chlorophyll content in POME-isolated microalgae (a) *Chlorella sorokiniana* UKM3, (b) *Coelastrella sp.* UKM4 and (c) *Chlorella sp.* UMACC324

Algae store their lipids in various ways; depending on the species, growth conditions and also the growth stage when microalgae are harvested. When algal cells are actively growing, the major lipids found within the cells are in the form of glycolipids and phospholipids. The overall lipid profile changes when algae enter a less active growth phase or encounter environmental stress. Algae will slow down their rate of proliferation and start to store Triacylglycerides (TAGs) as the dominant lipid in cell vacuoles [19, 57-59]. In this experiment, microalgae lipids were extracted by employing the Folch method and then estimated using the sulfophospho-vanillin (SPV) method. Furthermore, the lipid content was calculated by using the cholesterol standard curve. Figure 4 shows the lipid content ($mg.L^{-1}$) for each microalga, while Table 4 presents the percentages of lipid content and lipid productivity.

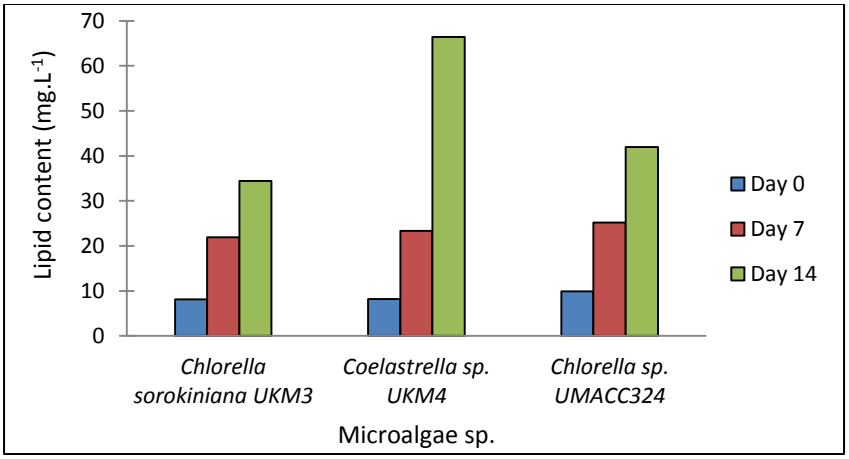

Figure 4. Lipid content ($mg.L^{-1}$) of POME-isolated microalgae

Table 4. Lipid content (%) and lipid productivity of microalgae in synthetic media

| **Microalgae sp.** | **Lipid Content (%)** | **Lipid Productivity ($mg.L^{-1}.d^{-1}$)** |
|---|---|---|
| *Chlorella sorokiniana* UKM3 | 4.65 | 221.03 |
| *Coelastrella sp.* UKM4 | 7.26 | 452.42 |
| *Chlorella sp.* UMACC324 | 6.68 | 269.74 |

Figure 4 depicts that the lipid content of microalgae increased as the culture grew from day 0 (lag phase) to day 14 (stationary phase). At the end of this experiment (day 14), the highest lipid content was recorded in *Coelastrella sp.* UKM4 (66.42±2.87 $mg.L^{-1}$), followed by *Chlorella sp.* UMACC324 (41.94±1.73 $mg.L^{-1}$) and *Chlorella sorokiniana* UKM3 (34.43±1.38 $mg.L^{-1}$). Although *Chlorella sorokiniana* UKM3 produced high biomass concentration compared to *Chlorella sp.* UMACC324, the values of lipid content and productivity had been the lowest. However, Tamil Selvam [49] reported that *Chlorella sorokiniana* attained 72.14±2.01 $mg.L^{-1}$ of lipid content, which is higher than the result obtained in this study. According to Sarmidi [60], the variation of lipid content in microalgae cultured in batch mode is directly related to the culture age, as well as nutrient depletion.

## Conclusion

This study examined the growth rates and biochemical compositions of POME-isolated microalgae when cultured in synthetic media. *Coelastrella sp.* UKM4 showed better performance in terms of growth rates, biomass concentration and lipid content. However, *Chlorella sorokiniana* UKM3 exhibited the highest chlorophyll content compared to other species. The studies pertaining to the microalgae growth are definitely useful and offer important data for cell growth optimisation process, besides understanding their adaptability in different growth conditions. The biochemical products generated by microalgae are also economically useful in various industries for a wide range of purposes. Microalgae species with high growth rate and biochemical content have the potential to be used in the production of biofuels, dyes, and other high valuable products. Therefore, future work is required to fully characterise the microalgae compositions in order to predict its potential for the future development of algae-based industries.

**Abstract**

A new analytical method development based on solid phase extraction (SPE) combined with high performance liquid chromatography (HPLC) was carried out. The optimum working conditions were obtained based on selection of 250 mL sample loading, 0.25 µL methanol as reconstitution solvent, 100% methanol as mobile phase and 270 nm as the optimum wavelength. Good linearity was obtained in the range of 0.015 – 400 mg/L and the regression coefficient, $R^2$, was 0.995. Limit of detection and quantification were calculated at LOD = 0.06 µg/L and LOQ = 0.2 µg/L respectively. Repeatability and robustness has showed good performance with low relative standard deviation less than 3.29% and 3.50% respectively. Time-of-flight mass spectrometry (TOF/MS) instrument was used to confirm that caffeine is definitely present in surface water with level of concentration ranged from 31.7 to 50.1 µg/L. All results were analyzed statistically using one-way ANOVA, Tukey with interval confidence 95% and P-value 0.05.

**Keywords:** caffeine, stimulant, emerging pollutant, water quality, time of flight/mass spectrometry

**Abstrak**

Pembangunan kaedah analisis baru berasaskan pengekstrakan fasa pepejal bersama kromatografi cecair prestasi tinggi (KPCT) telah dijalankan. Kaedah optimum diperolehi berdasarkan tetapan iaitu 250 mL muatan sampel, 0.25 µL metanol sebagai pelarut, 100% methanol sebagai fasa bergerak dan 270 nm panjang gelombang yang optimum. Nilai kelinearan baik diperolehi pada julat kepekatan 0.015 – 400 mg/L dan nilai pekali regresi, $R^2$ ialah 0.995. Had pengesanan dan kuantifikasi dihitung masing – masing pada LOD = 0.06 µg/L and LOQ = 0.2 µg/L. Kebolehulangan dan keteguhan kaedah menunjukkan prestasi baik dengan nilai sisihan piawai relatif yang rendah iaitu masing – masing kurang daripada 3.29% dan 3.50%. Spektrometri jisim masa penerbangan (TOF/MS) digunakan untuk mengesahkan kehadiran kafein di permukaan air dengan aras kepekatan antara julat 31.7 hingga 50.1 µg/L. Keputusan dianalisa mengunakan pendekatan statistik seperti ANOVA satu hala, Tukey dengan aras keyakinan 95% and nilai p 0.05.

**Kata kunci:** kafein, perangsang, pencemar baru, kualiti air, spektrometri jisim/masa penerbangan

## Introduction

Caffeine (1,3,7-trimethyxanthine) is a chemical substance widely used in foods, beverages and drugs materials. Caffeine content in chocolate usually ranges between 5 and 35 mg/oz while in medicine tablet such as Anacin and Excedrin within the range of 30 - 200 mg concentration per tablet [1]. In human body, only 0.5 - 10% of caffeine was required for energy metabolism and the remaining will be excreted [2]. The occurrence of caffeine residue in aquatic environment is related to its presence in food and beverage waste, clinical waste, agricultural and poultry industry either through direct wastewater discharges or disposal of effluent water treatment plants (WWTPs) [3-5]. In groundwater environment, the septic system failure could be the main source of pollution with pharmaceuticals [6]. The residue of caffeine in surface water usually traced at low level concentrations within the range of ng/L to µg/L [7,8]. Nevertheless, it is still threatening to aquatic ecosystem especially living organism likes coral, which is highly sensitive to caffeine [9]. Moreover, this chemical substance posing high solubility and slow rate of degradation, lead to be more persistent in aquatic environments [10]. However, Al-Qaim et al. reported that caffeine can be removed by electrochemical degradation using graphite-poly vinyl chloride as anode as well its by-products which are formed during treatment process [11].

The target drug residues normally occur at low (ng/L to µg/L) levels so the pre-concentration is required to increase the detection limit of caffeine. Solid-phase extraction (SPE) is one of the method which is usually chosen [12,13]. A part from this, solid-phase microextraction (SPME) [14,15] or liquid-phase microextraction [16] have also been developed for this purpose.

Analysis of caffeine residue in natural waters have been carried in many countries by using various instruments mainly by liquid chromatography [3,5,17] and gas chromatography [7,18,19]. However, information of caffeine residue present in Malaysian environment is still limited and unclear. To best of our knowledge, the study on the occurrence of caffeine residue in surface water of Malaysian aquatic environment has not been reported except one study [17] which was conducted by our team. Thus, this study was aimed to extend the optimize work on method development of caffeine residue in water samples and to evaluate the developed method to the analysis of real samples.

## Materials and Methods

Analytical grade standard of caffeine was purchased from Sigma Aldrich (USA). HPLC-grade solvents namely methanol and methyl tert-butyl ether were purchased from Merck (Germany) and J.T. Baker (USA). Solid phase extraction cartridges, Oasis HLB 3 mL were purchased from Waters (USA). Membrane glass microfiber filters with diameter 47 mm were purchased from Whatman (UK). Deionized water was obtained by using a Mili-Q Easypure Rodi, Barnstead (USA) instrument.

Caffeine stock solutions were prepared in methanol at 1000 mg/L level concentrations and stored at −18 °C. Primary mixture stock solutions were then subsequently diluted for optimization study. A series of stepwise dilution solutions (0.015 – 400 mg/L, n=11) were used for the construction of external calibration curves in order to determine the unknown concentration of caffeine. Repeatability test was performed at three concentration levels (50, 100 and 200 mg/L). Limit of detection and quantification of caffeine were obtained based on 3:1 and 10:1 signal to noise ratios respectively. Robustness was performed based on injection volume at three different values (20, 21 and 22 µL).

### Method extraction

In general, the method extraction was reported somewhere with a little modification [17], solid phase cartridge initially was conditioned with 2 mL methyl tert-butyl ether (MTBE), 2 mL methanol (MeOH) and 2 mL deionized water. Then required water samples were loaded continuously into the cartridge at flow rate 9.0 mL/min. Cartridge was then washed with 2 mL of deionized water before left for dryness approximately half an hour. After that, cartridge was eluted with 5 mL MTBE, 2 mL acetone-MeOH (21-9; v/v), and 3 mL acetone-MeOH (9-21; v/v). Extracted sample was placed under nitrogen stream to complete dryness prior to reconstitute with required volume of methanol.

**HPLC-UV analysis**
High performance liquid chromatography (HPLC PERKIN ELMER 785A) with Chromolith® Performance RP-18e (4.6 x 10 mm, 5 µm) column equipped with UV/Vis as detector was used in this study. The optimization work was divided into two portions namely extraction (SPE) and chromatographic performance (HPLC). During the extraction process, effect of changes on variables namely sample volume and re-constitute sample volume were investigated. Meanwhile HPLC performance was tested on optimum condition for variable mobile phase and wavelength. 20 µL was injected as a final volume of sample using HPLC. Each sample was injected at least three times to ensure the precision and for other statistical analysis.

**TOF/MS analysis**
Mass spectrometry was performed on ESI-TOF instrument (micrOTOF-Q, Bruker /Germany). The results were obtained with the following settings: MS capillary voltages, 4000/3500 (PI/NI); drying–gas flow rate, 8.0 L/min; drying gas temperature, 190 $^{0}$C; and nebulizer pressure, 4.0 bar. One adduct ion, namely $[M+H]^{+}$ was observed for ESI (+) analysis in PI mode. Caffeine was acquired using an independent reference spray via the LockSpray interference to ensure accuracy and reproducibility. A mixture of sodium hydroxide and formic acid (FA) was used as the lock mass m/z 90.9766 to 974.8132. The accurate mass was calculated using software Daltonics DataAnalysis incorporated in the instrument.

**Statistical analysis**
The statistical analysis of variance (one-way ANOVA) was achieved for sample volume, reconstitute volume, wavelength and mobile phase by using Minitab Version 17, Tukey with P = 0.05 and 95% as interval confidence.

**Sample collection**
Surface water samples were collected from Alur Ilmu, the storm water channel in Universiti Kebangsaan Malaysia. This channel was connected to the downstream of Langat River. Five stations were chosen during the period of study in November 2014. Samples were collected once from each sampling point. The coordinates for these sampling sites are listed in Table 1. Water sample was collected by using 1 litre glass bottle, capped and transferred directly to laboratory for further analysis.

Table 1. Description of sampling location

| Station | Longitude | Latitude | Remark |
|---|---|---|---|
| S1 | 02°55.336N | 101°47.280E | Upstream, nearby faculty cafeteria |
| S2 | 02°55.393N | 101°47.304E | Drainage after faculty cafeteria |
| S3 | 02°55.534N | 101°47.264E | Drainage before student centre cafeteria |
| S4 | 02°55.579N | 101°47.234E | Drainage after student centre cafeteria |
| S5 | 02°55.727N | 101°47.063E | Downstream, nearby university mosque |

## Results and Discussion

**Effect of sample volume and reconstitution volume on recovery**
This method was compared with other previous methods in terms of mobile phase and retention time. Alvi and Muhammad reported that they used a very complicated mobile phase (15 mM potassium phosphate (pH 3.5) and acetonitrile (83:17, v/v). The drawback of using buffer solution is to clog the column with the salt of buffer if there is no enough washing. Our study also compared with other previous reported work in terms of solvent consumption [20]. Chowdhury et al., reported that caffeine was separated after 20 min run at 1.0 mL which means each run could consume 20 mL [21], compared to our study, only 1.0 mL was consumed at 0.3 mL/min for each run.

The volume of sample was spiked at 100 µg/L of caffeine and three sample volumes (100, 250 and 500 mL) were tested. Sample with volume 250 mL indicated the highest recovery compared to 100 and 500 mL samples (Figure

1a). The recovery of caffeine was the lowest when 500 mL was used. This result is related to the unsuitability of using large volume of sample with the size of the cartridge (3cc). The volume 100 mL gives high recovery (84.57%) but still less than the recovery obtained by 250 mL (87.53%). However, 250 mL was selected to the next experiments for further considerations.

Figure 1b shows that three different volumes of methanol (0.25, 0.50 and 1.00 mL) were tested as reconstitution solvent after solid phase extraction loading. Highest recovery was obtained at 79.12% by using 0.25 mL of methanol as reconstitute solvent. Other volumes gave recovery at 72.03% (1 mL MeOH) and 71.66% (0.5 mL MeOH) which were not significantly different, more explanations in the next section. From these results, 0.25 mL reconstitute volume was selected for further experiments.

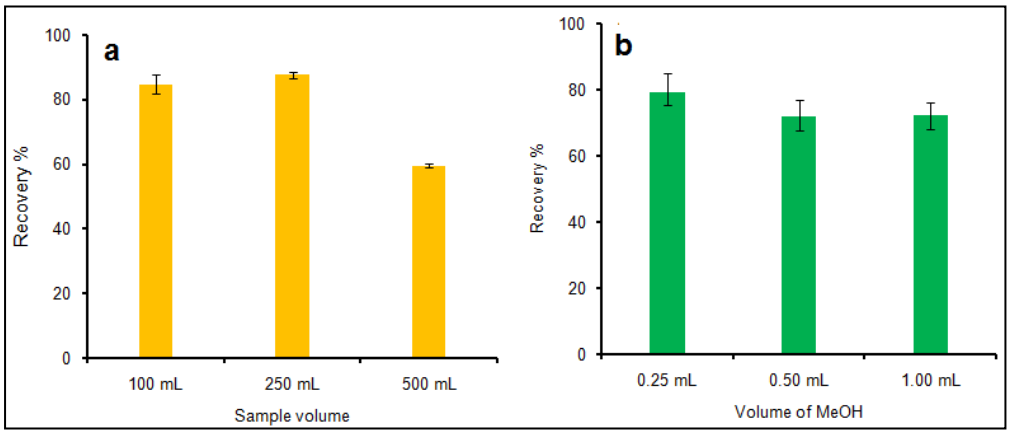

Figure 1. Effect of (a) sample volume, and (b) volume of solvent on the recovery of caffeine

**Effect of mobile phase and wavelength**

In this study, the isocratic elution program was used for seven mobile phases (100% MeOH (S1), DIW:MeOH (20:80) (S2), DIW:MeOH (40:60) (S3), DIW:MeOH (60:40) (S4), DIW:MeOH (80:20) (S5), 100% DIW (S6), ACN:MeOH (40:60) (S7)) as presented in Figure 2. Four mobile phases were presented because the others exhibited very low signal or not detected so they were excluded from the graph. However, the mobile phase chosen for analytical method validation was 100% MeOH, presented a mobile phase holdup time of 0.652 min and good separation as shown in Table 2.

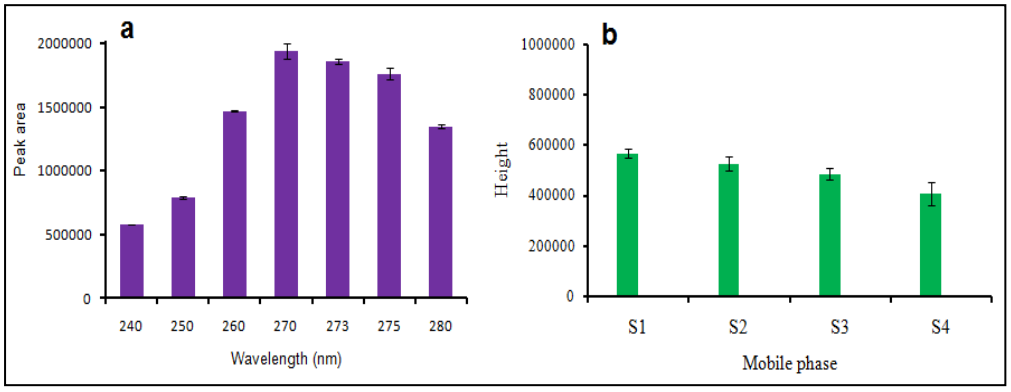

Figure 2. Effect of (a) wavelength, and (b) mobile phase on the sensitivity of caffeine analysis

Mobile phase ACN:MeOH (40:60) (S7) exhibited very low peak signal (peak area 8743 and peak height 2469) which means an additional of acetonitrile reduce the efficiency of elution for caffeine (data not shown). In case of mobile phase (100% DIW) no peak was obtained, may be this was attributed to the very low polarity of this mobile phases to be suitable for elution of caffeine. Consequently, the mobile phases DIW:MeOH (20:80) (S2), DIW:MeOH (40:60) (S3), DIW:MeOH (60:40) (S4) produced less peak height sequentially. From these results, increasing the amount of water in the mobile phase has led to low peak height and broad peak which are not good in terms of separation using high performance liquid chromatography.

Wavelength was another parameter considered in this study using HPLC instrument equipped with ultra-violet (UV) detector. Optimization of wavelength is very important because the targeted compound has optimum absorbance on its own wavelength. The optimum of chromatographic signal response was obtained at 270 nm. At this wavelength, caffeine signal response was obtained with maximum peak area which was observed at 1940353.25 µV/s.

Wavelength was optimised at 240, 250, 260, 270, 273, 275 and 280 nm. At 270 nm, the concentration of caffeine was the highest compared to the rest of the wavelengths. The peak area of caffeine was influenced by the wavelength but the retention time and the shape were not influenced. Wavelength was not responsible for elution of caffeine from column, but it only affected the absorbance. However, a significant difference was observed at all the wavelengths except at 270, 273 and 275 nm.

**Method performance**

Analytical performances namely linearity, repeatability, robustness, detection limit and quantification limit were tested and presented in Table 2 and 3, respectively. Good linearity was obtained by plotting external calibration of a series of caffeine standard solution (n = 11). Regression equation was expressed as $y = 13273x + 46610$ with regression coefficient $R^2 = 0.995$. Repeatability of the developed method was tested using intra and inter-day precision at 3 level concentrations (50, 100, 200 mg/L). Analysis of results indicated that repeatability of developed method was precise with RSD value < 3.29%, which explained good routine work. Limit of detection and quantification were calculated at LOD = 0.066 µg/L and LOQ = 0.20 µg/L respectively. Robustness test was performed on volume injection and flow rate of mobile phase. The results showed that the method is robust. Relative standard deviation for both effect of volume injection and flow rate ranged from 3.50% to 1.95% respectively.

Table 2. Precision of SPE method on caffeine analysis

| **Concentration (mg/L)** | **Intra-day (n = 9)** | | **Inter-day (n = 18)** | |
|---|---|---|---|---|
| | **Concentration ± SD** | **Rt ± SD** | **Peak Area ± SD** | **Rt ± SD** |

| 100 | 99.5 ± 7.662 | 0.652 ± 0.001 | 100.5 ± 0.603 | 0.654 ± 0.002 |
| 200 | 198.74 ± 2.027 | 0.652 ± 0.001 | 192.05 ± 1.108 | 0.652 ± 0.001 |

Table 3. Robustness test on HPLC performance for caffeine analysis (n = 3)

| **Variable** | **Level** | **Peak Area ± SD** | **Rt ± SD** |
|---|---|---|---|
| Volume injection (µL) | 20 | 50.9 ± 0.186 | 0.652 ± 0.001 |
| | 21 | 53.8 ± 0.078 | 0.651 ± 0 |
| | 22 | 55.22 ± 0.138 | 0.652 ± 0 |
| Flow rate of mobile phase (mL/min) | 0.30 | 52.45 ± 0.488 | 0.651 ± 0.001 |
| | 0.31 | 51.02 ± 0.209 | 0.632 ± 0 |
| | 0.32 | 48.34 ± 0.247 | 0.615 ± 0.001 |

**Statistical analysis**

The most significant results were obtained with volume of MeOH as reconstitute solvent, volume of sample, mobile phase composition and wavelength of caffeine absorbance. The significance value in terms of P-value was 0.000 in all cases which means high significant results were obtained. In case of volume used for MeOH, three volumes (0.25, 0.50 and 1.00 mL) were tested by one-way ANOVA. An amount 0.50 and 1.00 mL volumes were shared with same letter B means it was not significant but both volumes were significantly different from 0.25 mL volume.

Table 4. Statistical analysis of variance for the different independent factors using Tukey method and 95% confidence, P value less than 0.05.

Sample volume was statistically tested and exhibited very high significant difference in terms of peak area. The sample volumes (100, 250 and 500 mL) were totally statistically different as shown in Table 4. Sample volume (100 mL) was selected as the best sample volume because of its highest recovery. Mobile phase composition was also investigated statistically. However, mobile phase S1 and S2 were not differed significantly since both of them were

represented by letter A. Furthermore, the mobile phases S2 and S3, and S5 and S7 were not differed significantly. Mobile phase S4 was only significantly different from other mobile phases. Based on all these results, Methanol, S1, was selected as the best solvent because it produced sharp peak and well separated. Finally, seven mobile phases were tested to investigate the significance. All wavelengths were significantly different (all different letters) as shown in Table 4. The wavelength 270 nm was selected as the best wavelength based on its peak height.

**Analysis of real samples**

Analysis of caffeine residue in surface water was successfully carried out. Level of concentration was recorded within the range of 31.7 to 50.1 µg/L. The highest concentration was 50.1 µg/L recorded at S5 drainage nearby UKM's mosque (downstream) and the lowest concentration was 31.7 µg/L which was S1 nearby cafeteria (upstream). The concentration of caffeine at other stations were recorded 34.7 µg/L (S2) after cafeteria, 43.1 µg/L (S3) and 44.6 µg/L (S4). The results suggested that flushing from upstream to downstream as well as the discharge of water mixed with the tea beverages as the major factors for contribution the occurrence of caffeine in surface water. The increasing of caffeine gradually from S1 to S5 was not surprising because the number of sources increased as well in the same line. Finally, the site S5 was considered as the meeting point for all these sources thus it exhibited the highest concentration of caffeine. All results were tested statistically and showed a significant different among all sites as shown in Figure 3. The chromatogram peak of caffeine residue detected in water samples is presented in Figure 4.

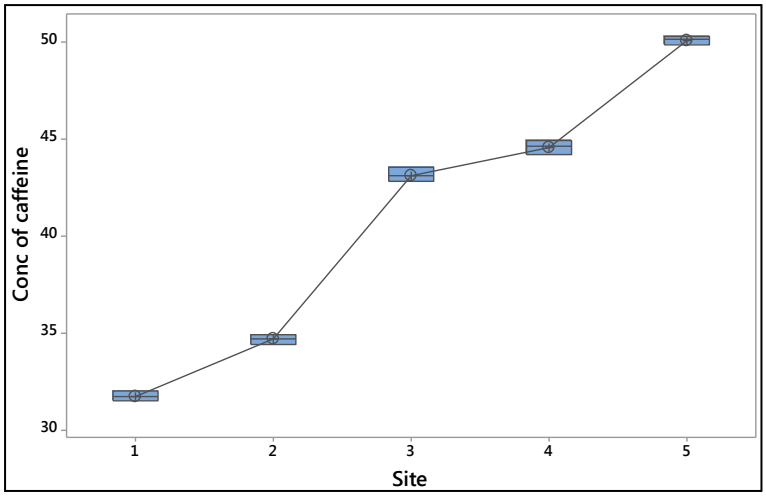

Figure 3. Box plot of the concentration of caffeine against sampling sites at 95% confidence interval and P-value 0.05

**TOF screening and confirmation**

For selection of the MS ionization mode, a standard solution of caffeine in 1:9 MeOH-$H_2O$ was separated and analyzed by LC-TOF/MS. The MS was tuned for $[M+H]^+$ ions in the ESI (+) ionization mode and for $[M-H]^-$ ions in the ESI (−) modes. The positive ionization mode was preferred for caffeine. Caffeine was not detected in the negative ionization mode. TOF/MS was selected as a better solution to confirm that caffeine was present in surface water (one sample was selected). The *m/z* of the caffeine was extracted from the total ionic chromatogram (TIC) in positive ionization mode as proton adduct $[M+H]^+$ with 0.2 ppm mass error through Bruker Daltonics DataAnalysis software as shown in Figure 5. To increase the selectivity of TOF measurements, a narrow accurate mass interval was used to reconstruct the chromatographic traces. Extracted ion chromatogram (EIC) was typically extracted using Bruker Daltonic software with 20 mDa mass window for caffeine in water sample.

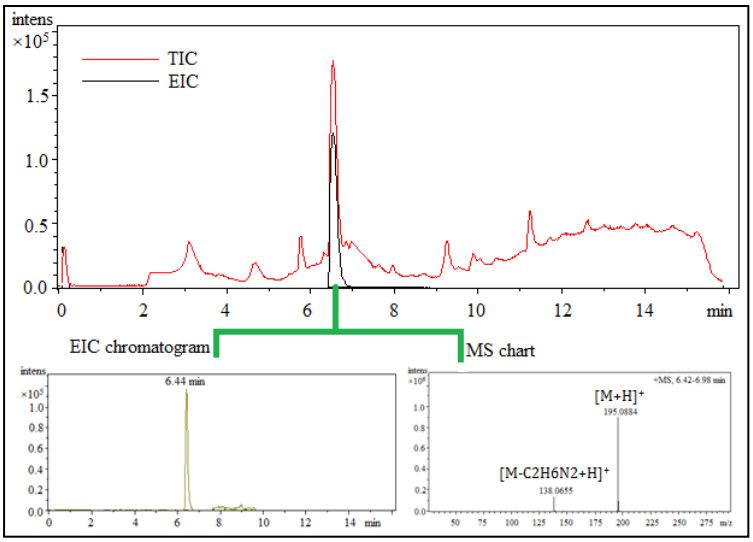

Figure 5. Confirmation profile for caffeine in surface water using LC-TOF/MS

## Conclusion

The optimization results showed that the HPLC developed method presented here can be considered reliable for the determination of caffeine residue in surface water. Good validation results were obtained in terms of linearity, precision, sensitivity and robustness on method extraction and HPLC performances. An application of the developed method on real samples showed that the occurrence of caffeine residue could reach to µg/L level of concentrations.

**Abstract**

Pulp and paper mill industry is one of the biggest water users that produce wastewater containing dye and various toxic compounds. The study was conducted to screen for potential tropical native aquatic plants, which can be used in phytoremediation mainly for the removal of colour and chemical oxygen demand (COD) from pulp and paper mill effluent. Three selected tropical native aquatic plants, *Scirpus grossus, Azola pinnata* and *Salvinia molesta* were planted in a greenhouse at UKM for screening test. Real final effluent from a pulp and paper mill in Pahang was characterized and contained 181 PtCo for colour and 72.4 mg/L COD at pH 8.1. This wastewater was exposed to weed plant, *Scirpus grossus* and floating plants, *Azola pinnata* and *Salvinia molesta.* The final effluent was analysed after 28$^{th}$ day of exposure. The percentage of colour removal for the three tropical native plants *Scirpus grossus, Azola pinnata* and *Salvinia molesta* were 50.28%, 43.09% and 49.72% respectively. While for COD removal, all the three plants successfully removed 100% COD. From the result, the best tropical native aquatic plant to remove colour and COD for pulp and paper mill effluent is *Scirpus grossus.*

**Keywords**: biological treatment, phytoremediation, effluent, colour, chemical oxygen demand

**Abstrak**

Industri kilang kertas adalah salah satu pengguna air yang terbanyak dan menghasilkan air sisa yang mengandungi pewarna dan pelbagai sebatian toksik. Kajian ini dijalankan untuk menyaring bagi tumbuhan tropika asli yang berpotensi untuk proses fitoremediasi dalam penyingkiran warna dan permintaan oksigen kimia (COD) daripada sisa air kilang pulpa dan kertas. Tiga jenis tumbuhan tropika asli telah dipilih iaitu *Scirpus grossus, Azola pinnata* dan *Salvinia molesta* ditanam dalam rumah tumbuhan di UKM untuk ujian saringan. Efluen sebenar dari sebuah kilang pulpa dan kertas di Pahang telah dicirikan dan mengandungi 181 PtCo untuk warna dan 72.4 mg/L untuk COD pada pH 8.1. Air sisa ini telah didedahkan kepada tumbuhan rumpai iaitu *Scirpus grossus* dan tumbuhan terapung *Azola pinnata* dan *Salvinia molesta*. Efluen ini dianalisis selepas diuji/didedahkan sehingga hari ke-28. Penyingkiran warna untuk tiga tumbuhan asli yang dipilih iaitu *Scirpus grossus, Azola pinnata* dan *Salvinia molesta* adalah masing-masing sebanyak 50.28%, 43,09% dan 49,72%. Manakala bagi penyingkiran COD bagi *Scirpus grossus, Azola pinnata* dan *Salvina Natans* ialah 100% penyingkiran. Daripada keputusan itu, tumbuhan tropika asli yang terbaik untuk menyingkirkan warna dan COD dari effluen kilang pulpa dan kertas adalah *Scirpus grossus*.

**Kata kunci:** rawatan biologi, fitoremediasi, efluen, warna, permintaan oksigen kimia

## Introduction

In Malaysia, there have been more than one billion capacities of pulp and paper. According to Roda and Rathi [1], Malaysia has 67 of pulp and paper mill industries that produce papers from pulp or recycled paper. These industries produce about 76 to 228 $m^3$ of water per tonne. Pulp and paper mill industries are also known as the sixth industry contributing pollution to environment [2-3]. Pollutants released from pulp and paper mill effluent into environment cause numerous problems and physiological impairment. Due to high organic pollutants in the pulp and paper mill effluent will affect aquatic communities [10].

The problems associated with pulp and paper mill effluents are pH, colour, and high levels of Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), Suspended Solid (SS) and Absorbable Organic Halides (AOX). Paper manufacturing process releases chlorinated substances in the effluent as the major contaminants formed [4-7]. Pulp and paper mill wastewater is a concern for the environment due to its after effects. Some researchers [8-10] more focused on environmental friendly technologies for treatment of wastewater. They use biological approach for the removal of contaminants from the effluent. The biological treatment processes are able to reduce colour, COD, BOD and toxic low molecular weight chlorinated lignin derivatives.

Last few decades, there has been an increase in improving the ability of plants to remove environmental pollutants. Genes from microbes and plants are being used successfully to enhance the ability of plants to tolerate, remove and degrade pollutants [11]. Therefore, phytoremediation on a basis of plant is suitable for biological treatment for pulp and paper mill effluent. Phytoremediation uses plants to treat contaminated effluent. This technology has been extensively reviewed through literature studies [12-19]. Phytoremediation takes advantage of the natural ability of plants to extract chemicals from water, soil and air using energy from sunlight. Some advantages and disadvantages are listed in Table 1. Its primary advantage is that it is approximately 10 times less expensive than conventional strategies [20]. Other advantages of phytoremediation over the engineering or bioremediation methods include the possibility of a useful product such as wood, pulp or bioenergy [21]. Plants act as soil stabilizer, minimizing the amount of contaminated dust that could leave the site and enter the surrounding neighbourhoods [11].

Table 1. Advantages and disadvantages of phytoremediation

| Advantages | Disadvantages |
|---|---|
| Less costly than mechanical methods | Limited to shallow contaminants |
| Passive, solar driven | Phytotoxicity of contaminants |
| High public acceptance | Slower than mechanical methods |
| Retains topsoil | Unknown effects of biodegradation products |
| Less secondary waste generation | Potential of contaminants to enter the food chain. |

Phytoremediation in pulp and paper mill effluent treatment may take one of several forms: phytoextraction, rhizofiltration, phytostabilization, and phytovolatilization. Phytoextraction refers to process in which plants are used to concentrate metals from the soil into the roots and shoots the plant; rhizofiltration is the use of plant roots to absorb, concentrate or precipitate contaminants from effluents. Phytostabilization is the uptake and release into atmosphere of volatile materials such as mercury [22].

The aim of this study is to screen for potential tropical native aquatic plants, which can be used in phytoremediation mainly for polishing of colour and COD from pulp and paper mill final effluent.

## Materials and Methods

### Plant propagation

The selected plant, *Scirpus grossus* were planted in a greenhouse at UKM for preliminary studies and as a stock for further studies in phytotoxicity. The plant sources were taken from Tasik Chini, Pahang. The tenure of *Scirpus*

*grosuss* is between 8 – 10 weeks. Upon reaching maturity, this plant was taken for preliminary test. For *Azola pinnata* and *Salvinia molesta*, they were grown in greenhouse. Figure 1 (a) shows the samplings of *Scirpus grossus* taken at Tasik Chini, (b) matured *Scirpus grossus* planted at greenhouse, (c) *Salvinia molesta* and (d) *Azola pinnata* in greenhouse, Universiti Kebangsaan Malaysia.

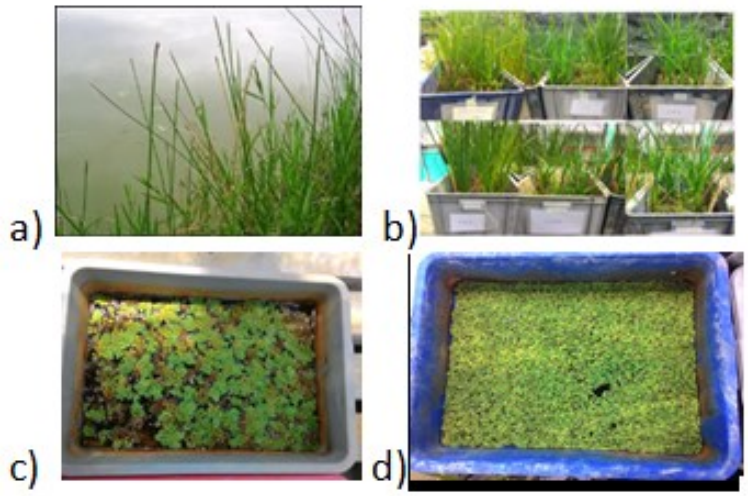

Figure 1. (a) *Scirpus grossus* at Tasik Chini, (b) matured *Scirpus grossus* at greenhouse, c) *Salvinia molesta*, (d) *Azola pinnata* at greenhouse

**Experimental set – up for preliminary test**

The preliminary test was conducted batch wise in crates of 10 L. Real final effluents from a pulp and paper mill industry in Pahang acted as a contaminant. All crates for *Scirpus grossus* filled with 5 kg of sands and 2 L of wastewater except for control contaminant (CC) filled with only tap water. All crates would be topped up with tap water by 1 L for every 2 days. The schematic diagram for experimented sets of *Scirpus grossus* is shown in Figure 2. There were four crates containing eight plants in each crate labelled as CC, R1, R2 and R3. The *Scirpus grossus* planted in two rows.

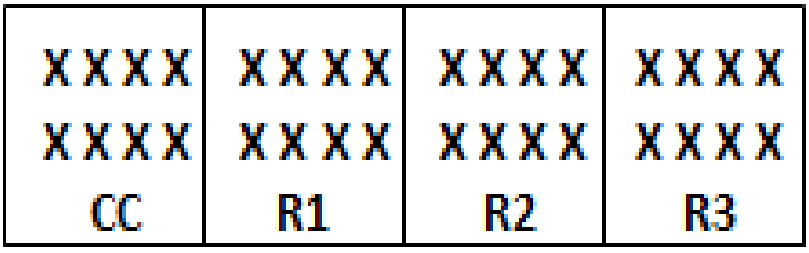

Figure 2. Schematic diagram of sets of *Scirpus grossus* in preliminary test

Floating plants of *Salvinia molesta* and *Azola pinnata* were prepared in three crates for each plant as shown in Figure 3 and Figure 4, respectively. Crate for control contaminant for *Salvinia molesta* and *Azola pinnata* labelled as SC and AC respectively containing 2 L of tap water. Crates for sample (S1/A1 & S2/A2) contained 2 L of wastewater. The crates were filled with 300g of the floating plants.

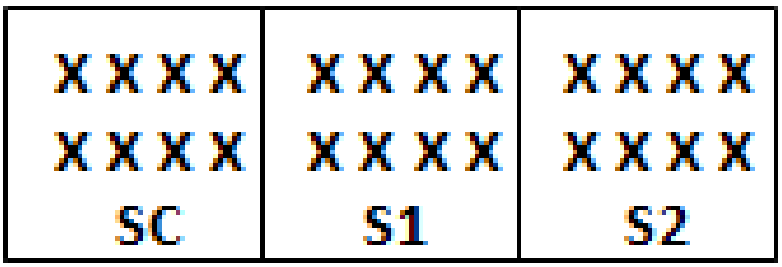

Figure 3. Schematic diagram of sets of *Salvinia molesta* in preliminary test

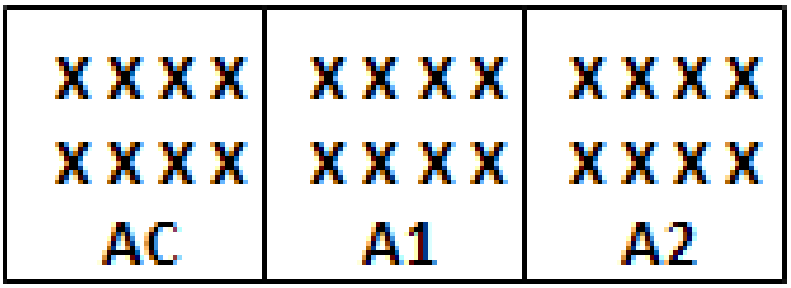

Figure 4. Schematic diagram of sets of *Azola pinnata* in preliminary test

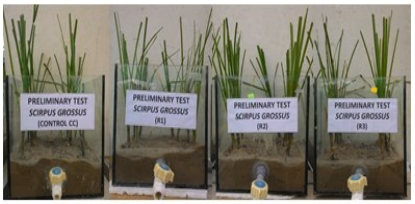
After 28th day exposure, liquid sample from each crate were collected for determining the colour and COD.

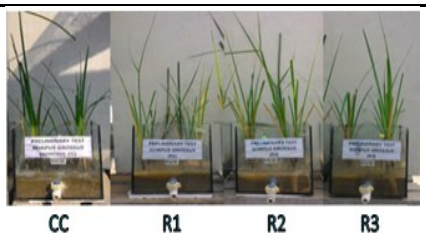
## Results and Discussion

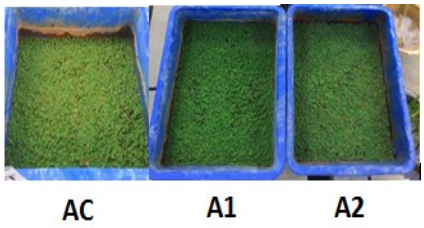
**Physical plant growth observation**

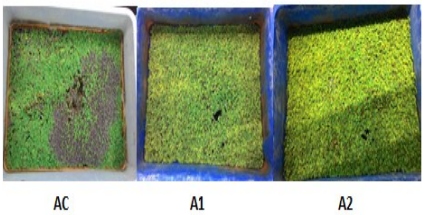
The observation on the physical appearance of *Scirpus grossus, Salvinia molesta* and *Azola pinnata* during the preliminary test when exposed to real wastewater was summarized in Table 2.

Table 2. Observation and physical appearance of *Scirpus grossus, Salvinia molesta* and *Azola pinnata* on day 0 compared to day 28









| Day of Exposure | Physical Appearance of Plants |
|---|---|
| | *Scirpus grossus* |
| Day 0 |  CC R1 R2 R3 |

Table 2 (cont'd). Observation and physical appearance of *Scirpus grossus, Salvinia molesta* and *Azola pinnata* on day 0 compared to day 28

| **Day of Exposure** | **Physical Appearance of Plants** |
|---|---|
| Day 28 |   |
| | *Salvinia molesta* |
| Day 0 |   |
| Day 28 |   |
| | *Azola pinnata* |
| Day 0 |   |
| Day 28 |   |

From the observation, the *Scirpus grossus* still survived until day 28. Nevertheless, there were also withered plants during the preliminary test. For *Scirpus grossus,* it started withered on day 7 compared to the control contaminant (CC) started on day 10. After day 28; the leaves grew in almost 20 cm higher than before, showing that after exposure, the *Scirpus grossus* can still survive and grow. *Salvinia molesta* and *Azola pinnata* withered starting on day 14 for both floating plants. The control crate withered faster than the contaminant crate. However, both floating plants can survive until day 28.

**Removal of colour and COD**

The characterization results of wastewater before and after exposure for all plants were summarized in Table 3. From the observation, colour and COD decreased from day 3. From Table 3, COD was totally removed by all plants. In addition, 50.28%, 49.72% and 43.09% of colour were removed by *Scirpus grossus, Salvinia molesta* and *Azola pinnata* respectively.

Table 3. Characterization of wastewater after exposure

| **Types of plants/characteristic** | | **Colour (PtCo)** | **COD (mg/L)** |
|---|---|---|---|
| *Scirpus grossus* | Average | 90 | 0 |
| | Percentage (%) | 50.28 | 100 |
| *Salvinia molesta* | Average | 91 | 0 |
| | Percentage (%) | 49.72 | 100 |
| *Azola pinnata* | Average | 103 | 0 |
| | Percentage (%) | 43.09 | 100 |
| Wastewater | | 181 | 72.4 |

Figure 5 shows the percentage removal of colour and COD. Hence, from this study, the most suitable tropical native plant used in colour and COD removal is *Scirpus grossus.*

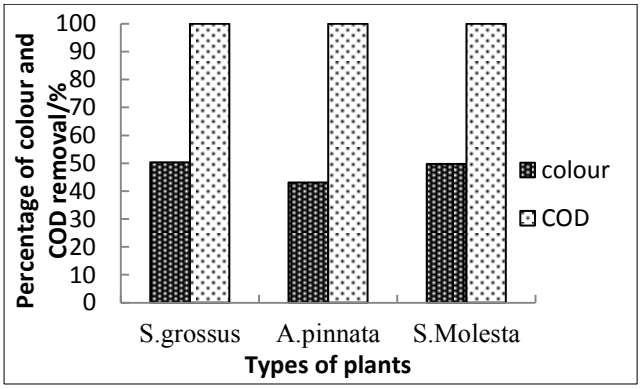


Figure 5. Removal of colour and COD by three plants *Scirpus grossus, Salvinia molesta* and *Azola pinnata*

## Conclusion

The results showed that between the three plants, *Scirpus grossus, Salvinia molesta* and *Azola pinnata* are able to remove colour and COD from real pulp and paper mill final effluent. Nevertheless, *Scirpus grossus* is the best tropical native plant for colour and COD removal through phytoremediation. Hence, *Scirpus grossus* is recommended for treatment wastewater pulp and paper mill.

# CHARACTERIZATION STUDIES OF SODIUM ALGINATE/SULFONATED GRAPHENE OXIDE BASED POLYMER ELECTROLYTE MEMBRANE FOR DIRECT METHANOL FUEL CELL

## (Kajian Pencirian Bagi Membran Elektrolit Polimer Berasaskan Sodium Alginat/Sulfonat Grafin Oksida untuk Sel Bahan Api Metanol Langsung)

**Abstract**

This work used blending and casting method to synthesis sodium alginate/sulfonated-GO (SA/SGO) polymer electrolyte membrane for direct methanol fuel cell (DMFC). The composition of sulfonated-GO in the membrane is varied from 0 wt% to 1 wt%. The functional groups in the membrane were confirmed by Fourier Transform Infrared analysis. The water uptake capacity of the membrane as observed was reduced with addition of sulfonated-GO as filler in the membrane. Thus, the proposed membrane has good potential to be an alternative membrane in DMFC application.

**Keywords**: fuel cell, graphene oxide, alginate, direct methanol fuel cell

**Abstrak**

Kerja ini menggunakan kaedah pemutus dan pengadunan untuk sintesis polimer membran elektrolit sodium alginat/ sulfonat-GO (SA/SGO) untuk aplikasi sel bahan api metanol langsung (DMFC). Komposisi sulfonat-GO dalam membran diubah daripada 0% berat kepada 1% berat. Kumpulan berfungsi dalam membran telah disahkan oleh analisis Infra merah transformasi Fourier. Kapasiti pengambilan air oleh membran seperti yang diperhatikan telah berkurangan dengan penambahan sulfonat-GO sebagai pengisi dalam membran. Oleh itu, membran yang dicadangkan mempunyai potensi yang baik untuk menjadi membran alternatif dalam aplikasi DMFC.

**Kata kunci:** sel bahan api, grafin oksida, alginat, sel bahan api metanol langsung

## Introduction

The advantages of DMFC as green technology exclusively in portable application tools such as laptop, camera and etc., has been attracted many researchers to explore their enhancement. With very less pollutant emission at the end process, low temperature works condition, compact design, and high power density is the enforcement of their commercialization today [1]. However, there are several things that hindered this commercialization process. The DMFC issues is relate to the low power density, sluggish in kinetic reaction of methanol oxidation, methanol crossover phenomena that leads to the mixed potential and fuel wasting in cathode side and also the very expensive of Nafion membrane that was used as main polymer electrolyte membrane in almost Fuel Cell types systems including DMFC [2].

Nafion is not well known as polymer electrolyte membrane due to its specialty in high proton conductivity, high mechanical strength, and strong chemical stability and well perform in fuel cell performance. It can be said that until now Nafion is the most ideal polymer electrolyte membrane candidate. But, the awareness of fuel cell researchers was increasing nowadays on the bad side of Nafion membrane especially their harmful material used in Nafion, fluorine, and high methanol crossover as well [3]. Thus, many efforts on finding new material for suited as polymer electrolyte membrane function to replace Nafion membrane. The environmental friendly, low cost, and low methanol crossover material seems the most needed characteristics to improved Nafion drawbacks. Alginate is the biopolymer who have that characteristics as it was selected in many applications such medical, packaging, also fuel cell as main polymer matrix membrane [4].

Alginate is a prominent water-soluble polysaccharide found in brown seaweed consisting of (1-4)-linked β-D-mannuronic acid (M) and α-L-gluronic acid (G) units. It has very high water absorption as can absorb 200-300 times its own weight in water. Alginate is able to be invented into a variety forms such as film, microspheres and fibers because of their reversible solubility [5]. However, the application of alginate is limited owing to several weaknesses that high water solubility and low mechanical strength [6]. Its hydrophilicity can be the major problem in DMFC performance because over water uptake in polymer electrolyte membrane will leads to the high swelling ratio thus burst the membrane during working process. Other than that sodium alginate membrane easy to dissolve in wet condition thus lowered its mechanical stability [7].

Inorganic filler such as CNT, zeolite, silica and graphene oxide is the common used to reduce hydrophilic characteristics of polymer. Nowadays, the graphene based material seems conquer the various function including as a filler in membrane [8]. Sulfonated Graphene Oxide is the product of graphene oxide modification process which has many attractive properties. The capability of SGO to be inorganic filler was recognized due to the presence of sulfonic acid group ($SO_3H^-$) on graphene oxide sheets which can contribute in good hydrogen bonding formation with other polymers. The formation of strong hydrogen bonding between SGO and Sodium Alginate polymer matrix can decreased the hydrophilicity and water uptake capacity due to the 'blocking effect' function of SGO [9]. Based on our research, there is no bio-composite Sodium Alginate/sulfonated-GO has been produced yet for DMFC application. Therefore, this research will combine the advantages of Sodium Alginate and sulfonated -GO to form a bio-membrane that have high durability which reduced their water uptake capacity to avoid swelling problem. Effect of sulfonated-GO addition and their interaction were studied using physical observation, Fourier Transform Infrared (FTIR) analysis and water uptake performance test.

## Materials and Methods

### Materials

TIMREX PG25 graphene oxide was purchased from TIMCAL Ltd. Methanol ($CH_3OH$,99.7%). Sodium alginate, hydrogen peroxide aqueous solution ($H_2O_2$, 35%), sulfanilic acid, and sodium nitrite solution were obtained from Sigma Aldrich. These chemicals were used as received without further purification. Deionized (DI) water through a Millipore system (Milli-Q) was used in all experiments.

### Preparation of sulfonated graphene oxide

Graphene oxide by 50 mg added to 8 ml of 0.06 M sulfanilic acid solution at a temperature of 70 °C. With continuous stirring, 2 ml of sodium nitrite solution is added dropwise to the mixture and let stand for 12 hours at a constant temperature of 70 °C. After reaction occurs, the mixture was washed and collected by centrifuge. Then, collected sulfonated-GO is washed for several times more with water until reaching pH 7. The washed SGO solution was dried and SGO powder was obtained.

### Preparation of sulfonated-GO based sodium alginate bio-composite films

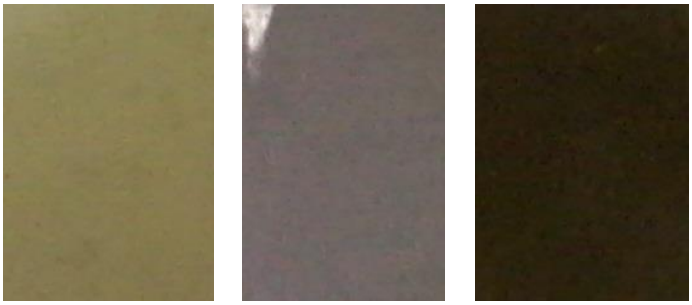
Sodium alginate was dissolved in deionized water 1 % (w/v) to obtain a solution of alginate. The various weight percentage of sulfonated-GO (0.2 wt% - 1.0 wt%) was added into Sodium alginate solution to produce a SA/SGO composite film. The mixture must be stirred continuously for 30 minutes with a magnetic stirrer. Heterogeneous solution was transferred to a glass substrate, left at room temperature for 72 hours for thin film formation process. A

series of bio-composite film were coded as SA, SA/SGO-1, SA/SGO-2, SA/SGO-3, SA/SGO-4, SA/SGO-5 according to the different wt% of sulfonated-GO loading.

**Characterization**

The functional groups of Al/SGO with were confirmed by Fourier transform infrared spectroscopy (FTIR). Thirty-two scans were accumulated for FTIR characterization with a resolution of 4 $cm^{-1}$ for each spectrum.

**Performance test (water uptake)**



Changes in weight and length (or thickness) of wet and dry membranes will be able to determine the rate of water absorption and swelling ratio of the membrane. The membrane was soaked in water for 24 hours at room temperature. In the wet condition, the weight of membrane was recorded which the liquid droplets on the membrane surface was removed. Earlier moist membrane was dried under vacuum pressure at temperature 100 ˚C for 1 hour. Weight of the membrane in the dry state was also recorded. Using equations (1), water uptake (WU%) can be determined.

$$WU\% = \frac{mass_{wet} - mass_{dry}}{mass_{dry}} \times 100 \quad (1)$$

## Results and Discussion

**Physical observation**

Polymer electrolyte based Sodium alginate thin film with different weight percentage of sulfonated-GO was observed physically and the Figure of each membrane thin film is presented in Figure 1. The colours of membranes become dark when concentration of sulfonated-GO was increased. However, the films were still flexible and homogeneous.

0.6 wt % SGO 0.8 wt% SGO 1.0 wt% SGO

Figure 1. Physical observation sodium alginate membrane with different wt. % of sulfonated-GO

**Fourier transform infrared spectroscopy**

The interactions between sodium alginate and sulfonated-GO were investigated by FTIR analysis. The FTIR spectrum for sodium alginate and SA/SGO membrane were presented in transmittance bands as shown in Figure 2. The FTIR spectrum of SA was compared with previous work and it seems similar. There are four major spectrum belongs to SA which at 3347 $cm^{-1}$, 1600 $cm^{-1}$, 1414 $cm^{-1}$ and 1030 $cm^{-1}$ and its attributed to OH stretching vibration, $COO^-$ stretching vibration of carboxylate salt group, and stretching vibration of C-O-C groups, respectively [10]. The dominant spectrum of GO was emerged at 3401 $cm^{-1}$ for OH group stretching vibration, 1624 $cm^{-1}$ for C=C stretching vibration and 1043 $cm^{-1}$ assigned to C-O groups vibration. All the spectrum of Sodium Alginate and Graphene Oxide was seen exist in the SA/SGO membrane composite. In addition, the membrane composite also has new spectra instead of SA and GO dominant spectrum which appear at around 1024 $cm^{-1}$, 1080 $cm^{-1}$ and 1280 $cm^{-1}$

which attributed to the S–O symmetrical, asymmetric stretching vibration (O=S=O), and sulfonic acid groups bands ($-SO_3H$), respectively.

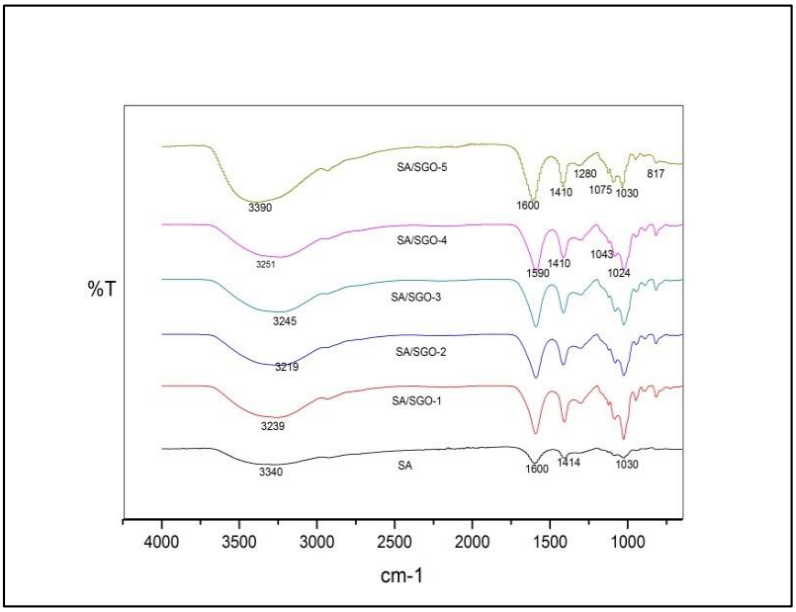


Figure 2. FTIR spectra of Sodium Alginate and various wt. % of sulfonated-GO in sodium alginate membrane

The broadening happened for OH group spectrum at 3347 $cm^{-1}$ it was shifted to the smaller wavelength of 3239 $cm^{-1}$ which is signal that existing of hydrogen bonding interaction between SA and sulfonated-GO [11]. Other than that, the spectrum of SA at 1414 $cm^{-1}$ was also somewhat shifted to the 1410 $cm^{-1}$ wavelength. This spectrum shifting occurred regarding to the existence of hydrogen bonding formation attributed to the interaction of hydroxyl groups in Alginate and polar groups in Sulfonated-GO [9]. This interaction is important factor for increase the mechanical stability of Sodium Alginate which can form and interactive 'blocking effect' especially for water solubility reduction.

**Performance test (water uptake)**

As mentioned above, the performance of polymer electrolyte membrane will be degrading if the amount of water absorbed is over the optimum range. The overloading of water leading to the swelling problem thus membrane will be ruptured. However, the water presence is still important for hydronium ion sources in proton transfer. Thus, the water uptake test is important to ensure that the polymer electrolyte membrane absorbed water in ideal range. Figure 3 are present the result of water uptake of SA-SGO membrane with variation of sulfonated-GO wt%. As presented, the pristine sodium alginate membrane has very high water uptake capacity (180%), which is contra to SA-SGO membrane that have lower water uptake capacity with different content of sulfonated-GO in the membrane. The increasing amount of sulfonated-GO has reduced water uptake due to the blocking ability as filler in the membrane [11]. Higher sulfonated-GO content brings to higher barrier for water absorption of the membrane. The hydrogen bonding existed between sulfonated-GO filler and sodium alginate polymer has strengthened the interfacial adhesion of the membrane composite thus reduce the water uptake capacity. The stronger interfacial adhesion, the lesser the gap size between filler and polymer which the gap is the space for water molecules pass through the membrane [9].

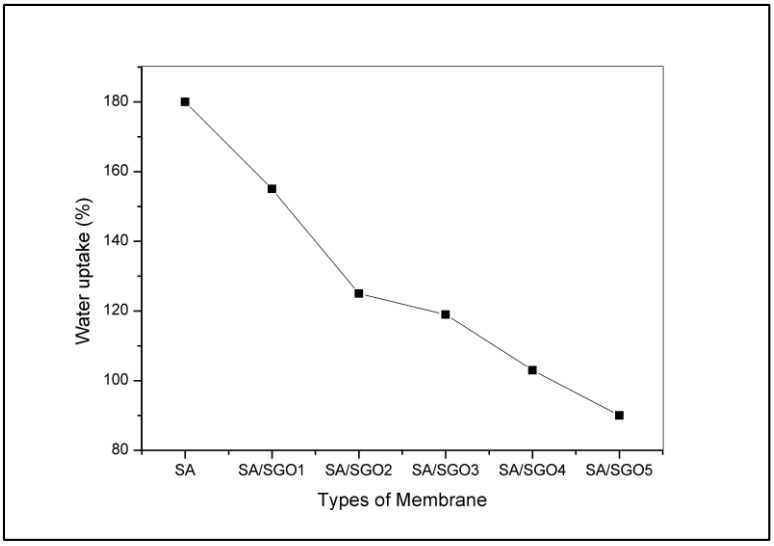

Figure 3. Water uptake of Sodium Alginate and SA/SGO membrane

## Conclusion

The FTIR analysis has confirmed that there is interaction between sodium alginate biopolymer and sulfonated-GO due to the presence of primary spectrum of sodium alginate and GO in the bio-composite. The hydrogen bonding interaction between SA and sulfonated-GO possibly increase the interfacial adhesion between SA and sulfonated-GO consequently enhance the mechanical stability of the bio-composite. The results showed that the existence of sulfonated-GO as filler in sodium alginate biopolymer has reduced the water solubility of the polymer. The lowest water uptake for bio-composite membrane is 90% (SA/SGO-5) with half reduction compared to pure sodium alginate. The present SA/SGO membrane suggested to be further explored in terms of morphology, structure and other performance such proton conductivity and methanol permeability. The excellent water uptake test is the good indicator that this membrane can perform well in DMFC application. The combination between Sodium Alginate polymer and sulfonated-GO seems match to each other with good interaction occur. The major drawback of Nafion also can be solved by using cheaper Sodium Alginate polymer. Thus, the findings in this study can be part of enforcement of DMFC application commercialization in future.

**Abstract**

Dehydrogenation of propane (DHP) was studied over a series of $Cr_2O_3$–$Al_2O_3$ and $Cr_2O_3$-$SiO_2$ catalysts, prepared by incipient wetness impregnation and sol gel (SG) method, respectively, to gain a better understanding of the nature and distribution of chromium (Cr) species and their catalytic function. To this end, the catalysts were characterized by $N_2$-physisorption and X-ray diffraction (XRD). $N_2$-physisorption analysis of $Cr_2O_3$-$SiO_2$ showed the relatively higher surface area of 391.1 $m^2$/g, compared with $Cr_2O_3$-$Al_2O_3$ of 224.3 $m^2$/g. The combination method of sol gel and sonothermal also produced smaller particles size of catalyst with higher microporosity of 23.5% and smaller pores size of 6 nm. The good surface properties of $Cr_2O_3$-$SiO_2$ enabled the high conversion of propane of 55% at 550 °C. At higher temperature of 600 °C, the Cr species might be reduced into lower oxidation state and inhibit the catalytic behavior to produce hydrogen.

**Keywords**: chromium (II) oxide, thermodynamic consideration, sonothermal, catalytic behavior, hydrogen energy

**Abstrak**

Tindak balas penyah-hidrogenan gas propana (DPP) telah dikaji menggunakan beberapa siri mangkin $Cr_2O_3$–$Al_2O_3$ dan $Cr_2O_3$-$SiO_2$ yang dihasilkan melalui kaedah impregnasi basah dan sol gel (SG) method, untuk memahami sifat dan serakan spesies logam Cr dan fungsi pemangkinannya. Dalam kajian ini, mangkin diciri menggunakan kaedah jerapan gas $N_2$ dan pembelauan sinar X (XRD). Analisis jerapan $N_2$ bagi mangkin $Cr_2O_3$-$SiO_2$ menunjukkan ia mempunyai luas permukaan yang paling tinggi sebanyak 391.1 $m^2$/g, berbanding mangkin $Cr_2O_3$-$Al_2O_3$ sebanyak 224.3 $m^2$/g. Kombinasi kaedah sol gel (SG) dan sonotermal menghasilkan mangkin yang bersaiz lebih kecil dengan keporosan mikro sebanyak 23.5% dan saiz liang sebanyak 6 nm. Ciri-ciri permukaan yang baik ditunjukkan oleh mangkin $Cr_2O_3$-$SiO_2$ menyumbang kepada aktiviti tindak balas yang baik dengan peratus penukaran propana yang tinggi sebanyak 55% pada suhu 550 °C. Pada suhu tindak balas 600 °C pula, spesies logam Cr boleh terturun kepada keadaan pengoksidaan yang lebih rendah dan merencat tindak balas pemangkin bagi menghasilkan gas hidrogen sebagai produk utama.

**Kata kunci:** kromium (II) oksida, pendekatan termodinamik, sonotermal, sifat pemangkinan, tenaga hidrogen

## Introduction

Propane is produced as a by-product of two other processes, natural gas processing and petroleum refining. The processing of natural gas involves removal of butane, propane, and large amounts of ethane from the raw gas, in order to prevent condensation of these volatiles in natural gas pipelines. Commonly, the dehydrogenation of propane can produce propene and hydrogen as a greener and future fuel sources and carried higher energy [1]. The reaction conditions play a major role to direct the reaction route and selected products. It is possible to produce hydrogen by catalytic dehydrogenation of propane, according to the following reaction (equation 1 and 2):

$$C_3H_8 \rightarrow C_3H_6 + H_2 \qquad \Delta H^o = 124\ kJ.mol^{-1} \tag{1}$$

$$C_3H_8\ (g) \rightarrow C\ (s) + C_2H_6\ (g) + H_2\ (g) \qquad \Delta H^o = 19.1\ kJ.mol^{-1} \tag{2}$$

However, this reaction cannot be carried out easily due to its strong endothermicity ($\Delta H^o_r = 124\ kJ.mol^{-1}$). Sattler et al. [2] were reviewed various type of catalytic dehydrogenation of light alkanes into other products namely methane, hydrogen, ethane and other series of alkenes. Several type of catalyst have been studied by researchers such as platinum-based, gallium oxide-based and vanadium oxide-based catalysts. In other work, Lee et al. [3] was reported the Sn addition to the $Pt_{0.5}/\theta\text{-}Al_2O_3$ catalyst can decreased the cracking products of $C_1$-$C_3$ and increase the stability and olefin selectivity.

This paper was focused on the hydrogen formation by catalytic dehydrogenation of propane. The effect of chromium species was also studied. The pure hydrogen can be produced from this reaction.

## Materials and Methods

### Thermodynamic consideration

The catalyst selection was performed using a simple thermodynamic approach based on thermodynamic data. Several pyrolysis routes have been selected to study the possibility. For example, the propane gas can be pyrolyzed into methane and hydrogen. There was some possible route for propane dehydrogenation reaction (equation 3 - 5).

$$C_3H_8 \rightarrow C_3H_6 + H_2 \tag{3}$$

$$C_3H_8 \rightarrow 2C + CH_4 + 2H_2 \tag{4}$$

$$C_3H_8 \rightarrow 3C + 4H_2 \tag{5}$$

### Synthesis of catalyst

The catalyst $15\%Cr_2O_3/\gamma\text{-}Al_2O_3$ was synthesized by using the wet impregnation method. 3.95g of $Cr(NO_2)_3{\cdot}9H_2O$ was dissolved in 10 ml of distilled water. Then, 8.5g of $\gamma\text{-}Al_2O_3$ was added into the solution and stir for 1 hour. The mixed sample was introduced to ultrasonicator for 10 minutes. The sample was dried at 110 °C and calcine at 400 °C for 3 hours before the catalyst is ready to test in reaction.

The $15\%Cr_2O_3/SiO_2$-sol gel (SG) was prepared by sol gel method by mixing the tetraethyl orthosilicate (TEOS) and ethanol with molar ratio of 1:1 to obtain a sol gel precursor solution. Then, several amount of $Cr(NO_2)_3{\cdot}9H_2O$ was dissolved in distilled water followed by some nitric acid addition. Both mixtures were stirred by vigorous magnetic stirring separately at room temperature until the pH 2 was observed. The solution was lifted for 24 hours until gelation is complete. The samples were dried at 110 °C and calcined at 400 °C for 3 hours before ready for use.

### Characterization of catalyst

Nitrogen adsorption at 77K (liquid nitrogen) was conducted using a Micromeritics ASAP 2010 instrument to obtain the adsorption isotherm of each sample. The Brunauer-Emmett-Teller (BET) surface area, micropore volume and micropore area were calculated from the isotherms. Before analysis was conducted, the samples were degassed at 350 °C for 6 hours. The crystallinity analyses of the samples were performed using a Bruker DB-Advance X-ray Diffractometer (XRD), Germany. The analyses were performed with 1-g samples, employing Cu Kα radiation at 2θ ranging from 10° to 80°.

**Propane pyrolysis reaction**

The propane pyrolysis was conducted using fluidized bed reactor under propane gas flows at ranging of 30 – 70 mL/min. The output gas was analyzed using GC-FID.

## Results and Discussion

**Thermodynamic consideration**

There were several possible reactions might be occurred during the pyrolysis of propane as showed in Table 1. The reactions 3 to 5 (R1-R5) are very favorable at low temperature. However, the possible R1 and R2 is need high temperature to occur (more than 972 k). Theoretically, R3 to R5 can occur at relatively low ranging temperature of 180 – 402 K. However, the presence of energy barrier or high activation energy during the reaction contributed the sum of error around 30 kJ/mol$^{-1}$ or 500 K. It was noted that the tendency to produce carbon during propane pyrolysis is high in the present of metal oxide catalyst [4,5].

Table 1. Thermodynamics data of possible reactions for propane pyrolysis

| Reaction Involved | ΔH (Kj·Mol$^{-1}$) | ΔS (J·Mol$^{-1}$·K$^{-1}$) | ΔG (Kj·Mol$^{-1}$) | T (K) | Reaction Possibility |
|---|---|---|---|---|---|
| $C_3H_6$ (g) → $C_3H_6$ (g) + $H_2$ (g) **R1** | 124.2 | 127.8 | 0 | 972 | Favourable at high temperature |
| $C_3H_8$ (g) → $C_2H_2$ (g) + $CH_4$ (g) + $H_2$ (g) **R2** | -197.7 | -153.8 | -5 | 1253 | Favourable at very high temperature |
| $C_3H_8$ (g) → C (s) + $C_2H_6$ (g) + $H_2$ (g) **R3** | 19.1 | 84.7 | -5 | 285 | Favourable |
| $C_3H_8$ (g) → 2C (s) + $CH_4$ (g) + 2$H_2$ (g) **R4** | 29.0 | 189.3 | -5 | 180 | Favourable |
| $C_3H_8$ (g) → 3C (s) + 4$H_2$ (g) **R5** | 103.8 | 270.9 | -5 | 402 | Favourable |

**Catalysts surface properties**

Figure 1 showed the adsorption-desorption isotherm of the fresh support and modified catalyst. The fresh $SiO_2$ (Figure 1 (a)) and $Al_2O_3$ (Figure 1 (b)) showed the adsorption isotherms type II and IV, respectively. However, the dispersion of $Cr_2O_3$ on $SiO_2$ (in Figure 1 (c)) was changed the adsorption isotherm into type I. Type I isotherms are observed for the adsorption of gases on microporous solids whose pore sizes are not much larger than the molecular diameter of the adsorbate. This property can bring forward the solid-gases reaction which is most of the reaction occurs in pores and surfaces [6]. On the other hand, the $Cr_2O_3/SiO_2$ catalyst (Figure 1 (d)) showed the hysteresis type IV represented to slit-shaped pores with uniform in size [7]. This type of hysteresis can maximize the reactant adsorption during reaction and desorbed the products easily. Table 2 showed the better surface properties of $Cr_2O_3/SiO_2$ with higher surface area and microporosity of 391.1 m$^2$/g and 23.5%, respectively. The higher surface area with maximum metal oxide dispersion would lead the higher active sites and subsequently contribute to good catalytic activity.

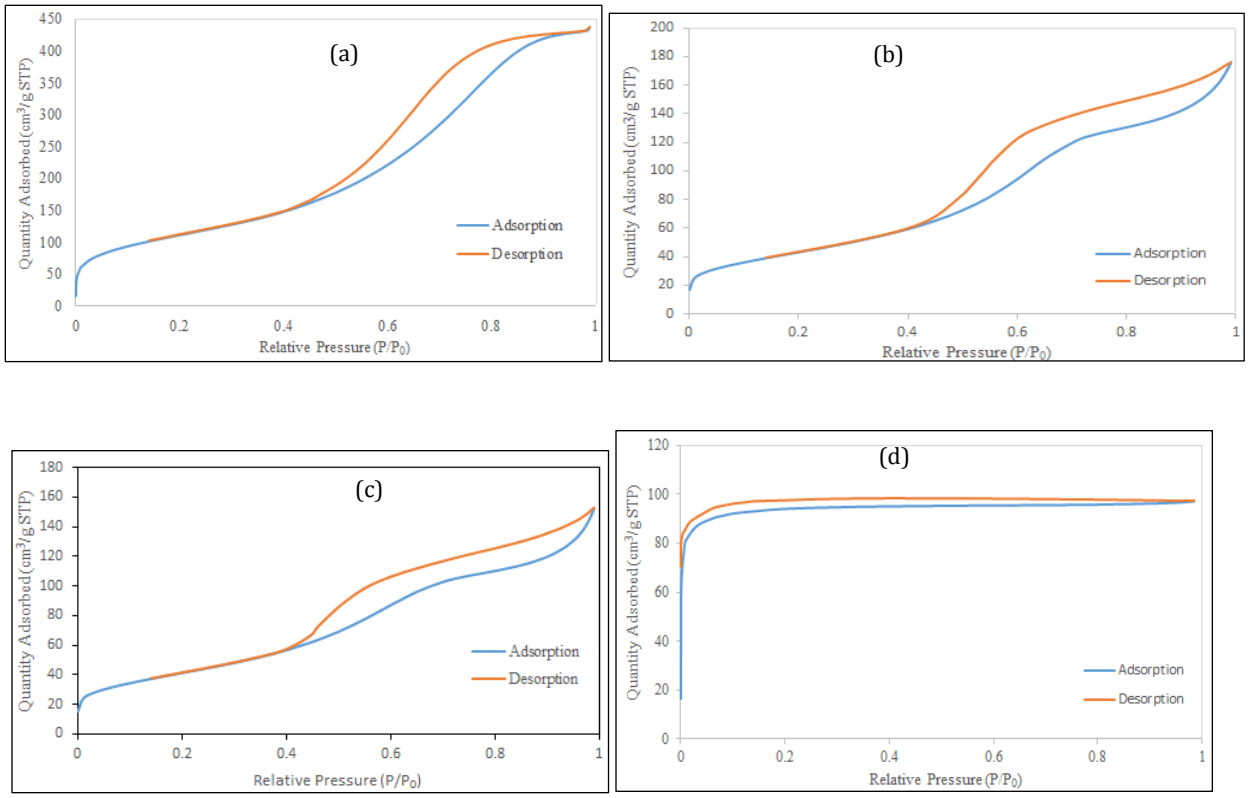

Figure 1. The isotherms of a) $SiO_2$, b) $Al_2O_3$, c) $Cr_2O_3$-$Al_2O_3$ and d) $Cr_2O_3$-$SiO_2$ SG

Table 2. The physical properties of catalysts

| Selected Catalysts | Microporosity (%) | Pores Size (nm) | Surface area ($m^2/g$) |
|---|---|---|---|
| $SiO_2$ | 4.8 | 6.83 | 391.1 |
| $Al_2O_3$ | 1.3 | 6.85 | 154.4 |
| $Cr_2O_3$-$Al_2O_3$ | 1.4 | 6.02 | 308.8 |
| $Cr_2O_3$-$SiO_2$ | 23.5 | 6.19 | 224.3 |

**Crystallinity of catalyst**

XRD analyses were performed for the $Cr_2O_3/Al_2O_3$, $Cr_2O_3/SiO_2$, $SiO_2$ and $Al_2O_3$ as a support. Figure 2 (a) and 2 (b) showed the XRD patterns for semicrystalline $SiO_2$ and crystalline $Al_2O_3$, respectively. Figure 2(c) showed the low intensity of $Cr_2O_3$ phase which detected at 34.8° and 54.4° with rhombohedral lattice system and the diffraction data match very well with JCPDS card of $Cr_2O_3$ (JCPDS 70-3765). No $CrO_2$ phase was detected in this catalyst. The $Cr_2O_3/SiO_2$ catalyst (Figure 2 (d)) showed three phases of $Cr_2O_3$ at 32.6°, 34.7° and 54.3° with rhombohedral lattice system. The single phase of $CrO_2$ was detected at 64.1° with orthorhombic lattice system and the diffraction data match very well with the JCPDS card of $CrO_2$ (JCPDS 75-7969). The high oxygen level of $CrO_2$ phase can accelerate the propane cracking into hydrogen, propene, methane and carbon deposition [8]. After reaction, the graphite phase was detected in the catalyst due to carbon deposition as one of the product of the reaction at relatively high temperature. Besides, the Cr(IV) was fully reduced into Cr(III) due to high temperature reaction of 600 °C.

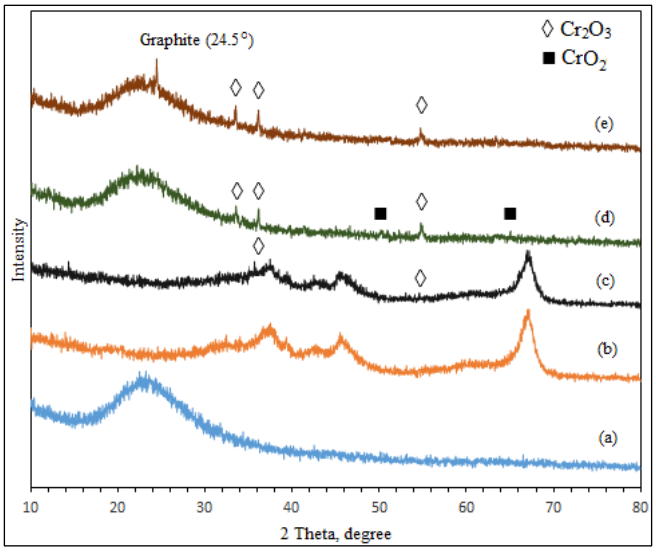

Figure 2. XRD diffractogram of (a) fresh $SiO_2$, (b) fresh $Al_2O_3$, (c) 15%$Cr_2O_3/Al_2O_3$, (d) 15%$Cr_2O_3/SiO_2$ and (e) 15%$Cr_2O_3/SiO_2$ after reaction

**Catalytic performances**

The pyrolysis reaction of propane gas was studied based on several parameters such as the effect of reaction temperature, reactant flowrate, reaction time and catalysts type. This reaction was performed in the range of temperature of 450 – 600 °C. The range was selected by calculation of thermodynamic data which was favorable to occur. Figure 3 showed the effect of reaction temperature on propane pyrolysis into hydrogen and other hydrocarbon or carbon due to highly dispersion of Cr species on $SiO_2$ surfaces. However, at 600 °C, the propane conversion was relatively decreases due to $Cr_2O_3$ fully converted to $CrO_2$ which decrease the catalyst activity of dehydration reaction with $C_3H_6$ and $H_2$ are dominant products. Figure 4 showed the effect of residence time to propane conversion. The residence time is depended to the flowrate of the reactant which reacted to the catalyst. In this reaction, it was noted that higher residence time of 30 seconds gave the longer time for reaction to be occurred and achieved the completion.

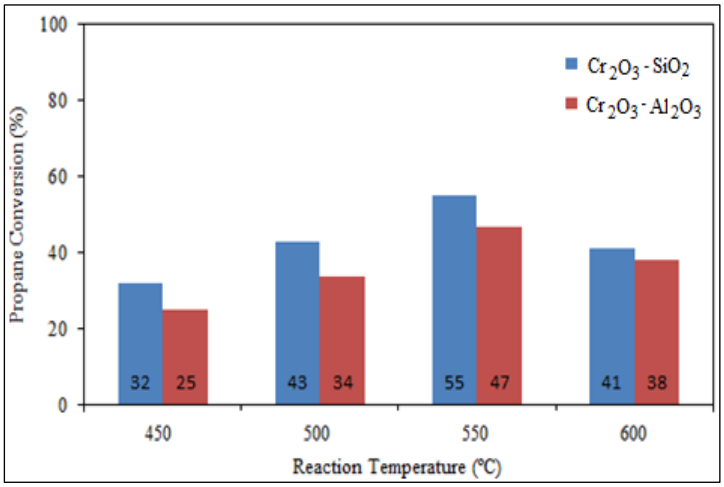

Figure 3. Effect of reaction temperature of (a) $Cr_2O_3/SiO_2$ SG and (b) $Cr_2O_3/Al_2O_3$ (Reaction carried out at flowrate of 60 mL/min)

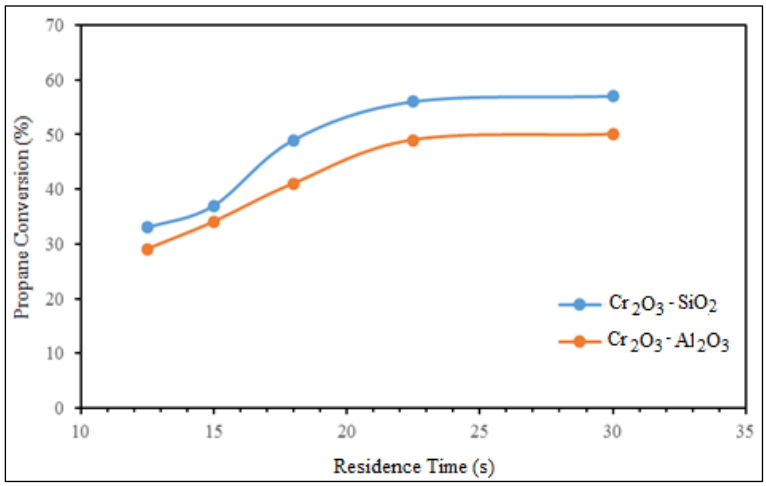

Figure 4. Effect of residence time of the reaction on $H_2$ production for (a) $Cr_2O_3$-$Al_2O_3$ and (b) $Cr_2O_3$-$SiO_2$ SG (Reaction carried out at 550 °C)

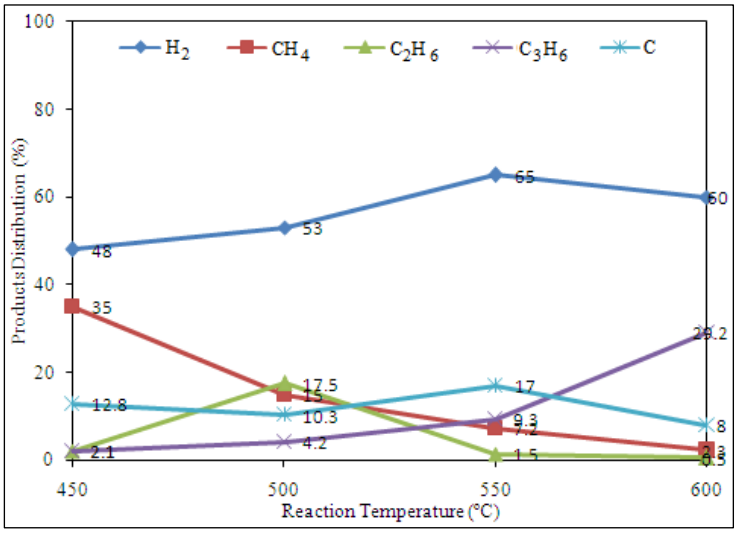
In Figure 5, at different reaction temperature, the $Cr_2O_3$-$SiO_2$ SG showed a series of products. At 550 °C, the hydrogen is a major product followed by carbon deposition and $C_3H_6$ formation. However, at 600 °C, the propene is significantly increased. It was noted that the high energy supply can bring forward the reaction route which produced hydrogen and propene as major products [3].



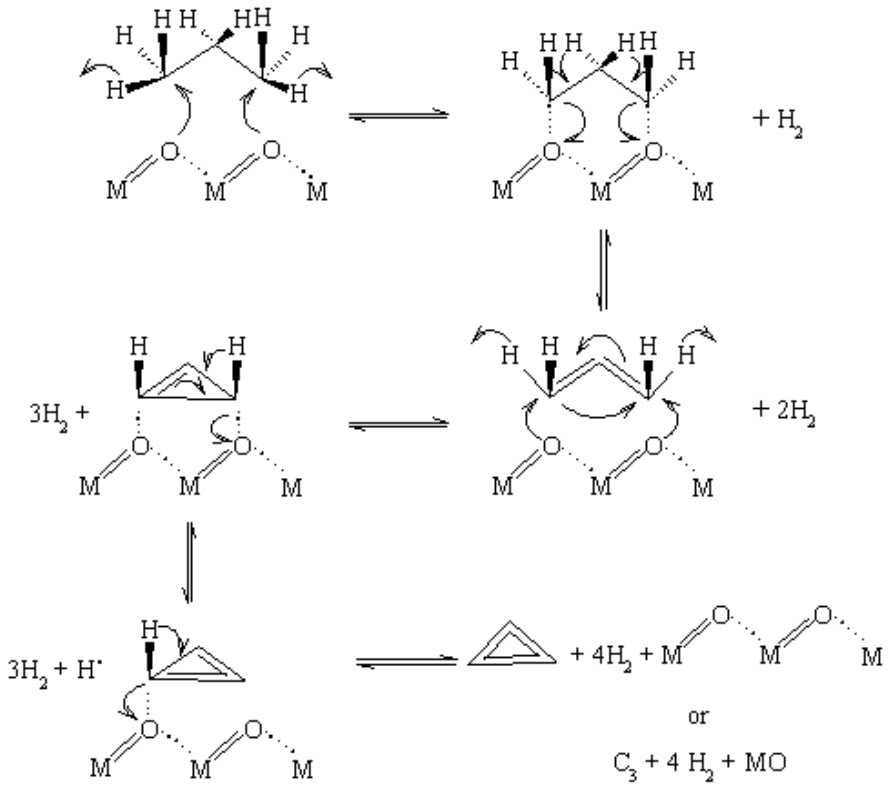


Figure 5. The products distribution from propane pyrolysis using $Cr_2O_3$-$SiO_2$ SG at optimum condition (Reaction was carried out at flowrate of 60 mL/min)

**Proposed mechanism**

Thermodynamics theory approach can be used for evaluation the potential of metal oxide (MO) as catalyst in propane pyrolysis process. Theoretically, the breaking of hydrogen chain from carbon can easier occur if the formation of the new bond between MO and carbon is stronger. The bond between the carbon and MO known as

physical interaction (van der wall bond), where the interaction is weak, but due to the effects of temperature, the heavier atoms (i.e., carbon and MO) tends easier to form a slightly stronger bonds than lighter atoms (i.e., hydrogen), consequently, the hydrogen bonds in the carbon is easier to break at lower temperatures. Thus, the catalyst material is expected to help increase the rate of hydrogen production and reduces the reaction temperature. The reaction mechanism between the MO with propane can be described in several possible routes as showed in Scheme 1.

Scheme 1. Proposed mechanism of propane dehydrogenation over metal oxide catalyst

A thermodynamic calculation to illustrate that the mechanism (1) may only occur at high temperatures (≈ 400 K) due to the entropy of the reaction is very high [9,10] . This due to the process of acquiring C is through the chain termination mechanism of double or triple bonds of C. In this case, all of the hydrogen atom consist of propane has been transformed into four moles of $H_2$ molecules and created a very stable double or triple bond of carbon which required a relatively high energy to dissociate. However, this mechanism just a form that is closest to clarify the possibility of the mechanism due to this mechanism is very complex which involves the variety of free radicals [11].

## Conclusion

Hydrogen as a green fuel was successfully produce by dehydrogenation of propane in the presence of Cr-based catalyst. Thermodynamic calculation showed the feasibility of propane pysolysis into several products such as hydrogen, methane, propene and carbon depends on the reaction temperature. The $Cr_2O_3/SiO_2$ catalyst showed the better surface properties with high surface area of 393.1 $m^2/g$, microporosity of 23.5% and slit-shaped micropores. These properties were contributed to the higher propane conversion of due to high catalytic and gas adsorption ability. At 550 °C, the hydrogen, $C_3H_6$ and carbon were dominant products with 55% of propane conversion. However, in long period, the high carbon deposition can deactivate the catalyst by covering the pores and surface and reduce the selectivity to hydrogen as a major product.

**Abstract**

The effect of blending method on the blend morphology as well as cellular structure of Polypropylene (PP)/Polystyrene (PS)/ Polymethyl methacrylate (PMMA) ternary polymer blend was investigated. The blending method highly influenced the dispersion and size of dispersed domain where the injection molding method was successfully reduced the size of dispersed domain from 10 µm by extrusion further down to 1 µm in average diameter. The batch pressure quenched foaming of the ternary blend prepared by extrusion and injection molding with supercritical carbon dioxide ($CO_2$) was conducted in the temperature range of 130 to 160°C to observe the controllability of bubble location and size in two different ternary blend systems. The experimental results showed that method of sample preparation is one of the important factors in controlling the cellular structure of ternary blend foam besides interfacial tension, foaming temperature, and viscoelasticity.

**Keywords:** polymer blend, extrusion, injection molding, cellular structure, foam

**Abstrak**

Kesan kaedah pencampuran pada morfologi dan juga struktur sel Polipropena (PP)/Polisterina (PS)/ Polimetil metaakrilat (PMMA) campuran pertigaan polimer telah dikaji. Kaedah pencampuran sangat mempengaruhi penyebaran dan saiz domain di mana kaedah pengacuan suntikan telah berjaya mengurangkan saiz domain dari 10 µm oleh kaedah penyemperitan kepada serendah 1 µm diameter purata. Proses pelepasan tekanan secara mendadak dengan karbon dioksida genting lampau ($CO_2$) telah dijalankan bagi penghasilan sampel busar daripada gabungan pertigaan polimer dalam lingkungan suhu 60-130°C untuk melihat kebolehkawalan lokasi gelembung dan saiz. Keputusan eksperimen menunjukkan bahawa kaedah penyediaan sampel, tegangan antara permukaan dua polimer, suhu pembentukan busar dan likat-kenyal adalah faktor penting untuk mengawal struktur sel dalam sistem gabungan pertigaan polimer.

**Kata kunci:** percampuran polimer, penyemperitan, pengacuan suntikan, struktur sel, busar

## Introduction

Polymer blends received many attentions due to the increasing application of plastic industry especially in automobile, packing, and many potential applications. Recently, much attention has been directed to ternary polymer blend [1]. Prior to develop a new material based on multi-component polymer, understanding and controlling the phase morphology are the primary interest. This is because the morphology is directly influenced the mechanical performance in polymer blend [2]. These final properties of polymer blend can be controlled by considering polymer molecular structure, composition, molecular weight [3], and method of blend preparation [4]. According to Guo et al. [5], in ternary polymer system, one of the minor components formed an encapsulating layer around domains of other minor components (encapsulation-type morphology) as shown in Figure 1. Whereas in other systems the two minor components formed independent phases (separation-type morphology).

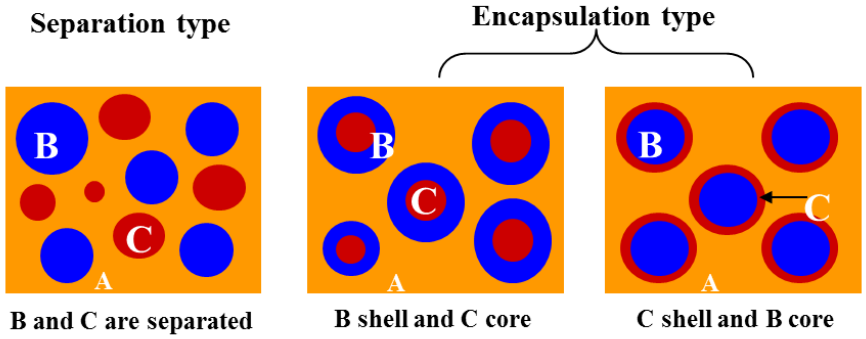

Figure 1. Three possible morphologies of ternary polymer blend, (A: matrix, B and C: dispersed phase)

They claimed that these ternary blend systems can also be predicted by calculating the Gibbs free energy or interfacial energy shown in the following equations [5]:

$$\left(\sum A_i \gamma_{ij}\right)_{B+C} = (4\pi)^{1/3}\left[n_B^{1/3} x^{2/3} \gamma_{AB} + n_C^{1/3} \gamma_{AC}\right](3V_C)^{2/3} \quad (1)$$

$$\left(\sum A_i \gamma_{ij}\right)_{B/C} = (4\pi)^{1/3}\left[n_B^{1/3} (1+x)^{2/3} \gamma_{AB} + n_C^{1/3} \gamma_{BC}\right](3V_C)^{2/3} \quad (2)$$

$$\left(\sum A_i \gamma_{ij}\right)_{C/B} = (4\pi)^{1/3}\left[n_B^{1/3} x^{2/3} \gamma_{BC} + n_C^{1/3} (1+x)^{2/3} \gamma_{AC}\right](3V_C)^{2/3} \quad (3)$$

where $A$ is interfacial area, $\gamma_{ij}$ is interfacial tension between component $i$ and $j$, $V$ is the volume of particle and $x = V_B/V_C$, $n_B$ and $n_C$ are numbers of particles of B and C phases in the system. The values of $\Sigma A\gamma_{ij}$ are compared for the three structures and the equilibrium phase structure of the system is predicted by considering the lowest free energy needed for creating the morphology.

In recent years, there are relatively few studies done on multicomponent blend foaming have been reported. In spite of the fact that the understanding on phase morphology of multicomponent blend is less understood, lack attention is given to ternary polymer blend foaming study. As in binary polymer blend foaming, the concept of creating a microcellular/ nanocellular foam based on solubility and diffusivity of $CO_2$ is also can be applied in ternary polymer blend foaming. By exploiting ternary polymer blend morphology as a template for foaming and by differentiating the solubility of foaming agent as well as the elasticity of the domain to be foamed from the domains to be kept solid state, the bubble location and size could be controlled in the targeting domains [6] as illustrated in Figure 2.

However, the cellular structure is determined not only by the morphology and physical properties of polymers such as viscosity, solubility and diffusivity of the physical foaming agent in the polymers, but also by the size of dispersed domain. Several studies showed that size of dispersed domain was successfully reduced by improving compatibility between polymers [7-10], adding third immiscible component to binary polymer blend [11] and preparing blend sample via injection molding [12].

The work described here is a follow-up to our previous study on PP/PS/PMMA ternary blend foaming [6]. In the current study, the effect of dispersed domain's size on cellular structure of ternary polymer blend was investigated. We compare the cellular structure of PP/PS/PMMA blend foams prepared by two different blending methods namely extrusion and injection molding. A series of pressure quench foaming experiments have been conducted to evaluate the role of blending method effects on size of dispersed domain and foaming behaviour of ternary polymer blend.

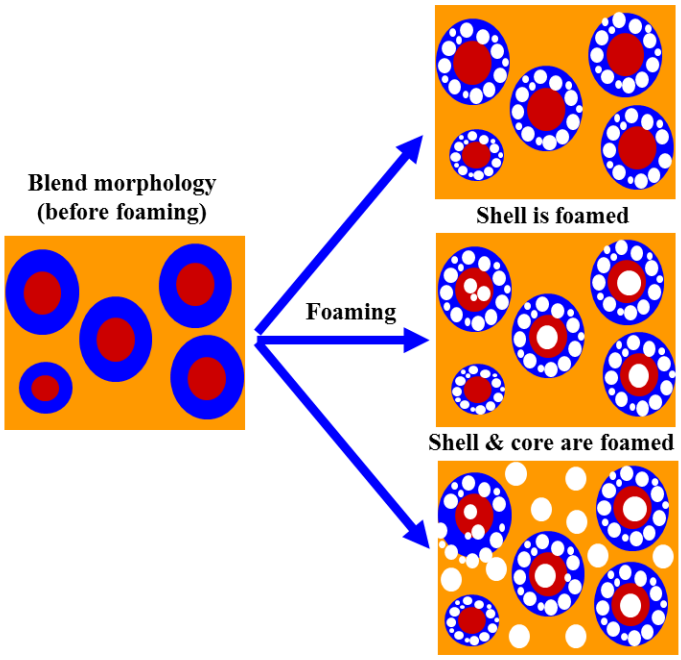

Figure 2. Possible cellular structures of ternary polymer blend foam

## Materials and Methods

### Materials

Polypropylene (PP, Mw= 410,000) and Polycarbonate (PC, Mw= 22,000) were supplied by Mitsubishi Chemical. Polystyrene (PS, Mw= 192,000) and Poly (methyl-methacrylate) (PMMA, Mw= 120,000) were obtained from Aldrich Chemical Co. All polymers were used as received.

### Sample preparation

Blend samples were mixed and compounded via injection molding at 260 °C for PP/PS/PMMA (80/10/10) and 280 °C for PC/PS/PMMA (80/10/10) blend samples. The morphology of the sheet was investigated via SEM (Tiny-SEM, Technex Lab Co. LTD., Tokyo, Japan).

### Batch physical foaming process

The injection molded PP/PS/PMMA ternary blend samples were placed in a high-pressure vessel. The pressure vessel was pressurized by $CO_2$ and was rapidly heated to the desired saturation temperature. After a given time of saturation (about 6 hours), the $CO_2$ in the pressure vessel was quickly released at a rate of 10 MPa/s to nucleate bubble in the polymer. The foamed blends were taken out for further analyses mainly by SEM.

**SEM analysis**

Blend as well as foam samples were cryo-fractured by nitrogen gas and were then gold coated prior been analyzed via SEM (Tiny- SEM, Technex Co. Ltd., Japan).

## Results and Discussion

**Blend morphology characterization**

In our previous study [6], the SEM micrographs of the obtained PP/PS/PMMA blends before acid acetic and cyclohexane treatments clearly showed the sea and island morphology where PP as a sea while PS/PMMA minor phases existed in the form of a dispersed spherical particles at approximately 10 μm in average diameter. It was also observed that some particles were detached while preparing the sample for microscopy analysis, and this resulted in voids in the matrix. According to Reignier et. al [13], there are three possible phase structures could be obtained for ternary blend system which are:

(i) the PMMA phase is encapsulated by the PS phase (PS/PMMA);
(ii) the PS phase is encapsulated by the PMMA phase (PMMA/PS); and
(iii) the PS and PMMA phases form separate phases (PS+PMMA).

For the purpose of identifying type of morphology in PP/PS/PMMA blend, the solvent etching was conducted. It was found that PMMA is encapsulated by PS where PMMA was selectively removed by acetic acid and PS by cyclohexane. The predicted morphologies by interfacial free energy model corroborated the morphologies experimentally as shown in Table 1. The most stable morphology is represented by the lowest value of surface energy of Gibbs energy of mixing [14].

Figure 3 shows the SEM micrographs of blend morphologies of the samples before and after solvent etching prepared by injection molding. The SEM results show that injection molded of PP/PS/PMMA blend gave elongated domain. The increasing shear flow gave increasing elongation until it reached a critical shear rate at which elongated domains dispersed into finer domain. Our results also show that injection molding was successfully reduced the size of dispersed domain while the morphology remained the same. This indicates that sample with a large number of finely dispersed domain could be achieved by injection molding. According to Zhong et al. [15], smaller dispersed domain can be achieved due to large force acting on the dispersed domains induced by high injection flow rate causes the particles became more deformed and were easier to break up.

Table 1. Predicted equilibrium morphology for PP/PS/PMMA ternary blends by Gibbs free energy or interfacial free energy

| Type of morphology | $\Sigma A\gamma_{ij}$ (dyne cm) |
|---|---|
| B+C | 40.1 N |
| B/C | 32.6 N |
| C/B | 42.0 N |

PP matrix (PP: A, PS: B, PMMA: C)

**Foaming behavior of PP/PS/PMMA (80/10/10) ternary blend system prepared by extruder and injection molding**

In our previous paper [6], we have reported that the pressure quench foaming result demonstrated an interesting phenomenon where a unique cell structure of PS/PMMA dispersed domain was kept their spherical shape and been encapsulated by large void space at foaming temperature range of 130 to 155 ºC. From the observation, we claimed that large bubbles were originated from the interface between PP matrix and PMMA/PS core-shell domain, and small bubbles were from PP matrix. For all foaming temperature studied, it was observed that controllability of bubble nucleation and location in PP/PS/PMMA blend was restricted by high interfacial tension between PP matrix

and PMMA/PS core-shell domain. High value of the interfacial tension between two polymers generally provides a channel for $CO_2$ diffusion. As a result, the nucleation of bubble is limited only in amorphous PP matrix and at the interface between PP matrix and PMMA/PS core-shell domain.

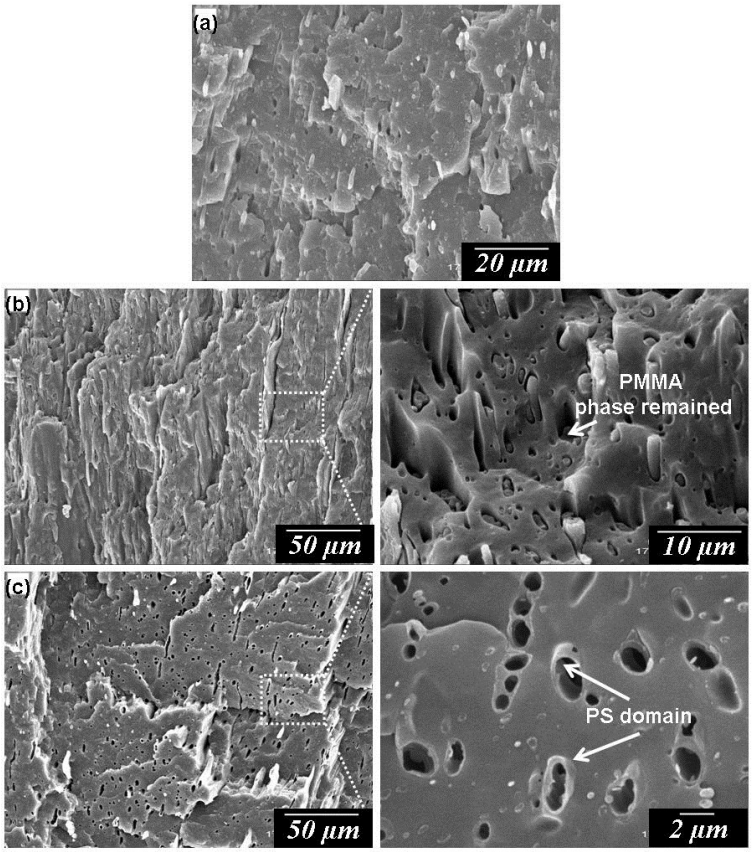

Figure 3. PP/PS/PMMA (80/10/10) ternary blend prepared by injection molding. (a) As-prepared; (b) After cyclohexane etching; and (c) After acetic acid etching.

By using the same concept of preparing microcellular/nanocellular foam as in our previous study, new approach is introduced in order to control the bubble nucleation at polymer interface. It is believed that smaller size of dispersed domain probably could reduce the loss of $CO_2$ via diffusion, and thus enhances bubble nucleation. We use the approach of preparing blend sample via injection molding to obtain smaller dispersed domain as compared to extruded blend sample. As reported by Son et al. [12] injection condition affects domain size where high injection flow rate and low injection temperature could successfully reduce the domain size of dispersed phase.

The observed encapsulation-type morphology of PP/PS/PMMA (80/10/10) blend was utilized as template for foaming. Batch foaming was then performed on the injection molded sample in the temperature range of 130 to 160 ºC while the saturation pressure and depressurization rate were kept constant. Figure 4 shows the cell structure of the blend sample corresponding to the SEM image shown in Figure 3. At 130 ºC sample was partly foamed. From the observation, the bubble was originated from amorphous PP while PMMA/PS domains remained as particles. At 150 ºC, fine well-distributed cell was obtained. An increased of domain distribution as well as the decreased of average domain size leads to a small cell size and high cell density. Figure 4c clearly shown the PMMA/PS domains

were adhered to the PP cell wall. Overall, blend sample prepared by injection molding which has smaller domain size leads to a cell size decrease and cell density increase.

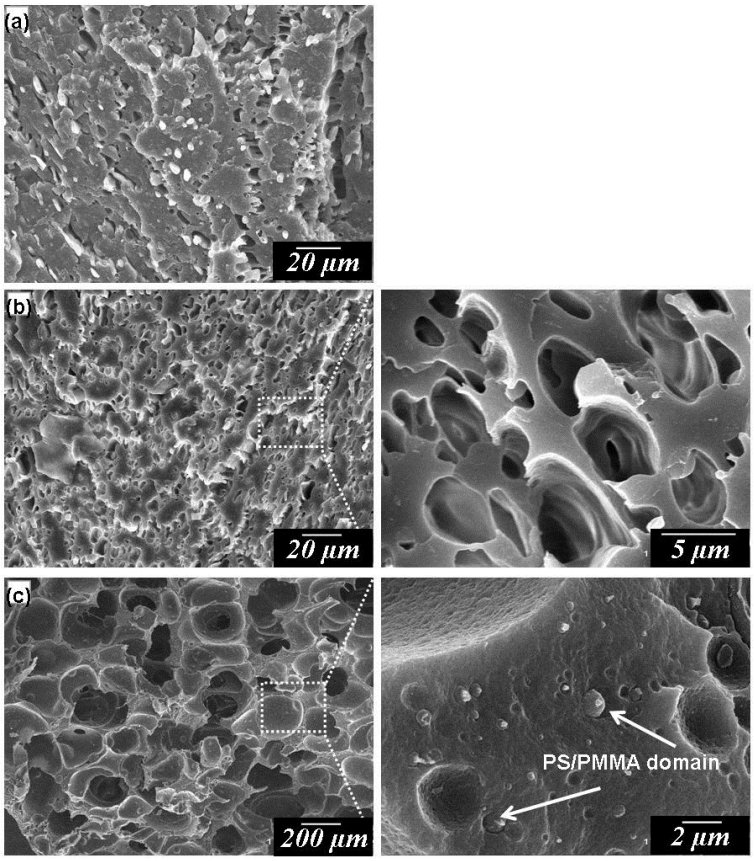

Figure 4. Cell structures of PP/PS/PMMA (80/10/10) foams prepared by injection molding at various foaming temperatures: (a) 130 ºC; (b) 150 ºC; and (c) 160 ºC

Figure 5 compares the graphs of the cell size distribution of PP/PS/PMMA (80/10/10) blend foams prepared by different methods; extrusion and injection molding. The uniformity of cell size was increased in sample prepared by injection molding. The cell size of the extrusion blend foam shows a broad distribution with cell size in a range of 4 to 45 μm. On the other hand, the cell size distribution of the injection molding blend foam becomes narrower than that of extrusion blend foam, and they are in range from 1 to 12 μm. Reducing size of dispersed domain showed a beneficial effect on the cellular structure of the investigated blend in terms of cell size and cell uniformity.

**Blend morphology and foaming behaviour of PC/PS/PMMA (80/10/10) ternary blend system prepared by injection molding**

PC/PS/PMMA (80/10/10) blend was prepared via injection molding to further investigate the effect of dispersed domain size on the cell structure. Blend morphology of sample was first examined to identify the type of morphology. Droplet-type morphology or so called sea-island morphology with nano-sized PS core and PMMA shell was obtained due to incompatibility between those polymers as depicted in Figure 6.

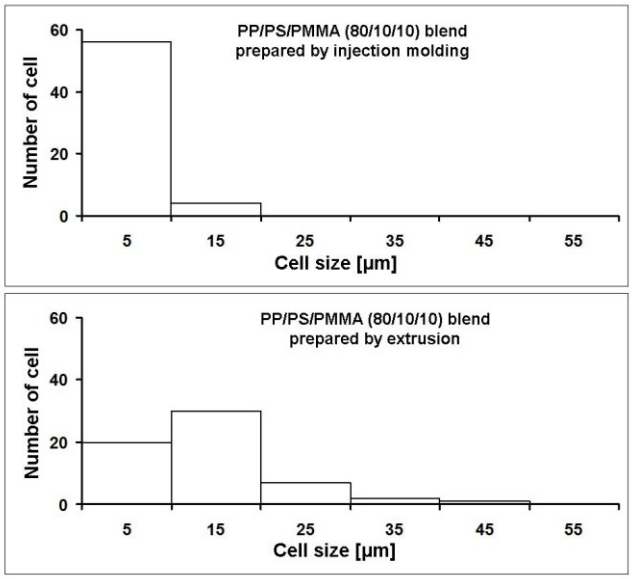

Figure 5. Cell size distribution of PP/PS/PMMA (80/10/10) blend foams at 150 ºC

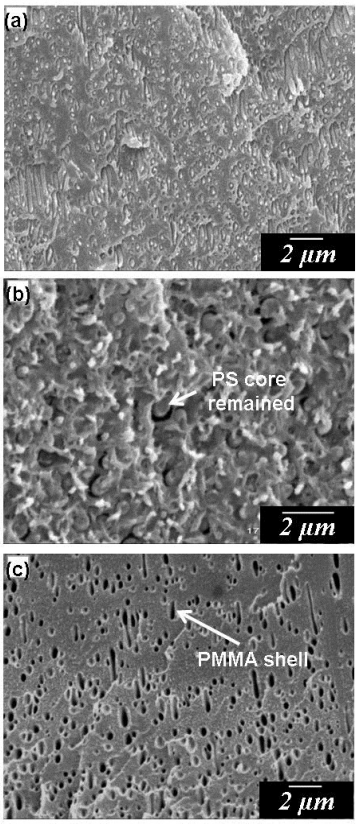

Figure 6. PC/PS/PMMA (80/10/10) ternary blend prepared by injection molding. (a) As-prepared; (b) After acetic acid etching; and (c) After cyclohexane etching

Under similar foaming conditions, PC/PS/PMMA blend foam was prepared. Figure 7a shows that sample could be foamed slightly at 130 ºC. As the foaming temperature increased to 150 ºC, bimodal cell structure was formed (Figure 7b). Enlarge image of Figure 7b shows that PS/PMMA domain remained as its original shape. When the blend sample was foamed at 160 ºC, the foam exhibited a small cell size and low cell density. This might due to the increase in $CO_2$ diffusivity with the increase of the foaming temperature. By comparison of cell structures of PP/PS/PMMA (80/10/10) blend samples prepared by extrusion and injection molding, it can be observed that the decreased in dispersed domain size is not only decreased the cell size, but it also reduced the $CO_2$ diffusion into the polymer interface. Hence, the cell properties of ternary polymer blend could be improved by preparing the sample via injection molding.

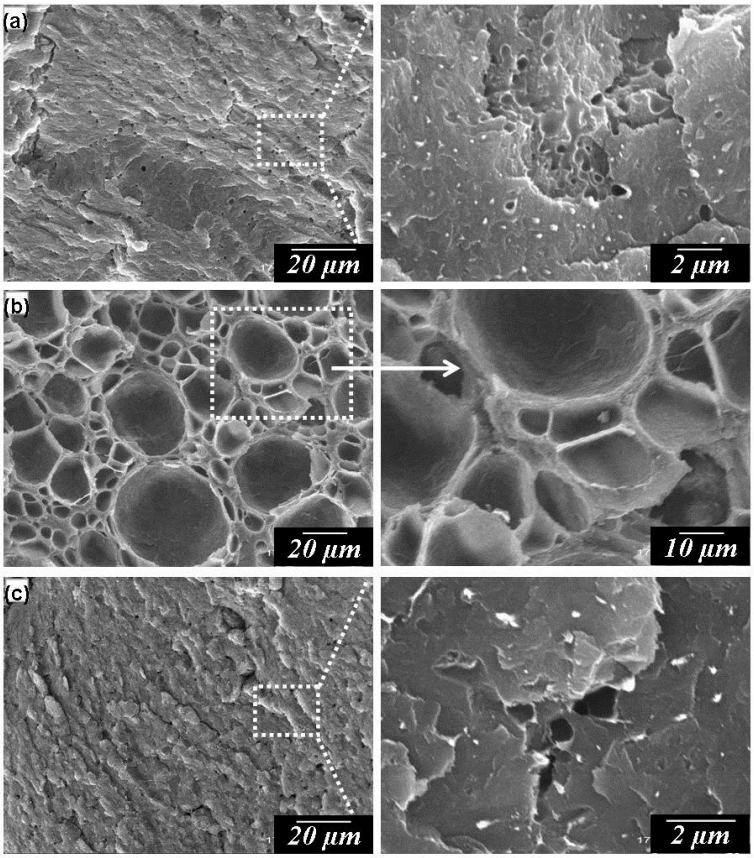

Figure 7. Cell structures of PC/PS/PMMA (80/10/10) foams prepared by injection molding at various foaming temperatures (a) 130 ºC, (b) 150 ºC and (c) 160 ºC

## Conclusion

The effect of blending method on the dispersed domain size and cellular structure of ternary blend was studied. The approach of preparing blend sample via injection molding has been introduced to control the dispersed domain size of the polymer blend. For the injection molded PP/PS/PMMA blend, an incredible drop of dispersed domain size was observed compared to extruded PP/PS/PMMA blend from approximately 10 µm in average diameter to almost 1 µm. Accordingly, reducing dispersed domain size was found beneficial effect on the cellular structure of the blend. Cell density and uniformity of PP/PS/PMMA blend can be enhanced with the reduction of dispersed domain size, which impedes $CO_2$ loss via diffusion through polymer interface.

**Abstract**

In this research, hydroxyapatite (HA) nano-size powder was synthesized using wet chemical precipitation technique under atmospheric pressure where calcium hydroxide ($Ca(OH)_2$) and ortho-phosphoric acid ($H_3PO_4$) were used as precursors. Distilled water was used as a diluting media for the reaction and sodium hydroxide (NaOH) was used to control the initial pH. The initial pH values, reaction temperature and calcined temperature play an important role in the morphology on HA as well as the phase formation and degree of crystallinity. Nano HA powder has been studied at different initial pH value which is between 9.00 to 11.00, reaction temperature from 80 °C to 100 °C and calcined temperature at 700 °C to 800 °C. The optimum initial pH value was found at pH 10.00, reaction temperature at 100 °C and calcined temperature was at 800 °C. The crystallographic properties were evaluated by X-ray diffraction (XRD), Fourier Transform Infrared (FTIR) and Field Emission Scanning Microscope (FESEM). The Design Expert version 9.0.2 with statistical and graphical analysis of the result, by using analysis of variance (ANOVA) was applied to optimize variable in the process of synthesis of HA. Based on analysis of variance (ANOVA) that has been perform, calcined temperature was to be influential variables on mass of HA with value of probability less than 0.05.

**Keywords**: hydroxyapatite, chemical precipitation, crystallinity, morphology, optimization

**Abstrak**

Dalam kajian ini, nanozarah hidroksiapatit (HA) dihasilkan melalui kaedah pemendakan di bawah tekanan atmosfera di mana kalsium hidroksida ($Ca(OH)_2$) dan asid orto fosforik ($H_3PO_4$) merupakan larutan asas bagi penyediaan HA. Air suling digunakan sebagai agen pelarut dalam menyediakan larutan asas bagi proses pemendakan ini. Larutan natrium hidroksida di gunakan bagi mengawal nilai pH. Nilai pH, suhu tindak balas dan suhu relau merupakan faktor penting dalam pencirian dan penghabluran nanozarah HA. Nanozarah HA disediakan pada nilai pH antara 9.00 hingga 11.00, suhu tindak balas 80 °C hingga 100 °C dan suhu relau pada 700 °C hingga 800 °C. Pencirian nanozarah HA di uji menggunakan X-ray Difractometer (XRD), Inframerah Transformasi Fourier (FTIR), dan Mikroskop Pengimbas Pancaran Medan (FESEM). Perisian Design-Expert 9.0.2 digunakan untuk menganalisis data dan pengoptimuman penghasilan mendakan HA. Berdasarkan analisis varian (ANOVA) yang dilakukan, suhu relau merupakan pemboleh ubah yang mempengaruhi berat HA dengan nilai kemungkinan kurang dari 0.05.

**Kata kunci:** hikdroksiapatit, mendakan bahan kimia, penghabluran, pencirian, pengoptimuman

## Introduction

Tissue disease and defect, and bone disease are serious health condition that can affect the life for those who suffer on it. Since last four decades, various revolution has been introduced in order to make improvement of the uses of

ceramic. This improvement is about special design ceramic for repair and reconstruction of diseased or damaged parts of the body. Ceramic used in this field is called bioceramic. Two alternative ways to replace tissue are transplantation and implantation. The advantages of bioceramic offer over transplant are availability, reproducibility and reliability. Bioceramic can be classified into two group which are bioinert (ceramic that have no influent on surrounding living tissue) and bioactive ceramic (capable of bonding with living tissue as example calcium phosphate (HA) and certain compositions of glasses. Over past few decade, synthetic hydroxyapatite (HA) has been recognize as important bone substitute materials in orthopedics and dentistry due to its biological similarity to the mineral phase of human bones [1]

Due to excellent biocompatibility and tissue bio-activity properties, hydroxyapatite (HA) which is inorganic bioceramic also known as calcium phosphate ceramic that being main inorganic composition of natural bone has been extensively investigated for medical application. Because of this reason, many techniques have been developed for synthesis of HA such as mechanochemical synthesis, combustion preparation, wet chemical deposition, electrochemical deposition, sol-gel method, hydrothermal synthesis and many more [2].

From the previous researcher, HA was successfully used in separation of protein enzymes, nucleic acid, virus and other biological molecules. HA act as a prototype for bones and teeth with proven compability, HA also widely used in medical implants [3].

The size of morphology of HA used in bone is nano-sized needle-like crystals. HA can be used in various form of shape including powders, granules, dense and porous block. There is a need to characterize the HA powder depending on desired application. Using wet synthesis technique, various parameters can be controlled such as purity, crystallinity, and morphology because different morphologies will be used in different application for example small spherical particle used in thermal spray coating while needle-shape or rod-shape used in bone repair composite material [4].

Recently, nano HA get attention from the researcher because nano HA play an important role in various biomedical application due to its unique function properties of high surface area volume ratio where its structure is ultra fine similar to natural bone. There are few method to synthesis nano HA such as chemical precipitation, spray drying, sol-gel and more. In natural bone and teeth, the nanoparticle sized of HA crystal is embedded in the collagen matrix with average length of 50nm. In fact, collagen is act as template in the controlled biomineralization process [5].

## Materials and Methods

### Precipitation

In order to obtain nano-HA by precipitation method, calcium hydroxide and ortho-phosphoric acid was used as initial precursor. The experimental involve additional of desired amount of 0.67 M of ortho-phosphoric acid (Merck, 85%) to desired amount of 1 M calcium hydroxide (Merck). The chemical equation involve is:

$$10Ca(OH)_2 + 6H_3PO_4 \longrightarrow Ca_{10}(PO_4)_6(OH)_2 + H_2O \quad (1)$$

### Characterization

The crystal phase and degree of crystallinity were characterized using X-ray diffraction (XRD, D8-Advance, Bruker company, Germany) with Cu Kα radiation (λ=0.15408). The XRD data were collected at room temperature over 2θ range of 20 – 55°. Chemical characterization of nano HA was performed using Fourier Transform Infrared spectroscopy (FTIR, Thermo Scientific, Nicolet 6700) The morphology and size distribution of synthesized nano HA were investigated by using Field Emission Scanning Microscope (FESEM, Zeiss SUPRA 55VP).

### Statistical analysis using Design of Experiment

Response surface methodology (RSM) with central composite design (CCD) was employed to investigate the effect of synthesis parameter process of HA response to mass of HA obtained. Three independent parameters namely, reaction temperature, pH value and calcined temperature at three different levels each, were employed. The parameters chosen and the levels were based on previous study [6,7,8] and suitability with the condition of the product, hydroxyapatite. The experimental plan was designed and the results obtained were analyzed according to

Design Expert version 9.0.2 software to build and evaluate models as well as to plot the three-dimensional response surface curves. The experiments is run in random in order to minimize the effects of unexpected variability in the observe responses due to irrelevant factors.

## Results and Discussion

### XRD and FTIR study on nano HA: Effect of pH variation

The effect of initial pH value was observed by variety the initial pH in range 9.00 until 11.00 at different reaction temperature which are at 80 until 100 °C and calcined temperature at 700 °C. In Figure 1 it can be seen that different pH value will affect the peak and crystallinity in XRD pattern. The variation of initial pH value give effect for the peak of XRD pattern where from the result it can be observe the pH 10.00 is most suitable value for synthesis HA where at pH 10.00, only peak for pure HA can be trace. In Figure 2 and Figure 3 show the peak for XRD for pH variation at reaction temperature 90 °C and 100 °C.

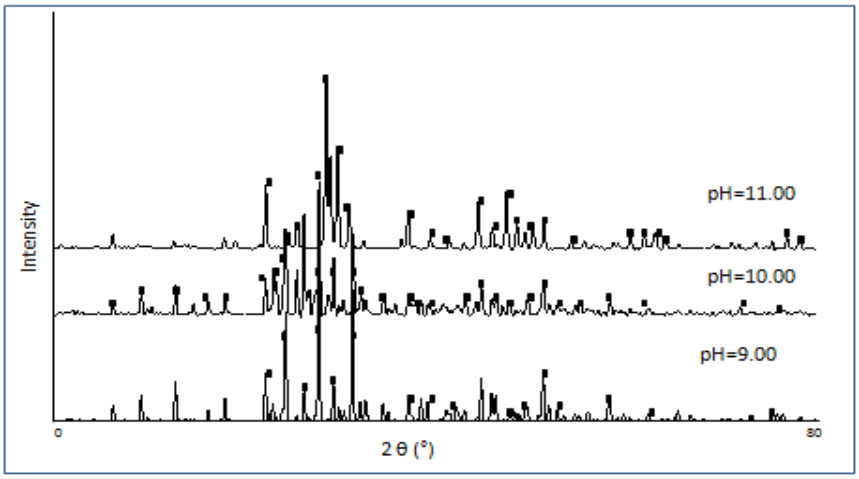

Figure 1. XRD pattern for pH variation at reaction temperature 80 °C and calcined temperature 700 °C

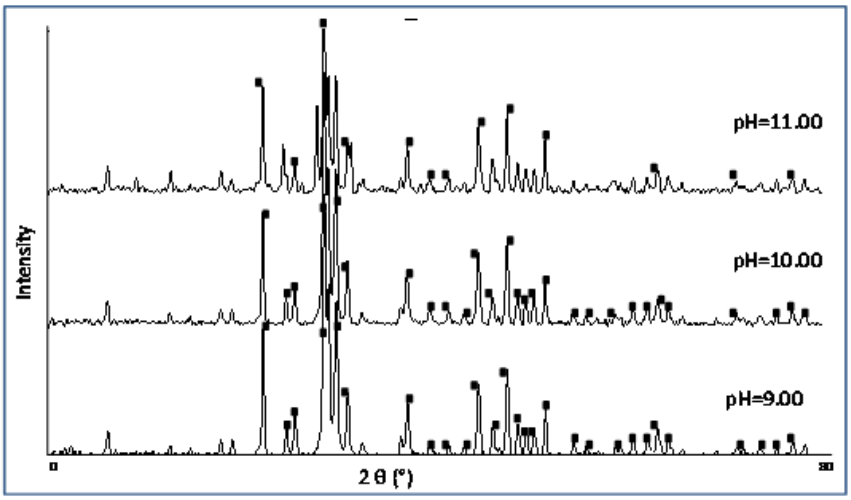

Figure 2. XRD pattern for pH variation at reaction temperature 90 °C and calcined temperature 700 °C.

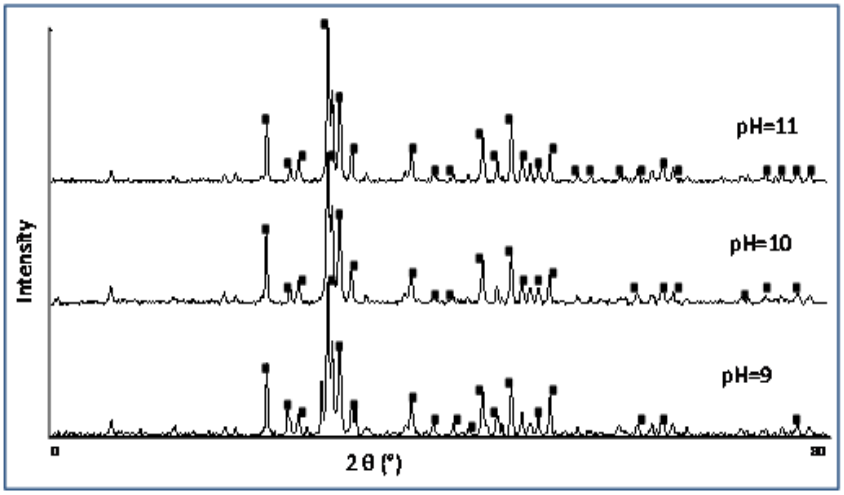

Figure 3. XRD pattern for pH variation at reaction temperature 100 °C and calcined temperature 700 °C.

For FTIR spectra it can be observe in Figure 4 all sample have similar pattern where the sharp band at 1414 $cm^{-1}$. The band 3571 $cm^{-1}$ is attributed to the bending of hydroxyl group ($OH^-$) and the band at 631 $cm^{-1}$ is related to bending vibration of hydroxyl group. Characteristic of HA are found at 1457 $cm^{-1}$, 1414 $cm^{-1}$ and 1416 $cm^{-1}$ which are represent carbonate ($CO_3^{2}$) group.

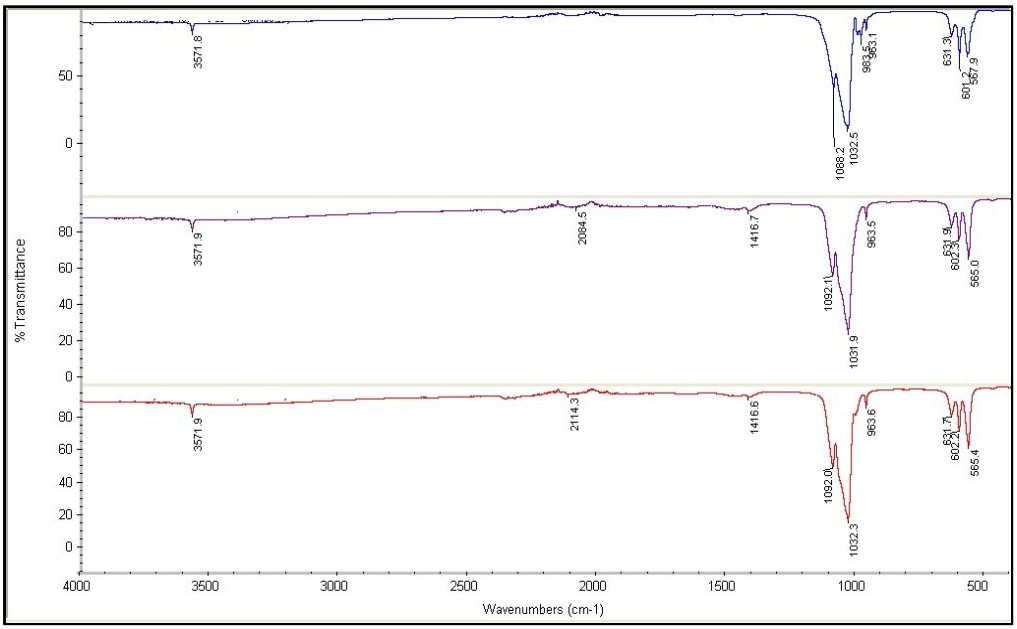

Figure 4. FT-IR spectra of nano HA at reaction temperature 80 °C and calcined temperature 700 °C

**Effect of reaction temperature**

The reaction temperature for stirring also play an important role that can affect the morphology of HA. The reaction temperature was varied from 80 °C to 100 °C. Temperature usually influenced the crystal phase and degree of crystallinity where during the crystallization process the reaction temperature was dependent factor on the morphology. Crystallinity is referring to the arrangement of the atom or molecules in periodic order. Depend on a certain condition, the shape of a crystal was determined by kinetics compared to thermodynamics. The kinetic of crystal face can be influenced by external factor as example supersaturation temperature and mixing [6]. All the diffraction pattern revealed peak of HA. The sharpness of the diffraction peak increase as the reaction temperature increase. Increase in sharpness of diffraction peak show increasing in crystallinity of the HA form [7].

Figure 5 shows the XRD pattern for synthesis of HA are different at different reaction temperature. The pH value was varied between 9.00 until 11.00 and the calcined temperature was varied from 700 °C and 800 °C. From the peak pattern, it shows as the reaction temperature increase, the peak become sharper and narrow that show the increase in crystallinity of the HA. It shows that the sample at highest reaction temperature which is at 100 °C have better crystallinity of HA compared to sample at 80 °C and 90 °C.

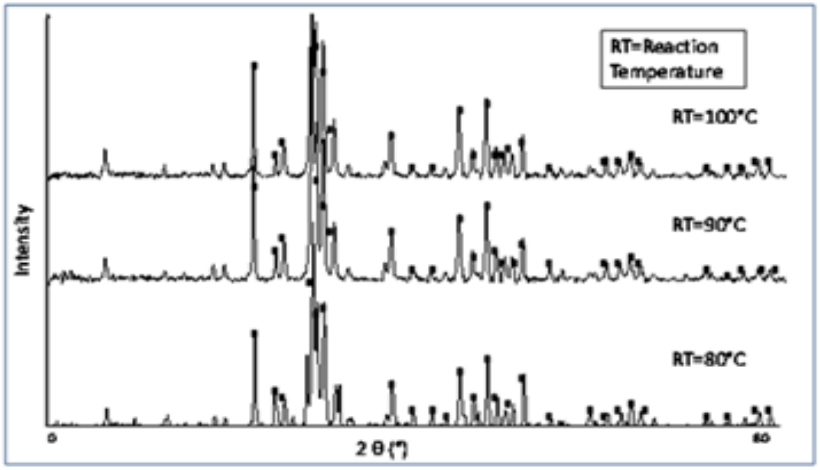

Figure 5. XRD pattern for reaction temperature variation at pH 9.00 and calcined temperature 700 °C

Figure 6 shows the FTIR spectra of HA at different reaction temperature. It can be observed that all the spectra have almost same peak where $PO^{4-}$ was obtained at 565, 602 and 1032 $cm^{-1}$ and $CO^{3-}$ was appear at 963 and 1416. There are two shoulder peak at 631 and 3571 which are typically stretching vibration and bending mode of HA.

**Effect of Calcined temperature**

Other than initial pH value and reaction temperature, calcined temperature also play an important factor in the synthesis of HA. From the previous researcher, increase in calcined temperature will increase the crystallinity as peak become narrow and sharp moving where the temperature was varied from 100 to 800 °C [8]. It has been proven as the peak of diffraction become narrow and sharp as the calcined temperature increase from 700°C to 800 °C.

The temperature for calcined was set at 700 and 800 °C at different pH value which are 9, 10 and 11 where for reaction temperature was varied from 80, 90 and 100 °C. From Figure 7 it can be observed the crystallinity of HA is increase when the temperature increase. For temperature calcined at 700 °C, the peak is lower compared to HA that calcined at 800 °C. It shows that calcined temperature also be the factor of preparing the HA.

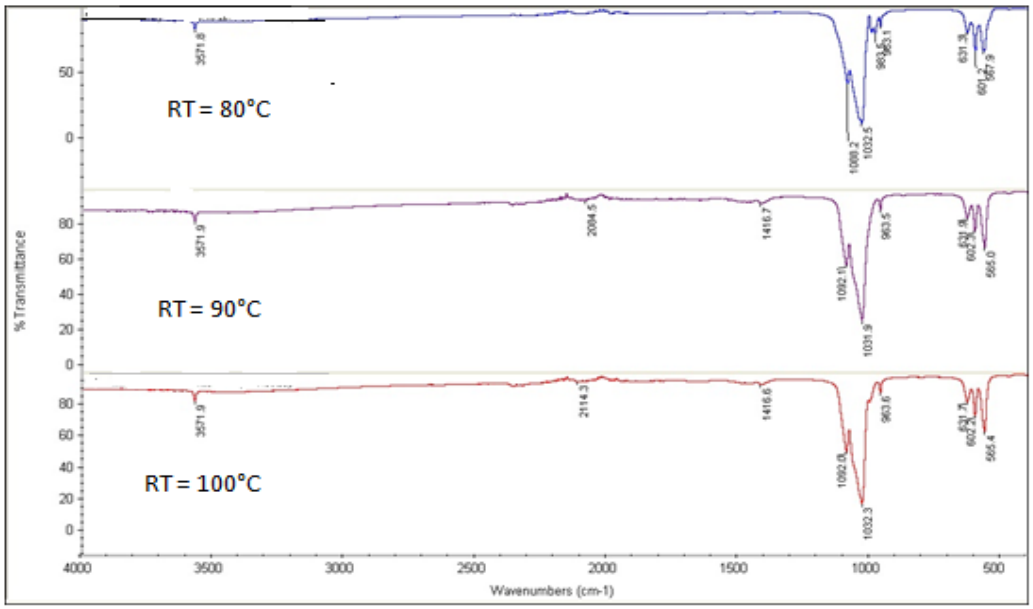

Figure 6. FT-IR spectra of nano HA at pH value 9.00 and calcined temperature 700 °C

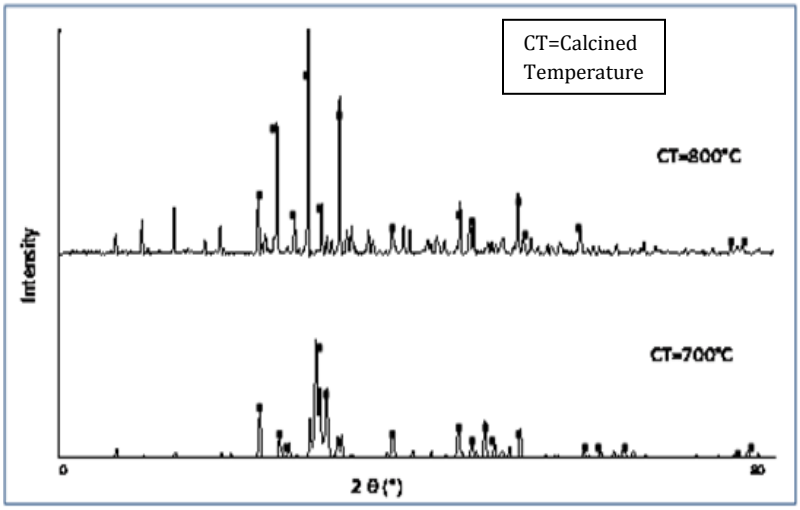

Figure 7. XRD pattern for calcined temperature variation at pH 9.00 and reaction temperature 80 °C

FTIR patterns was presented in Figure 8 The spectra possess an $OH^{1-}$ group in the region of 3571 $cm^{-1}$ and $PO_4^{3-}$ lies in region 1080 $cm^{-1}$. So, from this analysis, the detection of HA in all sample are confirmed. The peak at 700 °C are sharper compare to 800 °C. A weak band of $CO_3$ was detect at few sample in region 1416 $cm^{-1}$ and $H_2O$ also be detecting at band 1852 $cm^{-1}$. As the temperature increase the peaks are going to be weak which is in agreement with published data. The characteristic band of inorganic carbonate ion suggest that carbon gets dissolve in organic from atmosphere instead of dissolve in HA crystal [8].

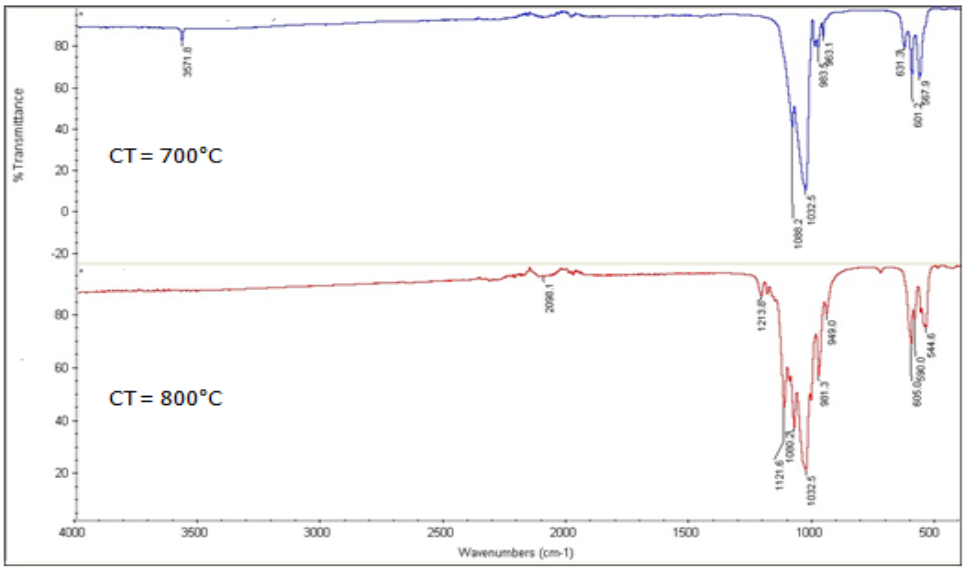

Figure 8. FT-IR spectra of nano HA at pH 9.00 and reaction temperature 80 °C

**The morphology of hydroxyapatite crystal: Effect of initial pH value**

From the FESEM analysis of HA particle that shown in Figure 9 and Figure 10 below show that initial pH value play an important role in morphology controlling HA particle. The HA that synthesis at pH 9.00 have sphere - like nano particle where the size of the particle about 209.9 nm. For nano particle HA at pH 10, the particle look like needle with average size 42.43 nm. For the research conduct by Abidi and Murtaza [8], at pH 10.00 and 11.00, the HA is sphere-like nano particle with narrow distribution range and good dispersibility at pH 10.00 where at pH 8.00, the shape of HA is needle-like.

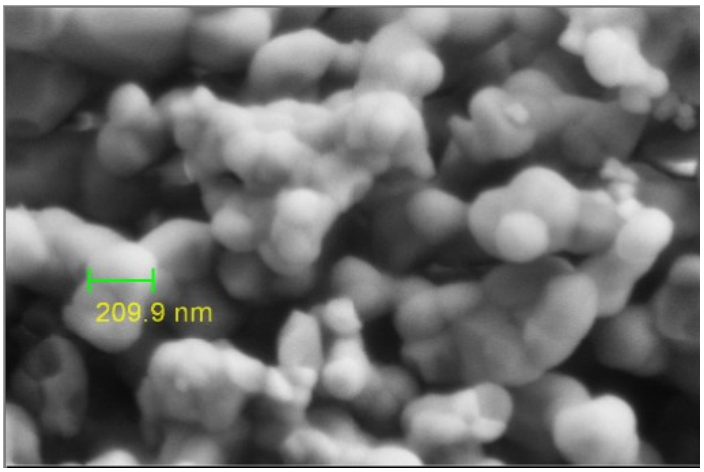

Figure 9. FESEM image for HA at pH 9.00

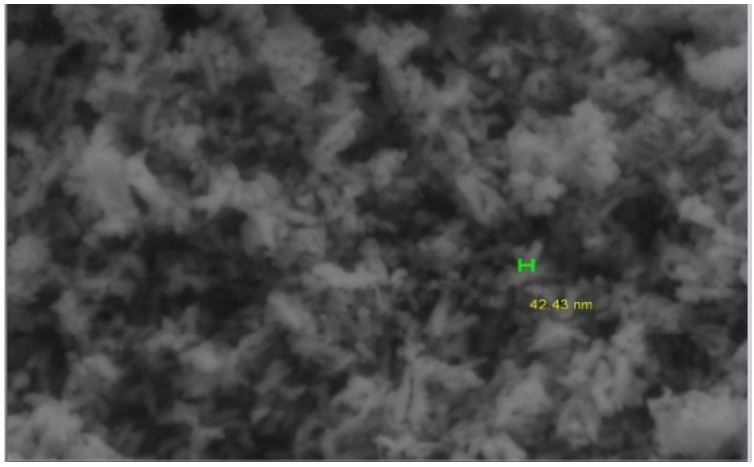

Figure 10. FESEM image for HA at pH 10.00

**Effect of reaction temperature**

The reaction temperature is an important factor in synthesis HA where it can affect the morphology of HA. Nanoparticle of HA can be exhibit in various morphologies which are needle-like and spherical-like, both shape is common and suitable used in many type of technologies application. The natural bone is composed of needle-like nanoparticle and because of that the synthesis of nanoparticle HA in needle-like shape is timely needed requirement [8]. In Figure 11 and Figure 12, the shape of the crystal is different where nanoparticle HA that prepare at temperature 80 °C has almost needle-like shape with 42.43 nm size where at reaction temperature 100°C it clearly shows the shape of the crystal is needle-like with size of the particle 58.06 nm. It shows that the temperature is an important role in morphology of HA.

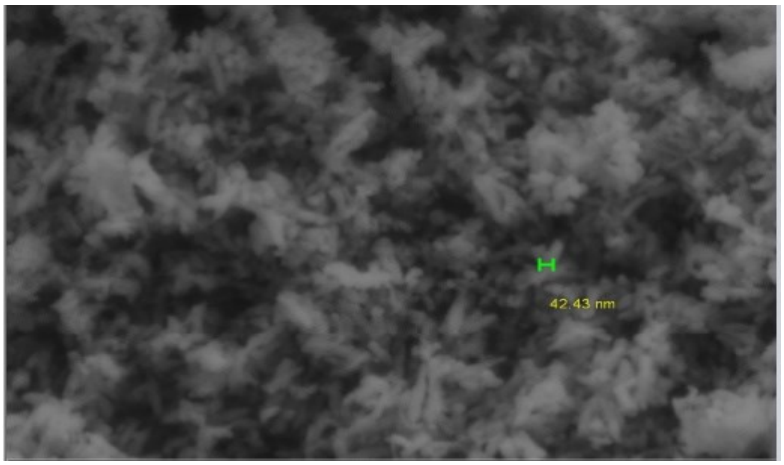

Figure 11. FESEM image for HA at reaction temperature 80 °C

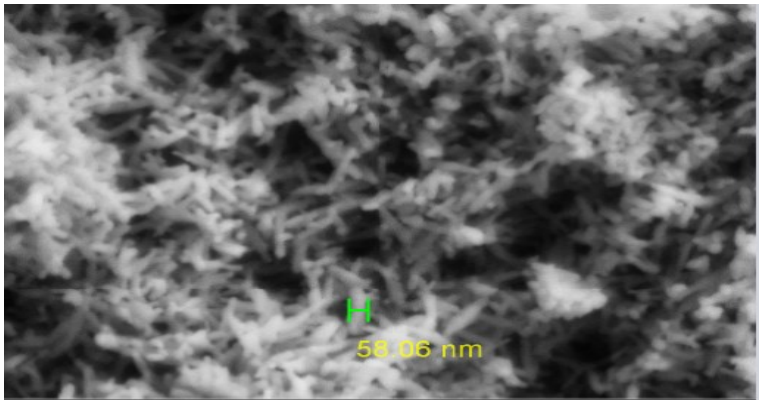

Figure 12. FESEM image for HA at reaction temperature 100 °C

**Effect of calcined temperature**

FESEM observation was performed to record the image of nanoparticle HA at calcined temperature 700 °C and 800°C. It is well known that spherical powder has better rheological properties compared to irregular powder and lead to produce better coating for hip implant. In order to produce high quality of powder for hip implant it's very important to control granule spherical morphology. It has been demonstrated by increase temperature cause HA precipitate size increase [8]. In Figure 13 and Figure 14, it can be observed that nanoparticle HA will give different shape when calcined at different temperature. At 700°C, the nanoparticle HA is needle-like shape with particle size 82.63 nm where at 800°C is spherical-like shape with particle size 227.8 nm These two shape is most popular in medical application. Different synthesis condition is performing according to the application.

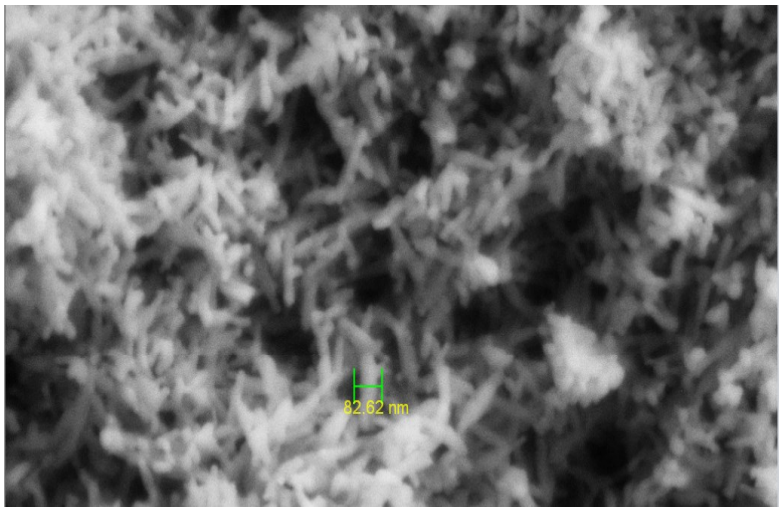

Figure 13. FESEM image for HA at calcined temperature 700 °C

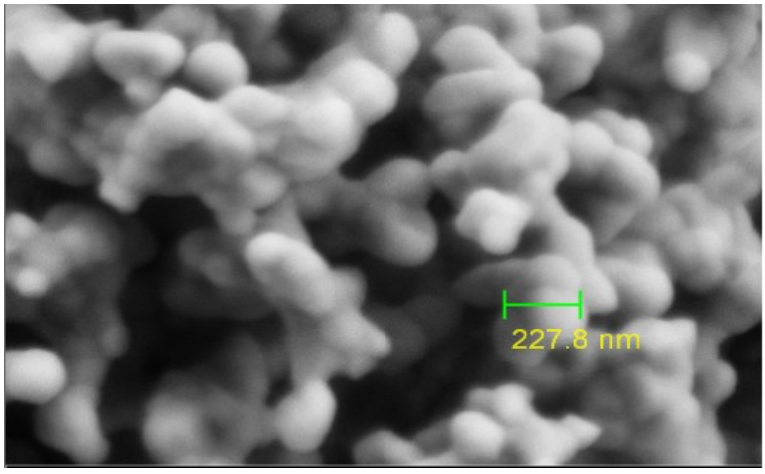

Figure 14. FESEM image for HA at calcined temperature 800 °C

**Design of Experiment (DOE): Statistical analysis**

For the three examined factors the CCD model efficiently designed a second order response to fit the surface. According to the design, the mass of synthesis HA was determined at different combination of parameters in order to evaluate the combined effect of these factors. The model used in this analysis was quadratic model. The degree of significance of each factor is represented in the table by its p-value. When a factor has a p-value of less than 0.05 ($P < 0.05$), it indicates model terms are significant with a confidence level of 0.95 [9]. The test result for Analysis of Variance (ANOVA) test for RSM parameter was shown in Table 1. From the table, F-value for model is 4.18 with p-value less than 0.05 which indicate model term are significant under selected condition. In this case, parameter C which is calcined temperature is a significant model term with p-value 0.0017.

Table 1. ANOVA for RSM parameter

| Source | Sum of Squares | df | Mean Square | F Value | p-value (Prob > F) |
|---|---|---|---|---|---|
| Model | 38.52 | 9 | 4.28 | 4.18 | 0.0363 |

ANOVA result for response parameter are shown in Table 2 . The value of $R^2$ provide a measure how much variation in the observed response value can be explained by the experimental factor and their interaction. The value of $R^2$ is always between 0 to 1. The closer $R^2$ value to 1, the stronger the model is and better it predict the response [9]. The value for $R^2$ for this test is 0.843.

Response surface methodology is use to trace the efficiently for the optimum value of the significant variable. In this research the focus in this study to optimize the parameter used which are reaction temperature, pH value and calcined temperature respect to mass of HA formed from synthesis process. In Figure 15, it shows the optimum pH value which is at pH 9.00 and the reaction temperature is at 90 °C.

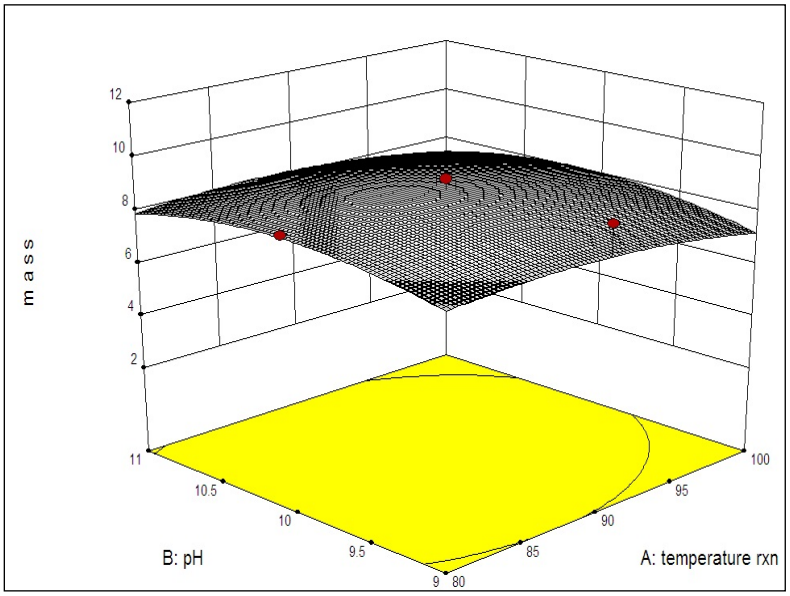

Figure 15. Response surface plot for combined variable pH value and temperature reaction

Table 3 shows the result for experimental and predicted mass of nanoparticle HA based on ANOVA. The predicted mass of HA differ from experimental result where the highest mass was predicted at 90 °C, pH 10.00 and 700 °C which is 9.54 g. Equation below is the linear corelation related the variables that influence the mass of HA formed from synthesis process

$$\text{Mass} = 8.82 - 0.26.A + 0.10.B - 1.58.C + 0.0135\ A.B - 0.16\ A.C + 0.26\ B.C - 0.46\ A^2 - 0.76\ B^2 - 0.86\ C^2 \quad (2)$$

A positive sign in the equation above represent a synergetic effect of the variable and negative sign represnet an antagoniistic effect of the variable.

Table 3. Result for experimental and predicted mass of HA

| Run | Factor 1 A: Reaction T (°C) | Factor 2 B: pH | Factor 3 C: Calcined T(°C) | Experimental Mass (g) | Predicted Mass (g) |
|---|---|---|---|---|---|
| 1 | 90 | 10.00 | 800 | 6.12 | 6.39 |

| 16 | 90 | 10.00 | 700 | 9.22 | 9.54 |
| 17 | 90 | 10 | 700 | 9.22 | 8.82 |

## Conclusion

The study of three tested parameters which are reaction temperature, pH value and calcined temperature were investigate and it show these parameters have significant effect on mass of HA formed, the characteristic and the morphology of the nanoparticle that synthesis using wet chemical precipitation method. Wet chemical precipitation method was used due to its reproducibility, simplicity and economical. The analysis of XRD, FTIR and FESEM show that all sample are in nanoparticle size. From the XRD pattern, the highest crystallinity occurs at condition reaction temperature 100 °C, pH value 10.00 and calcined temperature 800 °C. The spectra of FTIR show all the sample contain HA and from the image FESEM, nanoparticle HA formed from this research is needle-like and spherical-like with the range particle size between 40 to 200 nm. Optimization of parameters in synthesis of nanoparticle HA was determined using Design expert version 9.0.2. Based on analysis of variance (ANOVA) that has been perform, calcined temperature was to be influential variables on mass of HA with value of probability less than 0.05.

**Abstract**

Iron and manganese present naturally in groundwater. Both metallic ions at excessive amounts normally contribute to rusty taste and reddish color to the water. Membrane technology may improve the conventional groundwater treatment method which commonly requires a large area and a lot of manpower. The present experimental work focused on membrane filtration of iron and manganese in order to study the influence of pH adjustment to the prepared artificial groundwater based on the permeate quality and membrane performances. In this study, two commercially available polyamide nanofiltration and ultrafiltration membranes (PA-NF, PA-UF) were tested to examine their capabilities in treating groundwater for drinking water resources. In order to achieve WHO drinking water standard, permeate quality of the artificial groundwater is considered satisfy if concentration of iron and manganese has reached 0.3 and 0.1 mg/L, respectively. Experimental results showed that pH at a range of 3-11 have significantly improved membrane performance in terms of their rejection. Rejection of iron at a feed concentration of 100 mg/L increased as pH of the feed solution increased for all tested membranes. However, the manganese rejection with a feed concentration at 50 mg/L showed various pattern of performance for each membrane. The pH of feed solution played an important role in changing the membrane surface properties and also, the characteristic of solute. This concludes that solute-membrane interaction mechanism has improved the performance of the tested membranes.

**Keywords**: iron rejection, manganese rejection, artificial groundwater, pH adjustment, drinking water

**Abstrak**

Besi dan mangan wujud semulajadi di dalam air bawah tanah. Kedua-dua ion logam ini pada jumlah yang berlebihan menyumbang kepada rasa berkarat dan warna yang kemerahan pada air. Kajian ini memberi tumpuan kepada penurasan logam besi dan mangan oleh membran dengan tujuan untuk mengkaji kesan pelarasan pH terhadap air bawah tanah buatan berdasarkan kepada kualiti telapan dan prestasi membran. Dalam ujikaji ini, dua membran poliamida penurasan-nano dan penurasan-ultra (PA-NF, PA-UF) yang boleh didapati secara komersial telah diuji untuk mengkaji keupayaan dalam merawat air bawah tanah sebagai sumber air minuman. Untuk mencapai piawaian WHO bagi air minuman, kualiti telapan air bawah tanah buatan dianggap memuaskan jika kepekatan besi dan mangan masing-masing mencapai 0.3 dan 0.1 mg/L. Keputusan ujikaji menunjukkan bahawa pH di antara julat 3-11 dengan ketaranya telah menambahbaik prestasi membran dari segi penyingkiran. Penyingkiran besi pada kepekatan suapan 100 mg/L telah meningkat apabila pH suapan meningkat untuk semua membran yang diuji. Walau bagaimanapun, penyingkaran mangan dengan kepekatan suapan pada 50 mg/L menunjukkan kepelbagaian corak prestasi bagi setiap membran. pH larutan suapan memainkan peranan penting dalam mengubah sifat-sifat permukaan membran

dan juga sifat bahan terlarut. Kesimpulannya, mekanisme interaksi bahan terlarut-membran telah meningkatkan prestasi membran yang diuji.

**Kata kunci:** penyingkiran besi, penyingkiran mangan, air bawah tanah, pelarasan pH, air minuman

## Introduction

Most of countries around the world rely on surface water for their daily needs including for drinking water sources. This is because surface water can be easily found over the land surface either in rivers, ponds, lakes, swamps or other fresh (not salty) sources. However, this natural water resource is more easily contaminated and contains most bacteria and other microorganism. Along with surface water, groundwater resources play a vital role in the production of clean and adequate drinking water supply all around the world. In countries such as Germany, Canada and the United States of America, nearly 70% of drinking water originates from groundwater [1]. The quality of groundwater is much better than surface water as soils, sands or rocks underneath the ground have become the filtration layers. It has been reported that most of groundwater consists some metal such as iron and manganese which naturally leach from many types of rocks and soils [2]. Iron (Fe) and manganese (Mn) are common metallic elements that exist together naturally especially in deeper wells [3]. Both are commonly found in water and are essential elements required in small amounts by all living organisms. Presence of excess amount of Fe and Mn resulted in metallic taste of water, slightly reddish colored water and rusty-brown stains of products like paper, cloths, and plastics [4]. World Health Organization (WHO) suggested that Fe and Mn concentrations in drinking water should be less than 0.3 mg/L and 0.1 mg/L, respectively [5].

The natural occurrence of Fe and Mn in groundwater usually with very little or without existence of oxygen, typically in deeper wells, in areas where groundwater flow is slow, and also in areas where groundwater flows through soils rich in organic matter. Fe and Mn usually present in natural groundwater in their most soluble form as divalent ions, $Fe^{2+}$ and $Mn^{2+}$. In soluble form they are colorless in groundwater but when exposed to air, they get oxidized then turn to insoluble form of $Fe^{3+}$ and $Mn^{4+}$, respectively and leave the water with brown-red color. Several techniques have been applied to remove these metals from groundwater including ion-exchange and water softening, adsorption by activated carbon, aeration and filtration, biosorption, ionic liquid extraction, and so forth [6–10]. Recently, the application of membrane technology including nanofiltration (NF) in water treatment for producing drinking water resources has been increased rapidly. NF technology is able to overcome operational problems that used to associate with conventional technique. In addition, other advantages of NF membranes are high retention of divalent ions at lower operating pressure and higher flux with lower energy consumption.

Numerous studies have been reported in investigating the ability of membrane filtration in water treatment [11–13]. However, only a limited number of studies have examined the removal of Fe and Mn in groundwater by using NF membranes [14]. Therefore, this study was conducted with the aim to investigate the influence of operating variables on the retention of Fe and Mn in groundwater using NF membranes. Along with this membrane, the treatment was also conducted by UF membrane in order to compare their performances. In this work, Fe and Mn removal were investigated using polyamide NF and UF membrane assigned as PA-NF and PA-UF, respectively. The main objective of this study is to investigate the influence of feed solution pH on the prepared synthetic groundwater, quality of permeate samples and performance of the membranes. Further analysis according to surface morphology images was measured by field emission scanning electron microscopy (FESEM) to further understand the rejection mechanisms involved.

## Materials and Methods

### Chemicals and membranes

All of purchased chemicals were analytical grade with high purity and no further purification required before used. Ferrous chloride tetrahydrate ($FeCl_2.4H_2O$) was procured from HmbG® Chemicals and manganese chloride tetrahydrate ($MnCl_2.4H_2O$) was obtained from Bendosen Laboratory Chemicals. In the preparation of synthetic groundwater, both chemicals were used by dissolving them in ultra-pure water with conductivity less than 1µS/cm as a single component for filtration experiment. The feed solution with individual metal of Fe and Mn were provided at initial concentration of 100 mg Fe/L and 50 mg Mn/L, respectively. The synthetic groundwater was freshly prepared a day before filtration experiment and kept in a cold room. This procedure was conducted to avoid

the divalent ions from being oxidized. Ferrous iron reagent powder (HACH Permachem®, USA) was used for determination of the remaining $Fe^{2+}$ ion in permeate from each filtration. Manganese reagent set (HACH Permachem®, USA) consisting of buffer powder citrate type for Mn and sodium periodate were used for detection of $Mn^{2+}$ in permeate samples. Individual salt solutions of sodium chloride, sodium sulphate and calcium chloride (NaCl, $Na_2SO_4$ and $CaCl_2$) were freshly prepared using NaCl (Merck, Germany), $Na_2SO_4$ and $CaCl_2$ (Sigma, USA). Low concentration of hydrochloric acid (HCl) and sodium hydroxide (NaOH) were used for pH adjustment on the feed solution.

Two different type of membranes were employed in order to investigate their performances for groundwater treatment, specifically for Fe and Mn removal. Both NF and UF membranes were supplied by Sterlitech Corp., USA. The polyamide (PA) flat sheet NF and UF membranes denoted as PA-NF and PA-UF, respectively were soaked overnight prior to use. The specification of the selected membranes is provided in Table 1.

Table 1. Specification of membranes

| **Parameter** | **PA-NF** | **PA-UF** |

[a] – data provided by manufacturer, [b] – data obtained from contact angle measurement at ambient temperature, MWCO – molecular weight cut off

**Experimental set-up**

A bench-scale dead-end stirred cell procured from Sterlitech Corporation, WA (Model HP4750) that houses a 49 mm diameter flat sheet membrane with effective area of 14.6 $cm^2$ was used for filtration experiment. The filtration set-up comprises of a nitrogen gas tank, 2000 mL reservoir tank, 300 mL stainless steel stirred cell and a precision balance (Sartorious AG, Germany, Model AX6202) connected to a data acquisition personal computer. Filtration experiments by the selected membranes were conducted for 1 to 3 hour and permeate sample was collected for further water quality analysis. The remaining $Fe^{2+}$ and $Mn^{2+}$ ions in permeate was measured by using spectrophotometer (HACH, Model DR3900).

Filtration experiments were performed to investigate the ability of applied membranes based on permeability, flux and rejection using ultra pure water and samples of synthetic groundwater. All membranes were soaked in ultra-pure water for overnight prior to use. This step was purposely to remove preservatives, and the soaking step also considered as a wetting process for the membrane. Then, compaction of membrane was conducted for 30 to 45 minutes by pressurizing the stirred cell with nitrogen gas at 5 bar without stirring. After compaction, the pure water permeability test was conducted. For determination of flux and rejection, a volume of 250 mL of feed solution was placed into the stirred cell and filtered for permeate sample collection.

Pure water flux was calculated by the following Eq. 1 where, $J_w$ is pure water flux ($L \cdot h^{-1} \cdot m^{-2}$), $Q$ is amount of water collected (L) for $\Delta t$ (h) which is time duration using a membrane coupon with area $A$ ($m^2$).

$$J_w = \frac{Q}{A \Delta t} \quad (1)$$

The flux of sample of feed solution was measured by the following Eq. 2 where $J$ is the sample flux ($L \cdot h^{-1} \cdot m^{-2} \cdot bar^{-1}$), as a function of permeability, $L_p$ ($L \cdot h^{-1} \cdot m^{-2} \cdot bar^{-1}$) and applied transmembrane pressure, $\Delta P$ (bar) taking the osmotic pressure difference between feed and permeate, $\Delta \pi$ (bar) into account.

$$J = L_p\,(\Delta P - \Delta\pi) \tag{2}$$

The rejection of sample of feed solution and the removal efficiency of NF and UF membranes during the filtration was measured by Eq. 3, where $R_o$ is the observed rejection and $C_p$ and $C_f$ are the concentration of permeate and feed, respectively.

$$R_o = \left(1 - \frac{C_p}{C_f}\right) \times 100\% \tag{3}$$

**Characterization of membrane**

The detail protocol for determination of characteristics of the selected commercial membranes was described in earlier publication [15]. In that publication TFC-SR3 and GHSP were referred to the PA-NF and PA-UF membrane, respectively. The hydrophilicity of membrane surface was analyzed by contact angle measurements using a static sessile drop method by goniometer contact angle (Ramé-Hart, Model 290, Netcong, USA). The analysis was conducted by using ultra-pure water dropped on top of a clean membrane surface with three series of measurement at three different spots. Images of the top surface and cross-sectional morphologies of membranes were provided by field emission scanning electron microscopy (FESEM) (Zeiss SUPRA 55VP Oberkochen, Germany). The instrument was equipped with an energy dispersive X-ray (EDX) analysis system to identify foulants that have been filtered by the membranes. The membrane pure water permeability, $L_p$ was determined by measurement of water flux at operating pressure ranged of 1 to 5 bar using ultra-pure water at conductivity less than 1 µS/cm and conducted at room temperature. Membranes were immersed in ultra-pure water and kept for overnight before compaction at 5 bar for 30 to 45 min prior to use.

**Iron and manganese ion analysis**

Permeate samples of Fe and Mn were analyzed using spectrophotometer (HACH, USA, Model DR3900). The collected permeate after filtration process was checked for water quality analysis in identifying the best operating variables to meet the drinking water standards. Physico-chemical parameters were measured to investigate the efficiency of membranes. Conductivity, pH and TDS were measured using pH/EC/TDS benchtop meter (HANNA, UK, Model HI-2550), whereas turbidity were analyzed by using turbidimeter (HACH, USA, Model 2100AN). Color, Fe and Mn in permeate were detected by using spectrophotometer (HACH, Model DR3900). All parameters were analyzed according to the APHA standard methods.

## Results and Discussion

**Surface characteristic of NF and UF membranes: Water flux**

Three different coupons of PA-NF and PA-UF were used for measurement of water fluxes. The average volumetric water flux at applied pressure of 5.0 bar for PA-NF membrane was found 10.75 ± 0.5 L $m^{-2}$ $h^{-1}$. The result obtained was lesser than the PA-UF membrane flux at 15.85 ± 0.5 L $m^{-2}$ $h^{-1}$. From the observed results, these indicated that all coupons of PA-NF and PA-UF membranes conducted for this objective have permeability of 2.15 ± 0.5 L $m^{-2}$ $h^{-1}$ $bar^{-1}$ and 3.17 ± 0.5 L $m^{-2}$ $h^{-1}$ $bar^{-1}$, respectively. These results showed that the separation layer of PA-UF membrane was more permeable to water in comparison to PA-NF. Data obtained from manufacturer had reported that the molecular weight cut off for PA-NF and PA-UF were 200 and 1000 Da, respectively. Therefore, results of water flux were congruent with the specification of PA-NF and PA-UF membranes. Data of water fluxes is presented in Table 2 for comparison.

**Hydrophilicity**

The hydrophilicity of membranes was measured by static sessile drop method. The contact angle between pure water droplet and the clean surface of membrane is a measurement of wettability of membranes. The higher value of contact angle indicates that the membrane is more hydrophobic. Three series of measurement at three different spots of clean membranes were conducted a day after the samples were kept overnight in a desiccator. The average contact angles of three clean membrane coupons for each PA-NF and PA-UF was found at 44° ± 2.5 and 66° ± 2.5, respectively. Results showed that PA-NF is more hydrophilic than PA-UF membrane. The findings of contact angle

of the selected NF and UF membranes in this study revealed that both membranes were suitable for further application in treating groundwater. However, the potential of both membranes in rejecting contaminants and meeting the drinking water standard should be the main priority.

Table 2. Water permeability test of NF and UF membranes

| **Parameter** | **PA-NF** | **PA-UF** |
|---|---|---|
| Average volumetric water flux ($L \cdot m^{-2} \cdot h^{-1}$) | 10.75 ± 0.5 | 15.85 ± 0.5 |
| Membrane permeability ($L \cdot m^{-2} \cdot h^{-1} \cdot bar^{-1}$) | 2.15 ± 0.5 | 3.17± 0.5 |

**Effect of pH on solute and membrane**

The prepared synthetic groundwater containing of $Fe^{2+}$ and $Mn^{2+}$ ions was added with low concentration (0.1 M) of hydrochloric acid (HCl) or sodium hydroxide (NaOH) in order to adjust the pH of feed solution in the range of pH 3 to 11. Fig. 1 represents the physical observation on the feed solution of synthetic groundwater at pH 9 prepared for filtration experiment. This result is used to further show that there was color changed in the feed solution as the solute has transformed from lower to higher oxidation state.

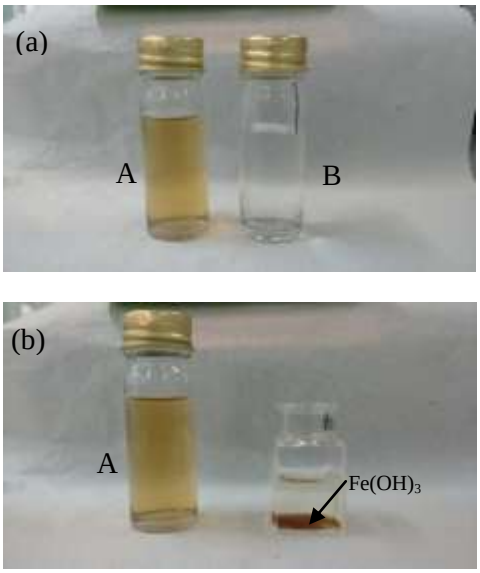

Figure 1. Physical properties of 100 mg Fe/L (a) at feed pH 9.3 (sample A), pH 6.5 (sample B) and (b) when $Fe(OH)_3$ formed as flocs

Insoluble trivalent ferric ions, $Fe^{3+}$ or known as iron solid commonly occur as colourful bright reddish-yellow to yellowish-brown stains as in sample A in Fig. 1(a). When sample A was exposed to air at ambient temperature for about 10 to 20 minutes, precipitate of iron hydroxide ($Fe(OH)_3$) was settled down at the bottom of cell as shown in Fig. 1(b). The initial pH of $FeCl_2$ and $MnCl_2$ feed solution right after preparation of the synthetic groundwater was found at 6.0 ± 0.5. At this condition, both divalent metal ions were soluble in water, with the prepared synthetic groundwater samples consist of either $Fe^{2+}$ or $Mn^{2+}$ ions were colourless as sample B in Figure 1(a). By increasing the pH, the soluble divalent ions were slowly oxidized to become insoluble and stable ions as the following Eq. 4 and Eq. 5;

$$Fe^{2+} + 3H_2O \rightarrow Fe(OH)_3 + 3H^+ + e^- \quad (4)$$

$$Mn^{2+} + 2H_2O \rightarrow MnO_2 + 4H^+ + 2e^- \quad (5)$$

The stability of $Fe^{2+}$ ions depend not only on pH but also on the activity of electrons. The occurrence and behaviour of $Mn^{2+}$ ions is not similar to Fe. It was found that $Fe^{2+}$ is more easily and rapidly oxidized than $Mn^{2+}$. Precipitation of $Fe(OH)_3$ and $MnO_2$ was due to the feed solution having bigger size of particles formed once the pH feed solution has increased. Therefore, size exclusion was expected to be the domain rejection mechanism for feed solution at higher pH and membrane performance has been significantly influenced by the feed pH adjustment.

**Permeate quality**

Fig. 2(a) presents the permeate concentrations measured after filtration experiments using feed solution with 100 mg Fe/L at adjustment of pH in the range of pH 3 to 11. Results show that at these pH range, the concentration of metallic ions detected in permeate decreased with increasing pH. For Fe removal by PA-NF membrane at pH 9 and 11, permeate concentration measured were well below than the acceptable limit for drinking water standard set by WHO which were 0.08 and 0.12 mg Fe/L, respectively. Whereas by using PA-UF membrane, results showed that the permeate quality (0.12, 0.07 and 0.13 mg Fe/L) was satisfied when feed solution used were at pH 7, 9 and 11. These results indicated that Fe rejection was succesful at pH 9 and above. It was found that poor rejection of Fe by both NF and UF membranes when feed solution pH was adjusted below 7. Thus, results proved that pH has importantly impacted Fe removal as also reported by other scholars [16]. The feed pH may change the nature of the membrane surface charge and pore size, as well as the dissolved metal species and therefore can affect the membrane separation efficiency [17]. Between pH 3 and 7, almost all Fe present as soluble $Fe^{2+}$. Higher than pH 8, Fe is predominantly present as insoluble $Fe^{3+}$ and easily precipitate as $Fe(OH)_3$ on the surface of membrane. Therefore, Fe removal at this point were mainly by size exclusion (seiving effect).

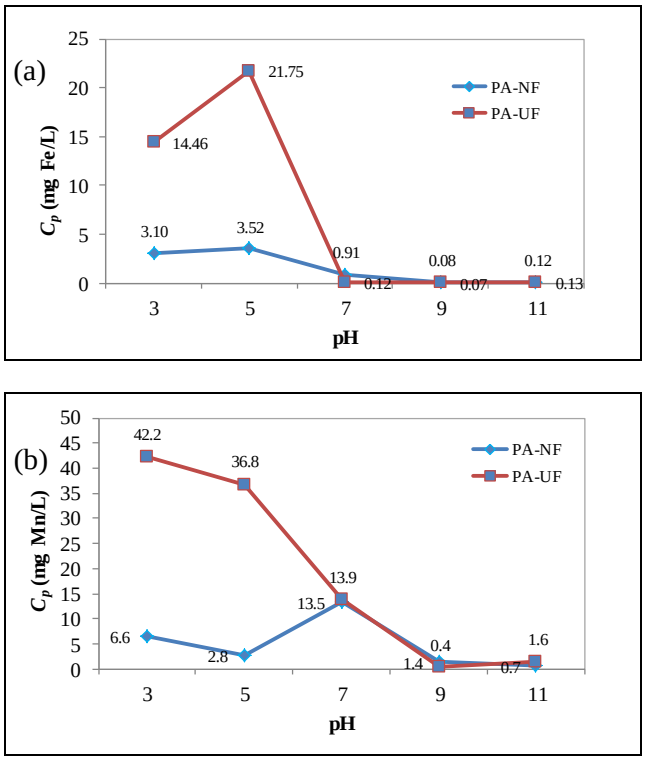

Figure 2. Effect of pH on permeate concentration for filtration of (a) Fe and (b) Mn from synthetic groundwater

For Mn removal with feed concentration at 50 mg Mn/L, it was found that the best quality of permeate achieved when using feed solution at pH 9 with detected permeate concentration at 0.4 mg Mn/L as shown in Fig. 2(b). This value was achieved by filtration using PA-NF membrane. However, it was considered as unsatisfied as for drinking water since the acceptable value should be at least 0.1 mg Mn/L. Poor quality of permeate at below than pH 9 especially by PA-UF membrane probably attributed by the effect of concentration polarization. The occurence and behavior of Mn is not similar to Fe, as $Fe^{2+}$ ions were easily and rapidly oxidized than $Mn^{2+}$ ions. At higher than pH 9, Mn is slowly exist as stable $Mn^{4+}$ and insoluble as $MnO_2$ which then precipitate on the surface of membrane or blocked in the pores. At this point, Mn removal could be attributed solely by size exclusion. Between pH 3 and 7, Mn exist as soluble $Mn^{2+}$ and thus, easily permeate and pass through membrane pores. As a result, poor rejection occured especially at pH 3 with high value of permeate concentration at 42.2 mg Mn/L was detected. In acidic feed solution, membrane pores could be expanded. At this point, PA-NF was reported to be positively charged. Low retention at pH 3 explained that solute-membrane interaction is the main mechanism and dominated by the nature of membrane pores.

**Rejection**

Fig. 3 presents the effect of feed pH on Fe and Mn rejection by using PA-NF and PA-UF membrane. In general, as the pH increased from 3 to 11, the rejection of these metallic ions inreased. This can be mainly caused by the solute-membrane charges interaction. It is obviously showed that rejection of Fe at various feed pH were higher than Mn. Lower rejection of Mn could be attributed solely to the electrostactic effect interaction between membrane material and $Mn^{2+}$ ions [18]. The isoelectric point (IEP) of PA-NF is in the range of 6 to 8 as reported by De Munari et al. [19]. This membrane is characterized as an amphoteric membrane whereby it is positively charged in solution less than pH 6 and negatively charged in solution more than pH 8. Between pH 3 and 5, the membrane is positively charged and lower Fe rejection could be due to dissolved $Fe^{2+}$ were easily permeate the membrane pores. Thus, charge repulsion and size exclusion are less important at this feed pH range. At pH 7, high Fe rejection mainly because of electrostatic interaction between the membrane and the ions was zero. Therefore, the ions did not easily permeate through the membrane and contribute to higher rejection of Fe at IEP of membrane.

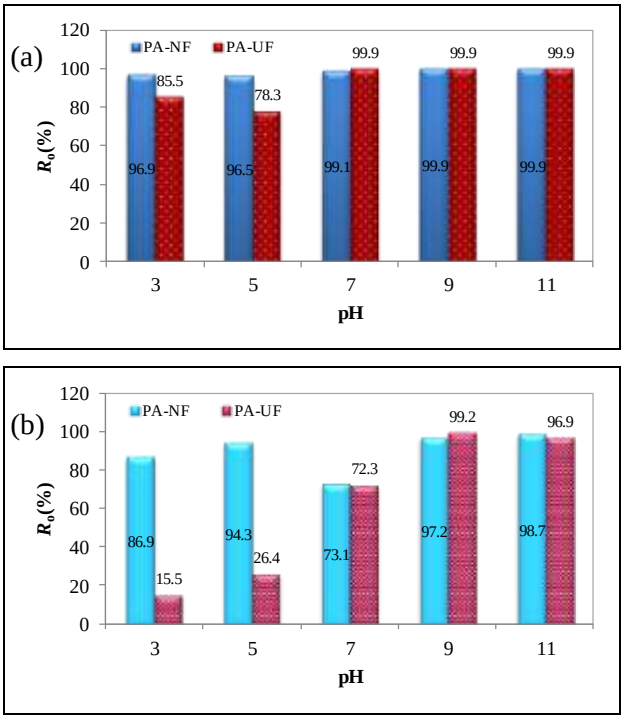

Figure 3. Rejection of (a) Fe and (b) at various feed pH by using 100 mg Fe/L and 50 mg Mn/L, 5 bar, 25 °C with 500 rpm stirring rate

The pH of feed solution may change the nature of the membrane surface charge and pore size, as well as that of dissolved metal species and therefore can affect the membrane separation efficiency. PA-NF membrane has reached higher rejection rate for both metals in comparison with PA-UF as depicted in Fig. 3(a) and 3(b), respectively. Similar findings for Fe removal has previously been reported by Jusoh et al. [7] and De Munari et al. [19]. Regarding to $Mn^{2+}$ ions, De Munari and Schafer [14] reported that PA-NF membrane has achieved more than 95% of rejection at pH 7. In Fig. 3(b), Mn rejection at pH 7 has inreased very well to >70% from 26% rejection at pH 5. At pH 9, higher Mn rejection was achieved to more than 95% and mainly because of changes of solute charges to a stable form which easily removed by membrane as further explained in the earlier section. The good rejection at this condition was mainly contributed by solute-membrane charge interactions. The charge of solute influenced the extent of rejection by NF membranes though the precise mechanism of rejection will depend upon the particular membrane in use [20].

**Surface morphology analysis**

An image of fouled PA-NF membranes for filtration of single metal component in synthetic groundwater at pH 9 is presented in Fig. 4. From visual observation, brownish cake layer become visible on top surface of membrane $(PA\text{-}NF)_A$, resulted from Fe removal. Whereas, blackish cake layer formed on the surface of membrane $(PA\text{-}NF)_B$ after filtration with synthetic groundwater solution with Mn ions. The cake layer formed mainly because of precipitation of $Fe(OH)_3$ and $MnO_2$ as explained in the earlier section. Bordoloi et al. [21] reported that the SEM image with EDS analysis of arsenic (As) and iron (Fe) removal from groundwater by oxidation-coagulation at optimized pH revealed that the sorption of As onto the poorly crystalline precipitate of $Fe(OH)_3$ and existence of a small amount of $MnO_2$. The FESEM images of the precipitate obtained in the presence of Fe and Mn for filtration by both PA-NF and PA-UF membranes at adjusted pH of feed solutions are depicted in Figure 5. The precipitates of $Fe(OH)_3$ on PA-NF and PA-UF membranes are presented by Fig. 5(a) and 5(c), respectively. Whereas, Fig. 5(b) and 5(d) indicate the precipitate of $MnO_2$ on the PA-NF and PA-UF membranes with aggregated large regularly shaped particles suggestive of stable crystallinity of precipitate. In comparison to $Fe(OH)_3$, $MnO_2$ was found more stable especially at pH higher than 8.

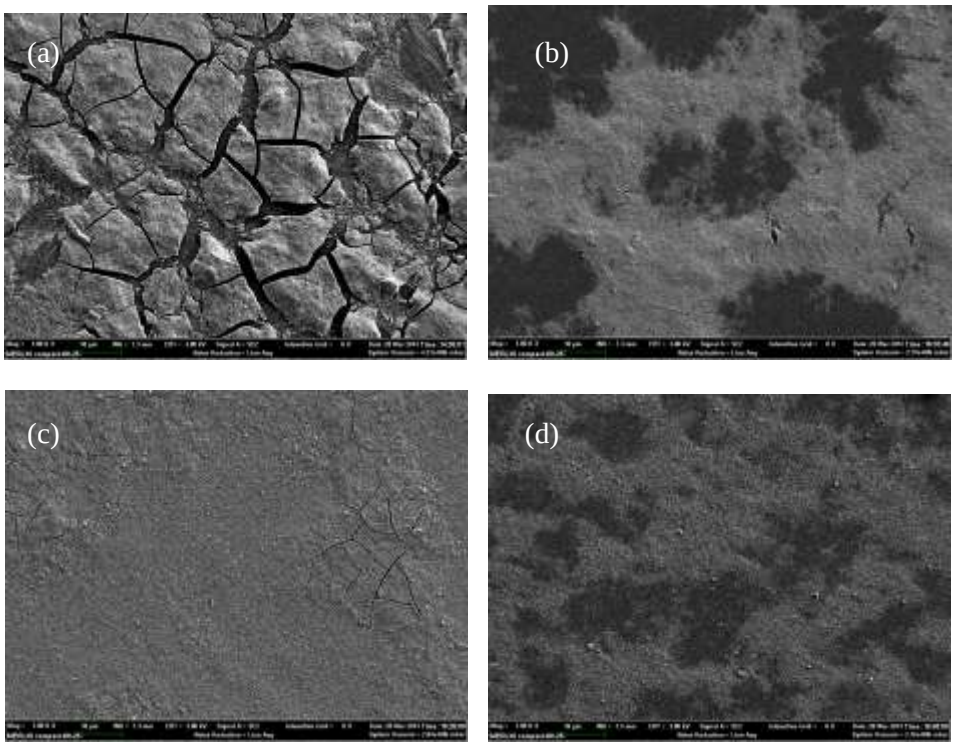

Figure 5. FESEM image of (a) $Fe(OH)_3$ (b) $MnO_2$ on PA-NF, and (c) $Fe(OH)_3$ (d) $MnO_2$ on PA-UF membranes

## Conclusion

The solute-membrane interaction during removal of iron and manganese from synthetic groundwater were investigated in this study. The rejection mechanism of both metallic ions by using PA-NF and PA-UF membranes were also identified and evaluated in this work. The main focus for this paper was to inspect the effect of adjustment on the initial pH of feed solution mainly on the rejection behaviour, permeate quality towards meeting the drinking water standard and also changes on solubility of solute in feed solution. The efficiencies of these membranes were assessed based on permeability, water flux and rejection capabilities at 5 bar and pH of feed solution (pH 3 - 11). The rejection for metallic ions ($Fe^{2+}$ and $Mn^{2+}$) in artificial groundwater using these membranes were significantly influenced by the adjustment of pH. Particularly, rejections of both metals by PA-NF were found higher than PA-UF for all cases. In addition, results proved that PA-NF membrane had efficiently rejected $Fe^{2+}$ and $Mn^{2+}$ ions to the allowable value for drinking water based on WHO standards. Excellent separation performance of PA-NF membrane was mainly due to its effective separation layer of membrane structure.

The significant contribution of solute-membrane charge interactions was determined and influenced by the initial pH of feed solution. It was observed that an increase of pH determined a higher efficiency of Fe and Mn rejections by PA-NF membrane. Higher pH of the feed solution contributed to transformation of soluble divalent $Fe^{2+}$ and $Mn^{2+}$ ions to insoluble $Fe^{3+}$ and $Mn^{4+}$ ions which were more stable and easily precipitated on membrane surfaces. The increase of feed solution pH has decreased the solubility of the divalent metallic ions ($Fe^{2+}$ and $Mn^{2+}$). Therefore, flocculation of metallic ions in the feed solution as the pH increased has resulted to higher rejection of the metal components from the synthetic groundwater. In conclusion, all findings in this study contributed to possibility of developing the membrane technology for Malaysia's groundwater treatment specifically in the removal of Fe and Mn for clean and safe drinking water resources.

**Abstract**

Higher adsorption capacities of activated carbon (AC) can be evaluate according to pore volume, porosity and surface area. AC with higher pore volume, porosity and surface area desired in the present study in order to enhance the properties of AC supercapacitor. Thus, the present studies focus on the chemical activation process to increase the characterization of AC. The study was using bamboo waste as a precursor and the activation process was conducted using microwave ultrasonic system. The chemical agent used during the process was KOH and $H_2SO_4$. Microwave activation was conducted at intensity 100 W and 300 W for 30 min and sonication frequency was constantly set at 200 Hz for 60 min. The sample was carbonized at temperature of 400 ºC and 800 ºC using furnace for 2 hours. Then, AC was characterized for surface area using BET analysis and functioning group using FTIR analysis. The results shown the carboxyl, aliphatic, aromatic and phenolic hydroxyl group are present on raw bamboo while new functional group such as alkyl halide and some of some weak bands appeared which analogous with out of plane bending mode of the C-H or O-H group occur for AC. Active surface area and total pore volume of AC supercapacitor in 5M of concentration for $H_2SO_4$ and KOH corresponded to 1167 $m^2/g$, 0.724 $cm^3/g$, 740.10 $m^2/g$, 0.462 $cm^3/g$, respectively.

**Keywords**: supercapacitor, microwave-ultrasonic, activation, chemical, carbonization

**Abstrak**

Kapasiti penjerapan yang tinggi pada karbon teraktif boleh dinilai mengikut isipadu liang, keliangan dan luas permukaan. Keaktifan karbon dengan isi padu liang yang tinggi, tahap keliangan yang besar dan luas permukaan yang tinggi amat dikehendaki di dalam kajian ini bagi meningkatkan sifat-sifat keaktifan karbon superkapasitor. Oleh itu, kajian ini memberi tumpuan kepada proses pengaktifan kimia untuk meningkatkan pencirian yang diperlukan dalam karbon aktif. Kajian ini telah menggunakan sisa buluh sebagai pelopor dan proses pengaktifan telah dijalankan menggunakan sistem ultrasonik-gelombang mikro. Agen kimia yang digunakan semasa proses pengaktifan adalah KOH dan $H_2SO_4$. Pengaktifan gelombang ketuhar telah digunakan pada intensiti 100 W dan 300 W selama 30 min dan kekerapan sonikasi telah ditetapkan pada 200 Hz selama 60 min. Sampel telah dikarbonisasi pada suhu 400 ºC dan 800 ºC mengunakan relau selama 2 jam. Kemudian, karbon aktif dikelaskan bagi mendapatkan luas permukaan dengan menggunakan analisis BET dan kumpulan berfungsi pula menggunakan analisis FTIR. Keputusan menunjukkan karboksil aliphatik, aromatik dan kumpulan fenolik hidrosil hadir pada bahan asas buluh manakala kumpulan berfungsi baharu seperti alkil halida dan beberapa kumpulan yang lemah muncul dimana serupa dengan lenturan mod bagi C-H atau O-H yang terhasil pada karbon aktif. Kawasan permukaan yang aktif dan jumlah isipadu liang

karbon aktif superkasitor pada kepekatan 5M untuk $H_2SO_4$ and KOH sepadan mengikut aturan 1167 $m^2/g$, 0.724 $cm^3/g$, 740.10 $m^2/g$, 0.462 $cm^3/g$.

## Introduction

Activated carbon (AC) is widely use as catalyst, catalyst support and adsorbent for the removal of pollutant order from liquid to gases and for purification or recovery of chemicals [1]. A wide range of carbonaceous materials such as agricultural wastes or industrial wastes, coconut shell, coal and wood can be used as activated carbon precursor. In industrial practice, coal and coconut shell are two major sources for the production of activated carbon [2]. Bamboo, one of the lignocellulosic resources is a potential precursor for activated carbon due to its flexible, efficient and economical materials [3]. Bamboo has a high volatile matter and low of ash content that required in AC processing with high adsorption capacities are related to property of pore volume, porosity and surface area. Current approach in AC processing gave AC with a small of surface area, limited power intensity and energy capacity and low of porosity [4]. In order to overcome these problems, chemical activation and microwave ultrasonic activation has been introduced to enlarge the surface area, extensive the power intensity and energy capacity and enhance the porosity of AC.

Activated carbon works by the process of adsorption. Adsorption is a process when one material adheres to the surface of another material by means of physical or chemical attraction between the materials. There are two processes involves in development the formation of AC which are activation and carbonization processes. In activation, there are two types of method in order to produce activated carbon from carbonaceous material which is chemical and physical method. Physical activation procedure required two step of process which are carbonization and followed by activation using steam, oxygen or carbon dioxide as an activation agent while chemical activation procedure involves a single stage by using chemical as activating agent such as zinc chloride, potassium hydroxide, phosphoric acid and others [5]. Chemical procedure takes a few of advantage than physical method which has higher carbon yield and better developed of pore structure [6].

Thus, in the present study, bamboo was prepared for AC by using different of chemical activation agent which is KOH and $H_2SO_4$ under microwave ultrasonic radiation for activation process and continues with a single step of carbonization process at different temperature. The aim of this study is to characterize the characteristics of bamboo properties as activated carbon with chemical activation in microwave-ultrasonic activation.

## Materials and Methods

### Materials

The chemicals used in this study are sulphuric acid ($H_2SO_4$) and potassium hydroxide (KOH) purchased from R&M Chemical, Inc. Both chemicals were analytical grade.

### Preparation of activated carbon

The precursor for activated carbon was residual bamboo obtained from Forest Research Institute Malaysia (FRIM). A total 50 g of dry bamboo was placed into crucible and the chemical agent, KOH or $H_2SO_4$ was added into the sample with ratio 1:1. Then, the sample undergoes microwave activation with different energy power for 2 hr. Activate sample was cooled and washed with distilled water until pH 6 to 7. The sample was dried in oven at 110 ºC for 24 hours and stored in desiccator before undergoes carbonization process. Next, the sample was carbonized in the Vermont Furnace (Carbolite, Keison) under the flow of 150 $cm^3$/min nitrogen for 2 hours. After carbonization process, the activated carbon was cooled to ambient temperature for further analysis. Parameter used in the present study is stated in Table 1.

Table 1. Parameter used in Microwave-ultrasonic system with chemical agent

| Sample | Experiment Procedure | Chemical Activating Agent |
|---|---|---|
| AC_OH_8 | Ultrasonic-MW (300W)-Carbonize (800°C) | Base - KOH |
| AC_OH_4 | Ultrasonic-MW (300W)-Carbonize (400°C) | Base - KOH |
| AC_H_8 | Ultrasonic-MW (300W)-Carbonize (800°C) | Acid - $H_2SO_4$ |
| AC_H_4 | Ultrasonic-MW (300W)-Carbonize (400°C) | Acid - $H_2SO_4$ |
| AC_K_8 | Ultrasonic-MW (100W)-Carbonize (800°C) | Base - KOH |
| AC_K_4 | Ultrasonic-MW (100W)-Carbonize (400°C) | Base - KOH |
| AC_SO_8 | Ultrasonic-MW (100W)-Carbonize (800°C) | Acid - $H_2SO_4$ |
| AC_SO_4 | Ultrasonic-MW (100W)-Carbonize (400°C) | Acid - $H_2SO_4$ |

**Proximate analysis of precursor**

The raw material sample was characterized for proximate analysis by using American Society for Testing and Materials standard in order to determine the moisture content of bamboo (ASTM D 2867-99), the presence of volatile matter (ASTM D 5832-98), the ashes content (ASTM D 2866-94) and the amount of fixed carbon and waxes composition [7].

**Characterization of activated carbon**

Brunauer, Emmett, Teller (BET) test (Xyracorp, Autosorb-1, Malaysia) was used in order to determine the specific surface area of a variety materials by the BET Nitrogen adsorption technique. The adsorption process handled in 1 hour by using quick single point and multipoint particular BET surface area determinations.

Field Emission Scanning Electron Microscope (FESEM) was carried out using Carl Zeiss, Supra 40VP, Germany in conducive to examine the morphology of the sample and to analyze the composition, distribution and phase structure of residual bamboo. The sample must be electrically connected to the sample holder in order to prevent charging and distortion of the image.

Fourier Transform Infrared Spectroscopy (FTIR) (Perkin Elmer, Spectrum One-FTIR, USA) was performed in order to identify chemical bonds in a molecule by producing an infrared absorption spectrum for functional group classification. FTIR creates the absorbance spectra representing the unique chemical bonds and the molecular structure of the sample material. FTIR spectra were recorded between 4000 and 500 $cm^{-1}$ by using AVATAR 360 Spectrophotometer.

## Results and Discussion

**Determination of surface area and pore size**

Table 2 shows the total of active surface area and total pore volume analyzed using nitrogen adsorption/desorption. The acquired results determined the surface of the chemical activation with base, KOH consist a greater surface area as well as pore volume as compared with chemical activation using acid activating agent, $H_2SO_4$. The carbonization of bamboo at 800 ºC gave a higher active surface area then carbonization at 400 ºC. The highest of active surface area obtained was 1162.73 $m^2/g$ with total pore value 0.7237 $cm^3/g$ using 300W of MW-ultrasonic radiation power. The active surface area obtain from the study was compare with previous research on AC derived from different agricultural waste and tabulated in Table 3. The result indicated that present study gave highest $V_{mic}$ and active surface area is at the power with another AC using KOH as activating agent. This comparison showed bamboo is one of the efficient and effective precursor in produce a high of $V_{mic}$ carbon.

Table 2. Chemical properties of produced activated carbon

| Experiment | Active Surface Area ($m^2/g$) | Total Pore Volume ($cm^3/g$) |
|---|---|---|
| AC_OH_8 | 1162.73 | 0.7237 |
| AC_OH_4 | 2.8791 | 0.0024 |
| AC_H_8 | 740.09 | 0.4019 |
| AC_H_4 | 478.14 | 0.2262 |
| AC_K_8 | 24.6062 | 0.0172 |
| AC_K_4 | 1.8299 | 00063 |
| AC_SO_8 | - | 0.0066 |
| AC_SO_4 | 4.7868 | 0.0078 |

Table 3. Pore structure from other agricultural wastes by MW with KOH activation

| Precursor | Power (W) | $S_{BET}$ ($m^2/g$) | $V_{mic}$ ($cm^3/g$) | Ref |
|---|---|---|---|---|
| Bamboo | 300 | 1162.73 | 0.7237 | This work |
| Oil palm fiber | 600 | 1223.00 | 0.4200 | [8] |
| Coconut husk | 600 | 1356.30 | 0.3920 | [9] |
| Pineapple | 600 | 1006.00 | 0.2800 | [10] |
| *Siris* seed pods | 620 | 1824.80 | 0.6450 | [11] |

**Proximate analysis**

Table 4 show the properties of raw bamboo precursor. Before undergoes the proximate analysis, raw bamboo has been dried into oven for 30 min (BamP) and 15 min (BamPr) of temperature in order to remove impurities and water content. From the results, it showed that BamP consist of low moisture content when compared to BamPr. For volatile and ash content, sample BamP gave a higher value which is 45.320% and 1.98% while BamPr sample obtain 40.178% of volatile content and 1.5% of ash content. For fixed carbon content BamPr sample have 58.322% whereas BamP consist of 52.7% of fixed carbon. High ash content is undesired in AC processing because it represents amount of inorganic material from the precursor activation and a numerous treatment needed to be take place [12].

Table 4. Proximate of raw bamboo precursor

| Experiment | Moisture Content (%) | Volatile Content (%) | Ash Content (%) | Fixed Carbon (%) |
|---|---|---|---|---|
| BamP | 13.300 | 45.320 | 1.98 | 52.7 |
| BamPr | 14.356 | 40.178 | 1.5 | 58.322 |

**Elemental analysis (CHNS-O analysis)**

Table 5 summarizes the results of elemental analysis which gave the percentage of carbon, hydrogen, nitrogen and sulphur present in the sample. The result indicated that the largest elements inside activated carbon are oxygen and carbon. With increment of activation temperature, there was decreasing in carbon content which probably due to the discharge of volatiles [13]. In chemical activation of acid activating agent, $H_2SO_4$ the activation process has

provoked a progress of discharge oxygen with notable loss at 800 ºC. Discharge of oxygen happened because element of oxygen intimate the fraction of oxygen content was not located around the pore entry of activated carbon [14]. High of moisture and volatile content also give a higher value for oxygen element. On the contrary, there was a decreasing of carbon content in a higher temperature. Besides that, there was a reduction of hydrogen element at a temperature 800 ºC. The percentages of carbon significantly high at temperature 400 ºC with radiation power 300 W and 100 W based on different type of activating agent. The precursor of carbon could barely be heated without impregnation of activation agent, demonstrating that activation agent acted as the fundamental MW absorber at the primary stage. With the evolution of pore structure, the AC itself could acquire MW energy [15]. At low microwave energy, the pore structure was not satisfactorily created which improved with the expanding of microwave power. Nevertheless, at tremendous radiation power, absorbed MW energy eclipse at some of power so that the overfull energy keep create a small feature of carbon burnt and the structure was destroyed [16].

Table 5. Result of elemental analysis

| Experiment | Carbon (%) | Hydrogen (%) | Nitrogen (%) | Sulphur (%) | Oxygen (%) |
|---|---|---|---|---|---|
| AC_OH_4 | 30.3338 | 2.5647 | 0.4022 | 0.0000 | 66.6993 |

**FTIR analysis**

The prepared activated carbon was analyzed for functional group using FTIR shown a following bands: 3308.78 $cm^{-1}$ was attributed to O-H vibration in hydroxyl groups. The location of hydrogen bonded OH groups usually at range 3200 – 3750 $cm^{-1}$ for alcohol and phenol which involve in hydrogen bonding may be due to adsorbed water [17], C=C stretching vibration of aromatic rings at 1599.98 $cm^{-1}$, the relatively intense band at 1031.89 $cm^{-1}$ can be assigned to alcohol or phenol groups of R-OH, 1234.05 $cm^{-1}$ with absence of C=O stretching from the esters (C-O) of strong intensity absorptions. Figure 1 shown band at range 756 – 540 $cm^{-1}$ with 667.07 $cm^{-1}$ is (C-O-H) twist abroad with strong aliphatic, 1350.48 $cm^{-1}$ of amines compound occurs which correlated out of plane bending absorption, alkanes (C-H $CH_2$) found at range of 1457.03 $cm^{-1}$ bending absorption of methylene groups and 1784.93 $cm^{-1}$ denotes C=O stretching from ketones (C=OR), aldehyde (C=OH) and carboxylic acid (COOH). Some weak bands also appeared in the range of 600 – 900 $cm^{-1}$ which associated with out-of-plane bending mode of (C-H) and O-H group. Heating at a high of temperature make some of peaks disappear in AC_K_8 and AC_H_8. The main surface functional groups present on the activated carbon of bamboo are lactones, ketones, carboxylic anhydrides, quinine structure and aromatic ring [18].

**Activated carbon morphology**

Figure 2 indicates the FESEM images of the raw bamboo and derived AC. There was no pore development on the precursor of raw bamboo residual and the structure of the surface is rough and uneven. From Figure 1a, many large pores shape and size were clearly found on the AC surface after the activation process of MW-ultrasonic and chemical activation. The well-developed pores had led to the large surface area and porous structure of the activated carbon had shown in Figure 1c and 1d. It can be seen that there was a significant difference between sample from KOH and $H_2SO_4$ surface texture. Pore development was caused by the breakdown of some material in the precursor due to thermal expansion during the activation step [19]. The reaction rate between the activating agent which is KOH and carbon also increase when the precursor is subjected to high activation temperature, thus leading to the formation of well-developed pores [20].

## Conclusion

The present investigation showed that bamboo is a promising precursor to be used in the preparation of activated carbon. In the view of experiment results, the best activated carbon properties of the sample prepared from the bamboo raw material by a one-step chemical activation with base activating agent, KOH with MW-ultrasonic radiation power 300 W were obtained at the carbonization temperature of 800 ºC with the highest of surface area, 1162.73 $m^2/g$. The active surface area of the bamboo activated carbon derived in this work was considered relatively high besides being mesopores. The result proved that the potentially of MW-ultrasonic activation was rapid, efficient and feasible as a viable activation method.

**Abstract**

A visible light-driven photocatalyst, $CeO_2$-$TiO_2$ catalyst with different ceria loading was synthesized by impregnation method between $TiO_2$ powder and cerium oxide nanoparticles slurry. The prepared catalyst samples were characterized by X-ray diffraction (XRD), surface area analysis, UV-vis absorption spectroscopy and photoluminescence spectroscopy (PL). The band gap of $CeO_2$-$TiO_2$ catalyst was found to be 2.15 – 2.4 eV. The band gap reduction clearly indicated the successful loading of $CeO_2$ on $TiO_2$. The photocatalytic activity was determined by measuring the photoreduction of $CO_2$ to methanol in aqueous solution under visible light. The effect of cerium loading in the range of 1 to 5 wt% on the photocatalytic activity was studied and 2 wt% $CeO_2$-$TiO_2$ was found to exhibit the maximum photoactivity of 18.6 µmol/g.catalyst after 6 hours irradiation. Results showed that the prepared photocatalyst is visible light active and may be used as effective catalyst in photoreduction of $CO_2$ to methanol.

**Keywords**: metal oxide, photocatalyst, band gap, nanoparticles

**Abstrak**

Fotomangkin yang boleh diaplikasi di bawah radiasi cahaya nampak iaitu mangkin $CeO_2$-$TiO_2$ yang berbeza muatan ceria telah disintesis dengan kaedah impregnasi serbuk titanium dioksida dengan mendakan partikel nano cerium dioksida. Ciri mangkin yang dihasilkan dikaji dengan menggunakan pembelauan sinar-X (XRD), analisis luas permukaan, UV-Vis spektrofotometer dan spektroskopi fotoluminesen (PL). Jurang tenaga mangkin $CeO_2$-$TiO_2$ adalah di antara 2.15 eV hingga 2.4 eV. Pengurangan jurang tenaga jelas menunjukkan pemuatan $CeO_2$ ke atas $TiO_2$ telah berjaya. Aktiviti fotopemangkinan ditentukan melalui tindak balas penurunan gas karbon dioksida ($CO_2$) di dalam larutan akueus kepada metanol dan dijalankan di bawah radiasi cahaya nampak. Kesan pemuatan 1 hingga 5 peratus berat cerium ke atas $TiO_2$ terhadap aktiviti fotopemangkinan telah dikaji dan $CeO_2$-$TiO_2$ dengan 2 peratus berat cerium didapati menunjukkan fotosensitiviti maksimum iaitu penghasilan 18.6 µmol/g.mangkin selepas 6 jam radiasi. Hasil kajian menunjukkan bahawa fotomangkin yang dihasilkan adalah aktif di bawah cahaya nampak dan dijangka efektif untuk penurunan $CO_2$ kepada metanol.

**Kata kunci:** logam oksida, fotomangkin, jurang tenaga, partikel nano

## Introduction

The photocatalytic reduction of carbon dioxide ($CO_2$) to fuel has been reported as an alternative way to tackle the global warming and shortage of fuels problem. Among the semiconductor photocatalysts that have been studied, titania dioxide ($TiO_2$) has been considered the most promising photocatalyst due to its non-toxic, low cost, and photostable [1]. One of the drawbacks of the existing semiconductor typically $TiO_2$ is that it has a wide band gap. This limits its catalytic activity under the visible light. In such cases, the photogenerated electron hole pair's recombination is fast, resulting less electron hole pairs availability that that can be utilized for $CO_2$ reduction. Several strategies have been reported by modifying the structure of $TiO_2$ to enhance its photoactivity under visible light and lower the recombination rate of photogenerated electron hole pairs. Among modifications made was doping rare earth element with the $TiO_2$. This study has demonstrated that the modified $TiO_2$ catalysts enhance the photocatalytic ability as to compare to $TiO_2$. Some examples are clearly shown in the researches of others; degradation of organic compounds such as Eu-$TiO_2$ for Rhodamine B (RB) degradation [2], La-$TiO_2$, Pr-$TiO_2$, Nd-$TiO_2$ for reduction of hexavalent chromium and degradation of methylene blue [3] and La-$TiO_2$ and Ce-$TiO_2$ for degradation of methylene blue [4].

Ceria was chosen by many researchers among the rare earth elements because it is one of the four most abundant rare earth elements. It appearances that composites of ceria-titania have shown remarkable photocatalytic activity under visible light irradiation for water splitting and degradation of organic compounds due to its capability in adsorbing visible light and inhibit the photogenerated electron hole pairs recombination [5]. To the best of our knowledge, there are a few reports on ceria-titania for $CO_2$ photoreduction. Recently, Xiong et al. and Matejova et al. studied the $CeO_2$-$TiO_2$ catalyst activity for photocatalytic conversion of $CO_2$ to liquid products (methanol and formaldehyde) and to gaseous products ($CH_4$ and CO), respectively [6,7]. However, the study was limited under UV light irradiation study only. Our previous study reported that $CeO_2$-$TiO_2$ showed a higher methanol yield than $TiO_2$ catalyst for $CO_2$ photocatalytic reduction under visible light irradiation [8]. This paper represents the extension of previous study by study the effect of ceria amount loading on characterization and $CO_2$ photocatalytic reduction to methanol under visible light irradiation.

## Materials and Methods

### Catalyst preparation

The $CeO_2$-$TiO_2$ powder was prepared based on our previous work [8]. In brief, firstly, $CeO_2$ nanoparticle slurry was prepared by dissolved required amount of (Ce $(NO_3)_3.6H_2O$) in 20% ethanol solution at 50 °C and subsequently, 3M ($NH_4OH$) was added under stirring. The process was completed when the reaction slurry color turned from colorless to light yellow. Then, 5 g of $TiO_2$ powder was added to the $CeO_2$ slurry and stirred for 5 hours. The slurry was filtered, dried at 100 °C overnight and calcined at 500 °C for 4 hours. The catalyst was prepared in 1 wt%, 2 wt% and 5 wt% of ceria loading.

### Catalyst characterization

The crystalline structure and phase purity of the catalysts were determined by X-ray diffraction (XRD) analysis using Bruker D8 Focus Advance powder diffractometer with a Cu Kα radiation of wavelength 0.15406 nm, scanned from 10 to 80° with 0.025° step size. The surface area and pore parameters of the samples was determined by nitrogen adsorption–desorption analysis at 77 K using a Micrometrics ASAP 2010, using the Brunauer- Emmet- Teller and Barrett- Joyner- Halenda (BET/ BJH) method over the pressure range $P/P_o$= 0.02 - 1.0. The diffuse reflectance spectra of the catalyst samples over a range of 200 – 800 nm were recorded by a UV-vis-NIR spectrophotometer. The photoluminescence spectra were measured by Edinburgh FS920 photoluminescence spectroscopy, using Xenon Lamp (450W) as the excitation source and 300 nm as the excitation wavelength over a range of 330 to 600 nm.

### Photocatalytic activity

The photoreduction of $CO_2$ was performed according to the procedure reported in our previous study [8]. In brief, 0.3 g catalyst powder was dispersed in the $CO_2$ aqueous solution. The $CO_2$ aqueous solution was prepared by bubbling 0.4 $L.min^{-1}$ of $CO_2$ for 30 minutes into 300 ml of 0.1 M NaOH solution in the reactor consists of 500 ml Pyrex glass reactor equipped with a quartz trap with 220 mm length which is irradiated using artificial visible light produced by a 500 W Xenon lamp (Jiquang, Shanghai) with a wavelength range of 300 to 800 nm. Then, the reaction was started by switching on the light. 5 ml of the suspension were withdrawn from the reactor at every 1hour interval of reaction for 6 hours of irradiation period, while the gas products were collected using gas bags. The liquid and gas products were analyzed using Agilent Gas Chromatography (GC) with a flame ionization detector (FID) and thermal conductivity detector (TCD), respectively. Analytical results indicated that the methanol is the main product in liquid sample and no products were detected in the gaseous samples.

## Results and Discussion

### XRD analysis

The crystal phase identification and crystallite size estimation were usually checked by XRD**.** Figure 1 shows the XRD patterns of the as-synthesized $CeO_2$-$TiO_2$ with different cerium loading. It can be seen that the peaks at 2θ

values of 25.17°, 37.60°, 47.76°, 54.01° and 62.60° which are indexed to the (101), (004), (200), (105) and (204) planes of the anatase phase of $TiO_2$ (JCPDS: 21-1272) appeared for all samples. It is noteworthy that no cerium oxide peaks could be observed in the XRD spectra for samples with 1 wt% ceria loading. This might be due to all the ceria ions were incorporated into the structures of titania or the size of the particles which are too small that cannot be detected by XRD. On the other hand, the small peak of cerium oxide was seen to appear in the spectra for 2 wt% loading and the peaks was clearly seen for 5 wt% loading. The crystallite sizes of anatase of samples were calculated using Scherrer's equation according to (101) peak. The values are 9.9 nm, 9.8 nm and 9.2 nm for $CeO_2$-$TiO_2$ samples of 1 wt%, 2 wt% and 5 wt% ceria loading on $TiO_2$, respectively. The crystalline size of the anatase phase formed decreased with the content of Ce oxide doped, which indicates that the Ce species inhibit the growth of anatase $TiO_2$ crystallite and it agrees well with the literature report [9].

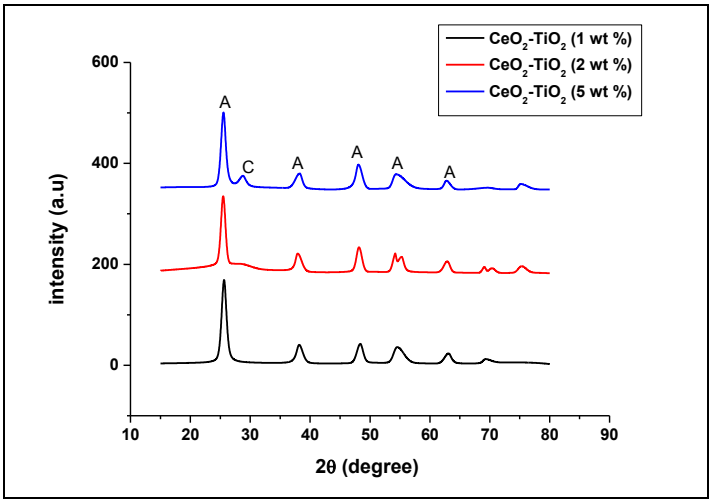

Figure 1. X-ray diffraction patterns of all photocatalysts (*A=anatase phase, C=Cerianite phase)

**BET/BJH Analysis**

Figure 2 shows the pore size distribution curves of all photocatalysts. The pore diameter was ranged from 8 – 15 nm indicating that the pores are mainly mesoporous in nature. The textural properties of the catalysts are summarized in Table 1, which shows that the surface area and pore volume changes was insignificantly with ceria loading of 1 wt% and 2 wt% but drastically decreases with 5 wt%. It was previously reported that the specific surface area and the pore volume of catalyst prepared by the impregnation method decrease with increasing metal loading [10].

Table 1. BET/BJH analysis of all photocatalyst

| Sample | Surface area ($m^2/g$) | Pore volume ($cm^3/g$) | Mean pore size (nm) |
|---|---|---|---|
| $CeO_2$-$TiO_2$ (1 wt%) | 105.4 | 0.37 | 12 |
| $CeO_2$-$TiO_2$ (2 wt%) | 104.9 | 0.40 | 15 |
| $CeO_2$-$TiO_2$ (5 wt%) | 63.9 | 0.16 | 8 |

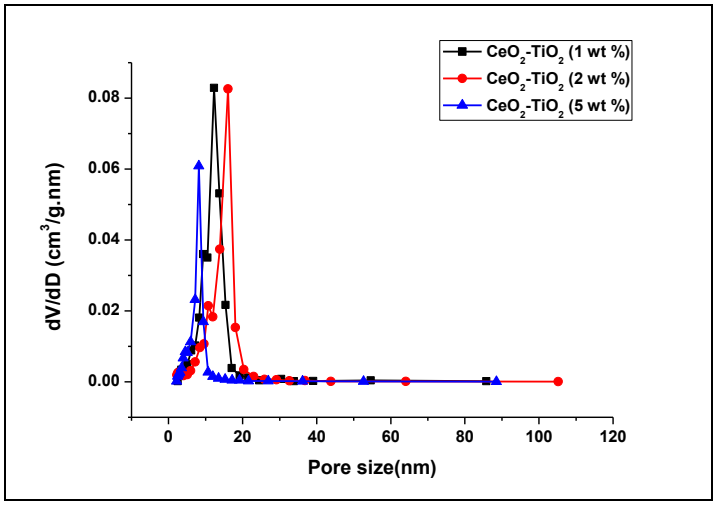

Figure 2. Pore size distribution of all photocatalysts

**UV-Vis-NIR analysis**

UV-Vis-NIR spectra of $CeO_2$-$TiO_2$ with different ceria loading are presented in Figure 3(a) to explore the influence of the ceria addition amount on the optical property of $TiO_2$. From the Figure 3(a), a slight shift to the visible light region occurred as the amount of ceria was increased corresponds to a band gap of 2.4, 2.2 eV, and 2.15 eV for 1 wt%, 2 wt% and 5 wt% ceria loading on $TiO_2$, respectively as shown in Figure 3(b). This indicates that the $CeO_2$-$TiO_2$ absorbs well in the visible light region due to presence of ceria. This is due to the charge transfer from impurity level to the conduction band. The impurity is caused by some of $Ce^{3+}/Ce^{4+}$ sites have been replaced by $Ti^{4+}$ ions [11]. The absorption increases with the increasing of ceria content since the color of $CeO_2$-$TiO_2$ changes from pale yellow to yellow from the observation in the catalyst preparation.

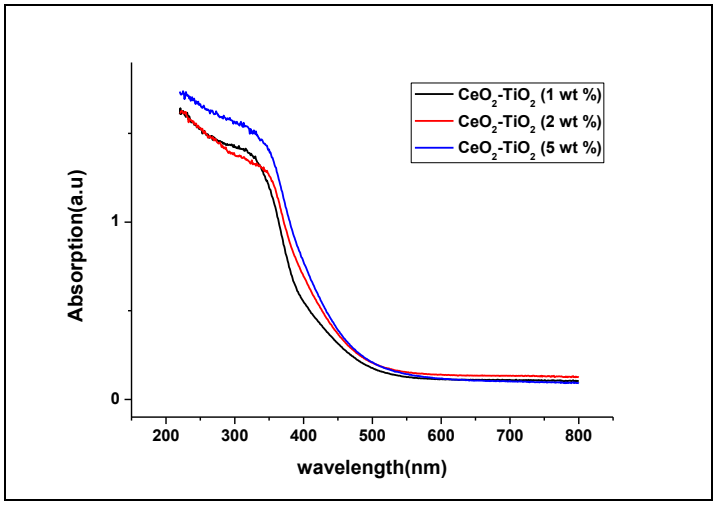

Figure 3(a). UV-vis NIR spectra of all photocatalysts

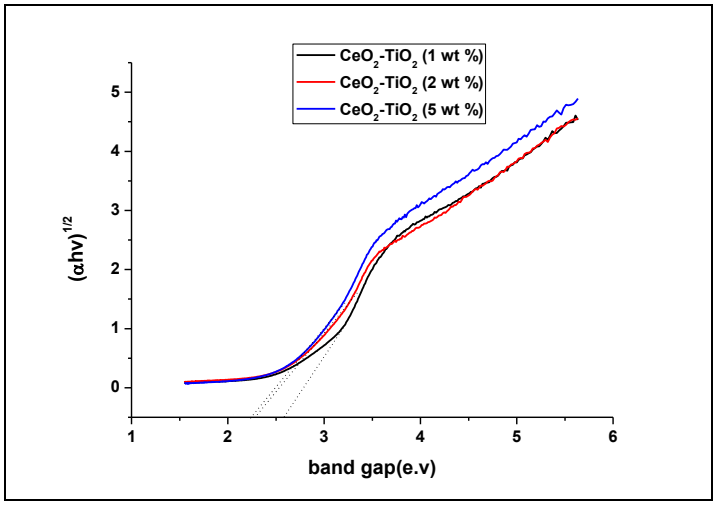

Figure 3(b). The optical absorption edges of all photocatalysts

**Photoluminescence analysis**

The photoluminescence spectra are useful to understand the surface process in which photogenerated electron-holes take part in photocatalysis. The existence of photoluminescence can be attributed to the recombination of excited electron-hole pairs. In Figure 4, there are two obvious PL peaks at 420 nm which attributed to the band-edge free exciton luminescence while the peak at 470 nm indicates the bound exciton luminescence [12]. The peaks positions for all samples are basically the same. However, the intensity of PL spectra is different. It shows that the intensity is decrease, indicating the lower rate of recombination of electron-hole pairs with increasing ceria loading. This is due to the possibility of $Ce^{3+}$ ions existence in $CeO_2$-$TiO_2$ that could interact with holes and inhibit the recombination of photogenerated electron-holes [6].

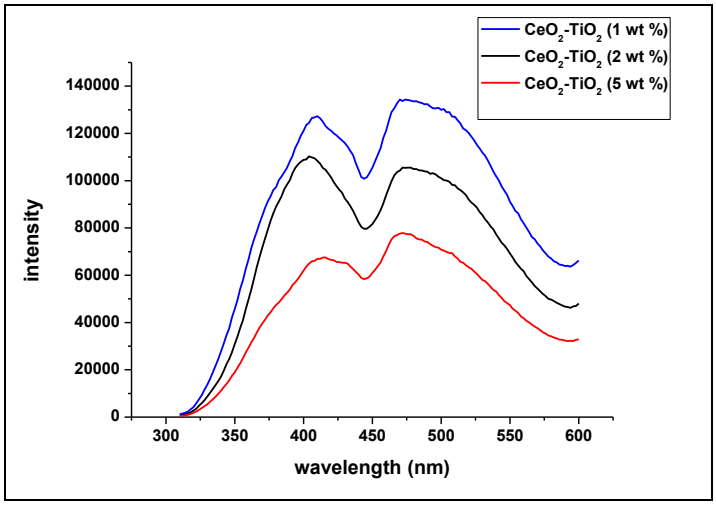

Figure 4. Photoluminescence Spectra of all photocatalysts

**Photocatalytic activity**

Methanol was determined in liquid phase while there were no products in gas phase. Other products such as formic acid and formaldehyde could also be formed [13], but they were undetectable. The methanol is possibly produced by the reduction of $CO_2$ and carbonate ($CO_2$ dissolve in water and form carbonate in water) as in Equation (1)-(3).

$$CO_2 + 6H^+ + 6e^- \longrightarrow CH_3OH + H_2O \quad (1)$$

$$H_2CO_3 + 6H^+ + 6e^- \longrightarrow CH_3OH + 2H_2O \quad (2)$$

$$CO_3^{2-} + 8H^+ + 6e^- \longrightarrow CH_3OH + 2H_2O \quad (3)$$

Figure 5 shows the yield of methanol formation by $CO_2$ photocatalytic reduction as functions of the irradiation time for $CeO_2$-$TiO_2$ with 1 wt%, 2 wt% and 5 wt% ceria loading. It can be seen that the yield of methanol increased with the irradiation time for all photocatalysts. The methanol yield increased with increasing ceria loading from 1 wt% to 2 wt%. This may be due to the extend response range into visible light region with increase the ceria loading, thus more photo energy could be absorbed by catalyst thus generate more electron-hole pairs. Moreover, the decreasing of electron hole recombination rate with increasing ceria loading also contributes in enhancing the methanol yield.

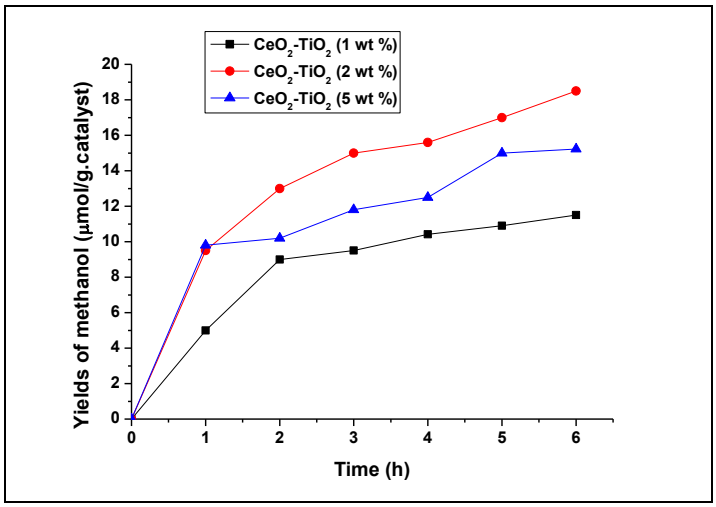

Figure 5. Yields of methanol as functions of irradiation time over all photocatalysts.

However, the methanol yield decreased after loading with 5 wt% ceria although the band gap and electron hole recombination rate decrease indicating that there is an optimum amount cerium loading for $CeO_2$-$TiO_2$. Moreover, the decreasing of specific surface area of 5 wt% $CeO_2$-$TiO_2$ catalyst also the factor that causes the decreasing in methanol yield since less reactant could be adsorbed onto the catalyst surface. The mechanism explanation of the decreasing of methanol yield could be described as follows: $TiO_2$ can adsorb carbonate species efficiently [14]. Then, $CeO_2$ which dispersed on the $TiO_2$ surface can absorb visible light and transfer the excited electrons to $TiO_2$ so that the carbonate species on the $TiO_2$ surface can be reduced to methanol. The coverage of $TiO_2$ surface by $CeO_2$ is optimum at 2 wt%, thus enough uncovered surface of $TiO_2$ for carbonate species adsorption. However, more $CeO_2$ has covered the surface of $TiO_2$ when the ceria loading increases to 5 wt%, resulted less surface of $TiO_2$ is in contact with carbonate species. Therefore, the photocatalytic activity decreases due to lowering of the available surface area even though the absorption of light by $CeO_2$ increases.

## Conclusion

The series of $CeO_2$-$TiO_2$ nano photocatalysts with different ceria loading were synthesized and characterized. The characterization results show that crystallite size, the surface area, the band gap and the electron hole recombination rate decreased as the ceria loading increased. The best ceria loading percentage to obtain optimum methanol yield in $CO_2$ phocatalytic reduction under visible light irradiation is 2 wt%.

**Abstract**

Composite catalyst ZnO/TiO$_2$ of molar ratio 0.75% was synthesized via sol gel method. The effect of preparation method on the crystal morphology was investigated. The catalyst particles were calcinated at 500 $^{o}$C,550 $^{o}$C and 600 °C for 3 hours. The XRD results revealed that calcination temperature controls the crystalline phase in terms of homogeneity and surface area of catalyst produced. The particle size was found to increase with calcination temperature suggesting the effect of different calcination temperatures on catalytic activity for complete degradation of phenol. The result found that ZnO/TiO$_2$ catalyst calcinated at 600 $^{o}$C resulted in 70% phenol degradation within five hours of irradiation time under visible light. The kinetic behavior of phenol degradation was found to fit with pseudo first order Langmuir-Hinshelwood kinetic model.

**Keywords**: sol gel, ZnO/TiO$_2$ catalyst, photocatalytic degradation, visible light, kinetic

**Abstrak**

Pemangkin komposit ZnO/TiO$_2$ dengan 0.75% nisbah molar telah di sintesis melalui kaedah sol gel. Kesan kaedah penyediaan pada morfologi kristal itu telah di selidiki. Zarah-zarah pemangkin telah dikalsinkan pada suhu 500 $^{o}$C, 550 $^{o}$C dan 600 $^{o}$C selama 3 jam. Keputusan XRD menunjukkan suhu pengkalsinan mengawal fasa kristal dari segi kesamaan dan kawasan permukaan pemangkin dihasilkan. Saiz zarah didapati meningkat sejajar dengan peningkatan suhu pengkalsinan mencadangkan kesan suhu pengkalsinan yang berbeza pada aktiviti pemangkin untuk penyingkiran penuh fenol. Keputusan mendapati pemangkin ZnO/TiO$_2$ yang dikalsinkan pada 600 $^{o}$C boleh menyebabkan 70% fenol terdegradasi bagi tempoh lima jam masa penyinaran di bawah cahaya nampak. Kelakuan kinetik degradasi fenol didapati sesuai dengan pseudo peringkat pertama model kinetik Langmuir - Hinshelwood.

**Kata kunci:** sol gel, mangkin ZnO/TiO$_2$, degradasi fotomangkin, cahaya nampak, kinetik

## Introduction

Phenol if present even in lower concentrations causes water pollution in terms of reduction in taste and strong odor. The toxicity imparted by phenol is mainly sourced from industrial wastewater especially petrochemical industries. To date, promising treatment using Advanced Oxidation Process (AOPs) which relies on highly reactive chemical compound such as hydroxyl radical (OH) are gaining favorable in water remediation [1]. The main reason for this immense attraction is because the process is capable to bring complete removal of pollutant by converting broad of them to water and carbon dioxide. Among various AOPs process, the photocatalytic oxidation methods appear to be most effective for the treatment of wastewater contaminated with phenolic compound as this process offer lower

cost compared to other AOPs treatments. In addition, other major advantages of photocatalytic treatment include ambient operating conditions and complete destruction of water pollutants without generation of secondary pollutants. Titanium dioxide ($TiO_2$) has been subject of the most work in photocatalytic treatment applications due to its high activity, relative chemical stability, inertia to corrosion, reducing cost and environment friendly. Nonetheless, photooxidation by $TiO_2$ photocatalytic alone relies on ultraviolet light which only makes up to 5% of solar light.

To address this, coupling two or more semiconductors that able to undergo photo-excitation under much broader visible light spectrum seem to provide a novel approach to achieve a higher efficient charge separation and enhances interfacial charge [2]. Specifically, absorption of $TiO_2$ can be extended to visible range [3] when coupling with other semiconductor or doping with non-metal or metal ion such as B, C, N, $Fe^{3+}$ and $Zn^{2+}$ [4] or metal oxides such as ZnO and MgO. Previous works reported that ZnO appeared as promising photocatalyst and alternative to $TiO_2$ since its photo degradation mechanism was identical to $TiO_2$. Furthermore, ZnO is known to have wider direct gap as well as higher solar reception and utilization efficiency for organic pollutant degradation [5]. In short, the doping energy level that is forming between ZnO-$TiO_2$ can generate more photon utilization and consequently, a higher photocatalytic activity will be attained. Therefore, it is highly advantageous to develop $TiO_2$-ZnO based photocatalyst to enhanced activities under visible light. At present, a number of synthetic methods have been used to synthesize the nanostructures of catalyst. Sol gel technique is common and convenient approach to obtain products of controlled shape and size at high purity and low cost [6]. Others advantages are low processing temperature, which resulting uniform nanostructures for easier control of the kinetics of the chemical reaction.

In this work, the photocatalytic degradation of phenol was carried using doped $TiO_2$ with ZnO operating under visible light. The photocatalytic activity of ZnO/$TiO_2$ was optimized by applying optimum calcination temperature during catalyst synthesis. This was followed by characterization using Scanning Electron Microscopy (SEM) and X-ray Diffraction (XRD) technique.

## Materials and Methods

### Synthesizing $TiO_2$/ZnO composite catalysts via sol gel method

The zinc and titanium precursor solutions were prepared separately. $TiO_2$ precursor sol was prepared by mixing 30 mL of tetraisopropyl titanate with 100 mL ethanol absolute forming solution A. The solution was stirred for half an hour. In order to obtain ZnO precursor sol, 0.04g of zinc acetate and 90 mL deionized water were mixed with 10 mL acetic acid to form solution B. The solution was then stir until zinc acetate completely dissolved. The starting materials ratio was equal to ZnO/$TiO_2$ (molar ratio) of 0.75% dopant concentration. Then, solution B was added drop by drop into solution A under vigorous stirring for 2 hours in order to increase the solubility. The mixed sol was aged for 24 hours at room temperature until forming gel. The product dried in an oven at 100 °C for about 24 hours in order to evaporate the solvent and to remove the organic residuals. The crystal form of sample was then ground using mortar and pestle before calcinate for 3 hours with the heating rate of 3C$^o$/minutes at three different calcination temperatures of 500, 550 and 600 $^o$C.

### Photocatalytic activity

The photocatalytic activity of the synthesized composite catalyst was tested with phenol as a model pollutant at atmospheric pressure and room temperature. A 100 ml of phenol solution with initial concentration of 10 ppm was mixed with 0.1 g of the ZnO/$TiO_2$ catalyst in the photoreactor. The catalysts were suspended in an aqueous solution of phenol in 100 ml beaker. The suspension was illuminated by a 25 Watt Fluorescent lamp in a closed box. Prior to irradiation, the suspension was magnetically stirred in dark for 30 minutes to attain the adsorption-desorption equilibrium between the catalyst and the solution and 2 ml of sample was taken out and analyzed. In order to maximize the energy exchange between the source of irradiation and reaction mixture, the lamp has been placed in the centre of the reactor with distance of 6 cm from phenol solution [7]. After 30 minutes' irradiation, 2 ml sample was taken out and centrifuge for 10 minute at 10000 rpm to separate catalyst and phenol solution. Next, 1 ml of supernatant was mixed with Folin reagent and finally analyst by UV-visible spectrophotometers at 750 nm. Consequently, the procedure was repeated after every 30 minutes until complete 5 hours reaction of lamp illumination. The experiments were repeated for different calcination temperature. Then, the photodegradation efficiency can be calculated from the equation 1:

$$\eta = \frac{[(c_o - c_t)]}{c_o} \; x \; 100\% \quad (1)$$

where η is define as phenol degradation rate efficiency, $C_o$ is define as concentration of phenol at initial time (before illuminate) and $C_t$ is concentration of phenol at specific time.

**Kinetic studies of photocatalytic degradation of phenol on ZnO/$TiO_2$**

Langmuir-Hinshelwood (L-H) model was used to describe kinetics of photocatalytic degradation of ZnO/$TiO_2$. It has been widely used for phenol catalytic reaction rate equations in liquid-phase photocatalysis for a surface-catalyzed reaction. When the concentrations of water and oxygen remain constant, the equation model can be presented as follows to determine the reaction rate:

$$r = -\frac{dC}{dt} = \frac{kK_{LH}C}{1+K_{LH}C} \quad (2)$$

where r is the reaction rate (mg $m^{-3}$ $min^{-1}$), C is the initial concentration (mg $m^{-3}$), K is the reaction rate constant (mg $m^{-3}$ $min^{-1}$) and $K_{LH}$ is the Langmuir adsorption constant ($m^3$ $min^{-1}$) related to the limiting rate of reaction at maximum coverage for the experimental conditions.

The reaction rate is dependent on the experimental conditions (experimental setup design, irradiation conditions, and inlet concentration) and also on the competitive mechanisms of photochemical reactions, and adsorption. At low concentrations of phenols, $K_{LH}C$ ($K_{LH}Ceq << 1$) is negligible and equation (2) becomes a pseudo-first-order rate expression (3), as denoted below:

$$r = -\frac{dC}{dt} = k_{LH}K_L C_{eq} = k_{app}C_{eq} \quad (3)$$

Integrating equation (3)

$$\ln\frac{C_{eq}}{C} = k_{app}t + \text{constant} \quad (4)$$

Equations (2) – (3) account for the adsorption of the reactant (phenols) only but do not consider the adsorption on catalyst of any intermediates or products formed during the course of the degradation reaction. When the adsorption is relatively low or when initial concentration of pollutants is very low, the reaction can be simplified to pseudo-first-order kinetics. A plot of − ln(C/*C*o) versus reaction time *t* yields a straight line, and the slope is the apparent rate constant *(*k).

$$\ln\frac{C}{C_o} = -kt \quad (5)$$

**Characterization**

The synthesized catalysts are characterized by XRD and SEM studies for their structural and morphological characteristics respectively. Structure and phase composition are determined by X-ray diffraction (XRD) and Cu Ka radiation (l = 1.5418 A˚) at 20 kV and the diffraction angle being in the range of $10^o$–$80^o$.The crystallite size of the samples were then calculate using Scherrer's equation (6).

$$D = \frac{k\lambda}{\beta\cos\theta} \quad (6)$$

where θ is the diffraction angle, λ is the X-ray wavelength (0.154059 nm), β is the full width at half maximum (FWHM) of the diffraction, D is the crystallite size and k is a constant (shape factor, about 0.9).

While, the morphology was characterized by a high-resolution scanning electron microscopy, SEM at an accelerating voltage of 50 kV.

## Results and Discussion

### Effect of calcination temperature

A comparative study was conducted to describe the effect of calcination temperature on the efficiency of synthesized ZnO/$TiO_2$. The rates of phenol degradation with respect to different calcination temperature are shown on Figure 1. The result shows the phenol was degraded up to 70% at calcination temperature of 600 $^oC$, (Figure 1 (a)) compared to 36% at 550 $^oC$ (Figure 1(b)) and 40% at 500 $^oC$ (Figure 1(c)). Complete removal only took 120 minutes' reaction at optimum 600 $^oC$ calcination temperature. The degradation rate of phenol turned drastically low after 120 minutes. This phenomenon may explain the presence of inhibition occurred on the surface of Zn-$TiO_2$ catalyst. Other than that, it is believed photo-corrosion effect adsorption on the surface of catalyst during photocatalytic reaction contributed to low degradation rate [8]. Furthermore, the lower photocatalytic activity of phenol possibly can be explained by the less photo-generated electron and holes participated in reaction [9]. Consequently, reducing the availability of surface actives site for reaction to take place. On other words, more recombination occurred at the interface due to less electrons and hole scavengers present in lower heat treatment of synthesized composite catalyst. In addition, higher aggregation shown Figure 4(a) lead to lower reaction rates since it possessed smaller surface area.

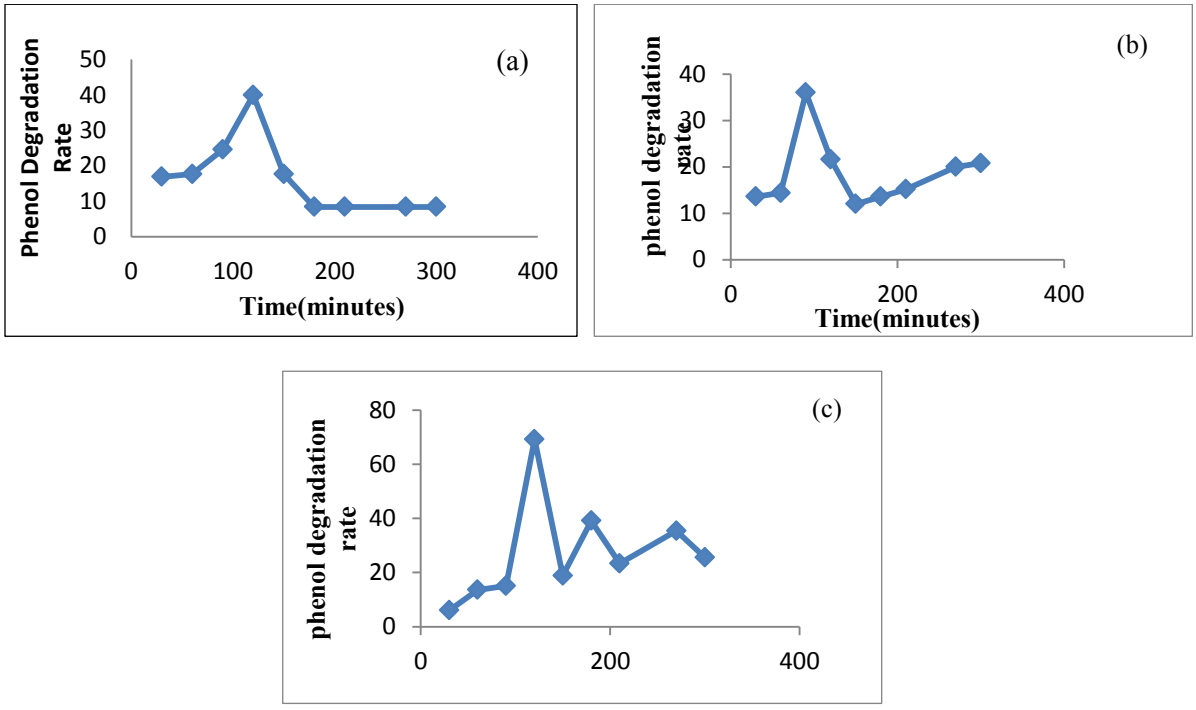

Figure 1. Phenol degradation profile by composite catalyst calcinated at different temperature: (a)500 $^oC$, (b)550 $^oC$ and (c) 600 $^oC$

These experimental results indicate that ZnO/$TiO_2$ synthesized at 600 $^oC$ works more effectively corresponding to the maximum formation of hydroxyl radical on the ZnO/$TiO_2$ surface resulting in the destruction of the target pollutant [10]. Morever, maximum phenol degradation achieved at this temperature was contributed by the formation of higher anatase phase which consequently enhances the crytallization of the phase [11]. Another reason, this can be due to the enhancement of the reaction rate took place between the organic molecules and the hydroxyl

radicals and due to the increasing collision frequency of molecules to make ZnO and $TiO_2$ highly reactive under light excitation.

Apparently, effective degradation rate in all samples suggested $TiO_2$ doping with ZnO resulted narrow band gap. Therefore, it can be deduced doping $TiO_2$ with some metal oxide such ZnO appears to be the most promising to enhance photocatalytic activity under visible light. It is therefore reasonable to conclude photocatalytic activity of $ZnO/TiO_2$ was remarkably improved by applying higher calcination temperature. Carina et al. [12] demonstrated doping $TiO_2$ with ZnO optimized photocatalytic activity of Rhodamine under visible light. The presence of ZnO precursor boosts the vacant hydroxyl radicals for oxidation of dye. In addition, to wider light adsorption spectrum to visible light, ZnO also provides large surface to volume ratio to maximize surface contact with the pollutant. Another study by Janitabar et al. [13] made point that longer wavelength than catalyst band gap was needed in order to excite the surface thus increasing rate of degradation against pollution. These studies highlighted the influence of ZnO application as doping material and light on efficiency of reaction rate.

**Kinetic studies of photocatalytic degradation of phenol on $ZnO/TiO_2$**

Kinetic of photocatalytic obeyed first order reaction since apparent constant increased with temperature. This illustration can be explained by considering Langmuir-Hinshelwood model. The relationship between ln C/Co versus time, t was shown in Figure 2. The values of $k_{app}$ represented by slope of graph can be obtained directly from linear curve in the plot. Value of rate constant shown in Figure 2 of photocatalytic degradation is influenced by calcination temperature. The lower reaction rate is probably due to impenetrability of the suspension and dissipation of light by catalyst particles [14]. However, the values obtained are still within the range of the previous studies (0.001-0.5).

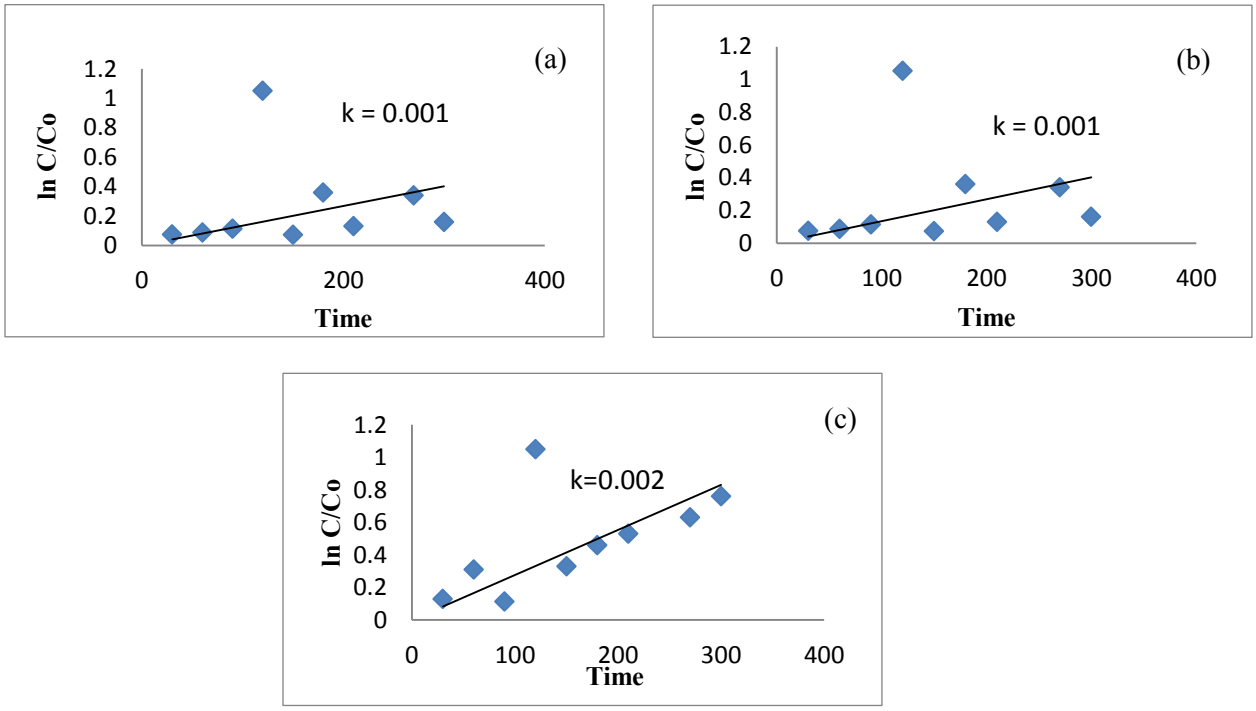

Figure 2. Pseudo first order kinetic plot by composite catalyst calcinate at different temperature: (a) 500 °C, (b) 550 °C and (c) 600 °C

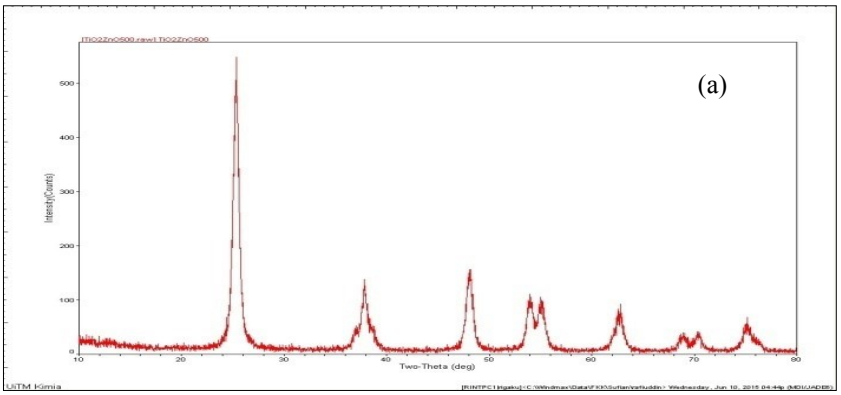
**X-ray diffractometer analysis**



X-ray diffractometer (XRD) pattern was used in the determination of phase structure of photocatalyst calcinated at various temperatures. Based on the standard card of #JCPDS 84-1286 [15], for the sharp diffraction peaks located at $2\theta$ = 25.0°, 37.2°,38.4°, 39.1°, 48.2°, 54.0°, 55.3° and 63.4°, can be attributed to the (101), (004), (112), (200), (105), (211), (118), and (220) planes, respectively. All samples posses' almost similar diffraction peaks (Figure 3) which suggested only anatase phase present in the structure without any detectable ZnO related peaks. Rajesh et al proposed that photocatalytic activity of $TiO_2$ can be enhanced with the presence of anatase phase for degradation of dyes and organic contaminant in water as compared to rutile phase [16]. Dorian et al found that influencing factor such as higher number of surface hydroxyl group adsorbed on the anatase phase and slower charge carrier recombination contributed to higher rate of photocatalytic degradation of many pollutant [17].

Furthermore, no trace of wurtzite could be detected in the XRD pattern. This probably due to small dopant concentration of ZnO used in this study which is only 0.75%. This finding is in agreement with the reported studies where disappearances of ZnO peaks is attributed to the very small of crystallite size [3]. Figure 3(a) illustrates the highest intensity at 600$^o$C and sharpen peaks indicate at higher calcination temperature up to 600 $^o$C promotes higher crystallinity of catalyst forming. The average of crystallize size of the powder were then calculated using Scherrer equation and tabulated in Table 1.

Table 1. Different crystallize size with respect to various calcination temperature

| Sample | Crystalline size, D (nm) |
|---|---|
| ZnO/$TiO_2$-500$^o$C | 8.76 |
| ZnO/$TiO_2$-550$^o$C | 17.59 |
| ZnO/$TiO_2$-600$^o$C | 29.24 |

An increase in the width of diffraction indicates a decrease in size of crystallite. As seen from Figure 3 where the line width of diffraction peak at different temperature changes considerably. The variation could be due to formation of anatase phase as crystallize size also increasing.

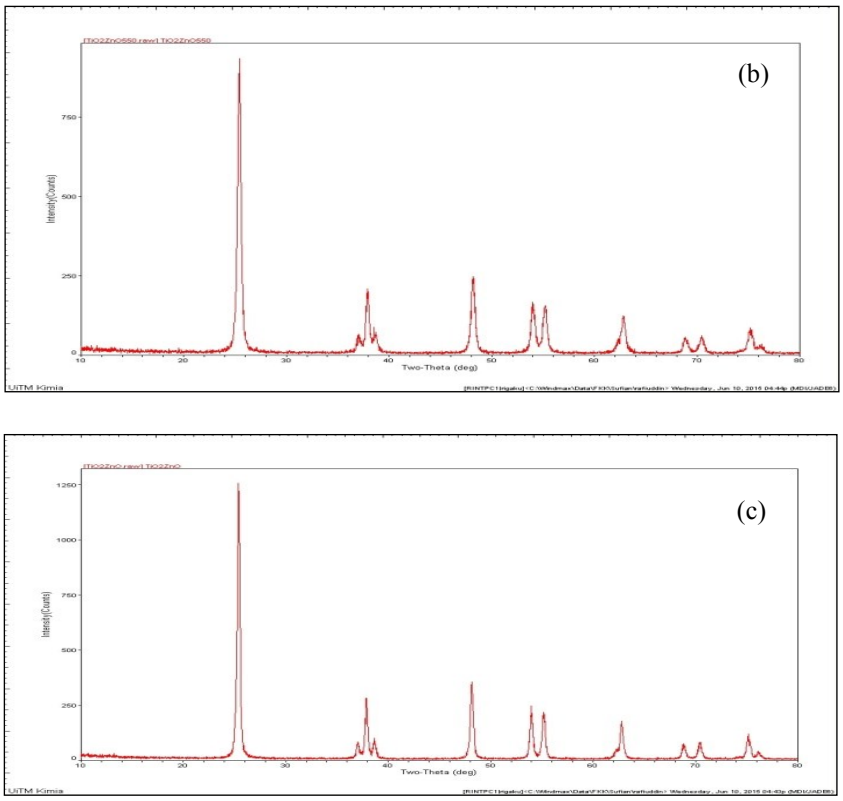


Figure 3. XRD analysis for ZnO-$TiO_2$ calcinated at different temperature: (a) ZnO/$TiO_2$-500 $^oC$, (b) ZnO/$TiO_2$-550 $^oC$, (c) ZnO/$TiO_2$-600 $^oC$

**Scanning electron microscopy analysis**

The morphology of ZnO/$TiO_2$ at different calcination temperature was characterized using Scanning Electron Microscopy (SEM). Based on observation, all prepared samples were found agglomerated and the particles were an irregular in size and shape. According to measurement, all sample as shown in Figure 4 having size of particles not more than 30 µm. Besides, the presence of small particles estimated to be less than 10 µm in diameter widely distributed within the samples were also observed.

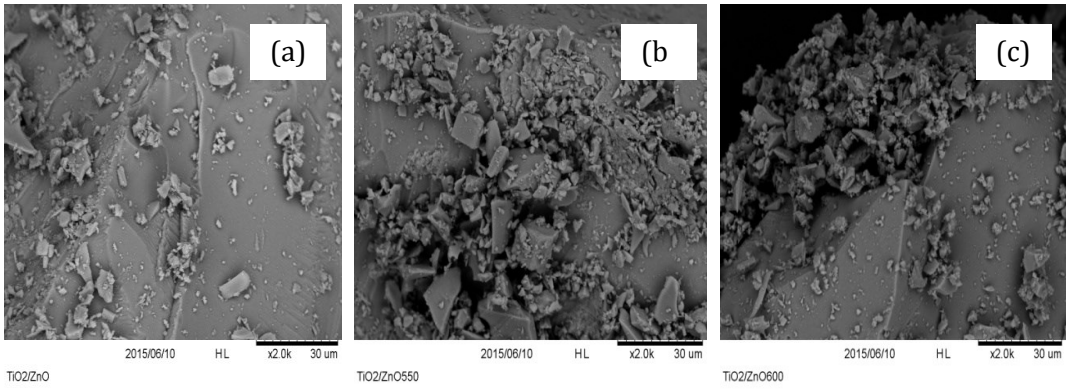

Figure 4. SEM analysis for ZnO-$TiO_2$ calcinated at different temperature:(a) ZnO/$TiO_2$ 500 $^oC$, (b) ZnO/$TiO_2$-550 $^oC$ and (c) ZnO/$TiO_2$ 600 $^oC$

In agreement with the result obtained from XRD, it seems that $TiO_2$ is major component whereby ZnO were widely dispersed. It can be noticed that there was coagulation of particles in Figure 4(a) compared to the result in figure 4(b) where flocculation reduced specific surface area of synthesized catalyst. While, less aggregation on the surface ZnO/$TiO_2$ observed from figure 4(c) suggests more prolonged lifetime of excited state which leads to more effective reaction rate. Therefore, it can be deduced that the smaller particles would give higher surface area which is favorable for higher photocatalytic activity. This is likely due to many factors such as time taken for complete stirring of catalyst suspension, rate of stirring as well as temperature used during calcination [18] step potentially induced the formation of particle size.

## Conclusion

The photocatalytic efficiency was evaluated using phenol solution as a model pollutant. The maximum efficiency of photodegradation rate of phenol was achieved at calcination temperature of 600 $^oC$. The crystalline size showed an increasing trend with respect to higher calcination temperature. The rate constant also increased with increasing calcination temperature. The adsorption kinetics was found to follow pseudo-first-order kinetics.

**Abstract**

Phytoremediation is an emerging technology that should be considered for the remediation of contaminated sites because of its aesthetic advantages and long-term applicability. The possibility of *Scirpus grossus* for degradation of a basic dye, methylene blue (MB) was investigated. The effect of the operational parameter of different dye concentrations (0, 200, 400, 600, 800 and 1000 mg/L) was determined, and the water quality parameters namely pH, dissolved oxygen (DO), biochemical oxygen demand (BOD), chemical oxygen demand (COD) and total organic carbon (TOC) were monitored. The UV-Visible absorption confirmed the degradation of MB within 72 days. The removal efficiency of methylene blue dye from synthetic wastewater was determined to be in the range of 86 – 38% for all treatments at different concentrations (200 – 1000 mg/L) respectively. Furthermore, the highest removals for BOD, COD in 400 mg/L and TOC in 200 mg/L MB were 69, 58 and 63% respectively.

**Keywords:** phytoremediation, *Scirpus grossus*, methylene blue, decolourisation, water quality

**Abstrak**

Fitopemulihan merupakan teknologi baru yang perlu dipertimbangkan untuk pemulihan tapak tercemar kerana kelebihan estetik dan kebolehgunaan bagi jangka panjang. Kemungkinan *Scirpus grossus* untuk degradasi pewarna asas, metilena biru (MB) telah dikaji. Kesan parameter operasiiaitu kepekatan pewarna yang berbeza (0, 200, 400, 600, 800 dan 1000 mg/L) ditentukan dan parameter kualiti air iaitu pH, oksigen terlarut (DO), permintaan oksigen biokimia (BOD), permintaan oksigen kimia (COD) dan jumlah karbon organic (TOC) dipantau. Penyerapan UV cahaya nampak mengesahkan degradasi MB dalam masa 72 hari. Kecekapan penyingkiran pewarna metilena biru daripada air sisa sintetik telah ditentukan dalam lingkungan 38 – 86% untuk semua rawatan dalam kepekatan yang berbeza (200 – 1000 mg/L) masing-masing. Tambahan pula, penyingkiran tertinggi bagi BOD, COD dalam 400 mg/L dan TOC dalam 200 mg/L MB masing-masing adalah 69, 58 dan 63%.

## Introduction

Major progress in textile industry has caused serious environmental problems, since the textile industries use dyes to colour their products and, as a result, generate a considerable amount of coloured effluents causing water pollution. These dyes can be mutagenic, carcinogenic and can impart toxicity to aquatic life [1]. Discharge of dye-bearing wastewater poses a severe problem. In textile industries, about 10 – 15% of the dye gets lost in the effluent during the dyeing process [2]. Effluents containing dye produce wastewaters having a high chemical oxygen demand

(COD), biological oxygen demand (BOD), and other toxic chemical compounds [3]. The values of COD, BOD and TOC in textile effluents are 276 – 1379, 99 – 350 and 74 – 530 mg/L, respectively [4]. Various techniques like adsorption, coagulation, ozonation, and electrolysis are used for the purification and decolourization of dyeing wastewater [5]. Due to low biodegradability of dyes, a conventional treatment process such as the physical-chemical method is not very effective. Moreover, all these methods have different colour removal capabilities, incur high costs, and have low efficiency [6].

In recent years, microorganisms have been reported for degradation of textile dyes [7–10]. The knowledge that plants can also be used to clean up contaminated soil has opened up new avenues of research, and has provided a basis for the present-day use of constructed wetlands for treating municipal and industrial waste streams. In this study, constructed wetland systems (CWs) employing horizontal subsurface flow were set up in a greenhouse, with and without *Scirpus grossus.* We aim to study the role of a native Malaysian plant, *Scirpus grossus* (*S. grossus*), in a subsurface batch system to remove textile dyes containing methylene blue dye (MB) at different concentrations (200, 400, 600, 800 and 1000 mg/L) from synthetic wastewater. *S. grossus* is an aquatic species with a high growth rate, and has the ability to degrade contaminants, giving an insight into the involvement of bacteria and the prediction of metabolic pathways behind the degradation of the dye. This technology has received attention lately as an innovative and cost-effective alternative to the more established treatment methods used at hazardous waste sites [11]. Thus, the phytoremediation potential of the plant for the synthetic dye of MB was evaluated.

## Materials and Methods

### Plant source of *Scirpus grossus*

*S. grossus* was collected from a freshwater lake, Tasik Chini in Pahang, Malaysia for propagation for one month until the first generation was produced.

### Concentration and analysis of dye in synthetic wastewater

This experiment was conducted in a greenhouse at Universiti Kebangsaan Malaysia (UKM), under subsurface batch system (SSF) using *S. grossus* plants on various dye concentrations for 72 days. 33 aquarium glasses were used in this study, 15 aquaria containing synthetic wastewater contaminated with MB, and each concentration with three replicates (R1, R2, R3). There were another three aquaria-containing MB-contaminated wastewaters, only without plants as contaminant controls (CC1, CC2, CC3) for each concentration of MB. The last three acquiria acted as plant controls (PC1, PC2, PC3), as illustrated in Figure 1a.

Each aquarium was layered from top to bottom with 8 cm of gravel with a size of Φ10–20 mm, 3 cm of gravel with a size of Φ 1–5 mm and 10 cm of sieved fine sand of Φ 2 mm (Figure 1b). Each aquarium was filled with 7 L of synthetic wastewater prepared by mixing tap water with MB (R&M Chemicals Marketing, UK) at different concentrations (200, 400, 600, 800 and 1000 mg/L). An aliquot of 10 mL of decolourised solution of the dye was centrifuged at 4000 rpm for 10 min to remove all particulate matter using Eppendorf Centrifuge (AG 22331 Hamburg, Germany), and then the absorbance of the solution was measured at 665 nm wavelength using UV/vis spectrophotometer (DR 3900 HACH). The decolourisation percentage for the respective dyes was calculated using equation 1 based on initial and final absorbance:

$$\text{Decolorization (\%)} = \frac{(\text{Initial absorbance at 0 h}) - (\text{Observed absorbance at t})}{(\text{Initial absorbance at 0 h})} \quad (1)$$

### Monitoring and analysis of operational parameters

The operational parameters were determined during 72 days of exposure with sampling performed on days 0, 7, 14, 28, 42 and 72. The parameters of pH temperature (T, $^{\circ}$C), dissolved oxygen (DO, mg/L) and oxidation reduction potential (ORP, mV) were recorded to observe the physicochemical changes in water using a Metrohan multi-probe of (Model 877, Swiss) for the pH, ORP and temperature measurements. For dissolved oxygen, the YSI sensor (Model 550A, USA) was used.

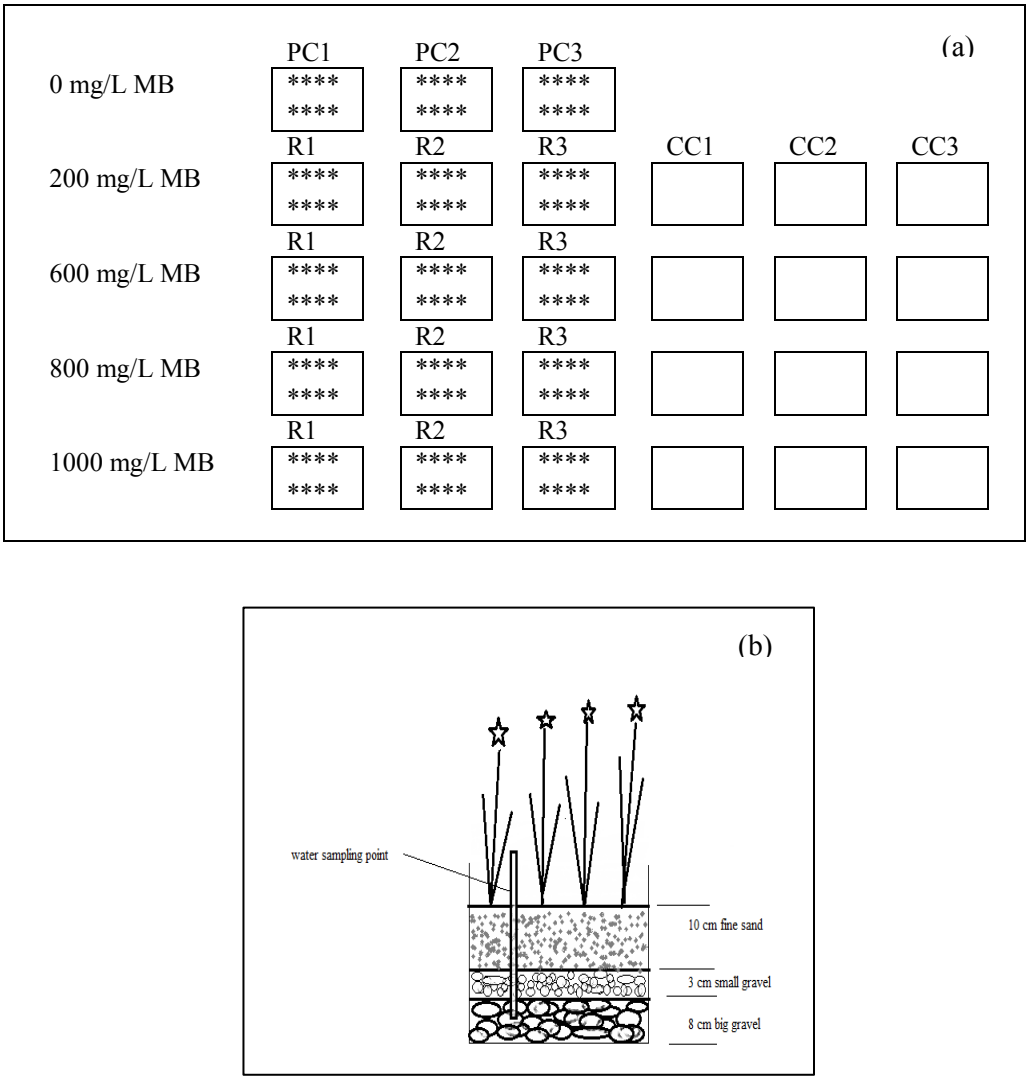

Figure 1. (a) Experimental set-up of the phytotoxicity experment, (b) Schematic diagram of an aquarium for the phytotoxicity test

**Analysis of water quality parameters (BOD, COD, TOC)**

BOD, COD and TOC of the MB contaminated water were determined. The COD and TOC values were determined using a spectrophotometer (DR3900 HACH, Germany). The BOD value was determined by measuring the dissolved oxygen levels in the sample before and after incubation for five days, according to Winkler's iodometric method [3]. BOD was calculated using equation 2 as follows:

$$\mathrm{BOD}\left(\frac{\mathrm{mg}}{\mathrm{L}}\right) = \frac{D_0 - D_5}{P} \quad (2)$$

where $D_0$ is define as initial DO concentration in the sample, $D_5$ is DO concentration after five days and $P$ is decimal volumetric fraction of sample used.

## Results and Discussion

### Variation of operational parameters for different dye concentrations

The physical parameters (i.e. T, pH, DO and ORP) were recorded throughout the phytotoxicity test, as shown in Table 1. For treatment with plants and without plants at different concentrations of MB dye (200, 400, 600, 800 and 1000 mg/L), the range of temperature with plants was between 28.3 – 29 $^{o}$C, while the temperature without a plant was 29 $^{o}$C. The pH ranged between 8.2 – 8.6 in the aquarium with plants; for the aquarium without plants, the pH ranged between 9 – 10, with increasing pH during the treatment of 72 days. With regard to DO, the average value range between 4.3 – 4.7 mg/L in the aquarium with plants, indicating that the organism used oxygen for MB degradation. The average value of DO in the aquarium without plants was between 2.7 – 3.4 mg/L. The ORP range value was between -201till -139 mV for the aquarium with plants, while the values of ORP in the aquarium without plants was -184 till -172 mV, with the reading increasing with time. The negative values of ORP throughout the MB dye treatment show that the condition was under anaerobic conditions [12]. However, for the aquaria with plants, the conditons were less anaerobic and became more aerobic with treatment duration.

Table 1. Average operational parameters in phytotoxicity test with and without *Scirpus grossus* in MB contaminant

| **Parameters** | **With *Scirpus grossus*** | **Without *Scirpus grossus*** |
|---|---|---|
| Temperature ($^{o}$C) | 28.4 ± 0.4 | 29 ±0.3 |
| pH | 8.2 ± 0.4 | 9.4 ± 0.6 |
| DO (mg/L) | 4.5 ± 0.2 | 3.2 ± 0.4 |
| ORP (mV) | -171 ± -24 | -180 ± -8 |

### Decolourisation of MB dye by *S. grossus*

In the screening experiments, the decolourisation of MB by *S.grossus* at different dye concentrations showed different decolourisation patterns. The decolourisations of 86, 52, 47, 34 and 38% were observed for 200, 400, 600, 800 and 1000 mg/L respectively, at the end of 72 day exposure. The maximum decolourisation occurred at 200 mg/L (86%); whereas the minimum decolourisation was obtained for 800 mg/L (34%). The increasing MB concentration caused decreasing percentages of MB decolourisation values monitored throughout 72 days (Figure 2), indicating some toxicity effects on the plants. The low percentage of decolourisation at higher concentrations of dye was due to the inhibitory effects of the dye transformation process (Figure 2). As for the comparison with the control aquaria without plants, the decolourisations of MB were only 31% (200 mg/L), 15% (400 mg/L), 19% (600 mg/L), 2% (800 mg/L) and 19% (1000 mg/L). These results confirm the ability of *S. grossus* plants to decolourise MB dye. In previous studies, 98% MB was removed using *Limna minor* after six days [13], while a removal effiency of 65.7–89.30% was obtained by [14] through an adsorption process using *peat* with MB concentration of 19–134 mg/, which is comparable with our results.

### Monitoring of BOD, COD and TOC

BOD, COD and TOC are widely used methods to determine organic matter in wastewater [15]. The BOD, COD and TOC values of synthetic wastewater for different dye concentrations were found to decrease in the test samples treated with *S. grossus* for 72 days, as depicted in Figure 3. The highest efficiency removal of BOD was 69% for 400 mg/L dye concentration; while the lowest was 21% for 800 mg/L. The BOD removals were 46, 25 and 37% for 200, 600 and 1000 mg/L respectively. Similarly, the highest efficiency removal of COD was 58% for 400 mg/L and the lowest was 21 % for 800 mg/L, while the COD removals were 40, 30 and 26 mg/L for 200, 600 and 1000 mg/L respectively. As for the TOC, the highest removal was 63% for 200 mg/L while the lowest was 26% for 1000 mg/L. 49, 36 and 39% were obtained for 400, 600 and 800 mg/L respectively. The results obtained for BOD, COD and TOC removal indicated that *S. grossus* has the ability to decolourise MB in contaminated water.

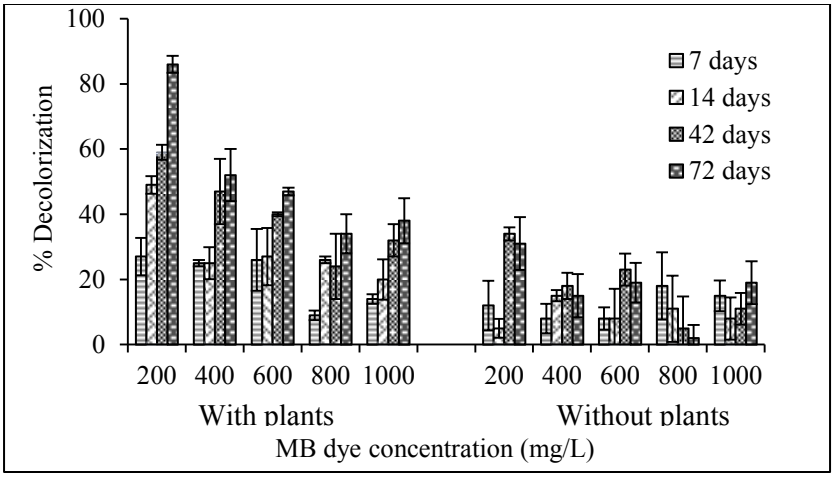

Figure 2. Effect of increasing concentrations of MB (200, 400, 600, 800 and 1000 mg/L) on the percentage of decolourisation monitored at 7, 14, 42 and 72 days with and without *S. grossus*

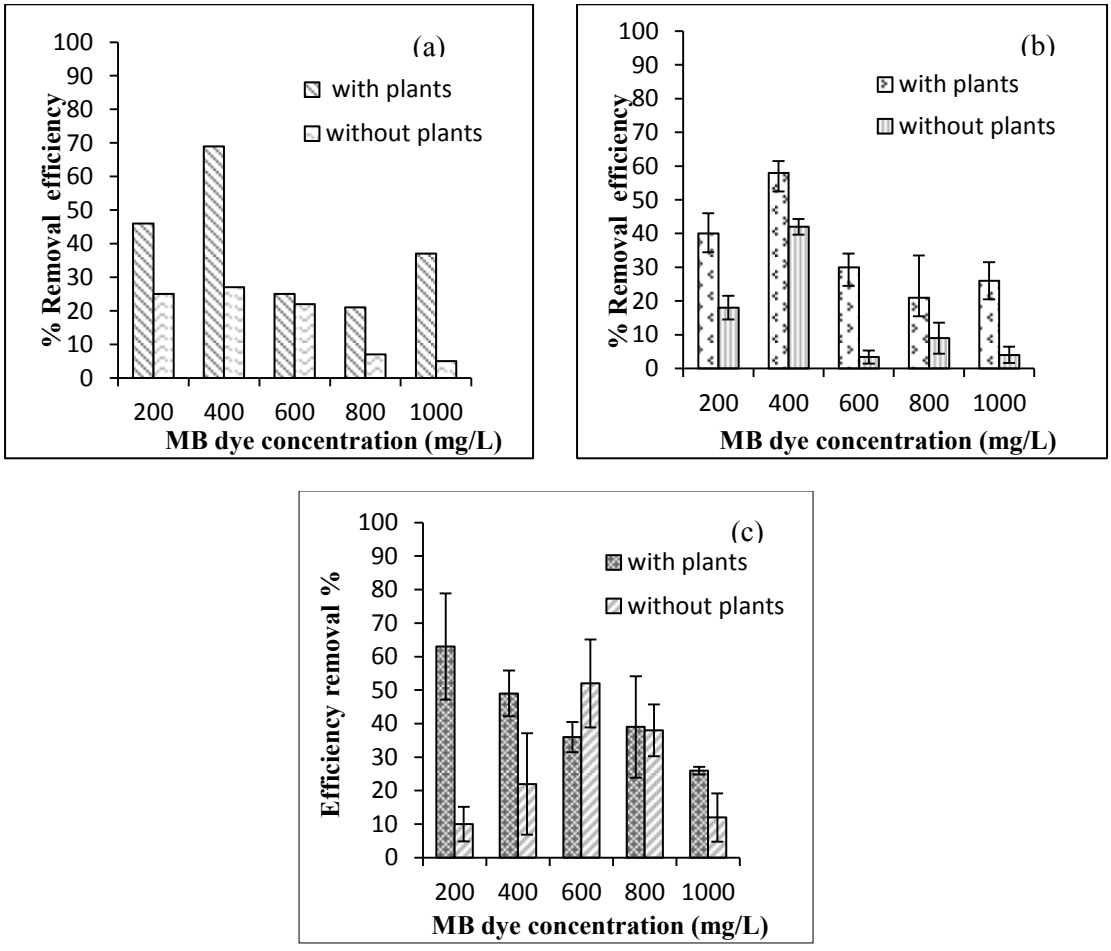

Figure 3. Removal percentages of (a) BOD, (b) COD and (c) TOC for different concentrations of MB dye

## Conclusion

We have demonstrated the ability of S. *grossus* to decolourise MB dye at different concentrations (200, 400, 600, 800 and 1000 mg/L) after 72 days in a subsurface batch system. Based on the results, the highest dye removal of 86% and 38% was obtained for MB dye concentrations of 200 and 1000 mg/L respectively. Compared to the results obtained from the aquarium without plants, the dye removals were only 31% and 2% at MB dye concentrations of 200 and 800 mg/L respectively. These results give evidence that *S. grossus* was able to remove dye from wastewater.

**Abstract**

The interest in Oil Palm Empty Fruit Bunch (OPEFB) as a promising feedstock for bioconversion into value added products is growing fast, thus a thorough analysis of its component becomes necessary. In this study, the biomass chemical composition and physical feature of OPEFB was analysed to explore and understand the potential of OPEFB as bioconversion feedstock. National Renewable Energy Laboratory (NREL) standard protocols were used to characterize and determine the chemical composition of OPEFB. Through this protocol, the structural and non-structural constituents and their compositions were determined based on unextracted and extracted native OPEFB. Structural constituents include the carbohydrate, such as the glucan, xylan and arabinan, and lignin accounted for 31.2%, 18.7%, 2.7%, and 27.7%, while the non-structural constituents mainly refer to ash and extractives accounted for 0.10% and 11.87%. In addition, Fourier Transform Infrared Spectroscopy (FTIR) and X-Ray Diffraction (XRD) analysis were also used to further characterize the chemical structure of OPEFB. The FTIR spectral peaks representing the functional groups cellulose, hemicellulose and lignin were observed. Through XRD analysis, the crystallinity index of native OPEFB fiber was calculated around 40%, while it was 37% for the powder form OPEFB. Nevertheless, the physical feature or surface morphology of the OPEFB fiber has been study by using Scanning Electron Microscopy (SEM). It shows a rigid strand's surface and the presence of silica bodies which commonly found in woody plant.

**Keywords**: lignocellulose, composition, morphology, spectroscopy, crystallinity

**Abstrak**

Minat terhadap tandan kosong buah kelapa sawit (OPEFB) sebagai bahan mentah secara penukaran bio telah menjanjikan hasil produk tambah nilai yang berkembang pesat, oleh itu suatu analisis yang menyeluruh komponennya menjadi keperluan. Dalam kajian ini, komposisi kimia biomas dan ciri-ciri fizikal OPEFB dianalisis untuk meneroka dan memahami potensi OPEFB sebagai bahan mentah untuk penukaran bio. Protokol piawai *National Renewable Energy Laboratory* (NREL) telah digunakan untuk mencirikan dan menentukan komposisi kimia OPEFB. Melalui protokol ini, juzuk struktur atau bukan struktur dan komposisi mereka telah ditentukan. Juzuk struktur termasuk karbohidrat, seperti glukan, xilan dan arabinan dan lignin menyumbang kepada 31.2%, 18.7%, 2.7%, dan 27.7%, manakala juzuk bukan struktur terutamanya merujuk kepada abu dan ekstraktif menyumbang kepada 0.10% and 11.87%. Di samping itu, analisis Spektroskopi Inframerah Transformasi Fourier (FTIR) dan belauan sinar-X (XRD) juga digunakan untuk mencirikan lagi struktur kimia OPEFB. Puncak spektrum FTIR yang mewakili kumpulan berfungsi daripada selulosa, hemiselulosa dan lignin telah diperhatikan. Melalui analisis XRD, indeks penghabluran gentian OPEFB asli dikira sekitar 40%, manakala ia adalah 37% untuk OPEFB berbentuk serbuk. Walau bagaimanapun, ciri atau permukaan fizikal morfologi serat OPEFB asli yang telah dikaji dengan menggunakan Mikroskopi Imbasan Elektron (SEM). Ia menunjukkan permukaan helaian yang tegar dan kehadiran badan-badan silika yang biasa ditemui dalam tumbuhan berkayu.

## Introduction

In the recent year, there are more than 5 000 000 hectares' oil palm are cultivated in Malaysia, making the country world's largest exporter of palm oil. As one of the leading producer and exporters of palm oil products, the palm oil industry in Malaysia collectively generate massive amount of oil palm lignocellulosic biomass waste, with oil palm empty fruit bunch (OPEFB) accounting about 16 million tons per year [1].

The OPEFB have traditionally been burnt in incinerator of palm oil mill and their ash recycled into the plantation as fertilizer. However, due to the environmental problem, the incineration of OPEFB has been discouraged [2]. In order to protect the environment and to ensure the sustainability of the oil palm industry, the lignocellulosic biomass waste must be fully exploited.

The building block of native OPEFB fiber is made up from a complex matrix of three main polymers which are cellulose, hemicellulose and lignin. It composed approximately around 44.2% cellulose, 33.5% hemicellulose and 20.4% of the lignin [3]. It also reported that OPEFB is composed 32.9% glucan, 22.4% xylan and 1.4% arabinan [4]. The lignocellulosic material from OPEFB has been considered as a very good source of fermentable sugar for conversion into value added products [5-7]. Cellulose and hemicellulose can be hydrolysed chemically by acid or enzymatically into glucose and a variety of pentose and hexose sugars, which can then be fermented to produce bioethanol.

The investigation on the potential utilization of OPEFB fiber as renewable bioresource require a comprehensive chemical and physical characterization of the biomass. Therefore, the objectives of this study were to examine the surface morphology of OPEFB and quantity of major and minor component of native OPEFB fiber with the aim to utilize them as raw material for biorefinery.

## Materials and Methods

### Raw material

The OPEFB used in this study was collected from Seri Ulu Langat's Palm Oil Milling Factory, Dengkil Selangor with initial moisture content of 55%. The OPEFB was then sun-dried for 72 hours until the moisture content reached less than 10%, and then grounded into approximately 2 mm particle size using a mill (Fritsch GmBH, Germany). The grounded OPEFB were packed in a sealed bag and stored at - 40˚C.

### Compositional analysis

The chemical analysis of native OPEFB fiber was carried out using National Renewable Energy Laboratory (NREL) standard biomass analytical procedure with 3 replication. Moisture content analysis was carried out using moisture analyser (Denver Instrument, Germany), while the ash analysis was conducted using a furnace at 575 ˚C for 24 hours [9].

### Extractive analysis

The total extractive determination was carried out with water for 8 hours followed with the 95% ethanol for 8 hours in a soxhlet extractor. The ethanol soluble material and water soluble material such as non-structural sugar, nitrogenous compound, inorganic compound and waxes were removed during the two-stage extraction process [10]. Non-structural materials must be removed from the biomass prior to analysis to prevent the inteferences.

### Carbohydrates and lignin analysis

The extractive-free sample were hydrolyzed using sequential acid hydrolysis procedure utilizing 72% sulphuric acid at 30 ˚C for an hour and followed by 4% sulphuric acid at 121˚C for an hour [11] [12]. The hydrolyzate was filtered and analyzed for monosaccharides using high performance liquid chromatography (HPLC) (Dionex Ultimate 3000, Thermo Scientific, USA) equipped with refractive index detector (RI) and Rezex Phenomex Monosaccharide column (RPM). The hydrolyzate samples and standards were analyzed at 60 ˚C with the flowrate of 0.6 ml/min and

20 µL injection volume [13]. Post-hydrolysis analyses of the liquid sample from water extraction were also done to quantify the oligomeric sugar. The insoluble portion filtered from the acid hydrolysis process were dried for overnight in a desiccator and were regard as acid insoluble lignin. The filtrate will then quantified spectrophotometrically at 320 nm using 1 cm pathlength cuvette for acid soluble lignin.

**Morphology study**
Scanning electron microscopy (SEM) analysis was conducted to view the surface structure of native OPEFB fiber. The freeze-dried sample was prepared by sputter-coated with gold prior to imaging with SEM with magnification power of 100 to 2000x.

**Spectroscopy characterization**
Fourier Transform Infrared spectroscopy (FTIR) analysis was performed to detect the functional groups presence in the cellulose, hemicellulose and lignin portion of the native OPEFB fiber. FTIR spectra were obtained using a KBr disc containing grounded sample. The sample were scan from 4000 to 400 $cm^{-1}$ with resolution of 4 $cm^{-1}$.

**Crystallinity study**
The crystallinity of cellulose in the native OPEFB were studied using X-ray diffraction (XRD) profile. The sample were scanned over scattering angle (2θ) from 10˚ to 50˚. The crystallinity index (CrI) of the sample was estimated by using equation (1) as follows [14]:

$$CrI = \left[\frac{I_{002} - I_{am}}{I_{002}}\right] x\ 100 \quad (1)$$

where, $I_{002}$ is the highest peak intensity of crystalline fractions and $I_{am}$ define as the low intensity peak at the amorphous region.

## Results and Discussion

**Compositional analysis**
The purpose of this part of the paper was to study the composition of native OPEFB fiber for utilizing them as raw material for production of value-added product. The composition of native OPEFB fiber were analyzed for structural carbohydrates, lignin, ash and extractives content. The compositional analyses of native OPEFB fiber were made based native-overall unextracted OPEFB, extractive-free OPEFB, and corrected native-whole OPEFB as presented in Table 1. These results were expressed as the percentage of the oven-dried, native whole unextracted OPEFB.

Since woody lignocellulosic biomass, such as OPEFB contain high amount of extractives which influence the compositional analyses of structural and non-structural constituents, the native-whole unextracted and solvent-extracted OPEFB were both analysed for the purposes comparing the composition of major constituents, determining the extractable non-structural constituents in the OPEFB, and finally making the appropriate corrections in the composition of particular constituents [15]. Characterization of native-whole unextracted OPEFB only, can be considered inaccurate because the hydrophobic extractives such as oil and waxes inhibit the penetration of sulphuric acid into the biomass causing incomplete hydrolysis thus affecting the analyses for structural carbohydrates [10]. While expressing the result in extractive free basis, also does not allow direct comparison between compositions of the extracted and unextracted materials, since removal of the extractives changes the composition of the constituents in the biomass [8]. Thus, in this study the identified constituents in the extractives were used to correct and convert the composition of the extractives-free OPEFB, from native-whole unextracted basis to the corrected native-whole OPEFB basis.

The structural carbohydrates are the major constituents that made-up structure of lignocellulosic biomass of OPEFB, varied from 57.9% in the native-whole unextracted OPEFB to 51.5% in the extractive-free OPEFB. This yielded about 6.4% reduction in the structural carbohydrates after the extraction which mainly composed of glucan and xylan with a small amount of arabinan. The compositions of these carbohydrate constituents between the native-whole unextracted and the extractive-free OPEFB differed respectively from 35.0% to 30.9% for glucan, from 20.3% to 18.2% for xylan and from 3.10% to 2.46% for arabinan. The arabinan has shown the largest composition difference, with a 21% reduction, and followed by glucan and xylan with 11% and 10% reduction

respectively. The removal of extractive also reduced the lignin content from 34.9% in the native-whole unextracted OPEFB to 27.5% in the extractive-free OPEFB. This shows that the extractives contained approximately around 21% of lignin, while the other 79% was still intact in the extractive-free OPEFB fiber. High lignin content in native-whole unextracted OPEFB was due to the presence of extractives which resulted in falsely high lignin values when unhydrolyzed carbohydrates condense with acid insoluble lignin.

All values are mean of duplicate ± standard deviation, NR= Not Relevant

In the non-structural constituent, the ash was greatly affected by the extraction process. The ash content decreased from 0.4% in the native-whole unextracted OPEFB to 0.1% in the extractive-free OPEFB. This indicates that the extractive-free OPEFB contained approximately only 25% of the ash content with the remaining 75% have been solubilize during the two-stage extraction process. The number of extractives for extractive-free OPEFB basis were accounted around 12.9% which made up of water and ethanol soluble constituents and other extractives. The other extractives composition maybe contains acetyl group, protein content, soluble ash, soluble lignin and many unidentified constituents. As reported in Table 1 the highest compositional content for corrected native-whole

OPEFB, was for the glucan component followed by xylan and arabinan with 31.2%, 18.7% and 2.7%. The amount of structural carbohydrate of corrected native-whole OPEFB were slightly higher than extractive-free OPEFB because the measured soluble sugar except sucrose in the extractives of the extractive-free OPEFB basis, have been used to correct the compositions of structural carbohydrate. These reduce the number of extractives for corrected native-whole OPEFB to 11.87% which is 92% of the total extractives from extractives–free OPEFB basis. The amount accounted for extractives in corrected native-whole OPEFB in this study is still high since many of its constituents such as soluble ash and lignin have not been measured properly. The lignin content of OPEFB fiber in this study is considered high as its make up more than half of the carbohydrates composition and hence the pretreatment step must be applied to the OPEFB to overcome the recalcitrance nature of this biomass for further used as the source of fermentable sugar. The lignin level was also comparable to the lignin content of hardwood. The composition of structural and non-structural constituents of corrected native-whole OPEFB fiber in this work was comparable to the previous studies as shows in Table 2.

**Morphology analysis**

Figure 1a and b illustrate the SEM images for the surface structure of native OPEFB fiber with different magnification. The native OPEFB fiber had a rigid surface with a layer of matrix material like lignin or waxes that covered the whole surface of the fiber. This layer might be the protective layer present in most plants to prevent water loss. The cell walls of this biomass are thicker than the hardwood which result in high coarseness and rigidity index as reported by previous studies [16].

Moreover, there are great numbers of silica bodies found embedded on the surface of the fiber strands as highlighted in the Figure 1a and b. The silica bodies are attach to circular craters which are spread uniformly over the strand's surface. In addition to cellulose, hemicellulose and lignin, OPEFB is also rich in inorganic elements such as silica and metal ions [17]. The main constituents present in the silica bodies are silicon and oxygen as reported by the previous works [18]. Silica bodies are the most often mineral found on the surface of woody plants, formed by the invasion and hardening of soil minerals into sedimentary cavities between and within cell wall during plant growth [19]. The surface recalcitrance of the native OPEFB fiber serves as a major physical barrier for enzymatic hydrolysis process due to the difficulty in penetrating the surface to access the cellulose and hemicellulose for sugar production.

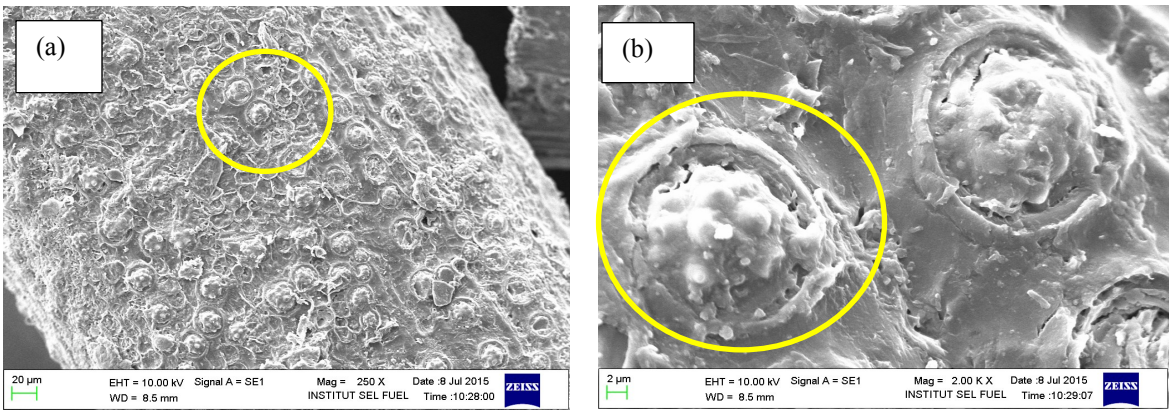

Figure 1. SEM images (a) and (b) of native OPEFB fiber at different magnification (200x; 2000x)

**Spectroscopy analysis**

FTIR spectroscopy was used to investigate the functional group presence in the native OPEFB fiber. Figure 2 shows the FTIR spectra of native OPEFB fiber. A strong and broad absorption was observed at a wavenumber of 3355 $cm^{-1}$ which is related to the stretching of H-bonded in hydroxyl group of cellulose, respectively [20]. The other prominent one around wavenumber of 2900 $cm^{-1}$ is due to the C-H stretching of $CH_2$ from the $CH_2$-OH group in cellulose [21]. In addition, the area of 1800 to 600 $cm^{-1}$ is called the fingerprint area of spectra which has many sharp and well defined absorption bands due to the various functional groups presence in each component of OPEFB. The distinctive bands in the fingerprint region and the components to which these peaks are shown in Table 3.

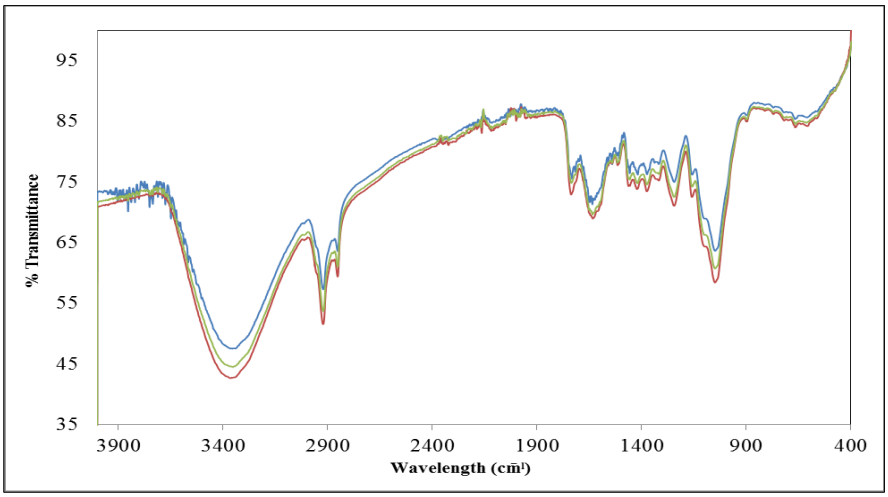

Figure 2. FTIR spectra of native OPEFB

The peak at around wavenumber of 1733$cm^{-1}$ can be seen from the spectra, which occur due to the C=O stretching of the acetyl and uronic ester groups of the hemicellulose ester. The peak also represents the carbonyl ester linkages of the carboxylic groups of ferulic and p-coumaric monomeric lignin [22]. The peak at 1635 $cm^{-1}$ was correspond to the bending vibration of the hydroxyl groups of cellulose. Sun and Cheng also reported that the band around 1600 $cm^{-1}$ was probably due to the bending mode of water, since hemicelluloses have strong affinity for water [23]. The

absorption band 1244 and 1541 $cm^{-1}$ are arise mostly from aromatic ring of lignin, while the band around 1635, 1375, 1049 and 667 $cm^{-1}$ are mainly due to carbohydrates and have no significant contribution from the lignin [24].

Table 3. FTIR wavenumber characterization of native OPEFB [20-27]

| **Wavenumber ($cm^{-1}$)** | **Compound** |
|---|---|
| 3355 | O-H stretching |
| 2850-2920 | C-H stretching in methyl and methylene group |
| 1733 | C=O stretching in unconjugated ketones, carbonyl and in ester groups |
| 1635 | O-H bending |
| 1541 | C=C stretching from aromatic ring of lignin |
| 1375 | C-H bending in cellulose and hemicellulose |
| 1244 | C-O-C stretching of aryl-alkyl ether |
| 1049 | Aromatic C-H in plane deformation-O deformation in primary alcohol |
| 667 | C-O out of plane bending mode |

**Crystallinity analysis**

The degree of cellulose crystallinity is a major factor in investigating the potential of OPEFB as the feedstock for bioconversion due to its effects on the enzymatic hydrolysis process as low crystallinity of cellulose increase the efficiency of cellulose hydrolysis by cellulase. Figure 3 shows the X-ray diffractogram of native OPEFB fiber and powder resulted from grinding process with particle size measured as less 250 µm.

By comparing with the cellulose standard available in the database of XRD system, two main peaks were observed from the XRD patterns at 2θ = 22.5 and 2θ = 16 representing peak $I_{002}$ and $I_{011}$, respectively. As in figure 3, peak $I_{011}$ for both samples are corresponding to the amorphous region of hemicellulose and lignin while peaks $I_{002}$ represent the crystalline region of cellulose [22]. The crystallinity index of native OPEFB fibers were calculated as 40%, while for the powder form of OPEFB fiber with particle size less than 250µm was 37%. Slight decrease in the crystallinity shows that smaller particle size cause decrease in the cellulose crystallinity of the fiber as reported by Sun & Cheng [23]. The X-ray diffractogram of the fiber and powder form of native OPEFB were also found to be comparable with the X-ray diffractogram of SigmaCell cellulose type 20 from the previous work [1].

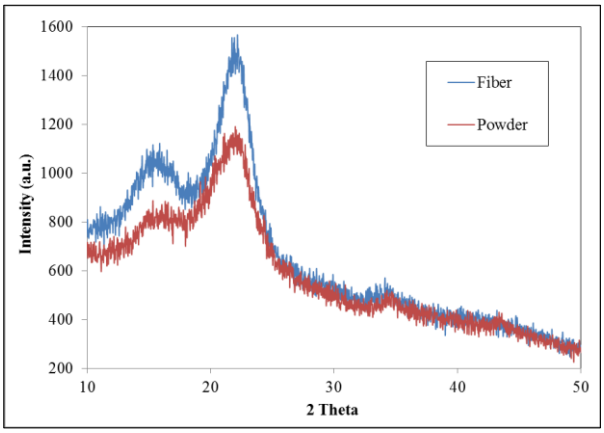

Figure 3. X-ray diffractogram of fiber and powder form of native OPEFB

## Conclusion

In the present study, it was found that the OPEFB fiber were made up of 31.4% of glucan, 18.6% xylan and 2.7% arabinan with the lignin accounted around 23,9%. As for non-structural constituents of OPEFB fiber, the ash and extractive content was around 0.1% and 8.18%. The morphological study by SEM shows the surface structure of OPEFB fiber is mainly consist of silica bodies. Spectroscopic analysis by FTIR shows a comparable result indicated the presence of the cellulose, hemicellulose and lignin in the fiber. While XRD analysis indicated the crystalline nature of cellulose in the native OPEFB fiber through the (200) peak at 2θ=22.5. OPEFB fiber has the potential as the low-cost feedstock for bioconversion as it contains the polymer of carbohydrates such as cellulose and hemicellulose but due to the surface morphology, crystallinity nature of its element, and the present of lignin, the process required a preliminary pretreatment step to optimize the production of fermentable sugar.

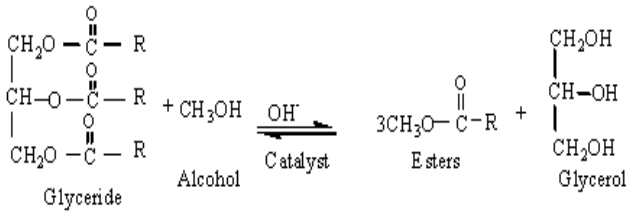
**Abstract**

A promising catalyst based on a biomass pyrolysis by-product, biochar, has been developed to produce biodiesel. A carbon-based solid acid catalysts were prepared by sulfonating pyrolysis char with concentrated sulfuric acids. The catalysts were characterized using thermogravimetric analyses (TGA), scanning electron microscope (SEM), Fourier transform infrared spectroscopy (FTIR) and surface area analyzer. Prepared catalysts were studied for their ability to catalyze transesterification of vegetable oils. The catalyst sulfonated with the concentrated sulfuric acid demonstrated considerable conversion in free fatty acid esterification. Further investigation of the catalyst was conducted to determine the effect of sulfonation time (1 and 3 hours) and surface area on the transesterification reactions. The surface area of the biochar was increased by chemical treatment using 10M potassium hydroxide through porosity development. Results showed the catalyst with the highest surface area and acid density to have the highest catalytic activity to produce biodiesel from canola oil in the presence of methanol as the reagent. The effects of alcohol to oil (A:O) molar ratio, reaction time and catalyst loading on the esterification reaction catalyzed by the sulfonated biochar were also investigated. Results revealed that more than 90% biodiesel yield was achieved at 15 wt% of catalyst amount, methanol to oil molar ratio was 9:1 and the agitation rate was 700 rpm. As a conclusion, the prepared biochar-based catalyst has a tremendous potential to be used in a process converting a high Free Fatty Acids (FFA) feedstock to biodiesel.

**Keywords:** transesterification, vegetable oil, palm kernel shell, biochar-based catalyst

**Abstrak**



Pemangkin yang berasaskan pirolisis biomass produk sampingan, biochar, telah dibangunkan untuk penghasilan biodiesel. Pemangkin asid pepejal berasaskan karbon telah dihasilkan daripada sulfonasi pirolisis char dengan asid sulfurik pekat. Pemangkin telah dicirikan menggunakan analisis termogravimetri (TGA), mikroskop imbasan elektron (SEM), spektroskopi infra merah transformasi Fourier (FTIR) dan penganalisa luas permukaan. Pemangkin yang tersedia telah dikaji keupayaannya untuk menjadi pemangkin transesterifikasi minyak sayur-sayuran. Pemangkin sulfonat dengan asid sulfurik pekat menunjukkan penukaran ini boleh dipertimbangkan dalam pengesteran asid lemak bebas. Kajian lanjut terhadap pemangkin telah dijalankan untuk menentukan kesan masa sulfonasi (1 dan 3 jam) dan luas permukaan pada tindak balas transesterifikasi. Luas permukaan biochar telah meningkat melalui rawatan kimia menggunakan 10M kalium hidroksida melalui pembangunan liang. Hasil kajian telah menunjukkan pemangkin dengan luas permukaan dan ketumpatan asid yang paling tinggi mempunyai aktiviti pemangkinan tertinggi bagi pengeluaran biodiesel daripada minyak kanola dengan kehadiran metanol sebagai reagen. Nisbah molar kesan alkohol kepada minyak (A:O), masa tindak balas dan muatan pemangkin keatas tindak balas pengesteran yang dimangkinkan oleh biochar sulfonat turut disiasat. Hasil kajian menunjukkan bahawa lebih daripada 90% hasil biodiesel telah dicapai pada 15 wt% daripada jumlah pemangkin, nisbah molar metanol kepada minyak adalah 9:1 dan kadar pergolakan adalah 700 rpm.

Kesimpulannya, pemangkin berasaskan biochar yang dihasilkan mempunyai potensi yang amat besar untuk digunakan dalam proses penukaran bahan mentah asid lemak bebas tinggi (FFA) kepada biodiesel.

**Kata kunci:** transeterifikasi, minyak sayuran, tempurung kelapa sawit, pemangkin berasaskan biochar

## Introduction

Increasing environmental problems, global fuel consumptions and strike increase in fossil fuel price has led to production of renewable fuels such as biodiesel. Biodiesel, consisting of methyl esters of long chain fatty acids has become very attractive as a biofuel due to its environmental benefits, renewable and less polluting alternatives. Biodiesel can be produced from straight vegetable oil, animal oil/fats, tallow and waste cooking oil. The largest possible source of suitable oil comes from oil crops such as rapeseed, palm or soybean. Biodiesel has a higher flash point than fossil diesel and so is safer in the event of a crash. The biodiesel yields are estimated 90% to 40% more energy than the energy invested in producing it [1]. Biodiesel can be produced by the transesterification of vegetable oils with alcohol which involved the reaction of a triglyceride (fat/oil) with an alcohol to form esters and glycerol in the presence of a catalyst. The economy of the process depends on the type and quantity of catalyst used among other factors. Transesterification of vegetable oil as shown in Scheme 1.

Scheme 1. Transesterification of vegetable oil

The reaction between the fat or oil and the alcohol is a reversible reaction and so the alcohol must be added in excess to drive the reaction towards the right and ensure complete conversion. The catalyst can be homogeneous or heterogeneous depending on whether it is in the same or different phase with reactants; oil and alcohols [2]. Homogeneous basic catalyst such as potassium hydroxide (KOH) is widely used in industrial processes. However, drawbacks such as difficulties in the recovery of the catalyst and the formation of abundant wastewater in the neutralizing and separating processes are the major disadvantages in alkali-catalyzed transesterification processes [3]. Therefore, heterogeneous catalyst is recommended due to easier operational processes, higher activity and selectivity and longer catalyst lifetimes [3]. Recently, sulfonated carbon precursors derived from the partial carbonization of sugar, starch, or cellulose for catalyzing the production of biodiesel is of great interest. Biochar as carbon based precursor is well established in recent literatures [4,5]. In this study, low cost and renewable carbon-based precursor (biochar) is investigated as a solid acid catalyst for the transesterification process of mixture of canola oil for biodiesel production. Surface chemistry and physical and structural changes biochar –based catalyst was also using Fourier Transform Infrared (FTIR) spectroscopy, Scanning Electron Microscopy (SEM), Bruner-Emmet-Teller (BET) surface area composition of methyl esters produced using Gas Chromatography-Mass Spectrometry (GC-MS) analysis.

## Materials and Methods

### Catalyst preparation

Palm kernel shells (PKS) biochar was used as carbon precursor. The as-received biochar was ground and sieved between 300 – 500 μm and then dried in an oven at 110 °C for 2 hours. The carbonized biochar mixed and stirred with 0.1 $molL^{-1}$ HCl for 1 hour. The activated biochar samples were then sulfonated using sulfuric acid for 15 hours at 150 °C and ambient pressure [6]. Subsequently, the sulfonated biochar was washed with excessive distilled water and dried in an oven at 110 °C overnight.

**Characterization study**

The BET surface area of the prepared catalyst was measured with surface area analyzer (Quantachrome AS1Win). Morphological study was carried out with a scanning electron microscopy (SEM) (HITACHI model, S-3400N, Japan). A Perkin-Elmer pyris diamond thermogravimetry (TG/DTG) was used for TGA. The presence of functional group on the surface of the PKS biochar and catalyst (after the sulfonation process) was analyzed by using Fourier Transform Infrared (FTIR) spectroscopy (model Perkin-Elmer 100 series, USA at the frequency ranges of 600 $cm^{-1}$ to 4000 $cm^{-1}$. Composition of the methyl ester was analyzed with gas chromatography-mass spectrometry (GC-MS) (QP2010 Plus SHIMADZU).

**Transesterification procedures**

Transesterification was carried out in a 250 ml 3 neck round bottom flask equipped with a reflux condenser and a magnetic stirrer. PKS-based biochar was used as catalyst with the amount varied from 5 to 15wt% and the methanol ratio was kept constant 9:1. Catalysts were first suspended in a methanol at 65 °C under vigorous mixing for 2 hours. Later, the catalyst was separated by centrifuge, and the reaction mixture was loaded into rotary evaporator to remove excess methanol. Methyl-ester phase was then obtained in a separating funnel. The obtained methyl ester was then washed and dried in the oven. Products in the biodiesel consist of methyl esters, monoglycerides, diglycerides and triglycerides. Composition of the methyl ester was analyzed using GC method. The experiments were repeated for other parameters includes molar ratio alcohol to oil (3:1, 6:1 and 9:1), catalyst loading (5 wt%, 10 wt% and 15 wt%) and agitation rate (350 rpm, 700 rpm and 1100 rpm).

## Results and Discussion

**Catalyst characterizations**

The measured BET surface areas are shown in Table 1. There was pronounced increases in micro pore surface area when the raw biochar was activated and treated with strong sulfuric acid. This is likely due to the nature of the biochar substrate, which were all forms of woody biomass. Visual observation of the catalyst samples via SEM was performed to gain insight into catalyst morphology and pores size. As shown in Fig. 1(a) and (b), the catalyst samples have a highly irregular, convoluted fibrous surface structure, with little regular texturing. The structure of the biochar had a highly complex network of pores, channels and otherwise fibrous ridged surfaces, as opposed to the planar structure of sugar-derived biochar.

Table 1. BET Surface area of raw biochar and biochar-based catalyzed

| Sample | BET surface area ($m^2/g$) |
|---|---|
| Biochar | 0.02 |
| Biochar-based catalyst | 290.44 |

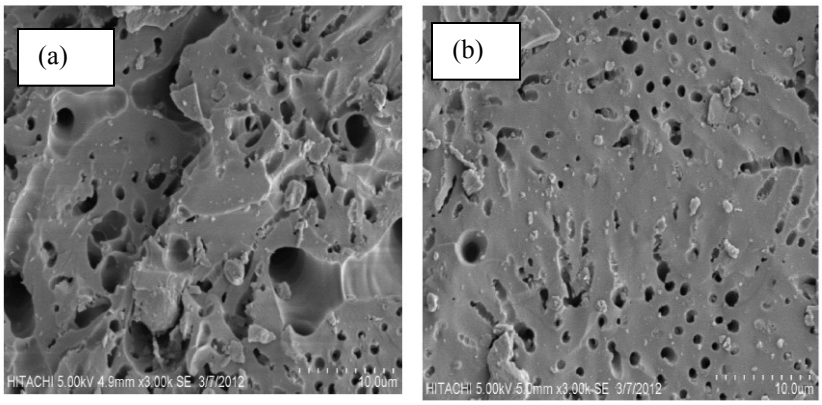


Figure 1. SEM images of (a) PKS biochar and (b) PKS-biochar based catalyst

Fig. 2 compares surface functional groups between raw biochar and biochar based catalyst. The IR spectrum of raw biochar shows a peak 724 $cm^{-1}$ and 830 $cm^{-1}$ for sulfonated char attributed to the ring C-H bonds of aromatic and heteroatomic compounds 11. In addition, peaks attributable to aromatic ring modes can be found at peaks 1498 $cm^{-1}$ for PKS biochar and 1495 and 1577 $cm^{-1}$ for sulfonated biochar. Peaks attributable to C-O-C asymmetric stretching are presented in both PKS biochar at 1170 $cm^{-1}$, and sulfonated biochar at 1119 and 1158 $cm^{-1}$.

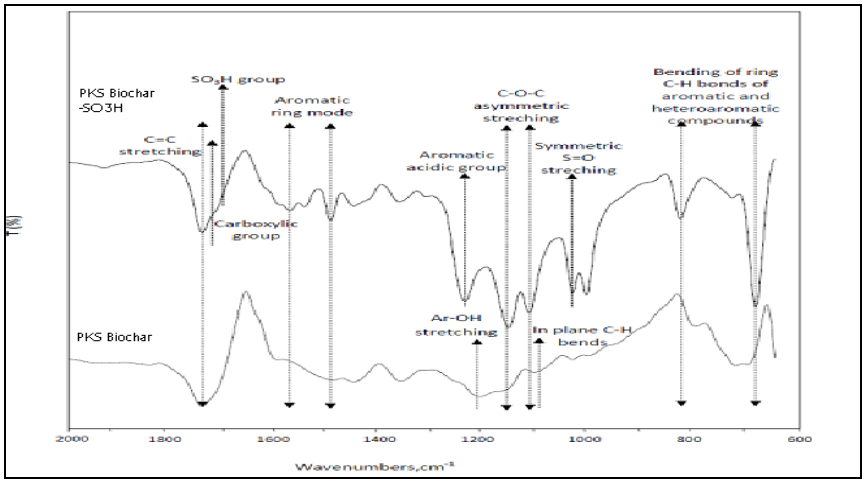

Figure 2. FTIR for PKS biochar before and after sulfonation

The PKS biochar also has peaks at 1107 $cm^{-1}$ which corresponding to in-plane C-H bends while at 1214 $cm^{-1}$ attributable to Ar-OH stretching. At peak 1745 $cm^{-1}$, both samples attributable to C=C stretching. The peaks attributed to aromatic acidic groups and carboxylic groups can be found at spectrum 1242 and 1730 $cm^{-1}$ for sulfonated char. Besides, the spectrum for sulfonated biochar exhibits a peak at 1035 $cm^{-1}$ which can be attributed to the symmetric S=O stretching and a peak at 1710 $cm^{-1}$ attributable to the presence of $SO_3H$ groups thereby confirming the incorporation of sulfonic groups onto the carbon matrix.

Fig. 3(a) and (b) shows TGA patterns for raw biochar and biochar based catalyst. The results indicated that the raw biochar has two distinctive peaks at 100 °C and 600 °C which corresponds to moisture content and lignin content respectively. While for sulfonated PKS biochar (catalyst demonstrated that desorption was occurring at 350 °C. The event can be attributed to desorption from a weak Brønsted acid site, which corresponds to the presence of COOH−groups as determined by FTIR. The event correlates with the sulfonic groups observed in the FTIR spectra for each catalyst. The TGA results were also analyzed to determine the approximate distribution of the type of acid sites.

**Effect of reaction conditions**

The effect of catalysts amount on the methyl ester content in the transesterification are showed in Fig. 4. The results showed that the use of 15wt% catalyst s, oil to molar ratio (9:1) and reaction times 3 hrs gave more than 90% methyl ester yield. However, when reducing the catalyst amount to 5 wt%, the methyl ester content decreased remarkably to below than 30%. This could be due to the fact that greater catalyst had increased the catalyst activity or transesterification due to high acidity [7]. This was verified with results shown in FTIR (see Fig. 2). Furthermore, as shown in Fig. 5 methyl ester yield about 90% after 2 hours reaction and there was no significant increase when the reaction time was prolonged. This is in accordance with which indicates that the reaction is completed [7].

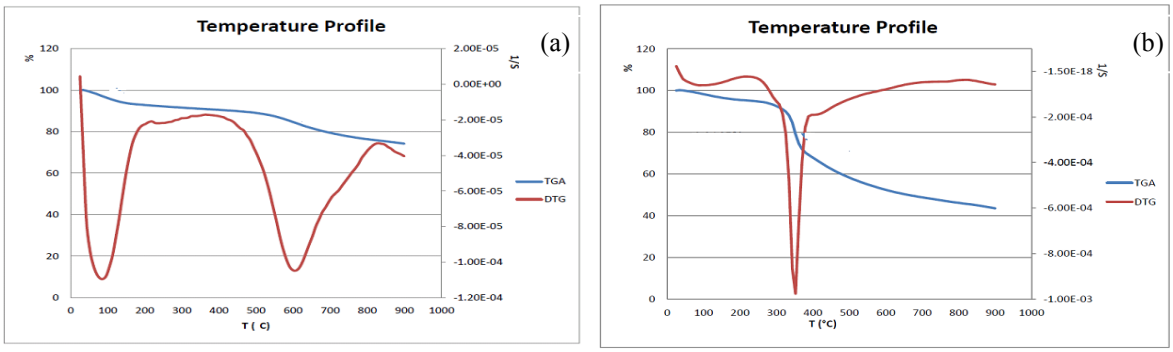

Figure 3. TGA patterns for (a) raw biochar and (b) biochar-based catalyst

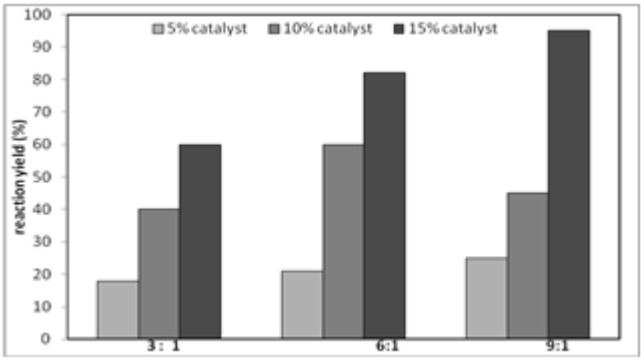

Figure 4. Reaction yields of methyl ester (ME) for various oil to methanol ratio and catalyst loading at constant speed ( 350 rpm)

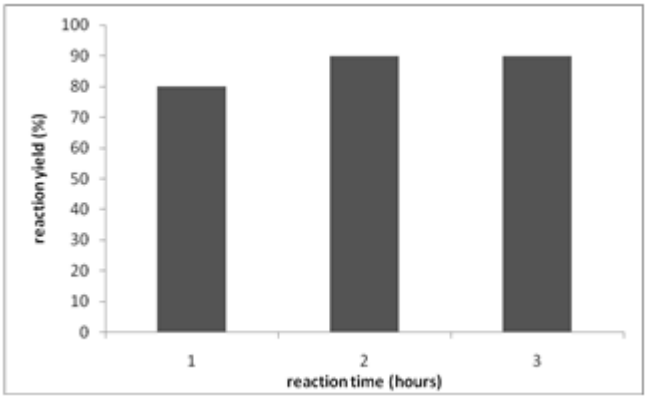

Figure 5. Reaction yields of methyl ester (ME) for different reaction time

Table 3 summarizes the chemical composition of the synthesized biodiesel of canola oil obtained in this study. It was observed that the fatty acid found in the biodiesel sample range from C6 until C22 FAME. The methyl ester compounds found in the sample are derived from the usage of methanol in the transesterification reaction. The main FAME in the biodiesel sample were oleic acid (C18:1), palmitic acid (C16:0), stearic acid (C18:0) and linolenic

acid (C18:3) The cetane number (quality of the diesel fuel) of biodiesel depends on the distribution of fatty acid in the original oil or fat from which it was produced. The major factor affecting FAME yields was the plant itself and variation will occur depending on climate and processing methods [8].

Table 3. Composition of FAME in canola oil biodiesel sample

| Peak | Retention Time (min) | Identity | % Area | Acid |
|---|---|---|---|---|
| 1 | 9.325 | C10 | 0.4492 | Decanoic acid (capric) |
| 2 | 12.019 | C12 | 7.9655 | Dodecanoic acid (lauric) |
| 3 | 12.868 | C22 | 0.0472 | Docosanoic acid (behenic) |
| 4 | 13.190 | C6 | 0.0838 | 2,4-hexadienedioic acid (sorbic) |
| 5 | 16.300 | C20 | 0.0657 | 11,14,17 eicosatrienoic acid (linolenic) |
| 6 | 16.341 | C18 | 0.1645 | 9-octadecenoic acid (oleic) |
| 7 | 16.533 | C16 | 6.7855 | Hexadecanoic acid (palmitic) |
| 8 | 16.689 | C10 | 1.9735 | Benzenepropanoic acid |
| 9 | 17.527 | C13 | 0.0624 | Tridecanoic acid |
| 10 | 18.258 | C18 | 78.049 | 9-octadecenoic acid (oleic) |
| 11 | 18.410 | C18 | 0.9745 | 9,12,15-octadecatrienoic acid (linolenic) |
| 12 | 18.475 | C18 | 2.7400 | Octadecanoic acid (stearic) |
| 13 | 20.056 | C20 | 0.4923 | cis-11-eicosenoic acid |
| 14 | 21.883 | C11 | 0.1460 | Undecanoic acid |

## Conclusion

Transesterification of vegetable oil was studied using biochar-derived catalyst to produce biodiesel with high methyl ester content under different conditions. It was found that biochar-based catalyst was successfully produced through sulfonation with sulfuric acid. The optimum conditions (with 90% conversion) for this reaction is suggested at 15wt% catalyst loading, oil to molar ratio (9:1) and 2 hrs reaction time and at moderate temperature 65°C. Thus, it proved that sulfonated PKS biochar shows considerable potential for use as a catalyst in biodiesel production.

**Abstract**

Catalyst deactivation is the loss of catalytic activity and /or selectivity over the course of time. Catalyst deactivation is a considerable and enduring problem in the operation of industrial catalytic processes. It is very costly in terms of catalyst replacement and process shutdown. The deactivation phenomenon not only affects the final product quality but also negatively influences the efficiency of the downstream processes. Therefore, a practical method which can accurately predict the deactivation rate can be a quite advantage to the industrial processes. In this paper, the deactivation rate of the industrial catalyst is predicted using operating data and catalyst specifications. The first principle model (FPM) is employed to predict the catalysts deactivation rate. The devised model is implemented into an industrial catalyst, which is palladium supported on carbon (Pd/C) utilized for the purification process of terephthalic acid, to show its applicability. The whole programs to obtain the rate of catalyst deactivation have been coded into Matlab R2013a environment. The model validated against industrial data. For the proposed catalyst, the catalyst sintering order is calculated with less that 3 percent error, and the pre-exponential values and the activation energy for the deactivation were calculated 0.00092 $h^{-1}$ and 5279 J $mol^{-1}$. Moreover, the catalyst is deactivated after around 360 days of operation. The methods, which are devised in this study, can be applied to any industrial catalyst to calculate the rate of deactivation.

**Keywords**: catalyst, deactivation rate, first principle model, sintering

**Abstrak**

Penyahaktifan mangkin adalah kehilangan aktiviti mangkin dan / atau kepilihan mangkin yang berkadaran dengan masa. Penyahaktifan mangkin adalah masalah besar yang sering berlaku dalam proses pemangkinan di industri. Ini kerana penggantian mangkin memakan kos yang tinggi dan boleh menyebabkan penutupan proses. Fenomena penyahaktifan tidak hanya memberi kesan kepada kualiti akhir produk tetapi juga mempengaruhi kecekapan proses hiliran. Oleh itu, satu kaedah praktikal yang mampu meramal dengan tepat kadar penyahaktifan boleh menjadi satu kelebihan untuk proses industri. Dalam penyelidikan ini, kadar penyahaktifan pemangkin industri diramalkan menggunakan operasi data dan spesifikasi mangkin. Model prinsip pertama (FPM) digunakan untuk meramalkan kadar penyahaktifan mangkin itu. Model yang dihasilkan ini digunakan sebagai mangkin di industri, iaitu palladium disokong pada karbon (Pd/C) digunakan untuk proses penulenan asid tereftalik, untuk membuktikan keterterapannya. Keseluruhan pengaturcaraan untuk mendapatkan kadar penyahaktifan mangkin telah dikodkan ke dalam perisian Matlab R2013a. Model ini telah disahkan terhadap data industri. Bagi mangkin yang dicadangkan, urutan pensinteran mangkin dikira dengan ralat kurang daripada 3 peratus, dan nilai pra-eksponen serta tenaga pengaktifan untuk penyahaktifan

yang dikira adalan 0.00092 $h^{-1}$ and 5279 J $mol^{-1}$. Selain itu, mangkin telah dinyahaktif selepas sekitar 360 hari operasi. Kaedah-kaedah yang direka dalam kajian ini boleh diaplikasikan untuk segala jenis mangkin industri bagi mengira kadar penyahaktifan.

**Kata kunci:** mangkin, kadar penyahaktifan, prinsip model pertama, pensinteran

## Introduction

Catalyst deactivation, the loss over time of catalytic activity or selectivity, is a considerable economical concern in the operation of industrial catalytic processes. Catalyst deactivation is referred to the interaction between the impurities and the catalyst in the process which the catalyst is utilized. Any physical or chemical interaction that declines the catalyst activity or selectivity is categorized as catalyst deactivation phenomena. Deactivation results in a shortened lifetime of the catalyst, and the replacement of the deactivated catalyst with a fresh one is required to maintain the product quality and the efficiency of the catalytic process. Deactivation of the industrial catalyst can vary from several seconds to several months. Shorter catalyst lifetime has a significantly adverse influence on the process economics. Therefore, to increase the catalyst lifetime can be considered as a great success in a catalytic process [1].

Catalyst deactivation is significantly related to the catalyst application and scientifically it has numerous challenges. Figure 1 displays the deactivation time for some processes in the refining and petrochemical industries. The deactivation time refers to the time after which a catalyst has lost so much of its initial activity that it must be replaced or regenerated. Regeneration is usually possible, but there is a limit. At the end of the cycle life the catalyst is recycled or, when this is more economical, disposed. It is clear that disposal should be postponed as long as possible and that recycling is becoming more and more important. In accordance to Figure 1, the deactivation time fluctuates prominently for the different processes. Depending on the process used the catalyst cycle life may vary from a few seconds, as in fluid catalytic cracking (FCC), to several years, as in for instance ammonia synthesis. Deactivation of a hydrodesulphurisation (HDS) catalyst is much slower, depending on the feed, in the order of months or a year [2].

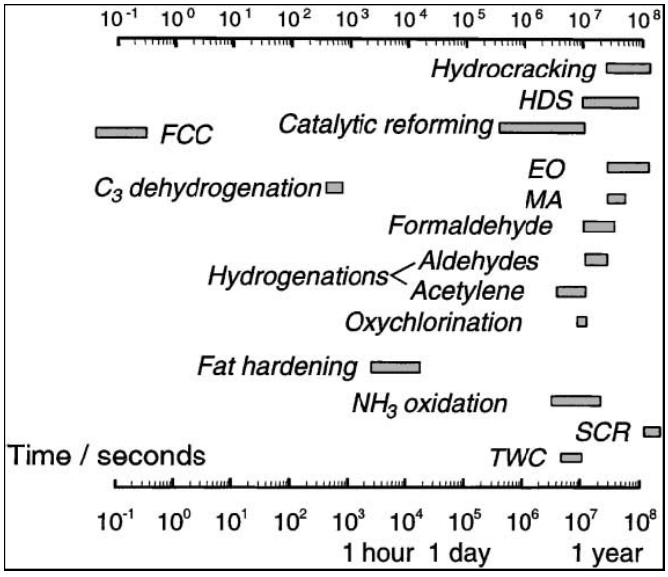

Figure 1. Time scale of deactivation of different catalytic processes

Modeling and simulation is an effective tool to analyse the process engineering systems. It is employed to improve the process efficiency and predict the process performance under different operating conditions. The accuracy of

the modeling effort is strongly related to the parameters involved into the developed model. The two most important parameters which are very influential on the model outputs precision are the rate of reactions and deactivation rate [3, 4]. The latter is considered when the catalytic process suffers from the deactivation phenomenon. Note that most of the industrial catalytic processes deal with the deactivation of the catalyst. Thus, to employ a suitable method which is able to accurately predict the rate of deactivation can improve the accuracy of the mathematical model considered for the catalytic process.

The reasons for catalyst deactivation can be divided into five categories as poisoning, fouling, sintering, mechanical deactivation through attrition or erosion, and corrosion/leaching by the reaction mixture [2, 5]. Therefore, the cause of the catalyst deactivation might originate from different reasons. Moreover, any catalysts depending on the type of process might encounter different mechanisms through the way of deactivation. Thus, to devise a model which ignores the complicated mechanisms of the deactivation and can be employed for the prediction of any catalysts utilized in the catalytic processes is a real and great advantage to the area of the modeling of such processes [6, 7].

Thermally induced catalyst deactivation is a major concern in high temperature catalytic processes. Thermal deactivation might take place due to different reasons. They might be loss of catalytic surface area, loss of support area, reactions/transformations of catalytic phases to non-catalytic phases, and loss of active material. The first two reasons are usually considered as sintering. Sintering phenomenon usually occurs at high temperature reactions, and its rates rely on temperature, reaction atmosphere, and catalyst formulation. Sintering is one of the significant reasons for the deactivation of supported metals catalysts. These precious metal catalysts are widely employed in the industries of petrochemicals, refineries, polymer, chemicals, and pharmaceuticals [8].

There are many studies carried out on the catalytic systems for the derivation of catalyst deactivation rate. Pellegrini et al. [9] did an extensive study on the several aged 0.5 wt.% palladium supported on carbon (Pd/C) catalysts taken from different purified terephthalic acid (PTA) production plants. The results verified that all catalysts experienced Pd sintering regardless of the nature and amount of contaminants. Li et al. [10] studied the positive effect of silica on the stability and activity of Ni/alumina catalyst. The results revealed that the addition of silica efficiently restricted the hydration of alumina support, and inhibited the deactivation of Ni/alumina catalyst. Salmi et al. [11] devised a model and applied it to a batch-wise hydrogenation of sitosterol to sitostanol on a platinum catalyst in the presence of a sulphurous poison. The model was able to determine the behaviour of the system based on the adsorption-reaction-poisoning idea. Sørensen [12] developed a methodology to estimate the deactivation models for industrial catalysts. The model employed the movement of the determined axial temperature profile to obtain the information on the deactivating phenomena. In this model, the temperature profile change determines the deactivation trend. The goal is to cover the calculated progress of the temperature profile through the reactor and deactivation models, estimating the deactivation model by means of non-linear least square. Keyvanloo et al. [13] investigated the impacts of carbon monoxide and hydrogen partial pressures on the deactivation by carbon of a CoPt/AlSi Fischer-Tropsch catalyst.

The objective of this paper is to predict the deactivation rate of industrial catalysts encountering sintering phenomenon utilizing first principle model and the process data. The operating data including the catalytic process information and catalyst specifications are used to devise the relevant model. In the developed model, the operational variables are incorporated into the model, and the catalyst deactivation rate is calculated considering the effects of the variables simultaneously.

Purified terephthalic acid (PTA) is the ninth largest industrial chemical, which is utilized as a raw material for the production of polyester, especially polyethylene terephthalate. Terephthalic acid (TA) is produced via the transition metal-catalyzed oxidation of p-xylene (PX) in acetic acid (AA), which is one of the largest industrial-scale applications of homogeneous catalysis. Co, Mn, and Br are the components of the catalyst [14]. Following reaction shows the PX oxidation:

$$H_3C - C_6H_4 - CH_3 \xrightarrow{Air/(Co-Mn-Br)} HOOC - C_6H_4 - COOH \quad (1)$$

The crude terephthalic acid (CTA) produced from PX oxidation consists of 4-carboxybenzaldehyde (4-CBA), which results in the discoloration of CTA. The purification of CTA is carried out in a fixed-bed reactor (FBR) contained Pd/C catalyst through the hydrogenation of 4-CBA to para-toluic acid (pta) in the water. The hydropurification reaction can be summarized as follows [9]:

$$OHC - C_6H_4 - COOH \xrightarrow{H_2/(Pd/C)} H_3C - C_6H_4 - COOH \quad (2)$$

Pd/C catalyst bears sintering of Pd particles, which is an inevitable reason for the catalyst deactivation. Sintering phenomenon is one the most commonly reasons for the industrial catalysts deactivation [9].

## Materials and Methods

In order to devise the model, the data of the catalyst and operation are required. The following sections deal with the data acquisition of industrial Pd/C catalyst and the hydropurification process.

### Materials: Catalyst and characterization

Samples of deactivated 0.5 wt. % Pd/C catalyst were gathered from different PTA production plants. Inductively coupled plasma (ICP), x-ray powder diffraction (XRPD), extended x-ray absorption fine structure (EXFAS) spectroscopy, transmission electron microscopy (TEM), energy dispersive spectroscopy (EDS), CO chemisorption, and catalyst activity methods were carried out to analyse the deactivation phenomenon of Pd/C catalyst [9].

### Pd surface area

The Pd surface area considerably decreases when the temperature increases. Industrial 0.5 wt. % Pd/C catalyst was used for the Pd surface area measurement. A chemisorption stoichiometry of Pd/CO equal to 2 and a surface Pd atomic density of $1.27 \times 10^{19}$ atoms/m$^2$ were taken into account to estimate the Pd surface area [15].

### Powder analysis

The PTA powder analysis was done in the industrial plant. Samples of the PTA powder were taken at the end of the dryer at certain times of the daily operation. The samples were analysed using the HPLC machine [16].

### Operating data

The operating data including the hydropurification system and the catalyst specifications are required. The operating data can usually be found in the process flow diagram, and the catalyst specifications are included into the operating manual.

### Methods

In this section, the methodology employed for the perdition of the deactivation rate is explained. Figure 2 shows the methodology used for this study.

The operating data including the catalyst specifications are used to calculate the deactivation rate parameter using the following mass balance for the different components, which their values are analysed for each particular-time:

$$C_{i,in} - C_{i,out} + (r_k)\,\rho_B\,\tau\,a(t)\,\eta_k = 0 \quad (3)$$

where $C$ is the component concentration, $r$ is the rate of reaction, $\rho_B$ is the bulk density, $\tau$ is the residence time of the component, $a$ is the deactivation rate parameter, and $\eta$ is the effectiveness factor. For the hydrogenation of 4-CBA, three reactions are considered as depicted in Figure 3 [17].

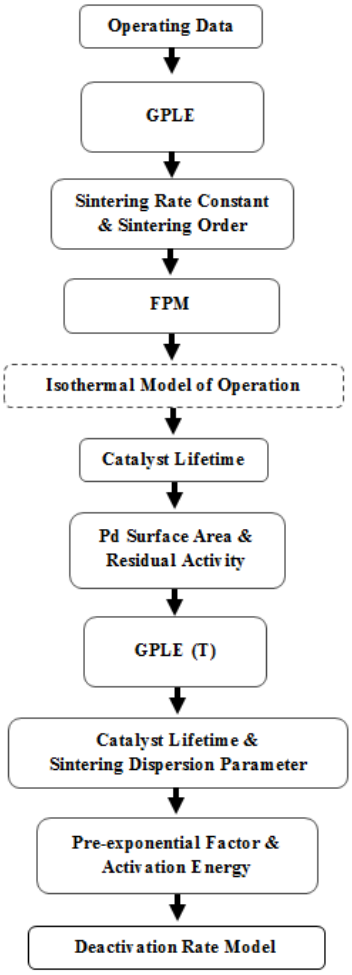

Figure 2. Flowchart for methodology

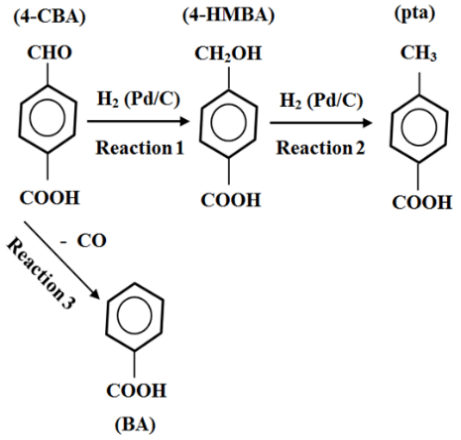

Figure 3. Hydrogenation reactions of 4-CBA

The calculated parameter is incorporated into the general power law expression (GPLE), which is usually used for the presentation of sintering phenomenon for the catalyst. The following equation shows the GPLE [5]:

$$-r_d = -\frac{da}{dt} = k_d a^m = k_{do} exp\left(\frac{-E_d}{R}\left(\frac{1}{T}-\frac{1}{T_R}\right)\right)\left(\frac{S}{S_o}-\frac{S_{eq}}{S_o}\right)^m \quad (4)$$

where $k_{do}$ is the pre-exponential factor; $a$ is the metallic sintering dispersion parameter; $m$ is the sintering order; $k_d$ is the sintering rate constant; $S$ is the active surface of the catalyst; $S_o$ is the initial active surface of the catalyst; $E_d$ is the activation energy; $T_R$ is the reference temperature; and the ratio of $S_{eq}$ to $S_o$ is the residual active surface of the catalyst.

The calculated sintering rate constant and sintering order via writing a code into Matlab2013a environment using nonlinear technique are emerged into a simple deactivation rate model. The preliminary simple model is incorporated into first principle model (FPM) consisting of mass balances of the catalytic process at isothermal condition to predict the catalyst lifetime.

Then, the measured Pd surface area and the residual activity of the catalyst, which is different for different types of catalyst, are incorporated into GPLE to finally derive the catalyst lifetime and sintering dispersion parameter under different operating conditions. Using the obtained values, the pre-exponential factor and activation energy for deactivation are computed, which results in the derivation of the catalyst deactivation rate model.

The whole program was coded into Matlab 2013a environment. First, the partial differential equations were transformed into ordinary differential equation using backward difference method. The resulted equations were solved using *ode45* and *optimset* commands with the tolerance less than $10^{-8}$.

## Results and Discussion

The experimental and modeling results are analysed in this section. To implement the devised strategy, the data of the operation and catalyst are required. The study on the deactivated industrial Pd/C catalyst reveals that the most part of Pd particles are segregated. Moreover, Pd/C catalyst is aged owing to the sintering of Pd and the reduction of Pd active surface area [9]. Figure 4 shows a deactivated Pd/C catalyst. Regarding the measurement of Pd surface area, Pd/C catalyst was thermally treated at different temperatures up to 800 °C. The results showed that Pd experiences the sintering phenomenon. The relation between Pd surface area with the temperature can be found in Pernicone et al. [15]. Regarding the residual activity of the aged catalyst, Table 1 signifies the values of residual activity for different samples of Pd/C catalyst taken from different PTA production plants [9].

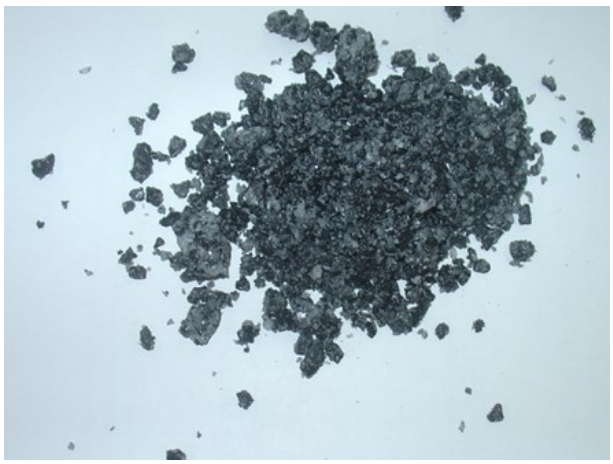

Figure 4. Deactivated Pd/C catalyst taken from the bottom of the reactor

Table 1. Residual activity of different Pd/C catalysts

| Catalyst Sample | Residual Activity (-) |
|---|---|
| A | 0.11 |
| B | 0.09 |
| C | 0.1 |

In this study, the average residual activity was considered as 0.1. PTA powder analysis was done in the PTA plant laboratory, and the results were reported at Azarpour et al. [18]. The operating data and the Pd/C catalyst specifications are shown in Table 2 [16].

Table 2. Operating data of the hydropurification process and Pd/C catalyst specifications

| Item | Value |
|---|---|
| Pressure (barg) | 73.5 |
| Temperature (°C) | 285 |
| Feed flowrate (t $h^{-1}$) | 196 |
| Hydrogen flowrate (kg $h^{-1}$) | 13.2 |
| TA concentration (wt.%) | 23 |
| Catalyst bed length (m) | 7.4 |
| Catalyst bed diameter (m) | 2.8 |
| Particle diameter (mm) | 3.53 |
| Bulk density (kg $m^{-3}$) | 475 |
| Bed void fraction (-) | 0.44 |
| Particle porosity (-) | 0.61 |

Table 3 includes the modeling outputs for different sintering orders along with the model error values. The pre-exponential values and the activation energy for the deactivation were calculated 0.00092 $h^{-1}$ and 5279 J $mol^{-1}$. Table 4 incorporates the trend of the catalyst deactivation through the operation days. It implies that the catalyst is totally deactivated after 360 days of operation. More information on the modeling and the derivation of the deactivation rate of Pd/C catalyst are available in the published papers [19, 20].

Table 3. Sintering order values and the relevant percent relative errors

| Sintering Order | Percent Relative Error (%) |
|---|---|
| 1 | 12.9 |
| 1.4 | 8.3 |
| 1.8 | 3.7 |
| 1.9 | 3.0 |
| 2.0 | 2.6 |
| 2.1 | 2.4 |
| 2.2 | 2.6 |
| 2.6 | 6.1 |
| 3.0 | 9.9 |

Table 4. Pd/C catalyst deactivation trend over the days of operation

| Operation Days | Deactivation Trend (%) |
|---|---|
| 30 | 17 |
| 60 | 27 |
| 90 | 37 |
| 120 | 46 |
| 150 | 55 |
| 180 | 64 |
| 210 | 73 |
| 240 | 82 |
| 270 | 90 |
| 300 | 95 |
| 330 | 98 |
| 360 | 100 |

## Conclusion

A methodology to derive the deactivation rate of the industrial catalysts was given. It is used for the catalysts encountering sintering phenomenon, which is one of the commonest reasons for the industrial catalysts deactivation. The model considers the operating data, catalyst specifications, functionality of catalyst surface area on temperature, and residual activity to structure the model. The study was applied to the industrial Pd/C catalyst, which is used for the hydropurification process in PTA production plant. The model validated against industrial data. For the proposed catalyst, the catalyst sintering order is calculated with less that 3 percent error, and the pre-exponential values and the activation energy for the deactivation were calculated 0.00092 $h^{-1}$ and 5279 J $mol^{-1}$. Moreover, the catalyst is deactivated after around 360 days of operation. The model can be used for the industrial catalysts suffering from sintering phenomenon.

**Abstract**

This study investigates the production of acetone, butanol and ethanol (ABE) in sterilized sludge of palm oil mill effluent (POME) with the addition of glucose by *Clostridium acetobutylicum* NCIMB 619. Glucose concentrations of 5 g/L, 10 g/L and 15 g/L were used with volume percentage of 3% (v/v) and 5% (v/v) for each concentration. The highest ABE production of 9.89 g/L was observed with the addition of 10 g/L glucose with volume percentage of 5% (v/v) compared to 0.49 g/L in the control batch, with highest ABE productivity and yield, $Y_{P/S}$ of 0.14 g/L/h and 1.36 g ABE/g substrate, respectively. Providing culture with 15 g/L glucose with volume percentage of 5% (v/v) was found to reduce the ABE production with lower productivity and ABE yield. The lower production at higher sugar level might be due to sugar inhibition that occurred during the process.

**Keywords**: acetone-butanol-ethanol fermentation, palm oil mill effluent, *Clostridium acetobutylicum*, glucose addition

**Abstrak**

Kajian ini dilakukan bagi menentukan kesan penamabahan glukosa terhadap penghasilan aseton, butanol dan etanol (ABE) di dalam medium mendakan efluen kilang kelapa sawit (POME) steril oleh *Clostridium acetobutylicum* NCIMB 619. Kepekatan glukosa yang digunakan adalah 5 g/L, 10 g/L dan 15 g/L dengan peratus isipadu sebanyak 3% (v/v) dan 5% (v/v) bagi setiap kepekatan. Penghasilan ABE yang paling tinggi iaitu sebanyak 9.89 g/L diperoleh pada penambahan 10 g/L glukosa dengan peratus isipadu 5% (v/v) berbanding 0.49 g/L ABE yang diperoleh di dalam medium kawalan. Produktiviti dan hasil ABE yang diperoleh juga adalah yang tertinggi iaitu masing-masing sebanyak 0.14 g/L/j dan 1.36 g ABE/g substrat. Penambahan 15 g/L glukosa dengan peratus isipadu sebanyak 5% (v/v) didapati mengurangkan penghasilan ABE dengan produktiviti dan hasil ABE yang paling rendah disebabkan oleh perencatan gula yang berlaku semasa proses fermentasi.

**Kata kunci**: fermentasi aseton-butanol-etanol, efluen kilang kelapa sawit, *clostridium acetobutylicum*, penambahan glukosa

## Introduction

The biological production of Acetone-Butanol-Ethanol (ABE) via fermentation have started during the First World War declined 1960s due to introduction of chemical process and higher cost of raw materials [1]. The interest in ABE fermentation was once again increases due to the rapid depletion of petroleum resources, fluctuating fuel price

as well as increase in public awareness on effects of toxic and greenhouse gases produced from fossil fuel combustion [2,3]. All these factors sparked in the attention of alternative fuels namely acetone, butanol and ethanol production through bioprocesses.

The most challenging aspects in ABE fermentation are to make the process economically feasible with zero competition with food crops to obtain raw material resources [4]. One of the solutions is to utilize industrial waste such as palm oil mill effluent (POME) that is readily available in Malaysia and able to reduce the cost of raw material. POME is an industrial waste that comes under the group of lignocellulose biomass consisting of various suspended components including cell wall, organelle and fiber, carbohydrate components which covered hemicellulose and simple sugar, nitrogenous compound including protein and amino acid and free organic acids and all these features make POME as a potential substrate for ABE fermentation [5-7].

POME characteristics as shown in Table 1 depend on the quality of raw material and method of oil processing in palm oil mill [8]. More than 50% of water used in crude oil production eventually ended up as POME [9,10]. POME was generated from three unit processes in a palm oil mill namely sterilization of fresh palm fruit (FFB) (38%), clarification process of extracted crude oil (6%) and hydro cyclone separation (4%) [11]. Based on previous studies, ABE fermentation using POME as media can produce total solvent between 0.30 and 2.66 g/L [7,12-15].

Several studies have reported that limited glucose content in the substrate produced higher amount of organic acids compared to ABE [1]. The cell metabolic shifting to ABE production will not occur if the glucose concentration in the substrate less than 7 g/L [16,17]. Other studies also reported that fermentation with limited presence of glucose resulting in the insufficient of final product of acids to achieve the desired amount of ABE [18-20]. Therefore, the objective of this study was to investigate the effect of glucose addition in ABE production via fermentation using sterilized POME sludge by *C. acetobutylicum* NCIMB 619.

Table 1. Characteristics of palm oil mill effluent (POME) [21]

| **Parameter** | **Average** | **Range** |
|---|---|---|
| pH | 4.2 | 3.4 - 5.2 |
| Biological oxygen demand (BOD) (g/L) | 25000 | 10250 - 43750 |
| Chemical oxygen demand (COD) (g/L) | 51000 | 15000 - 100000 |
| Total solid (g/L) | 40000 | 11500 - 79000 |
| Suspended solid (g/L) | 18000 | 5000 - 54000 |
| Volatile solid (g/L) | 34000 | 9000 - 72000 |
| Oil and grease (g/L) | 6000 | 130 - 18000 |
| Ammoniacal nitrogen (g/L) | 35 | 4 - 80 |
| Total nitrogen (g/L) | 750 | 180 - 1400 |

## Materials and Methods

### Organism, maintenance and inoculum preparation

*C. acetobutylicum* NCIMB 619 was obtained from NCIMB Ltd (Aberdeen, UK) and the laboratory stocks were routinely maintained as spore suspensions in sterile deoxygenated Reinforced Clostridial Medium (RCM) at 37 $^{o}$C. Raw POME obtained from Sime Darby's East Palm Oil Mill in Carey Island was centrifuged at 2000 rpm for 5 minutes to separate the supernatant and the sludge. Sterilization of the sludge was conducted using autoclave at 121 $^{o}$C for 15 minutes.

### Fermentation process and analysis

The fermentation process was carried out anaerobically in 250 mL conical flask at 37 $^{o}$C for 72 hours with working volume of 170 mL without agitation and no pH correction was made. Glucose concentration of 5 g/L (POME5),

10 g/L (POME10) and 15 g/L (POME15) were used with volume percentage of 3% (v/v) and 5% (v/v) for each concentration. The glucose was added into sterilized POME sludge and deoxygenated using purified nitrogen gas for 15 minutes to achieve the anaerobic condition. Samples for analysis of pH, cell concentration, reducing sugar and solvents production were taken at regular interval. The pH values were determined using pH meter, while cell concentration and reducing sugar in the samples were determined by volatile suspended solid (VSS) and Miller methods [22], respectively. The concentrations of acetone, butanol, ethanol and organic acids were measured by gas chromatography (Eppendorf, German) that is equipped with flame ionization detector (FID) with initial operating temperature of 40$^{o}$C for 8 minutes and then increased to 130 $^{o}$C at the rate of 4 $^{o}$C/minute for 2 minutes. The temperature of injector and detector was operated at 250 $^{o}$C with helium as the carrier gas.

**Liquid-liquid extraction**

Liquid-liquid extraction was conducted to recover ABE from the fermentation broth before the samples were injected into gas chromatography. Oleyl alcohol was used as solvent which has been reported as a potential separation solvent for ABE [23]. Oleyl alcohol was added into the sample in centrifuge tube at the ratio of 1:1 (oleyl alcohol-sample). The solution was then mixed using vortex mixer at 1600 rpm for 1 minute in order to increase the interaction between oleyl alcohol and the sample. To complete the phase separation, the solution was centrifuged at 2000 rpm for 5 minutes. Assuming the organic and aqueous phase were separated completely, all samples were diluted with 99.5% dichloromethane (DCM) at the ratio of 0.5:1 (DCM:sample). Samples from both phases were mixed by vortex mixer at 1600 rpm for 1 minute to ensure the interaction between samples and DCM occurred effectively. A complete mixing will produce two layers of liquid due to the different density. The bottom layer was taken and filtered using 0.2 µm nylon syringe filter before being transferred to sealed GC vial tubes for further analysis.

## Results and Discussion

**ABE production with the addition of 3% (v/v) glucose**

The summary of total ABE and organic acids production is presented in Table 2 and Figure 1 with ethanol as the major product. It also shows that the production of ABE increased as the glucose concentration increased where in the control batch, only 0.49 g/L ABE produced with a yield, $Y_{P/S}$ of 0.04 g ABE/g substrate and productivity of 0.007 g/L/h. POME15 produced the highest amount of ABE which is 3.44 g/L with the production of acetic acid and butyric acid of 123.9 g/L and 1.17 g/L, respectively. POME5 produced the lowest amount of ABE (2.84 g/L) and produced the highest amount of organic acids which is 165.7 g/L with 163.4 g/L of acetic acid and 0.34 g/L of butyric acid. All three medium produced a high concentration of acetic acid. ABE production was related to the activity of proteolysis enzyme that could affect the degradation of enzymes activity that involved in ABE fermentation [24]. The activity of proteolysis enzyme also might degrade the activity of tiolase enzyme that can change acetyl-CoA to acetoacetyl-CoA in the culture which is important in the production of acetone and butanol [25].

Table 2. Summary of ABE fermentation performance with the addition of 3% (v/v) glucose

| Parameter | Glucose Concentration | | |
|---|---|---|---|
| | 5 g/L | 10 g/L | 15 g/L |
| Initial pH | 4.26 | 4.27 | 4.30 |
| Max. cell concentration (g/L) | 63.5 | 59.0 | 58.0 |
| Total ABE (g/L) | 2.84 | 3.30 | 3.44 |
| A:B:E ratio | 0.2:0.6:9.2 | 0.3:0.7:9 | 0.3:0.9:8.8 |
| Total organic acids (g/L) | 165.7 | 106.0 | 125.1 |
| $Y_{P/S}$ (g ABE/g substrate) | 0.57 | 0.81 | 0.82 |
| $Y_{X/S}$ (g cell/g substrate) | 0.71 | 0.98 | 0.71 |

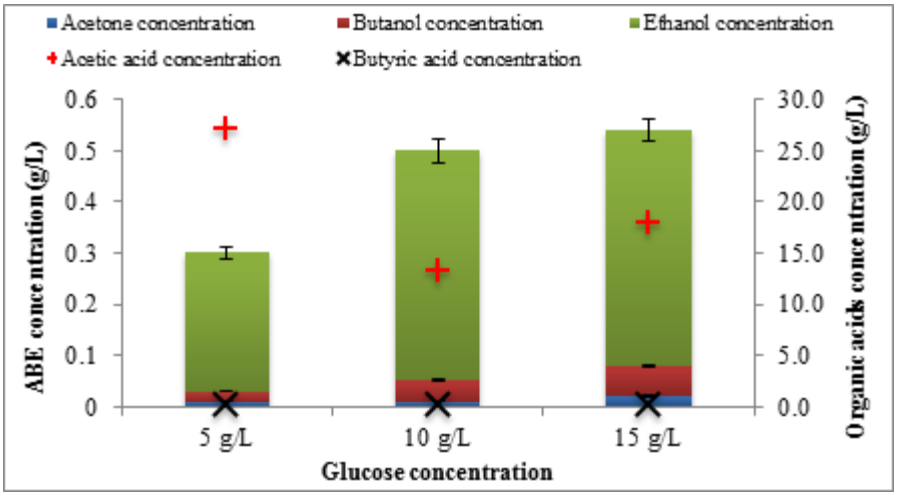

Figure 1. Maximum concentration of ABE and organic acids with the addition of 3% (v/v) glucose

**ABE production with the addition of 5% (v/v) glucose**

Total production of ABE and organic acids with the addition of 5% (v/v) glucose was summarized in Table 3 and Figure 2 with ethanol as the major product. For POME5 and POME10, the maximum ABE concentration of 0.50 g/L and 0.52 g/L, respectively was collected after 48 hours of fermentation while for POME10, maximum ABE concentration of 1.95 g/L was obtained after 72 hours of fermentation. POME5 produced 30.6% and 86.7% more acetone compared to POME15 and POME10.

Other than that, POME5 also produced 0.60 g/L butanol which is two folds higher compared to POME15 that only produced 0.26 g/L and 45.8% more butanol than that in POME10. At the same time, POME10 produced the highest concentration of ethanol which is 9.44 g/L while POME5 and POME15 produced 2.87 g/L and 1.88 g/L ethanol, respectively. Total ABE of 9.89 g/L produced in POME10 was the highest with total organic acids of 40.05 g/L. POME15 produced the lowest concentration of ABE (2.82 g/L) with organic acids concentration of 6.83 g/L.

Table 3. Summary of ABE fermentation performance with the addition of 5% (v/v) glucose

| **Parameter** | **Glucose Concentration** | | |
|---|---|---|---|
| | **5 g/L** | **10 g/L** | **15 g/L** |
| Initial pH | 4.30 | 4.48 | 4.31 |
| Max. cell concentration (g/L) | 63.5 | 59.0 | 62.3 |
| Total ABE (g/L) | 4.45 | 9.89 | 2.82 |
| A:B:E ratio | 2.2:1.3:6.5 | 0.13:0.33:9.5 | 2.4:0.9:6.7 |
| Total organic acids (g/L) | 0.14 | 40.05 | 6.83 |
| $Y_{P/S}$ (g ABE/g substrate) | 0.62 | 1.36 | 0.28 |
| $Y_{X/S}$ (g cell/g substrate) | 0.84 | 0.76 | 1.63 |
| Productivity (g/L/h) | 0.06 | 0.14 | 0.04 |

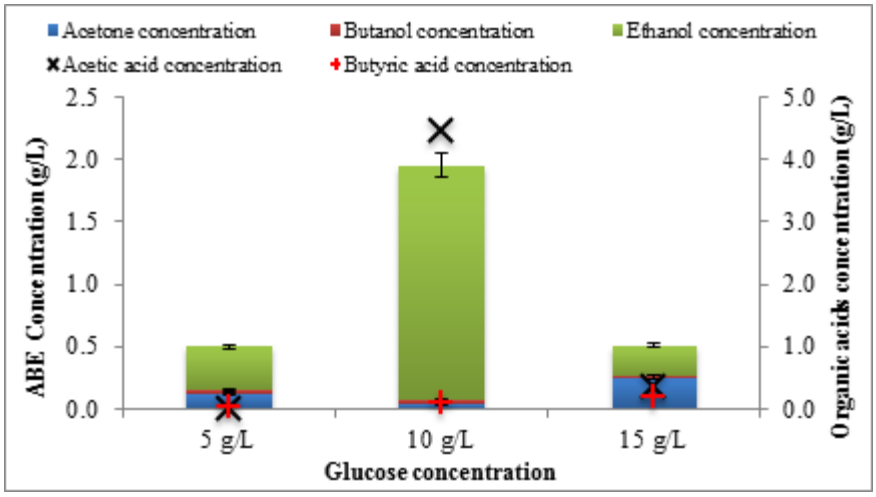

Figure 2. Maximum concentration of ABE and organic acids with the addition of 5% (v/v) glucose

**Comparison of ABE fermentation performance with the addition of 3% (v/v) and 5% (v/v) glucose**

Based on Figure 3, it was found that with the addition of 3% (v/v) glucose, enhanced the ABE production where in control batch, only 0.49 g/L ABE was produced with yield, $Y_{P/S}$ of 0.04 g ABE/g substrate and productivity of 0.007 g/L/h (Data was not shown). POME5 produced 2.84 g/L ABE with yield, $Y_{P/S}$ of 0.57 g ABE/g substrate. POME10 and POME15 produced 3.30 g/L ABE with yield, $Y_{P/S}$ of 0.81 g ABE/g substrate and 3.44 g/L ABE with yield, $Y_{P/S}$ of 0.82 g ABE/g substrate, respectively.

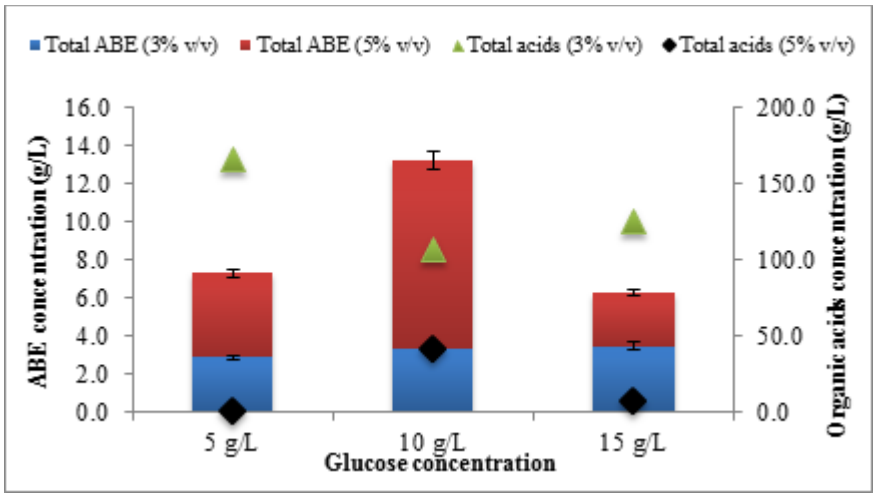

Figure 3. Comparison of ABE performances with the addition of glucose

However, ABE production was decreased at 15 g/L glucose with the addition of 5% (v/v) where high level of sugar in the medium was found to inhibit the production of ABE [26]. ABE fermentation using a high carbon source concentration may be controlled by the mass transfer rate, where high concentration carbon source could increase the viscosity of the culture and reduced the rate of mass transfer altogether [27].

Other than that, POME10 produced the highest ABE concentration which is 9.89 g/L with yield, $Y_{P/S}$ of 1.36 g ABE/g substrate while POME5 and POME15 produced 4.45 g/L and 2.82 g/L ABE, respectively where POME15 produced the lowest yield, $Y_{P/S}$ of 0.28 g ABE/g substrate. It was also found that the addition of 3% (v/v) glucose produced the highest amount of organic acids that might be due to the acid crash that occurred when the un-dissociated acids in the culture was more than 57-60 mmol/L [28]. Furthermore, the results obtained from this study are comparable to previous reports as shown in Table 4.

## Conclusion

The addition of glucose in sterilized POME media was found to increase the ABE production. Based on the results of this study, the production of ABE and organic acids is higher as the glucose concentration increasing using 3% (v/v). However, for the glucose addition of 5% (v/v), the high level of sugar present in the culture was found to inhibit the ABE production. Glucose concentration of 10 g/L produced the highest concentration of ABE (9.89 g/L) with product yield, $Y_{P/S}$ of 1.36 g ABE/g substrate while glucose concentration of 15 g/L produced the lowest concentration of ABE and product yield, $Y_{P/S}$ with 2.82 g/L and 0.28 g ABE/g substrate, respectively.

**Abstract**

Obtaining high purity of xylitol is a stone corner in medicine industries. Many conventional techniques (crystallization and adsorption) were used for xylitol purification from fermentation media. Recently, membrane technology received a great attention due to its high performance in xylitol purification. Among renowned copolymers used for polymer blending to produce membranes, pluronic is receiving much attention due to its strong hydrophilic characteristic and could work as pore former and surface modifier. Polyethersulfone (PES) polymer has been reportedly used for polymer blending as it possesses mechanical and chemical stabilities. Therefore, this work demonstrates the preparation of nanofiltration (NF) membrane using: (1) PES and (2) PES blended with 1.71% and 5% of Pluronic (F127), via phase inversion method. All fabricated membranes were subjected to investigations such as contact angle for hydrophilicity and water and solution flux for membrane performance. The findings showed increasing in water flux from 24.6 L/m$^2$.h to 70.2 L/m$^2$.h as 5% of Pluronic added. Further, the hydrophilicity improved from 80.1 ± 1.93$^o$ to 72 ±0.3$^o$ and 67.6 ± 0.72$^o$ when 1.71 and 5% of Pluronic F127 added respectively. Therefore, the addition of Pluronic f127 has a great impact on PES membrane for xylitol permeation.

**Abstrak**

Memperoleh ketulenan yang tinggi bagi xilitol merupakan salah satu batu loncatan di dalam industri perubatan. Terdapat banyak teknik konvensional (penghabluran dan penjerapan) yang telah digunakan untuk penulenan xilitol daripada media penapaian. Baru-baru ini, teknologi membran banyak menarik perhatian dengan prestasinya yang bagus dalam penulenan xilitol. Antara kopolimer yang sering digunakan untuk campuran polimer dalam penghasilan membran adalah pluronik yang telah menerima perhatian kerana sifat hidrofiliknya dan boleh membantu dalam pembentukan liang serta pengubahsuai permukaan membran. Polimer polietersulfon (PES) telah dilaporkan digunakan untuk polimer campuran kerana ia mempunyai kestabilan mekanikal dan kimia. Oleh itu, kerja ini menunjukkan penyediaan membran penurasan-nano (NF) menggunakan: (1) PES dan (2) PES dicampur dengan 1.71% dan 5% Pluronik (f127), melalui kaedah fasa songsangan. Kesemua membran yang dihasilkan dicirikan menggunakan sudut sentuhan untuk sifat hidrofilik dan fluks air serta larutan bagi prestasi membran. Hasil kajian menunjukkan peningkatan dalam fluks air daripada 24.6 L/m$^2$.h kepada 70.2 L/m$^2$.h apabila 5% Pluronik F127 ditambah. Selanjutnya, sifat hidrofilik membran bertambah baik iaitu daripada 80.1 ± 1.93$^o$ kepada 72 ± 0.3$^o$ dan 67.6 ± 0.72$^o$ apabila 1.71 dan 5% Pluronik F127 ditambah. Didapati penambahan Pluronik F127 memberi kesan yang besar ke atas membran PES untuk penyerapan xilitol.

**Kata kunci:** polietersulfon, pluronik F127, xylitol, membran NF, penulenan

## Introduction

Xylitol is classified as a non-cariogenic, beside as a sweetener, it becomes valuable for those who suffer caries and diabetic [1]. This non-cariogenic property makes xylitol an important product in cosmetic, pharmaceutical and food industries [2]. The upstream processing of xylitol production can be achieved by chemical and biotechnological methods [3, 4], while the downstream xylitol purification can be accomplished by crystallization, adsorption and membrane technology [2, 5]. Nanofiltration (NF) membrane has been targeted to be used by many researchers due to its molecular weight cut-off (MWCO) ranges from 200 – 2000 g/mol [6] that will be suitable to purify xylitol (152.15 g/mol) [1, 5]. To fabricate this NF membrane, polyethersulfone (PES) was reportedly used due to its advantages such as easy to synthesize, high chemical resistance and vast pH tolerance [7, 8]. Further, PES arise an outstanding oxidative stability [9]. However, the most imperfection of using PES is the lack of hydrophilicity of this polymer, which could leads to fast membrane fouling [10]. This drawback can be minimized by blending hydrophilic copolymer to PES membrane matrix such as polyvinyl pyrrolidone (PVP), polyethylene glycol (PEG) and Pluronic. Among these copolymers, Pluronic F127 was considered as a good pore forming agent and surface modifier because of its chemical stability [11, 12].

In recent years, poly (propylene oxide) (PPO) Pluronic triblock copolymers of poly (ethylene oxide) and (PEO) have worked as dual functions as pore former and surface modifier in membrane fabrication [13]. The Pluronic additive (PEO–PPO–PEO) segregated during phase inversion process to the polymer/water interface because of the low interfacial energy between the water and hydrophilic segment, as the water-insoluble, hydrophobic segment of the copolymer promptly anchored in the polymer matrix. [14]. The possible reason is that Pluronic f127 is perfect surfactant, as the surface chemistry of Pluronic F127/PES blend membrane might be reconstructed to reduce the interfacial free energy [15]. PEO chain introduced to the membrane matrix as hydrophilic part where works as adsorption resistant (antifouling) of the molecules as well as hydrophilicity enhancer. i.e. surface modifier. Meanwhile PPO segments represented the hydrophobic units of Pluronic copolymers and distributed closer to the centre of membrane pores [10, 16, 17]. Overall, there are two main processes (presented in Figure 1) lead to formation of PES/ Pluronic F127 via: (1) Aggregation of hydrophilic units which were responsible of surface modifier, and (2) Micellization of hydrophobic units that form the membrane pores.

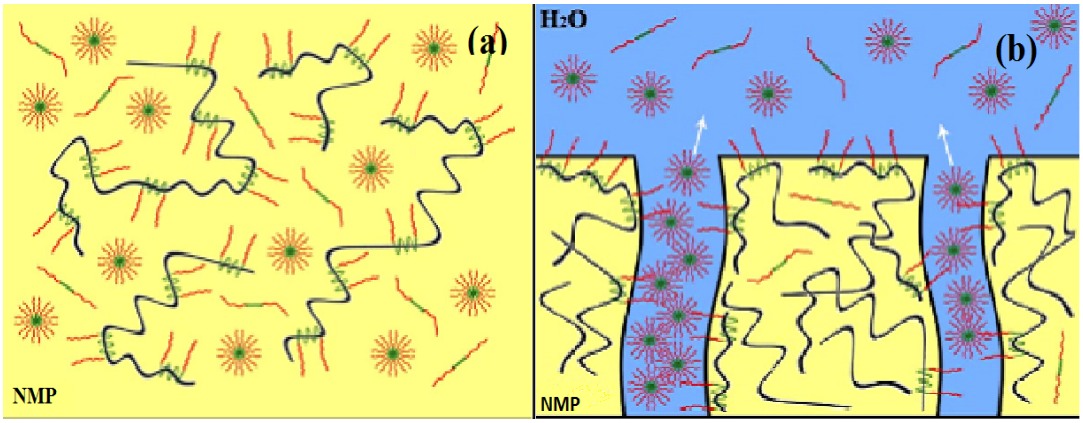

Figure1. Dual function of Pluronic F127 in the membrane formation process via: (a) blending of polymer with Pluronic F127 in a homogeneous dope solution, (b) immersing the membrane in a water bath to form the surface structure and pores in membrane [16].

In most NF membranes synthesis reported, the fabrication via phase inversion process was repeatedly found in the literature due to its simplicity for certain input parameters e.g. using water as the non-solvent [7, 18]. The incorporation of pluronic at a specific ratio to the main polymer was reported [10, 11, 15] where the main polymer became the backbone of the membrane structure and pluronic acted as the co-polymer. It was also reported on the addition of different additives composition depending on their screening work or optimization conducted, e.g.

Zhang et al. [15] used 20 to 100% of pluronic, the 20% was the best composition for dyes rejection. Chao et al. [13] studied the effect of 1 to 9% of pluronic on membrane morphology and found that the water flux increased as well as pores and porosity. Ng et al. [19] found that 1.71 % of polyvinyl alcohol (PVA) is a significant composition to achieve high salt rejection, while Loh et al. [14] investigated systematically the effect of adding 5, 10 and 15% of pluronic on pore forming of PES membrane and it was found that the best composition is at 10% as it achieved the highest pure water flux. On the other side, different composition of additives added to the solution could give a significant impact on the mechanical properties of the synthesized membrane as reported by Ng et al. [19]. Based on the studies, two different composition of Pluronic F127 at 1.71 and 5% are considered for the fabrication of the membrane using PES and the flux/ rejection of xylitol separation difference is measure.

Thus the aim of this study was to fabricate NF membranes from pure PES and PES blended with Pluronic F127 in 1.71 and 5 % as reported in [14, 19] via phase inversion method. Next these membranes were characterized to investigate the pure water flux (PWF), contact angle, separation performance of xylitol mixture solution and the rejection test of xylitol mixture solution.

## Materials and Methods

### Materials

Polyethersulfone (PES) granule, (Good fellow) as the membrane main polymer. Pluronic F127 (Nanoamor) has been used as the copolymer. N-methyl-2-pyrrolidone (NMP) with analytical purity 99.7% (Fluka, Germany) was used as solvent and distilled water was used as non-solvent. Xylitol, xylose and arabinose powder of 99% (Acros Organic) were used as received.

### Membrane preparation

The three NF membranes were fabricated via phase inversion under different preparation parameters as tabulated in Table 1. Initially, PES granules were dried at 60 °C for 72 hours to remove moisture. Each doped solution was stirred for 4 hours to make a homogenous solution. Next, to avoid pinholes and highlights on the membranes, the homogeneous solution was left for 24 hours to release air bubble. Then, the casting machine Elcometer 4340 Automatic Film Applicator with the speed at 76 mm/s was used to cast the membranes. A suitable amount of suspension was poured on a glass sheet and cast by casting knife set at 200 µm at room temperature. Finally, the fabricated membranes were left for 30 s for evaporation before submerged in deionized water for 2 hours for solvent exchange purposes. The synthesized membranes were stored in distilled water at ambient temperature prior to use.

Table 1. Polymer doped solution composition and parameters

| PES (wt. %) | Pluronic f127 (wt. %) | NMP (wt. %) | Temperature ($^{o}$C) | Stirring speed (rpm) |
|---|---|---|---|---|
| 18 | - | 82 | 60 | 450 |
| 18 | 1.71 | 82 | 60 | 450 |
| 18 | 5 | 82 | 60 | 450 |

### Membrane characterization: Contact angle

The contact angle was used to find out the changes in the hydrophilicity to figure out the hydrophilicity of PES and PES/Pluronic F127 membranes. All membranes were dried at room temperature for 48 hours followed by measuring the contact angle using the contact angle goniometer (Rame-Hart model 200) equipped with DROPimage Software with an accuracy of 60.10 °. The conditions used to measure the contact angle were under deionized water and air at (25 – 28 °C).

**Pure water flux (PWF)**

Dead-end permeation cell (Sterlitech HP4750, Sterlitech Corporation, USA) was used to evaluate the pure water flux (PWF) of the membranes. The schematic diagram of the dead-end cell is illustrated in Figure 2. The filtration was performed at three different pressures (4, 6 and 8 bar). The PWF was calculated using equation (1):

$$J = \frac{\mathrm{V}}{\mathrm{A}*\mathrm{t}} \quad (1)$$

As J is PWF (L/m$^2$.h), A is the effective membrane area (14.6 cm$^2$), V is the permeate volume (L) and t is sampling time (h). To minimize experimental errors, 3 to 5 samples were collected and then the average value of Flux was reported.

**Permeate flux performance**

The permeate flux performance was conducted using the dead-end cell (Figure 2) at 4 bar with using xylitol mixture solution (xylitol, xylose, and arabinose) and calculated using equation (1). The concentrations of the components in the xylitol mixture are tabulated in Table 2 and the composition is based on the real xylitol fermentation broth as reported by [2].

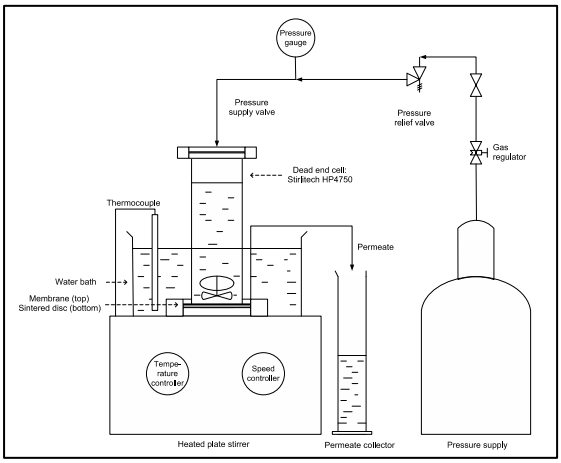

Figure 2. Schematic diagram of the dead end permeation cell [20]

Table 2. Xylitol mixture compositions

| Component | Concentration (g/L) |
|---|---|
| xylitol | 2 |
| xylose | 0.15 |
| arabinose | 0.3 |

**Rejection test**

The xylitol mixed solution rejection was evaluated on the batch type filtration by using dead-end cell. 300 ml of xylitol mixed solution was poured into this cell. The test was conducted at 4 bars. Equation (2) was used to calculate rejection:

$$\mathrm{R}\ \% = (1 - \frac{Cp}{\mathrm{Cf}})*100 \quad (2)$$

where R is the rejection, $C_p$ is the permeate concentration and $C_f$ is the feed concentration.

The standard calibration curve was plotted to calculate $C_p$. High performance liquid chromatography (HPLC) (Ultimate 3000, Thermo scientific, USA) coupled with refractive index detector (RID) was used to obtain the solute concentrations under these conditions: Column type: RPM (Rezex, dimension: 300 x 7.8 mm, USA), mobile phase: DI water, detector: Refractive Index (RI) (Refractomax 520, ERC, USA), flow rate: 0.6 min/ml and Temperature: 60 $^oC$.

## Results and Discussion

### Membrane characterization: contact angle

As clearly seen in Table 3, the pure PES membrane has the highest contact angle at 80.1 ± 1.93$^o$. However, when Pluronic F127 at 1.71% and 5% were incorporated with the PES membrane, the contact angle has dropped to 72 ±0.3$^o$ and 67.6 ± 0.72$^o$, respectively. These results indicated that there was an essential surface modification happened at the membrane upon the copolymer incorporation [16, 21]. Lower contact angle represented higher hydrophilicity. Vatanpour et al. [22] explained that when hydrophilic additives were added to the main polymer during the phase inversion process, the hydrophilic additives migrates spontaneously to the membrane/water interface in order to minimize the interface energy and thus resulted in lower contact angle value.

Table 3. Contact angle of all membranes measured at 25 $^oC$

| Membrane Type | Contact Angle ($^o$) |
|---|---|
| PES | 80.1 ± 1.93 |
| PES/Pluronic 1.71% | 72 ± 0.3 |
| PES/Pluronic 5% | 67.6 ± 0.72 |

It is also possible that the porous structure on the outer membrane surface is the reason in the contact angle variation, not only influenced by polymer/copolymer interaction during the synthesis [11]. It is believed that by enhancing hydrophilicity of the membrane will result in a better membrane resistance to fouling [23]. Fouling can be occurred due to solution molecules adhesion during the filtration process, which can be considered as a major drawback in membrane application.

### Pure water flux

All pure and Pluronic incorporated PES membranes were initially wetted and further subjected to compaction at 12 bars for 30 min until the PWF have achieved steady state. The PWF of pure and blended PES membranes have varied greatly with the addition of different compositions of the copolymer (Pluronic f127). As shown in Figure 3, the water flux of PES membrane was 24.6 L/m$^2$.h at 4 bars, while for PES/Pluronic F127 at 1.71 and 5% membranes increased to 63.8 and 70.2 L/m$^2$.h respectively. This variation might happens due to the change in the hydrophilicity [10] (as discussed in previous section). Vatsha et al. [21] reported that when additive of PVP at 2–10% was added to neat PES membrane, the water flux increased with regards to the improvement in the membrane hydrophilicity, as well as the enlargement of membrane pores after additive addition.

### Permeate flux

The permeate flux was carried out at 4 bars with the volume capacity of 300 mL of xylitol mixture solution to evaluate the flux rate profile for PES membranes incorporated with F127 at 1.71 and 5% in comparison to the pure PES membrane. The concentration of the simulated xylitol mixed solution used in this study exactly followed the work reported by Mussatto [2], which have used real fermentation broth solution to purify xylitol from sugarcane bagasse. Figure 4 showed the improvement of membrane separation after adding 1.71% and 5% of pluronic F127. The permeate flux of xylitol mixture was about 27 L/m$^2$.h for pure PES membrane while PES/Pluronic F127 of 1.71 and 5% membranes could achieved 2-3 times higher fluxes, around 50 and 82 L/m$^2$.h respectively. Zhao et al. [16] reported that the increase of permeate flux of PES/pluronic membrane compared with pure PES membrane was

considerably acceptable due to the adjustment/enlargement of PES/Pluronic membrane pore size comparing to PES membrane. These results is also comparable to the work by Susanto et al. [11].

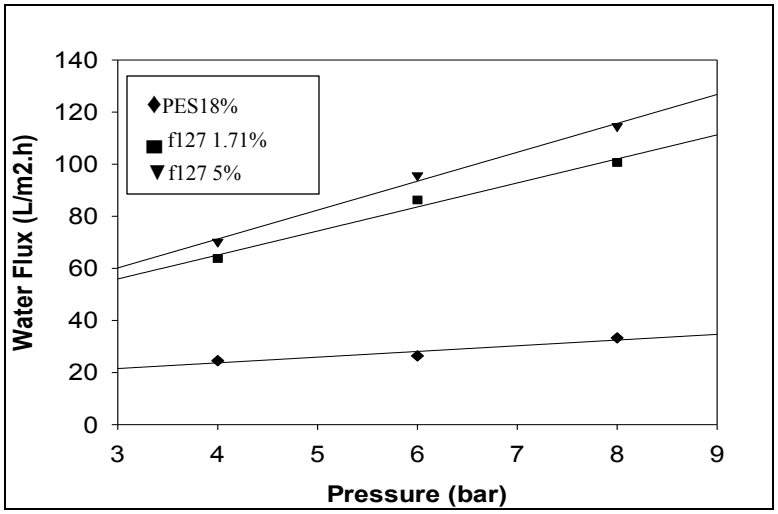

Figure 3. The pure water flux of neat PES and PES/Pluronic F127 (1.71% and 5%) at Temperature: 25 $^{o}$C

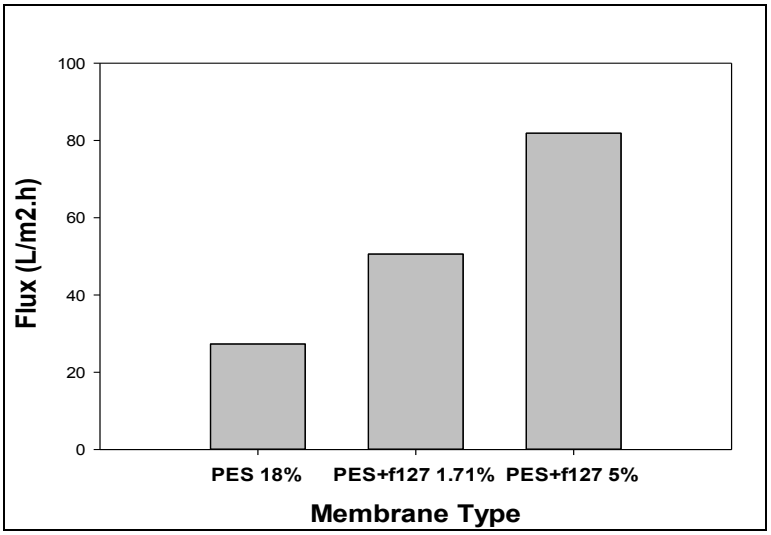

Figure 4. The separation performance of PES and PES/Pluronic membranes. (Stirring speed: 450 rpm, Temperature: 25 °C, Pressure: 4 bar).

However, PES/Pluronic membrane at 5% showed higher normalized fluxes with time compared to pure PES and PES/Pluronic 1.71% membranes as shown in Figure 5. The flux dropped dramatically at the initial run due to the adsorption and/or deposition of xylitol solution droplets on the membrane surface especially in the first few minutes of operation by the permeate flow. Subsequently, PES/Pluronic 1.71% membrane achieved slightly higher than neat PES membrane. The permeate fluxes have enhanced because of Pluronic presence, the higher the pluronic composition, the better flux observed for the synthesized membrane. It can be obviously seen that fouling has occurred in PES membrane even at the starting time due to the membrane property, which is less hydrophilic (80 °)

than the PES/pluronic membrane. This result is agreed by Zhao et al. [16] where PES controlled membrane had a remarkably lower flux recovery ratio (FRR) comparing to PES/Pluronic F127 and the FRR value indicates that the higher FRR value for the membrane, the better antifouling and hydrophilicity properties its possess. The xylitol normalized flux was increased in PES/pluronic membranes due to the function of pluronic as pore forming agent. The flux declined over the filtration time is possibly because of the deposition of sugar molecules on the membrane surface to create concentration polarization/ fouling.

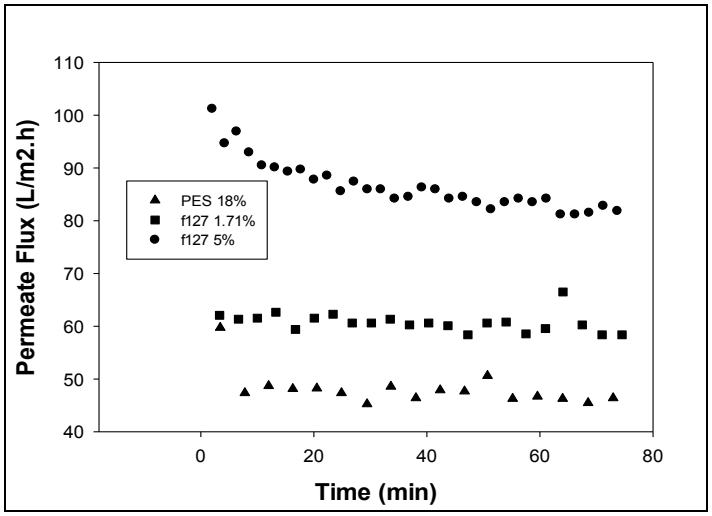

Figure 5. The normalized flux vs time of PES and PES/Pluronic membranes. (Stirring speed: 450 rpm, Temperature: 25 $^{o}$C)

From the analytical side, addition of pluronic to the dope solution during the synthesis process may have affected on the membrane structure, the hydrophilicity of PES was enhanced; this is because of pluronic hydrophilic character [11]. Thus, the fouling phenomenon was mitigated due to the improvement of hydrophilicity. Zhang et al. [15] observed that when pluronic was added to PES membrane, the hydrophilicity improved positively from 68.4° ± 3° to 43.3° ± 2° as pluronic composition increased from 20 to 100% (polymer weight ratios of $W_{f127}$ /$W_{PES}$ are varying in casting solutions ).

**Rejection test**

The rejection test was performed to study the capability of PES and PES/Pluronic F127 membranes at 1.71 and 5% to purify xylitol. It was performed under constant pressure at 4 bars by using xylitol mixture solution. Basically, the calibration curve for three components (xylitol, xylose, and arabinose) was plotted and presented in Figure 6. The calibration curve is required to calculate the permeate concentration, where the equations on the Figure 6 were used for that purposes. Based on the permeate concentration calculated, equation (2) was used to compute the rejection for single PES membrane and for the 1.71 and 5% PES/ Pluronic F127 membranes. $R^2$ value (linearity) was super high (≥ 0.96) for all plots. This indicates the reliability of the calibration curves to be used to measure the xylitol rejection later.

Table 4 illustrated the rejection results of PES and PES membranes incorporated with 1.71 and 5% pluronic. It is clearly marked that PES/Pluronic 5% membrane had the highest rejection 88.1% compared to 1.71% PES/ pluronic F127 membrane at 80.6% and the pure PES membrane rejection was 87.9%. Chao et al. [13] reported that the effects of pluronic composition (1,3,5,7 and 9%) on the PES membrane has increased the BSA rejection from about 70% to around 80% (about 10% difference), and doubled the water flux from 210 to 380 L/$m^2$.h, respectively. Their results are highly corresponded with these findings when 1.71 and 5% of pluronic F127 were added to PES membrane. Similar results were also reported by Susanto et al. [11] upon conducting the comparison study among

PVP, PEG and pluronic with PES. They found that the rejection has declined from 87% (PES membrane) to 72% (PES/ pluronic 10% membrane). This shows that with addition of small amount of pluronic F127 to PES membrane, the xylitol rejection rate slightly decreased compared with PES membrane. Whereas, when pluronic composition increases, the rejection slightly increases and relatively better than single PES membrane. It is suggested that PPO units effectively work as pore forming agent due to its hydrophobic character. Moreover, the micellization process is responsible in forming the membrane pores and thus the pore diameter of PES/ Pluronic F127 membrane enlarges. The proposed mechanism is that, during the solvent exchange process, the micelles of Pluronic F127 trap in the skin layer. The interaction between PES and Pluronic F127 micelles lose the skin layer of the shaped membranes. Upon extraction of the hydrophilic Pluronic F127 micelles from the membranes via non-solvent during phase inversion, the regions left in the membranes control the pore size of it. Therefore, the pore radius of the skin layer is strongly affected by the size of Pluronic f127 micelles, which establishes an indirect judgment for pore structure changes, as observed in this work. In addition to that, Kochkodan et al. [24] found that the significant pore enlargement in the membrane surface leads to an increase in the water flux and loss in rejection of bovine serum albumin (BSA).

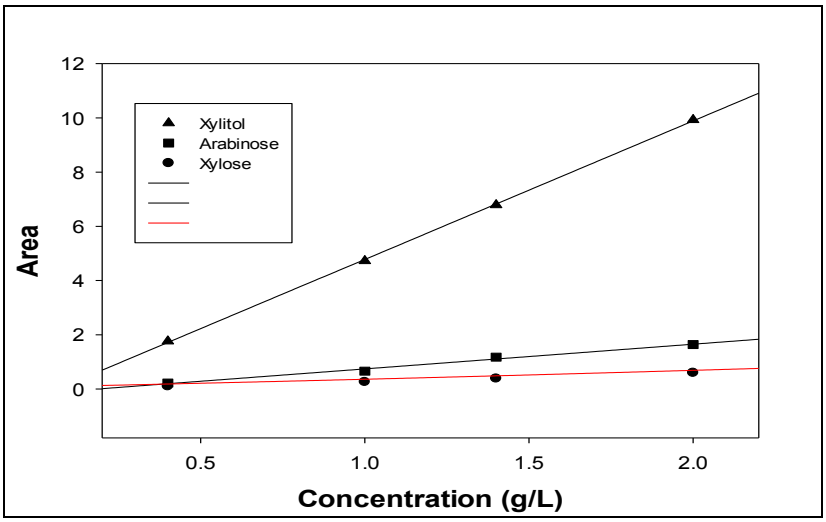

Figure 6. The calibration curve of xylitol, xylose, and arabinose

Table 4. The xylitol, arabinose and xylose rejection of all membranes (T : 25 $^{o}$C, Stirring speed : 450 rpm, P: 4 bar)

| Membrane Type | Xylitol Rejection | Arabinose Rejection | Xylose Rejection |
|---|---|---|---|
| PES | 87.9 | 82.7 | 74.7 |
| PES/Pluronic 5% | 88.1 | 82.3 | 76 |
| PES/Pluronic 1.71% | 80.6 | 76.3 | 66.7 |

## Conclusion

The hydrophilic copolymer of Pluronic F127 at two different compositions was successfully incorporated to PES membrane as pore forming agent and surface modifier. This PES blended with Pluronic F127 membranes at 1.71 and 5% were compared with pure PES membrane. All membranes were fabricated via phase inversion method to purify the desirable xylitol from simulated biomass fermentation broth. The PWF and permeate flux increased to 2-3 times in presence of Pluronic F127 due to the enlargement of pore diameters and modification of the membrane

surface by pluronic presence. Whereas, the rejection slightly decreased at the lower amount of pluronic (1.71%) used which due to PPO role of forming the membrane pores. Characterization for the contact angle of the membranes found that the hydrophilicity improved because of the presence of hydrophilic PEO unite properties in pluronic F127. Both hydrophilic PEO segments and hydrophobic PPO units respectively work as surface modifier and pore former in pluronic.

**Abstract**

Low yields and productivity in fermentation industry usually due to poor quality of seed culture (inoculum). As the first stage in the fermentation process, inoculum consistency in terms of size and quality is clearly important for high yield of enzymes production. Selection of microorganism also plays an important role in improving the productivity. Fungi type of white rot basidiomycetes species is a well-known cellulolytic enzymes producer and capable to degrade many types of lignocellulosic biomass. Cellulolytic enzymes produced from white rot fungi, *Pycnoporus sanguineus* (PS) were investigated. The PS cultured on different agar media and parameter conditions of seed culture preparation in liquid medium broth were compared. Seed culture conditions of PS were influenced by many factors such as type of medium used for fungal growth, temperature, incubation time in liquid medium and subculture time on agar medium. PS was full-grown on potato dextrose agar (PDA) on day 5 compared to malt extract agar (MEA) on day 7. Seed culture conditions was determined using standard liquid medium, potato dextrose broth (PDB) at constant temperature (30 °C), agitation speed (150 rpm) and pH (4.8) for duration of seven days using two different subculture of PS that were grown for five and seven days. It was found that the five days' subculture of PS shown 3.93% higher cell dry weight of fungal biomass (3.44 g/L on day 5) and higher cellulolytic enzymes activity; 95.49% (FPase), 3.14% (CMCase), 7.71% (exoglucanases) and 14.93% (xylanases). Maximum cellulolytic enzymes were found after 48 hours' incubation with filter paper activity (FPase) of 1.79 U/mL, carboxymethyl cellulase activity (CMCase) of 3.36 U/mL, exoglucanase activity (Avicelase) of 0.59 U/mL and xylanase enzymes activity of 0.66 U/mL. Reducing sugars concentration decreased from day 1 to 7 due to consumption of sugars for fungal growth. Seed culture conditions were strongly influenced by subculture and incubation time in liquid medium to produce high yield of cellulolytic enzymes from PS.

**Keywords**: white rot fungi, *Pycnoporus sanguineus*, seed culture, cellulolytic enzymes, fermentation

**Abstrak**

Hasil dan produktiviti yang rendah dalam industri fermentasi biasanya disebabkan oleh kultur benih (inokulum) yang kurang berkualiti. Pada peringkat pertama proses fermentasi, konsistensi inokulum dari segi saiz dan kualiti sangat penting bagi pengeluaran enzim yang tinggi. Pemilihan mikroorganisma juga memainkan peranan penting dalam meningkatkan produktiviti. Jenis kulat pereput putih dari spesies basidiomycetes sangat terkenal sebagai pengeluar enzim selulolitik dan ia mampu untuk mengurai pelbagai jenis bahan lignoselulosa. Dalam kajian ini, enzim selulolitik dihasilkan daripada kulat pereput putih, *Pycnoporus sanguineus* (PS) yang dihidupkan di atas agar dan perbandingan parameter berbeza penyediaan kultur benih dalam medium cecair dikaji. Kultur benih PS dipengaruhi oleh pelbagai faktor seperti jenis medium yang digunakan untuk pertumbuhan kulat, suhu, masa pengeraman di atas medium agar dan di dalam medium cecair. Pertumbuhan maksimum PS di atas agar kentang dekstrosa (PDA) dicapai pada hari ke-lima berbanding dengan agar ekstrak malt (MEA) pada hari ke-tujuh. Kultur benih ditentukan dengan menggunakan medium piawai iaitu medium kentang dekstrosa (PDB) pada suhu malar (30 °C),

kelajuan pengadukan (150 rpm) dan pH (4.8) untuk tempoh masa tujuh hari menggunakan dua kultur PS berbeza yang dieram selama lima dan tujuh hari. Didapati bahawa kultur PS 5 hari menunjukkan berat kering sel kulat yang lebih tinggi iaitu 3.93% (3.44 g/L pada hari ke-lima) dan aktiviti enzim selulolitik lebih tinggi; 95.49% (FPase), 3.14% (CMCase), 7.71% (ekoglukanase) and 14.93% (xilanase). Pengeluaran enzim selulolitik maksimum diperolehi selepas 48 jam pengeraman dengan aktiviti kertas turas (FPase) 1.79 U/mL, aktiviti karboksimetil selulase (CMCase) 3.36 U/mL, aktiviti eksoglukanase (Avicelase) 0.59 U/mL dan aktiviti enzim xilanase 0.66 U/mL. Selain itu, kepekatan gula penurun berkurang dari hari 1-7 disebabkan oleh penggunaan gula untuk pertumbuhan kulat. Ini menunjukkan bahawa keadaan inokulum dipengaruhi oleh jenis kultur dan masa pengeraman dalam medium cecair untuk pengeluaran hasil enzim selulolitik yang tinggi dari PS.

## Introduction

Cellulolytic enzymes productions have been studied extensively throughout the world. These enzymes produced using microorganisms either bacteria or fungi. Commercially, fungi types from *Trichoderma* species have been used for production of cellulase [1]. Today, studies have been carried out to discover other potential of fungi that can produce high cellulolytic enzymes. These enzymes responsible to convert cellulose into glucose; fermentable sugars that will be used in fermentation industry to produce biofuel and value added products. Cellulolytic enzymes consist of complete cellulase system that classified into three major classes; endoglucanases, exoglucanases and β-glucosidases [2]. All enzymes have their specific roles; endoglucanases act randomly on soluble and insoluble cellulose chains, exoglucanases release the cellobiose from the reducing and non-reducing ends of cellulose chains and β-glucosidases release glucose from cellobiose release by exoglucanases [3].

*Pycnoporus sanguineus* (PS) is one of basidiomycetes species of white rot fungi also known as wood decaying fungi that has highly potential for lignocellulolytic enzymes production. It could degrade the lignocellulosic component of cellulose, hemicellulose and lignin. It acts as a biological pre-treatment as well as to produce value added products [4]. PS has a promising capacity with multi applications, so that it can be a feedstock bio refinery sector as well as for enzymes industry [5]. PS is also a good and thermostable cellulase producer that can maintain more than 90% of activities above temperature of 90 $^{\circ}$C [6]. It can grow at moderately high temperature (37 $^{\circ}$C) [1]. This fungus was applied in agro-industrial waste because of their good results in many applications [7].

In fermentation industry, there are a few stages involved in enzymes production starting from subculture of microorganism on agar medium followed by seed culture or inoculum preparation before proceed for the production culture of enzymes production. Efficient enzymes will be the main catalyst for fermentable sugar production in fermentation industry. Since degradation process of lignocellulosic biomass using enzymes is slow and less economical, new methods have been explored to enhance the fermentable sugars for high yield production [8]. One of the factors is during seed culture or inoculum preparation stage that will be the key for the enhancement of product yield. The critical step for enzymes production is seed culture stage and the selection of its correct conditions will influence the yield of cellulolytic enzymes produced. There are many factors influenced the seed culture conditions such as type of medium used for fungal growth, temperature, pH, incubation time in liquid medium and subculture time on medium agar. Production of enzymes using PS at temperature ranging from 30 to 40 $^{0}$C can maintained its activity up to 85% and the optimum pH is 5 [1]. pH of medium is important since it plays an important role in fungal growth by inducing its morphological structural and enzymes secretion [7].

The aimed of this study is to determine the seed culture conditions of PS as inoculum to produce cellulolytic enzymes. Identification of maximum cellulolytic enzymes activities was carried out using different subcultures of PS to determine the effect of subculture incubation time on product yields.

## Materials and Methods

### Fungal strain

White rot fungi PS was obtained from the Wood Mycology Laboratory, Forest Research Institute Malaysia. It was collected from a dead tree in the FRIM Campus. In the laboratory, the fungus was firstly grown on Petri dish containing two different agar media namely, Malt extract agar (MEA)(12.75 g/L maltose, 2.75 g/L dextrin, 2.35 g/L

glycerol, 0.78 g/L peptone and 15.0 g/L agar) and Potato dextrose agar (PDA)(4 g/L potato starch, 20 g/L dextrose and 15 g/L agar) to determine the mycelia growth diameter at temperature of 30 °C for seven days.

**Seed culture condition**

For the seed culture preparations, 1 $cm^3$ mycelia disc cut of PS using sterilized cork borer from the petri dish were inoculated into seven shake flasks containing 100 mL of PDB. The experimental works were carried out in triplicates. The liquid medium used for seed culture preparation in this experiments consist of 4 g/L potato and 20 g/L dextrose, with pH of medium is 4.8. The seed culture was incubated at temperature of 30 °C and was shaken at 150 rpm [9]. The sampling of seed culture broth was carried out every day. The flask containing mycelia of fungi was filtered using filter paper to determine the cell dry weight of fungal biomass. The fungal biomass was oven dried at 60 °C in an oven for 24 hours until reached a constant weight. The filtrate collected known as supernatant was further analyzed for its reducing sugars content and cellulolytic enzymes activities.

**Reducing sugars and enzymatic assays**

Reducing sugars and enzymatic assays were assayed from the supernatant collected from the filtration of seed culture. Reducing sugars released were assayed based on the method described by Miller [10]. 1 mL of sample of supernatant was mixed with 3 mL DNS reagent and boiled for 5 minutes in a water bath. After cooled down, 20 mL of distilled water was added to reaction mixture and the sample was analyzed using UV-Vis spectrophotometer at 540 nm to obtain the absorbance value. The reducing sugar released was calculated based on the standard curves.

Cellulase and xylanase activities were assayed based on the method described by Ghose [11] and Ghose & Bisaria [12], respectively. The activities were measured based on the concentration of reducing sugar released. For cellulase enzymes activities, reaction mixture consists of 0.5 mL substrate solution and 0.5 ml sample. For substrate solution, it consists of 1% of Carboxymethyl cellulose (CMCase assay) and 1% of avicel (Avicelase assay) in 0.05 M sodium citrate buffer. The reaction mixtures were incubated for 30 minutes at temperature of 50 °C. An amount 3 mL of DNS reagent was then added into the mixture and boiled for five minutes before being analyzed using spectrophotometer to determine the absorbance value. For filter paper activity (FPase), the reaction mixture consists of 1 mL 0.05 M sodium citrate buffer, Whatman filter paper (No. 1) strip measuring 1 cm x 6 cm. and 0.5 mL sample. The reaction mixtures were incubated for one hour at 50 °C. For xylanase enzyme activities, similar method as the CMCase was carried out to determine cellulase activities but only 1% xylan was used in 0.05 M sodium citrate buffer as substrate solutions. Enzymes activities for cellulase and xylanase enzymes were measured using standard curve of glucose and xylose respectively.

## Results and Discussion

**Effect of different agar media on growth of *Pycnoporus sanguineus***

The growth diameter of PS was studied using different agar media namely; MEA and PDA. It was found that the PS grew faster on PDA compared to MEA as shown in Figure 1. The fungal growth rate on PDA and MEA recorded were 1.27 cm/day and 0.93 cm/day, respectively.

These results could suggest that the fast growth rate of PS on PDA was probably influenced by the present of dextrose in the agar medium. The present observations are in the agreement with a previous report, where dextrose has been proven to be the best carbon source for fungal growth during incubation time compared to maltose [13]. Instead of using PDA as medium for fungal growth, lignocellulosic biomass has been added in medium as substrate for fungal growth. Rice husk as substrate in agar medium can increase the growth rate (1.24 cm/day) of PS at growth conditions of 28 °C for seven days [14]. As compared to this study, using PDA alone and by increasing the incubation temperature (30 °C) can increase the growth rate up to 1.27 cm/day for five days.

**Effect of different subculture of pycnoporus sanguineus on cell dry weight (CDW) of fungal biomass**

The growth rate of PS was also influenced by the conditions of seed culture. In this study, the PS was grown at two different conditions on agar plate known as subculture five days (Sc PS-5) and subculture seven days (Sc PS-7). It was found that the seed culture using Sc PS-5 produced higher CDW of the fungal biomass 3.44 g/L compared to Sc PS-7 (3.31 g/L) at day five of incubation time (Figure 2). It shows that 3.93% decreased of CDW when the Sc PS-7 was applied for seed culture production. However, the mycelia growth based on CDW of fungal biomass did not

have direct correlation with production of cellulolytic enzymes [14]. It has been proven in this study for Sc PS-5. When CDW was 3.44 g/L at day 5, the CMCase was 3.36 U/mL. While at day 2, CDW was only 1.88 g/L with highest activity of CMCase (2.44 U/mL).

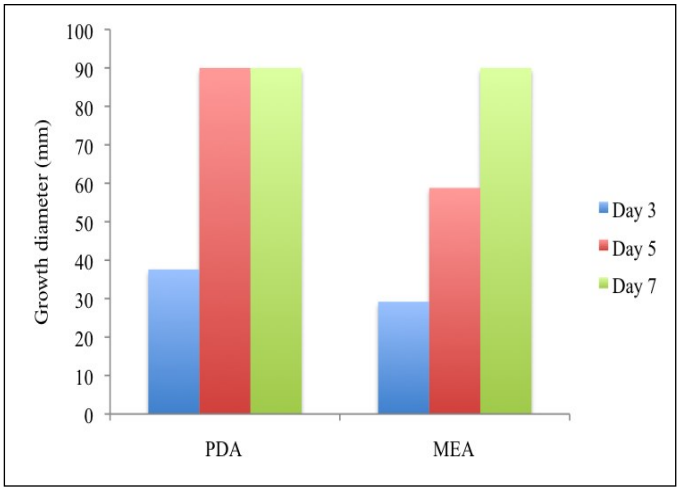

Figure 1. Growth of *Pycnoporus sanguineus* on MEA and PDA

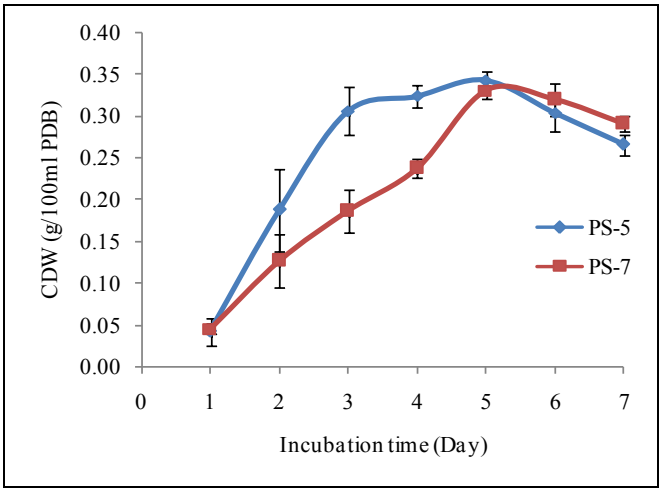

Figure 2. Cell dry weight (CDW) of *Pycnoporus sanguineus*

**Reducing sugars assay of *Pycnoporus sanguineus***

Reducing sugars (RS) for both subcultures of PS decreased from day 1 to day 7 of incubation time as shown in Figure 3. This is due to the glucose consumption during fungal growth and the initial glucose present in the liquid medium was utilized for fungal growth [15]. Sc PS-7 consumed more glucose (17.75 mg/mL) as compared to Sc PS-5 (16.80 mg/mL) for its growth. It is because older cultures need more nutrients to maintain its further growth.

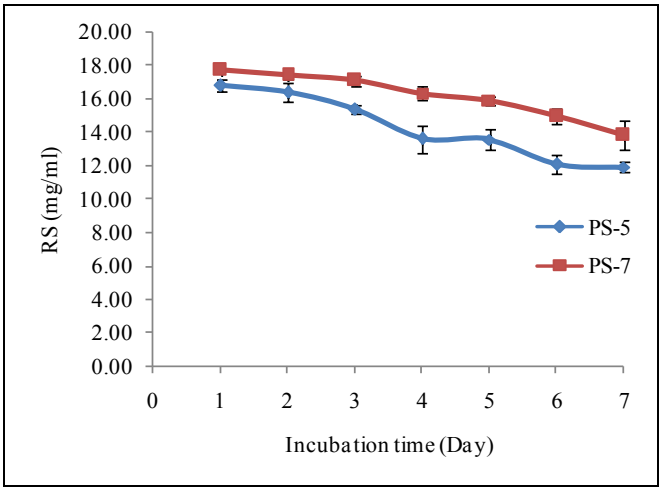

Figure 3. Reducing sugars (RS) of *Pycnoporus sanguineus*

**Cellulolytic enzymes activities of *Pycnoporus sanguineus* for different incubation time of subcultures**

***Filter paper assay activities (FPase)***

FPase is a total cellulase activities resulting from the combination of different cellulase enzymes in the culture filtrate [2]. Figure 4 shows the comparison of filter paper activities of PS. It is found that the maximum FPase activity obtained using Sc PS-5 was 1.79 U/mL after 48 hours' incubation time. As compared to other *Pycnoporus* species; *Pycnoporus coccineus* produced 0.93 U/mL of FPase after incubated for three days [16].

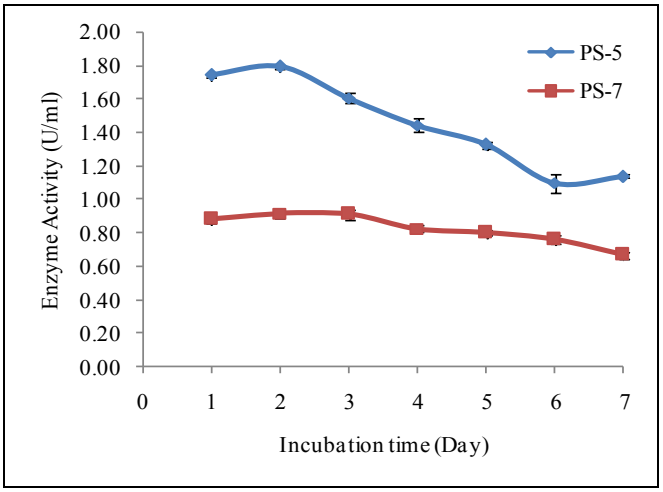

Figure 4. FPase of *Pycnoporus sanguineus*

***Carboxymethyl cellulase @ Endoglucanase enzymes activities (CMCase)***

CMCase enzymes activities for both subcultures have been analyzed and compared as shown in Figure 5. It is found that maximum CMCase activity was 3.36 U/ml after 48 hours' incubation time using Sc PS-5. Previous research reported that PS produced maximum CMCase activity level (1.43 U/mg on 8$^{th}$ day) at pH 5.0 and decreasing or

increasing the pH value will decrease the activity level [1]. For *Pycnoporus coccineus*, it produced 0.95 U/ml of CMCase after incubated for three days [16].

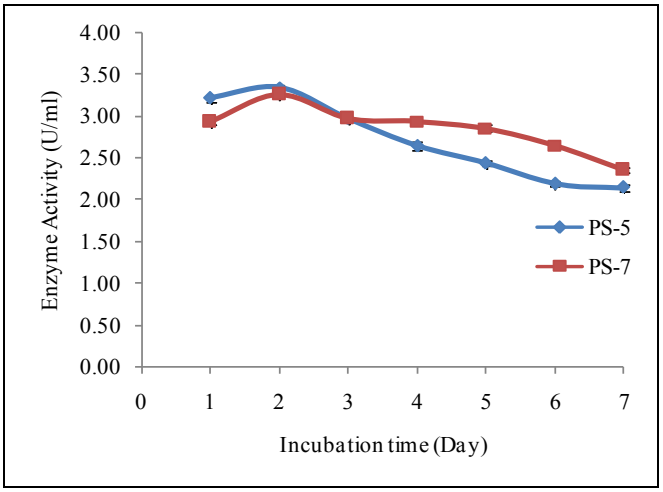

Figure 5. CMCase of *Pycnoporus sanguineus*

***Avicelase @ Exoglucanases activities***

Exoglucanase known also as avicelase enzyme activity was measured using microcrystalline cellulose (Avicel) as the substrate. The activities for avicelase enzymes were compared and shown in Figure 6. It is found that the maximum Avicelase activity (0.59 U/ml) was obtained after 48 hours' incubation time using Sc PS-5. As compared to Sc PS-7, it shows very small significant different with 6.78% of activities decreased. Previous research reported that 0.30 U/mg of Avicelase produced from PS after 8$^{th}$ day [1].

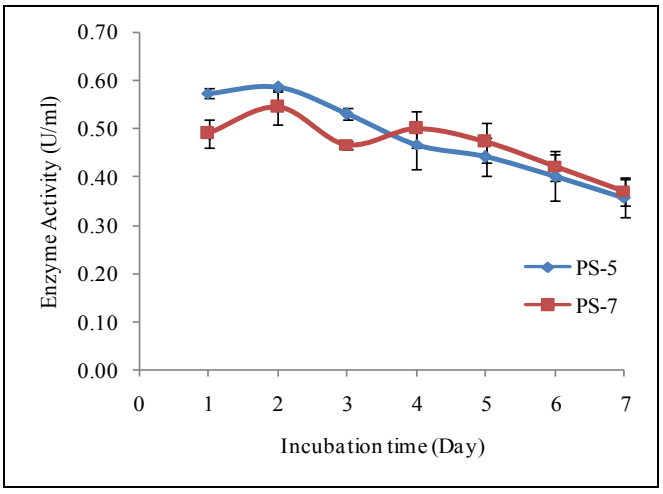

Figure 6. Avicelase of *Pycnoporus sanguineus*

***Xylanase enzymes activities***

Maximum xylanase enzymes activities for Sc PS-5 (0.66 U/mL) were higher than Sc PS-7 (0.57 U/mL) after 48 hours' incubation time (Figure 7). Previous research reported that *Aspergillus niger* was produced 0.71 U/mL of xylanase activities after 30 hours' incubation times [17].

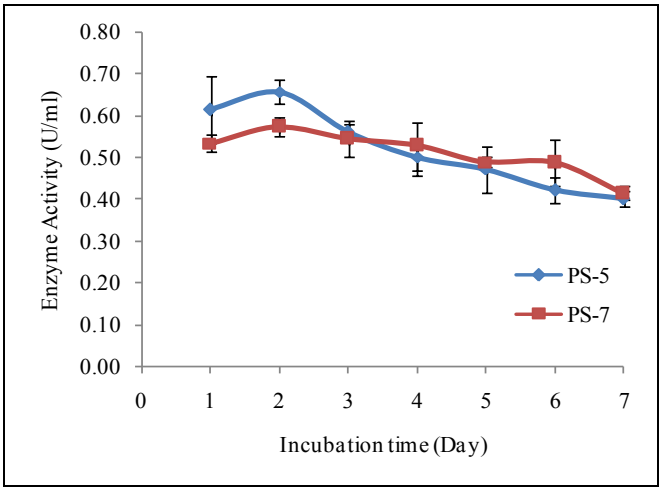

Figure 7. Xylanase of *Pycnoporus sanguineus*

**Comparison of seed culture conditions using different subculture of *Pycnoporus sanguineus***

Based on the findings, comparisons between both subcultures were analyzed. It was found that the seed culture condition to produce cellulolytic enzymes was obtained using Sc PS-5 on agar medium followed by 48 hours' incubation time during seed culture or inoculum preparation. These findings were achieved at constant temperature of 30 $^{\circ}$C, agitation speed of 150 rpm and pH of 4.8 using 1 cm$^3$ of mycelia disc as fungal inoculum source. Table 1 below shows the summary of cellulolytic enzymes produce at 48 hours' incubation time using both subcultures.

Table 1. Comparison of *Pycnoporus sanguineus* cellulolytic enzymes activity at 48 hours' incubation times

| **Enzyme** | **Sc PS-5** | **Sc PS-7** |
|---|---|---|
| FPase (U/mL) | 1.79 | 0.92 |
| CMCase (U/mL) | 3.36 | 3.25 |
| Avicelase (U/mL) | 0.59 | 0.55 |
| Xylanase (U/mL) | 0.66 | 0.57 |

From Table 1, it shows that all the cellulolytic enzymes activity was higher using Sc PS-5 compared to Sc PS-7. This seed culture conditions can be used as a base-line study for enzymes production from PS. Besides, it can reduce the culture times from seven to five days as commonly applied by other researchers [5,4,18].

## Conclusion

The seed culture conditions of PS to produce enzymes was obtained using Sc PS-5 with the highest cellulase; FPase (1.79 U/mL), CMCase (3.36 U/mL), Avicelase (0.59 U/mL) and xylanase enzymes activities (0.66 U/mL) after 48 hours' incubation time. Results obtained at the constant pH medium (pH 4.8), temperature (30 $^{\circ}$C), agitation speed (150 rpm), and mycelium disc size (1 $cm^3$). These findings help to reduce the inoculum preparation time.

# CRUDE PALM OIL BIODIESEL BY TRANSESTERIFICATION PROCESS USING CHOLINE HYDROXIDE CATALYST

## (Biodiesel Minyak Sawit Mentah Melalui Proses Transesterifikasi Menggunakan Mangkin Kolin Hidroksida)

**Abstract**

Biodiesel is generally made by transesterification using alkaline catalyst. Choice of catalyst used greatly affects the biodiesel produced. Choline Hydroxide (ChOH) catalyst is a basic ionic liquid having excellent catalytic reactions in the synthesis of palm biodiesel from Crude Palm Oil (CPO). This catalyst is able to produce biodiesel without soap formation which at the end of the reaction, three layers formed. They are biodiesel, the catalyst itself and glycerol. This makes it easy to separate biodiesel from the by product. Several other important variables in addition to the choice of catalyst and is catalyst dosage, molar ratio of ethanol to CPO and reaction time. The highest yield of biodiesel produced is 99.84% with molar ratio of ethanol to CPO is 9:1, reaction time is 90 minutes, 5.5% catalyst (w/w) at 70 °C and 400 rpm stirring speed. The most influential variable is catalyst dosages that give the significant difference yield of biodiesel produced. It evidenced by more dosages of catalyst used will provide a higher yield of biodiesel.

**Keywords**: choline hydroxide, crude palm oil, ethanol, ionic liquid, palm biodiesel

**Abstrak**

Biodiesel umumnya dihasilkan secara transesterifikasi menggunakan mangkin beralkali. Pilihan mangkin yang digunakan sangat mempengaruhi biodiesel yang dihasilkan. Kolin hidroksida (ChOH) adalah cairan ionik bes yang memiliki tindak balas pemangkinan yang sangat baik dalam sintesis biodiesel sawit dari minyak sawit mentah (CPO). Mangkin ini mampu menghasilkan biodiesel tanpa pembentukan sabun di mana pada akhir tindak balas membentuk tiga lapisan. Lapisan tersebut adalah biodiesel, mangkin itu sendiri dan gliserol. Hal ini memudahkan pemisahan biodiesel dari produk sampingan tersebut. Beberapa pemboleh ubah penting selain pilihan mangkin adalah dos mangkin, nisbah molar etanol terhadap CPO dan masa tindak balas. Hasil tertinggi dari biodiesel adalah 99.84% dengan nisbah molar etanol terhadap CPO adalah 9:1, masa tindak balas 90 minit, 5.5% mangkin (w/w) pada 70 °C dan kelajuan putaran 400 rpm. Pemboleh ubah yang paling berpengaruh adalah dos mangkin yang memberikan perbezaan hasil yang signifikan terhadap biodiesel yang dihasilkan. Ini membuktikan dengan semakin banyak dos mangkin yang digunakan akan memberikan hasil biodiesel yang lebih tinggi.

**Kata kunci:** kolin hidroksida, minyak sawit mentah, etanol, cecair ionik, biodiesel sawit

## Introduction

Biodiesel, an alternative diesel fuel, is made from renewable biological sources such as vegetable oils and animal fats. It is biodegradable and nontoxic, has low emission profiles and so is environmentally beneficial [1]. According to the statistics, 70% of manufacturing cost in producing biodiesel is contributed by feedstock [2]. Indonesia has a

big potential for producing biodiesel because the developments in Indonesia's Crude Palm Oil (CPO) production is increasing every year.

Biodiesel is mostly produced by a transesterification reaction, from oil with an alcohol and the presence of a catalyst to generate mono-alkyl esters and glycerol, which are then separated and purified [3]. Alcohols such as methanol and ethanol are the most commonly used. The yield of biodiesel using ethanol as alcohol reactant and ChOH catalyst is higher than using methanol as alcohol reactant [4]. In addition, ethanol can be produced from renewable agricultural resources [5]. So the use of ethyl esters is more environmentally friendly than the use of methyl ester.

Ionic liquids have been successfully used as a catalyst to catalyze transesterification reaction towards biodiesel production with good performance, higher conversion and selective production of biodiesel and glycerol conversion [6]. Ionic liquids are organic salts with a low melting point and very low vapor pressure [7]. Choline hydroxide (ChOH) catalyst exhibited better catalytic activity compared with other basic ionic liquid catalysts [8]. Ionic liquid-based catalyst choline does not cause the formation of soap. Reaction conditions such as temperature, time, molar ratio and dose of catalyst are optimized to obtain highest conversion in producing biodiesel [9]. The structure ChOH shows the presence of ion $OH^-$ in Figure 1.

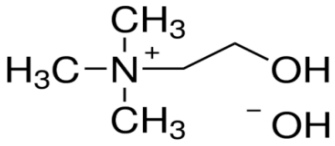

Figure 1. The ionization structure of choline hydroxide

**Materials and Methods**

The raw materials used are crude palm oil (CPO) obtained from PT Perkebunan Nusantara IV (PTPN IV). Alcohol used is ethanol ($C_2H_5OH$) and choline hydroxide (ChOH) was used as catalyst. Transesterification reaction is carried out by the stirring speed 400 rpm and a constant temperature of 70°C with process variables as follows: 1) dose of catalyst, 2) the molar ratio of ethanol:CPO and 3) reaction time.

CPO with a certain amount of weight is weighed and followed by the preparation of ethanol and a catalyst ChOH. CPO and ethanol were mixed at a specific molar ratio in a flask equipped with reflux condenser, thermometer and stirrer. Afterwards, ChOH was added and the mixture was stirred and heated using a hot plate till a constant temperature was reached. After that, the mixture was separated using a separator funnel until 2-3 layers were formed, then washed until the washed water is clear. Analysis can be performed after the ethyl ester prepared.

Factors that influence the reaction such as catalyst dosage, molar ratio of ethanol toward CPO and reaction time were analyzed systematically with the response surface methodology (RSM) with a central composite design (CCD). Level code and the combination of research can be seen in Table 1 and Table 2, respectively. Design equation models offered during the three factors which are as follows [10].

$$Y = \beta_1 + \beta_2\chi_1 + \beta_3\chi_2 + \beta_4\chi_3 + \beta_5\chi_1\chi_2 + \beta_6\chi_2\chi_3 + \beta_7\chi_1\chi_3 + \beta_8\chi_1^2 + \beta_9\chi_2^2 + \beta_{10}\chi_3^2 + \varepsilon \quad (1)$$

## Results and Discussion

**Free fatty acid (FFA) and water content**

Analysis free fatty acids and moisture have been done to raw materials CPO. Comparative analysis of the levels of free fatty acids for CPO against palm oil degummed (DPO) can be seen in Figure 2.

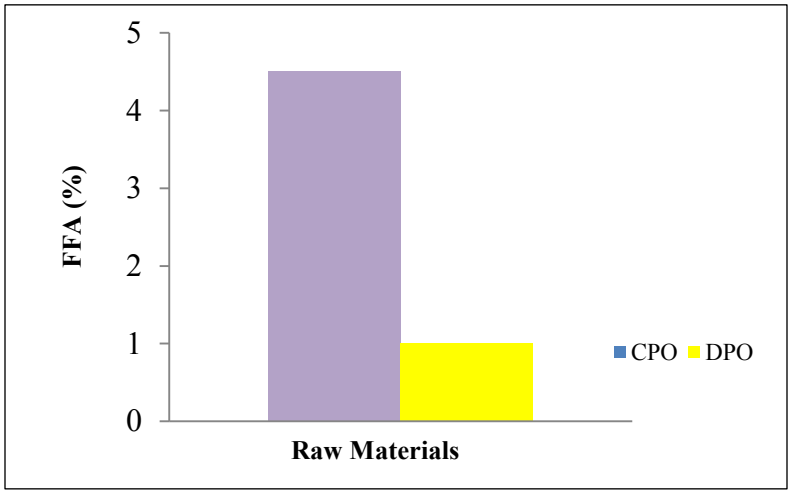

Figure 2. Free fatty acid level

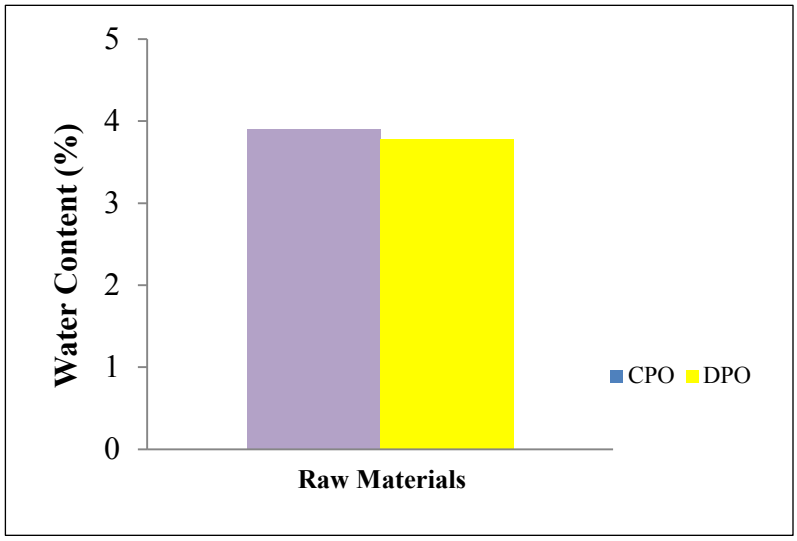

Figure 3. Water content

Low water content can generate higher products conversion. In addition to FFA and water, CPO also contain gum that can interfere the performance of the catalyst, therefore CPO needs to be degummed.

**CPO as the raw material**

Preliminary research has been done on CPO and DPO as basic of raw material selection. With the same reaction conditions, % yield of the ethyl ester of CPO and DPO can be seen as shown in Figure 4.

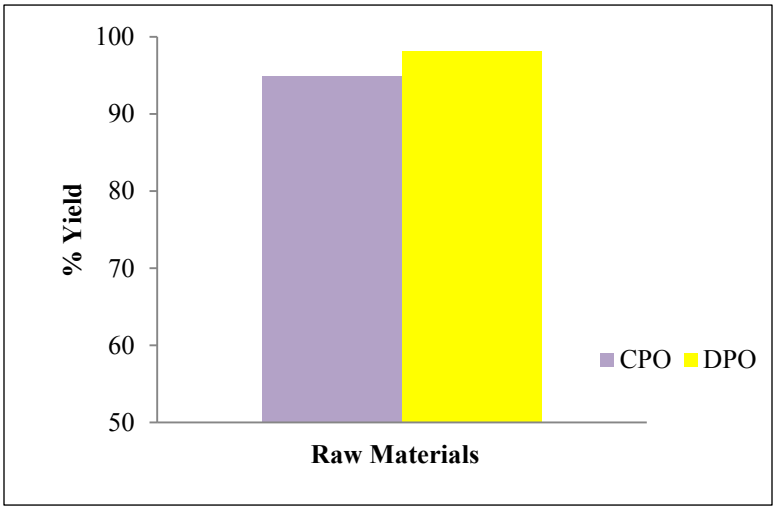

Figure 4. Percentage yield ethyl ester of CPO and DPO

Figure 4 shows the percentage yield of ethyl ester of CPO and DPO with reaction temperature at 70 °C and a stirring speed 400 rpm. Catalyst dosage used was 4% (w/w), molar ratio of ethanol against the raw material is 9:1

and reaction time is 90 minutes. Percentage yield of DPO is 98.17 and 94.92 for CPO. Based on the data above, the raw materials are selected in this study is the CPO as percentage yield obtained from the experiment is not too far difference from DPO. With the high FFA and high water content of CPO, the ionic liquid ChOH able to catalyze the transesterification reaction very well, with percentage yield of ethyl ester is 94.92%.

Manufacturing biodiesel from CPO, as raw materials without pre-treatment is able to lower production costs. The cost of raw materials contributes about 70% of the total cost of production. Pre-treatment CPO make the preparation of raw material more complex, so the cost of it as raw material higher than no pre-treatment CPO. Therefore, using CPO as raw material for biodiesel production was instrumental in lowering the total cost of production so that the price of biodiesel can be predicted cheaper.

**Effect of process variables toward percentage yield**

Following the experimental results data in a central composite design and the combination of the research can be seen in Table 3.

Table 3. Yield ethyl ester in central composite design

| No | Dose of Catalyst (w/w) | Molar Ratio Ethanol:CPO | Reaction Time (minute) | % Yield |

Experimental data were analyzed using STATISTICA program, to get the parameters from the model that will provide the estimation of influence of variables against ethyl ester percentage yield. Statistical analysis to determine the significant influence of variables is shown in Table 4.

Table 4. Regression coefficients

| Model Parameter | Parameter Estimate | Standard Error | Computed T-Value | *P*-Value |
|---|---|---|---|---|
| Intercept | 97.617 | 5.188 | 18.813 | $2.35 \times 10^{-7}$ |
| $X_1$ | 20.863 | 5.148 | 4.052 | 0.004 |
| $X_2$ | -13.147 | 6.377 | -2.061 | 0.078 |
| $X_3$ | 9.957 | 4.943 | 2.014 | 0.083 |
| $X_1^2$ | 2.459 | 5.408 | 0.454 | 0.662 |
| $X_2^2$ | -8.149 | 4.943 | -1.648 | 0.143 |
| $X_3^2$ | -10.460 | 5.408 | -1.934 | 0.094 |
| $X_1X_2$ | -17.282 | 6.435 | -2.685 | 0.031 |
| $X_1X_3$ | 1.681 | 6.435 | 0.261 | 0.801 |
| $X_2X_3$ | 0.091 | 6.435 | 0.014 | 0.989 |

Based on the Table 4, the most significant parameter is the dose of the catalyst and combination of catalyst dosage and molar ratio ethanol to CPO. Since p-value is 0.05, the other parameter is considering as insignificant. Polynomial equation is expressed as equation 2 below.

$$Y_{yield} = 976179 + 208637X_1 - 131470X_2 + 24599X_1^2 - 172828X_1X_2 \quad (2)$$

The experimental data are shown in graphical form contour plot that showing the relationship the two variables against percentage yield (see Figure 5, 6 and 7). Figure 5 shows the relationship between the dose of the catalyst and the molar ratio of ethanol to CPO against percentage yield of ethyl esters. Based on the graph, it shows that the effect is given by catalyst dosage to the percentage yield of ethyl esters greater than molar ratio. The greater dose of the catalyst makes the process of converting oil into ethyl ester higher. Low doses of catalysts can also produce biodiesel with high yields but is followed by the amount of the molar ratio of ethanol: CPO. The use of catalysts with high enough doses followed by the high molar ratio of ethanol to CPO can raise percentage yield of ethyl ester.

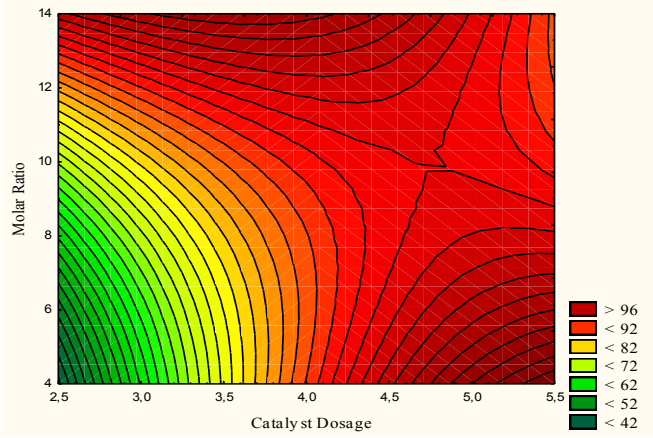

Figure 5. Contour plot of catalyst dosage and molar ratio ethanol: CPO against percentage yield

Figure 6 shows the relationship between the dose of the catalyst and reaction time against percentage yield. In this figure, it can be seen that the use of catalysts ChOH with high enough doses, the conversion of triglycerides into biodiesel is also high, but must be followed by the optimal reaction time. If the transesterification reaction time is too long exceeding the optimum time, the conversion of the resulting biodiesel can be low. For a short time, the biodiesel produced is high enough so that the use of catalysts ChOH is very advantageous in biodiesel transesterification reaction. The catalyst dosage and reaction time effect on yield greatly significant.

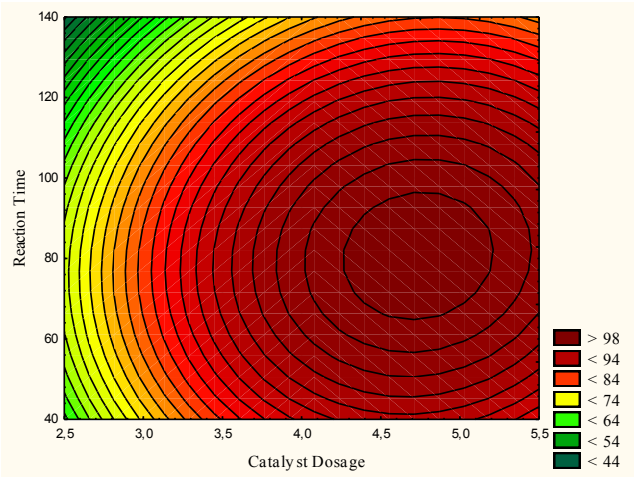

Figure 6. Contour plot of catalyst dosage and reaction time against percentage yield

Figure 7 shows the relationship between the molar ratio of ethanol: CPO and reaction time against percentage yield of ethyl ester. From this contour plot, it can be seen that the high molar ratio of ethanol to CPO, can produce biodiesel with a high percentage yield. As for the reaction time, on the contrary, the long reaction times, can cause biodiesel produced is low. Transesterification short reaction time is sufficient to produce the high percentage yield of ethyl ester. Effect of reaction time on biodiesel is more dominant than the molar ratio of ethanol to CPO.

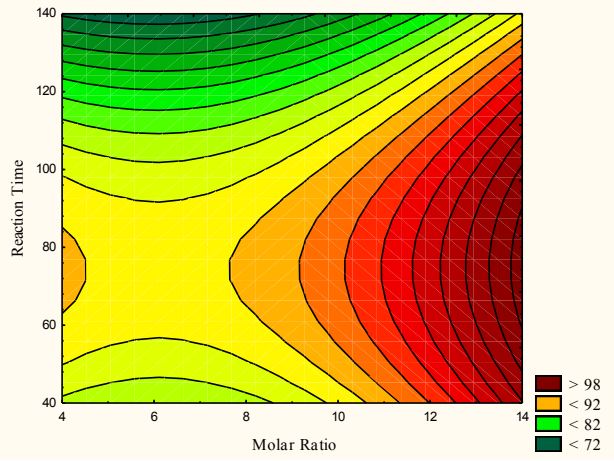

Figure 7. Contour plot of molar ratio ethanol: CPO and reaction time against percentage yield

## Conclusion

CPO as feedstock in biodiesel production without going through the pre-treatment can produce good enough yields of biodiesel using a basic catalyst ionic liquid choline hydroxide (ChOH). Ethanol has great potential in biodiesel production as a reactant alcohol because it is renewable and included in agricultural cycle. The optimum point in biodiesel production is 99.84% at 70 °C with a molar ratio of ethanol against crude palm oil was 9:1, the catalyst dosage 5.5% (w/w) and the reaction time is 90 minutes. The variables that most influence are the catalyst dosage followed by reaction time and the molar ratio. The lower of catalyst dosage and more doses of catalyst and molar ratio of ethanol: CPO will produce higher percentage yield.

**Abstract**

In this study the synthesis, characterization and catalytic performance of $CeO_2$ (Ceria) supported Co catalyst was investigated. First, the ceria was synthesized by direct thermal decomposition of $Ce(NO_3)_3.6H_2O$ and subsequently impregnated with 20 wt.% Co using aqueous solution of $Co(NO_3)_2.6H_2O$ as a precursor. The synthesized catalyst was characterized using TGA, $N_2$-adsorption-desorption, X-ray Diffractometry (XRD), Field Emission Scanning Electron Microscope (FESEM-EDX), and Fourier Transformation Infrared (FTIR). The catalytic property of the ceria-supported cobalt catalyst was tested in methane dry reforming using a stainless steel fixed bed reactor. The dry reforming reaction was performed at the temperature range of 923-1023 K under a controlled atmospheric pressure and constant gas hourly space velocity (GHSV) of 30000 $h^{-1}$. The effects of reactant ($CH_4$ and $CO_2$) feed ratio was investigated on reactants conversion, product yields, and selectivity. The ceria-supported cobalt catalyst recorded highest catalytic activity at a $CH_4$: $CO_2$ ratio of 0.9 and temperature of 1023 K. The highest values of 79.5% and 87.6% were recorded for the $CH_4$ and $CO_2$ conversions respectively. Furthermore, highest yields of 41.98% and 39.76%, as well as selectivity of 19.56% and 20.72%, were obtained for $H_2$ and CO respectively. Syngas ratio of 0.90 was obtained from the dry reforming of methane, making it suitable as feedstock for Fischer-Tropsch synthesis (FTS).

**Abstrak**

Dalam kajian ini, sintesis, pencirian berserta prestasi tindakbalas pemangkin $Co/CeO_2$ telah dijalankan. Terdahulu, ceria disintesis daripada penguraian terma secara langsung ke atas $Ce(NO_3)_3.6H_2O$, diikuti oleh formulasi dengan 20% logam Co menggunakan larutan akueus $Co(NO_3)_2.6H_2O$ sebagai pelopor. Mangkin yang diperolehi dicirikan dengan menggunakan kaedah TGA, $N_2$-penjerapan penyaherapan, pembelauan sinar X (XRD), Mikroskop Pengimbas Elektron Pancaran Medan – Sinar-X Serakan Tenagan (FESEM-EDX) dan Inframerah Tranformasi Fourier (FTIR). Prestasi pemangkin $Co/CeO_2$ telah diuji untuk tindakbalas penghasilan metana kontang di dalam reaktor keluli tahan karat. Tindakbalas kimia tersebut telah dijalankan pada suhu berjulat daripada 923-1023 K, tekanan 1 atm serta GHSV bersamaan 30000 $h^{-1}$. Kesan nisbah reaktan ($CH_4$ and $CO_2$) terhadap penukaran reaktan serta hasil dan pemilihan produk telah disiasat. Mangkin $Co/CeO_2$ mencatatkan aktiviti pemangkin paling tinggi pada nisbah $CH_4/CO_2$ bersamaan 0.9 dan suhu 1023 K. Penukaran $CH_4$ and $CO_2$ mencatatkan nilai tertinggi bersamaan 79.5% dan 87.6%. Tambahan pula, hasil tertinggi bersamaan 37.6% dan 40% berserta sifat pemilihan bersamaan 19.56% dan 20.72% untuk $H_2$ dan CO telah direkodkan. Nisbah gas sintesis bersamaan 0.9 telah diperolehi daripada penghasilan semula metana kontang bersesuaian untuk tindakbalas sintesis Fischer-Trosch.

## Introduction

The utilization of energy derived from fossil sources as transportation fuel has been one of the major concerns of researchers in the past five decades [1,2]. This is due to the emissions of greenhouse gases such as $CO_2$ into the biosphere during the combustion of these fuels [3,4]. Several reports have shown that these greenhouse gases are the main causes of global warming through "greenhouse effect" [5–7]. Efforts of researchers have been concentrated on how to mitigate the emissions of these greenhouse gases [3,8,9]. Methane ($CH_4$) is one of the key components of greenhouse gases as well as a major source of fossil fuel [10]. It is inexpensive and abundance in nature, hence a good building block for $C_1$ chemistry [11]. One way to mitigate the emissions of the greenhouse gases, as well as increasing energy output via dry reforming process [9].

Dry reforming of methane depicted in Equation (1) has received wide research attention due to its advantage to utilize both $CO_2$ and $CH_4$, the two principal components of greenhouse gases for production of synthesis gas (a mixture of $H_2$ and CO) [12–14]. This syngas can be used as chemical intermediates for the production of synthetic fuel via Fischer-Tropsch synthesis (FTS) [15,16].

$$CO_2 + CH_4 \rightarrow H_2 + CO \qquad \Delta H_{1023K} = 261\text{kJ}mol^{-1} \tag{1}$$

Dry reforming of methane as a highly endothermic process is majorly constraint with catalyst deactivation from sintering and carbon deposition [17,18]. There have been concerted efforts by researchers in the field of catalysis in designing and developing catalysts with high activity and stability to overcome challenges of sintering and carbon depositions [19,20].

Up to date, the activity and stability of supported metal-based catalysts such as Pt, Pd, Ru, Rh, Ir, Ni and Co, have been investigated for dry reforming of methane [21]. Reports have shown that supported noble metals catalysts such as Pt, Pd, Ru, Rh, and Ir are very active and highly stable during dry reforming of methane [22–24]. However, these noble-metal catalysts are not readily available and very expensive [25]. Hence, the application of these noble metals to catalyze dry reforming of methane will not be economical in the event of scale up. Supported Ni-based catalysts have high activity and are inexpensive [26]. Nevertheless, the usage of Ni-based catalysts in dry reforming of methane has been constraint by their susceptibility to catalyst deactivation via sintering and carbon depositions [27]. Supported Co-catalyst which is less expensive compared to noble-metal catalysts has been reported as a good alternative to Ni-based catalysts in terms of stability [28].

In addition to using good metal-based catalysts, its play a significant role in enhancing the thermal stability of catalysts during dry reforming of methane [29]. Reports have shown that efficient dispersion of active metals on supports such as $SiO_2$, $\alpha$-$Al_2O_3$ $CeO_2$, $La_2O_3$ and $ZrO_2$ to a large extent affect the pore morphology, confinement and chemical effect of the catalysts [30]; [14]. This will invariably retard coke formation as well as reduce the tendency of the active metal to sinter. The use of ceria ($CeO_2$)-supported Co catalyst has been extensively studied for ethanol steam reforming [31–33]. However, there are limited studies on the dry reforming of methane over ceria supported Co catalyst [34, 35].

This present study focuses on the synthesis, characterization and catalytic performance of ceria supported Co catalyst for dry reforming of methane. The ceria support was prepared by thermal decomposition of cerium (III) nitrate hexahydrate and subsequently used for the synthesis of the $Co/CeO_2$ catalyst via wet impregnation method [36].

## Materials and Methods

### Catalyst synthesis

The schematic diagram depicting the steps involved in the catalyst synthesis is shown in Figure 1. First, the ceria support used for the catalyst synthesis was prepared by thermal decomposition of $Ce(NO_3)_3.6H_2O$ (99.99% trace metal basis, Sigma-Aldrich) at 773 K for 2 hours to obtained $CeO_2$ powder [36,37]. The $CeO_2$ powder was

subsequently impregnated with aqueous solution of $Co(NO_3)_2.6H_2O$ (20 wt% Co loading) by wet impregnation method and then stirred continuously for 3 hours at room temperature. Thereafter, the mixture containing the catalyst precursor and the support was dried at 393 K for 24 hours and then calcinate at 873 K for 5 hours.

**Catalyst characterization**

The physicochemical properties of the fresh 20 wt% $Co/CeO_2$ catalyst were determined by temperature programmed calcination using thermogravimetric analyzer (TA instrument, Q 500). The catalyst sample was heated from 298 to 1173 K at heating rates of 10, 15 and 20 K/min. The specific surface area, pore volume and average pore diameter of the catalyst were measured by $N_2$ adsorption-desorption isotherm at 77 K using Thermo Scientific Surfer Analyzer. Prior to the $N_2$ adsorption-desorption experiment, the catalyst was degassed at 573 K for 3 hours. Phase identification, as well as the crystallinity of the 20 wt% $Co/CeO_2$ catalyst, was determined by Rigaku X-ray powder diffraction analysis (XRD) (Miniflex II) with Cu Kα (45kV, 0.154 nm) radiation.

The morphology and elemental composition of the catalyst sample were carried out using JEOL FESEM (JSM-7800F) equipped with EDX. Temperature-programmed reduction (TPR) of the fresh catalyst was performed in a fixed bed reactor. The catalyst weighing 200 mg was heated from 373 – 1073 K in a flow of 60 ml/min of $H_2/N_2$ (1:5). The amount of hydrogen consumed was measured using gas chromatography (GC) equipped with thermal conductivity detector (TCD). The GC consists of two packed columns namely Supelco Molecular Sieve 13x (10 ft × 1/8 in OD × 2 mm ID, 60/80 mesh, Stainless Steel) and Agilent Hayesep DB (30 ft × 1/8 in OD × 2 mm ID, 100/120 mesh, Stainless Steel). Helium gas with flow rate of 20 ml $min^{-1}$ was used as the carrier at operating column temperature of 393 K.

The nature of chemical bond of the catalyst was measured using Perkin Elmer Fourier transform infrared (FTIR) (Nicolet iS-50) spectrometer. The sample was analysed using an attenuated total reflectance (ATR) method within 4000-400 $cm^{-1}$.

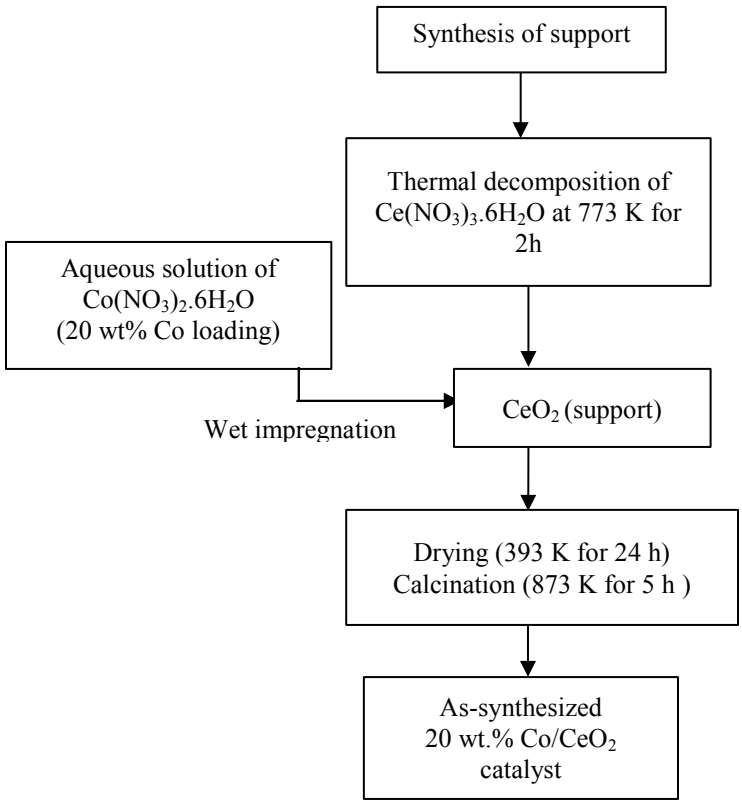

Figure 1. Schematic diagram of steps involved in the synthesis of the 20 wt% $Co/CeO_2$ catalyst

**Catalyst activity test**

The catalyst activity test was performed in a stainless steel fixed bed reactor under controlled atmospheric pressure. The stainless steel tubular reactor was loaded with 200 mg catalyst sample supported with quartz wool. The fixed bed reactor was positioned in a furnace equipped with a Type-K thermocouple to monitor the temperature of the catalytic bed. Prior to the commencement of the activity test, the catalyst was reduced *in situ* in a flow of 60 ml/min of $H_2/N_2$ (1:5) at 873 K for 1 h. The flow of the reactant gases ($CH_4$ and $CO_2$) into the reactor was monitored using Alicat digital mass flow controller. The dry reforming of methane was performed at varying feed ratios ranged 0.1-1.0 and reaction temperature ranged 923 – 1023 K. The compositions of the reactant gases as well as the products ($H_2$ and CO) were monitored using GC-TCD. The activity of the catalyst was measured based on the conversions of the reactants, the yield, and selectivity of the products formed as shown in equations (2) – (7).

$$CH_4 \text{ conversion } (\%) = \frac{F_{CH_{4in}} - F_{CH_{4out}}}{F_{CH_{4in}}} \times 100 \quad (2)$$

$$CO_2 \text{ conversion } (\%) = \frac{F_{CO_{2in}} - F_{CO_{2out}}}{F_{CO_{2in}}} \times 100 \quad (3)$$

$$H_2 \text{ yield} = \frac{F_{H_{2out}}}{2 \times F_{CH_{4in}}} \times 100 \quad (4)$$

$$CO \text{ yield} = \frac{F_{CO_{out}}}{F_{CH_{4in}} + F_{CO_{2in}}} \times 100 \quad (5)$$

$$H_2 \text{ Selectivity} = \frac{F_{H_{2out}}}{F_{H_{2out}} + F_{CH_{4out}} + F_{CO_{2out}} + F_{CO}} \times 100 \quad (6)$$

$$CO \text{ Selectivity} = \frac{F_{H_{2out}}}{F_{CH_{4out}} + F_{CO_{2out}} + F_{COout}} \times 100 \quad (7)$$

$F_{CO_{2in}}$, = inlet molar flow of $CO_2$; $F_{CO_{2out}}$ = outlet molar flow of $CO_2$; $F_{CH_{4in}}$, = inlet molar flow of $CH_4$; $F_{CH_{4out}}$ = outlet molar flow of $CH_4$; $F_{H_{2out}}$, = outlet molar flow of $H_2$; $F_{COout}$ = outlet molar flow of CO.

## Results and Discussion

**Catalyst characterization**

The temperature programmed calcination of the fresh catalyst is shown in Figure 2. Four distinct peaks (I to IV) can be identified from the TGA curve. Peaks I-III can be attributed to sequential loss of physical and hydrated water while peak IV depicts decomposition of the cobalt nitrate to obtain $Co_3O_4$. This trend is consistent with the findings of [38] in their study on dry reforming of methane over alumina supported cobalt catalyst.

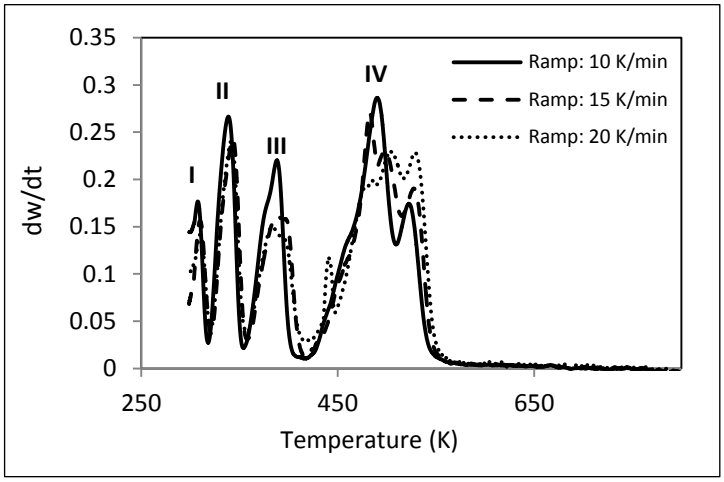

Figure 2. Temperature Programmed Calcination of the 20 wt% $Co/CeO_2$ catalyst

The determination of the mesoporous structure and specific surface of the 20 wt% $Co/CeO_2$ catalyst from $N_2$ adsorption-desorption isotherm is depicted in Figure 3. The $Co/CeO_2$ catalyst isotherm has a characteristic of Type IV isotherm curve with H3 hysteresis loop. Since the relative pressure (P/P°) is > 0.55, the catalyst exhibited uniform mesoporous structure with capillary condensation. The BET specific area of the catalyst was estimated from the sorptomatic data processing software as 39.89 $m^2g^{-1}$ while the pore volume and average pore diameter obtained from Barrett, Joyner, and Hallenda (BJH) method were estimated to be 0.0141 $cm^3g^{-1}$, and 1.16 nm respectively.

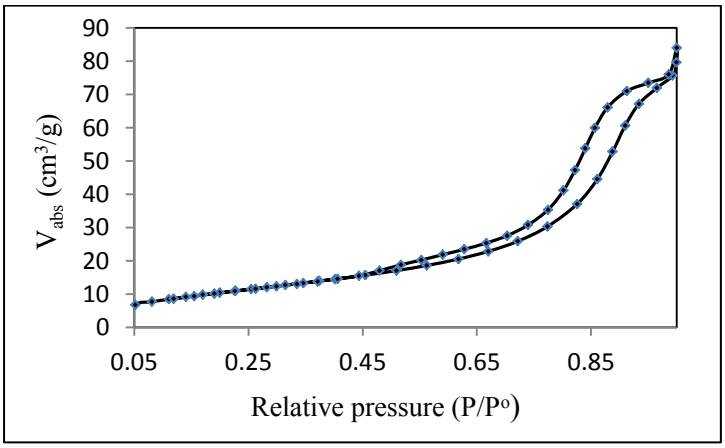

Figure 3. $N_2$ adsorption-desorption isotherm of the 20 wt% $Co/CeO_2$ catalyst

The XRD pattern of the catalyst sample is depicted in Figure 4. Distinct peaks of $CeO_2$ and $Co_3O_4$ crystals can be seen at 2θ = 29.4°, 38.4°, 48.7°, 57.9° and 2θ = 31.3°, 44.5°, 59.7°, 65.1°, 67.7°, 77.1° respectively. The diffraction peaks obtained for $CeO_2$ can be assigned to the crystalline phase of (111), (220), (311), (220) and (422) which represent faced-centre cubic structure [39].

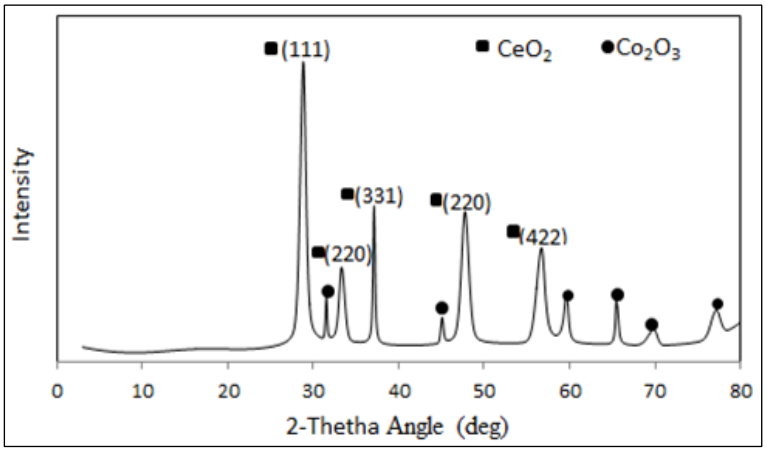

Figure 4. XRD pattern of the 20 wt% $Co/CeO_2$ catalyst

The FESEM micrograph and EDX dot mapping showing the morphology and the elemental composition of the 20 wt% $Co/CeO_2$ catalyst are depicted in Figures 5-7 respectively. The FESEM micrograph (Figure 5) shows the

irregularity and the agglomeration of the catalyst particle sizes. While the EDX dot mapping (Figure 6) confirms the presence of Co, Ce and O as stimulated during the synthesis of the catalyst. The elemental compositions of the catalysts obtained from the EDX dot mapping (Figure 7) corresponds to the stimulated amount used for the catalysts synthesis.

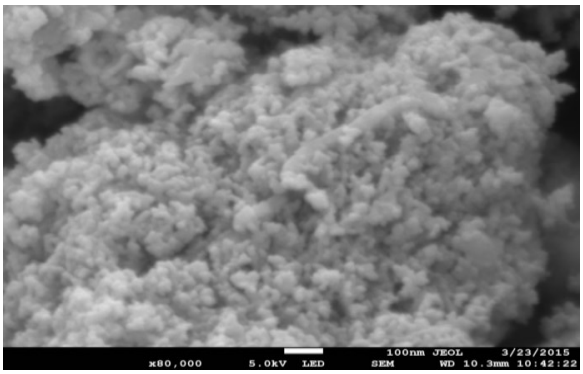

Figure 5. The FESEM micrograph of the 20 wt% $Co/CeO_2$ catalyst

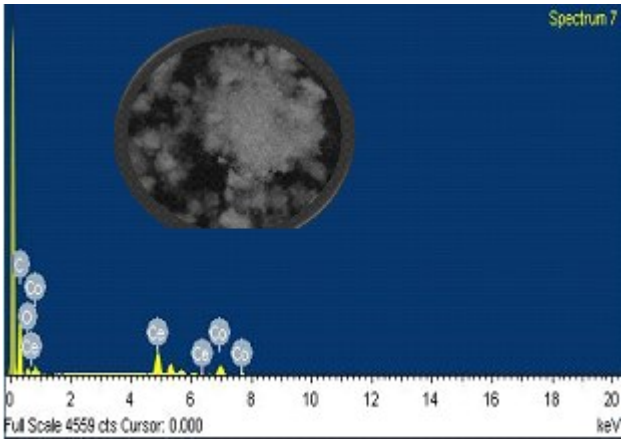

Figure 6. The EDX dot mapping of the 20 wt% $Co/CeO_2$ catalyst

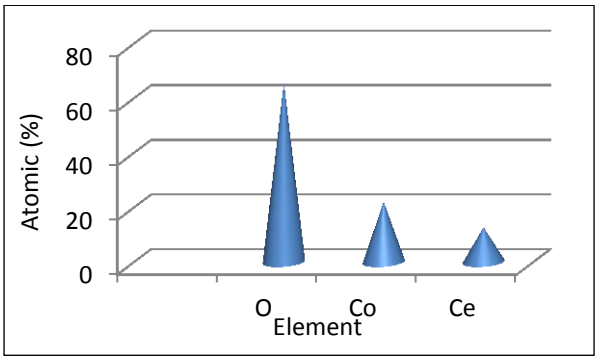

Figure 7. The elemental composition of the 20 wt% $Co/CeO_2$ catalyst obtained from EDX-mapping

In order to check the reducibility of the catalyst in a flow of $H_2$, the catalyst was subjected to $H_2$-TPR. Significantly, two peaks centralized at a temperature of 423, and 673 K can be identified from the $H_2$-TPR profile. The peaks could be attributed to the sequential reduction of $Co_3O_4$ to Co crystallite represented in equation 8. The peak at 423 K could be attributed to the reduction of $Co_3O_4$ which has a weak interaction with the support to CoO. The peak at 577K with a stronger interaction can be attributed to the reduction of CoO to Co [40].

$$Co_3O_4 \rightarrow CoO \rightarrow Co \quad (8)$$

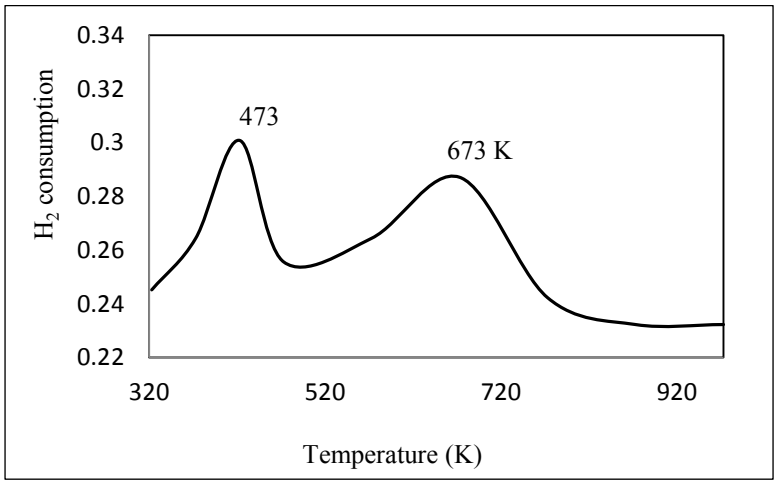

Figure 8. $H_2$-TRP profile of the 20 wt% $Co/CeO_2$ catalyst

The FTIR spectra of the catalyst are shown in Figure 9. The spectra band can be identified at 3400, 1670, 667 and 567 $cm^{-1}$ respectively. The bands at 3400 and 1670 $cm^{-1}$ can be attributed to $OH^-$ which is due to water moisture and COO from dissolved atmospheric $CO_2$. The band obtained at 1670 and 667 $cm^{-1}$ can be attributed to stretching metal oxides (M-O) bond from Co-O and Ce-O respectively.

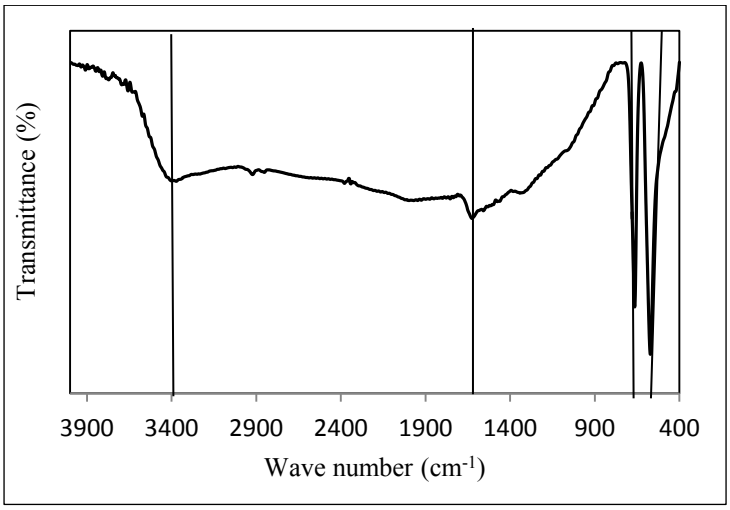

Figure 9. FTIR spectra of the 20 wt% $Co/CeO_2$ catalyst

**Catalyst activity**

The performance of the ceria supported Co catalyst was measured from the conversions of the reactant gas to syngas, the yields of the syngas produced as well as the products selectivity. The effects of feed ratios (0.1-1.0) and temperature (923 – 1023K) were investigated on the catalyst activity in terms of conversions, yields, and selectivity in methane dry reforming process. The conversions of $CH_4$ and $CO_2$ depicted in Figures 10 and 11 increases with feed ratio and temperature signifying the temperature dependent nature of the dry reforming reaction. The conversion of $CH_4$ increases from 43.2% to a maximum value of 79.5%. Similarly, conversion of $CO_2$ increases from 17.8% to 87.6%. The catalyst shows higher activity towards $CO_2$ conversion compared to $CH_4$. This could be as a result of reversed water gas shift reaction shown in equation 9 [41].

$$CO_2 + H_2 \rightarrow H_2O + CO \quad \Delta H_{298} = 41\text{kJmol}^{-1} \tag{9}$$

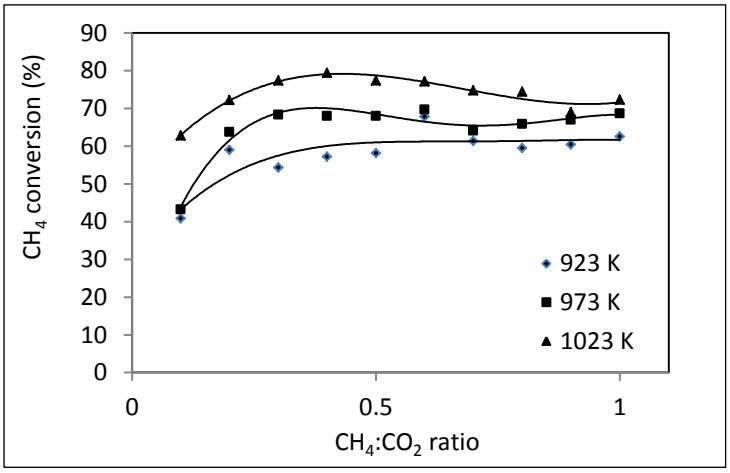

Figure 10. Effect of feed ratio and temperature on conversion of $CH_4$ over 20 wt% $Co/CeO_2$ catalyst

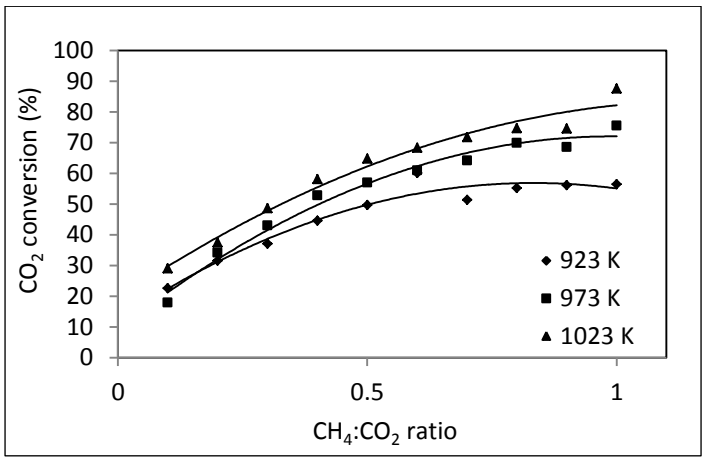

Figure 11. Effect of feed ratio and temperature on conversion of $CO_2$ over 20 wt% $Co/CeO_2$ catalyst.

The catalytic performances of the 20 wt% $Co/CeO_2$ catalyst in term of products (CO and $H_2$) yields are depicted in Figures 12 and 13, respectively. It is noteworthy that both $H_2$ and CO yields increase with feed ratios and temperature. The yield of $H_2$ increases from 1.69% to reach a maximum value of 41.98%. While the yield of CO increases from 6.56% to the maximum value of 39.76%. A similar observation has been reported by Sajjidi et al. [42] for dry reforming of methane over $Ni–Co/Al_2O_3–ZrO_2$ nanocatalyst. The highest yield of 42% and 58% were obtained for $H_2$ and CO respectively. In the present study, at the highest yield of $H_2$ and CO, syngas ratio of 1.05 was obtained. This makes the syngas produced from the dry reforming of methane over the 20 wt% $Co/CeO_2$ catalyst suitable as a chemical intermediate to produce oxygenated fuel via FTS. Apparently, the catalyst shows a higher activity towards $H_2$ yield compared to CO yield. The observation could be attributed to temperature dependent nature of $CH_4$ decomposition. The decomposition of $CH_4$ increases with temperature leading to an increase in the formation of $H_2$ [43].

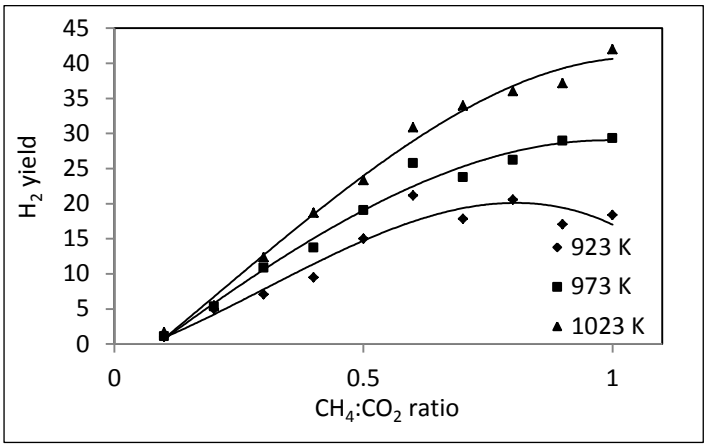

Figure 12. Effect of feed ratio and temperature on the yield of $H_2$ over 20 wt% $Co/CeO_2$ catalyst

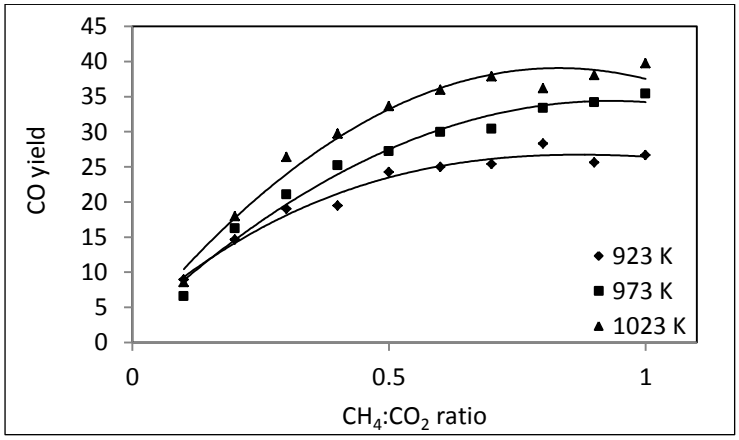

Figure 13. Effect of feed ratio and temperature on the yield of CO over 20 wt% $Co/CeO_2$ catalyst

The selectivity of the 20 wt% $Co/CeO_2$ catalyst towards $H_2$ and CO production is shown Figures 14 and 15, respectively. The $H_2$ and CO selectivity significantly increase with feed ratio and temperature from 1.16% and 8.56% to reach a maximum value of 19.56% and 20.72% respectively. This observation is consistent with the findings of Zheng et al. [44] who employed $Co/\gamma\text{-}Al_2O_3$ for dry reforming of methane to syngas. The authors,

however, obtain a higher selectivity of 95% and 85% for $H_2$ and CO. The difference in result could be linked to high surface area $\gamma$-$Al_2O_3$ used as support compared to Ceria as well as the difference in experimental conditions.

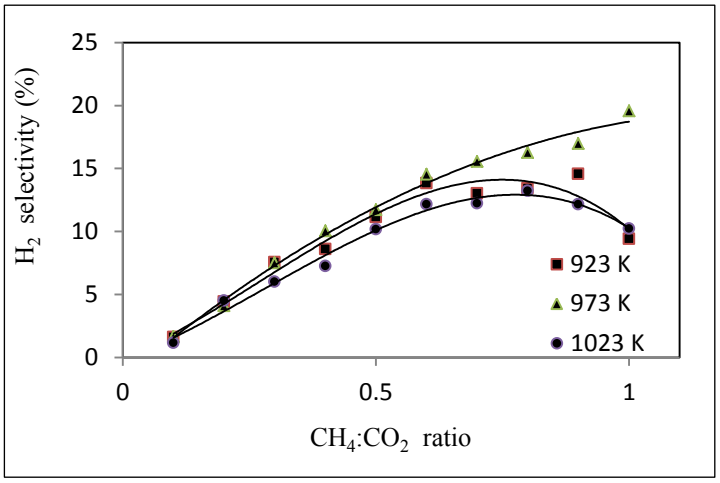

Figure 14. Effect of feed ratio and temperature on the selectivity of $H_2$ over 20 wt% $Co/CeO_2$ catalyst

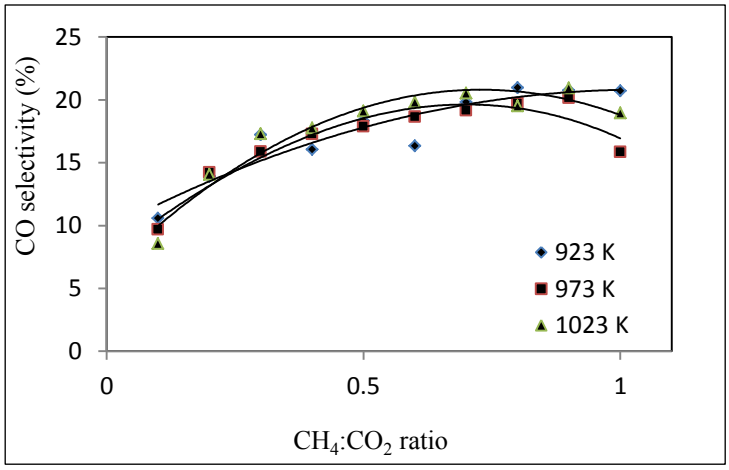

Figure 15. Effect of feed ratio and temperature on the selectivity of CO over 20 wt% $Co/CeO_2$ catalyst

## Conclusion

In this study, we have reported the synthesis, characterization and catalytic performance of ceria supported Co catalyst. The catalyst was synthesized by wet impregnation method and characterized by different physicochemical properties using techniques such as TGA, $N_2$-adsorption-desorption, XRD, FESEM-EDX, and FTIR. The catalytic performance of the as-synthesized catalyst was tested in dry reforming of methane for the production of syngas. The catalyst shows good performance towards reactant conversion, products yield, and selectivity. Syngas ratio of 0.9 was produced from the dry reforming of methane over the ceria supported catalyst, making the process suitable for the production of feedstock for FTS process.

**Abstract**

Bacterial cellulose (BC), a pure form of three-dimensional biopolymer is gaining extensive interest due to its unique physical and mechanical properties. The effects of different agitation conditions on BC synthesis by *Acetobacter xylinum 0416* have been compared. Fermentations were carried out at 150 and 200 rpm using rotatory incubator shaker and rotatory shaker in a constant temperature room of 30 ºC. Matured coconut water was used as a sustainable medium due to its low cost and availability. The medium was adjusted to pH 4.5 or pH 5.5 and BC pellets were collected after 7 days of fermentation. The constant temperature room appeared to has fluctuate degree of heat during fermentation up to 37 °C and suppressed the BC production. In rotatory incubator shaker, the BC produced have insignificant different in comparison to pH and rotation speed. These results indicate that matured coconut water has potential as the carbon source for BC synthesis and optimization of fermentation temperature is important to produce enormous yield of BC.

**Keywords:** bacterial cellulose, matured coconut water, fermentation, agitation speed

**Abstrak**

Selulosa bakteria (SB) iaitu sejenis tiga-dimensi biopolimer sedang mendapat tumpuan yang meluas disebabkan oleh sifat fizikal dan mekanikalnya yang unik. Kesan goncangan yang berbeza terhadap sintesis SB oleh bakteria *Acetobacter xylinum 0416* telah dibandingkan. Proses fermentasi telah dilakukan pada kelajuan 150 rpm dan 200 rpm menggunakan inkubator penggoncang berputar yang tertutup dan inkubator penggoncang berputar terbuka yang terletak di dalam bilik malar pada suhu tetap 30 °C. Air kelapa tua digunakan sebagai medium mapan kerana mudah diperoleh pada kos yang rendah. Media ini dilaraskan pada pH 4.5 atau pH 5.5 dan pelet BS dikumpulkan selepas 7 hari fermentasi. Suhu bilik malar didapati berubah-ubah sepanjang fermentasi sehingga meningkat kepada 37 °C dan membantutkan penghasilan SB. Melalui penggunaan inkubator penggoncang berputar yang tertutup, SB yang terhasil mempunyai perbezaan kuantiti yang tidak signifikan dari segi pH dan kelajuan goncangan. Keputusan ini menunjukkan air kelapa tua mempunyai potensi sebagai sumber karbon bagi sintesis SB dan pengoptimuman suhu fermentasi adalah penting untuk menghasilkan SB yang banyak.

**Kata kunci**: bakteria selulosa, air kelapa tua, fermentasi, kelajuan goncangan.

## Introduction

Cellulose is the most abundant biological polymer on earth, mainly synthesized on the plasma membrane of plants and assemble within the cell wall. It plays an important role in sustaining the integrity of this structure. Cellulose exhibited high stiffness, strength and high thermal stability. Concerning on its properties and enormous quantity available in nature, plant cellulose has been used in numerous purposes by man. However, plant cellulose has many impurities such as hemicellulose and lignin which require harsh treatment for removal [1]. Indeed, this development regrettably had created great problems to biosphere ecology particularly deforestation issue.

To overcome these problems, the use of bacterial cellulose (BC) has been suggested as a better choice in replacing plant cellulose. BC is synthesized extracellular by some bacteria especially by acetic acid bacteria [2]. Even though, BC has similar chemical formula with plant cellulose, its fibrils formation is chemically pure and possess superior physiochemical properties that plant cellulose cannot provide. This cellulosic microfibrils become a promising biomaterial in various fields including biomedical [3], food [4,5,6] and electronic [7,8]. Most *Acetobacter xylinum* strains produce high level of cellulose under static condition. However, development of large scale BC production by improving its fermentation system is important for cellulose production.

Coconut palm is the fourth important industrial crop planted in Malaysia after palm oil, rubber and paddy [9]. Food and Agriculture Organization of The United Nations Statistics Division [10] has state Malaysia had produced an average of 646932 tonnes of coconuts in 2013. Some coconut products traded in the world markets are coconut oil, copra, desiccated coconut and coir. In the meantime, matured coconut water become a common waste product from this process. The matured coconut water which is available in plenty amount and contains various essential contents [11] that support the growth of bacteria is suitable as an economical culture medium.

Thus, the objective of this study is to investigate the best conditions for cellulose growth from *Acetobacter xylinum 0416* in an economic cost using matured coconut water as culture medium. The effect of three factors that are pH of the growth medium, rotation speed and incubation condition on the amount of cellulose produced were determined.

## Materials and Methods

### Bacterial strain

*Acetobacter xylinum 0416* used in this study was supplied by The Malaysian Agricultural Research and Development Institute. The strain was sub-cultured in matured coconut water medium contains the following constituents per liter: D-glucose 80 g, ammonium sulphate 5g, 10% of inoculum and acetic acid glacial. All media were autoclaved at 120 °C for 15 minutes. The working culture were prepared at 30 °C for 3 days before used.

### Fermentation medium

For fermentation, medium, matured coconut water residues were collected from copra dealer and been adjusted with glacial acetic acid to 4.5 or 5.5. The culture medium was sterilized by autoclave at 120 °C for 15 min.

### BC synthesis

Bacteria were fermented in matured coconut water culture medium of different pH and different rotation speed, 150 rpm and 200 rpm for BC production (Table 1). Two types of fermentation condition were compared: 1. Fermented in rotatory incubator shaker; 2. Fermented by rotatory shaker that has been placed in a constant temperature room of 30 ºC (Controlled room) (Figure 1). The fermentation process was carried out at 30 °C for 7 days using experimental design shown in Table 1.

Figure 1. a) Rotatory incubator shaker; b) Rotatory shaker

Table 1. Experimental design of process variables.

| No. | Incubation Types | Rotation Speed (rpm) | Initial pH |
|---|---|---|---|
| 1 | Incubator | 150 | 4.5 |
| 2 | | | 5.5 |
| 3 | | 200 | 4.5 |
| 4 | | | 5.5 |
| 5 | Controlled room | 150 | 4.5 |
| 6 | | | 5.5 |
| 7 | | 200 | 4.5 |
| 8 | | | 5.5 |

At the end of fermentation, pH changes were measured using pH meter. The BC samples, harvested in both culture medium, were rinsed with water and subsequently treated with 0.1M NaOH solution for 20 minutes at 100 °C and thoroughly washed with water until total neutralization.

**Dry weight of BC**

To determine the dry weight of BC, the purified samples were dried at 45 °C until reaching constant weight and kept for further characterization.

## Results and Discussion

In coconut water medium, acetic acid was used to bring down the pH as it had a better effect on *Acetobacter xylinum 0416* growth compared to other acids [12]. The acetic acid was broken down to carbon dioxide and water which allow more energy generated by bacteria. Thus, leading to more efficient utilization of sugars for cellulose synthesis [13].

After 7 days of fermentation, the final pH of each samples was measured. Most the highest yield for *Acetobacter xylinum 0416* strains were achieved after seven days of incubation [14,15]. Figure 2 represents reductions of pH from their initial values. Both pH of culture in fermented in rotatory incubator shaker decreased to less than pH 3.7 while fermentation in controlled room have pH reduction in a range of 4.08 to 4.38. This analysis suggests that culture in incubator have better carbon consumption for growth than culture in controlled room.

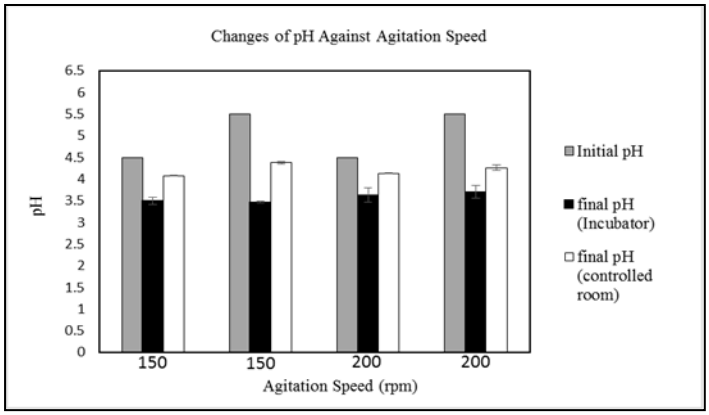

Figure 2. pH changes on various agitation speed and incubation types

Comparison on BC structure (Figure 3) and yield of both fermentation conditions were made. BC commonly produced in the form of gelatinous pellicle through static condition. However, some strains of cellulose-producing bacteria could produce sphere-like cellulose under agitated process while other strains were unable to exhibit this capability even under the same condition. The formation of this sphere-like shape might result from the shear force produced during agitation cultivation that cause intertwine of cellulose ribbon. In this study, *Acetobacter xylinum 0416* was unable to produce sphere-like cellulose. The cellulose had irregular shape which appear in chunk and aggregate form. This finding suggesting that the structure of cellulose is not universally produce by *Acetobacter xylinum 0416* strains [16].

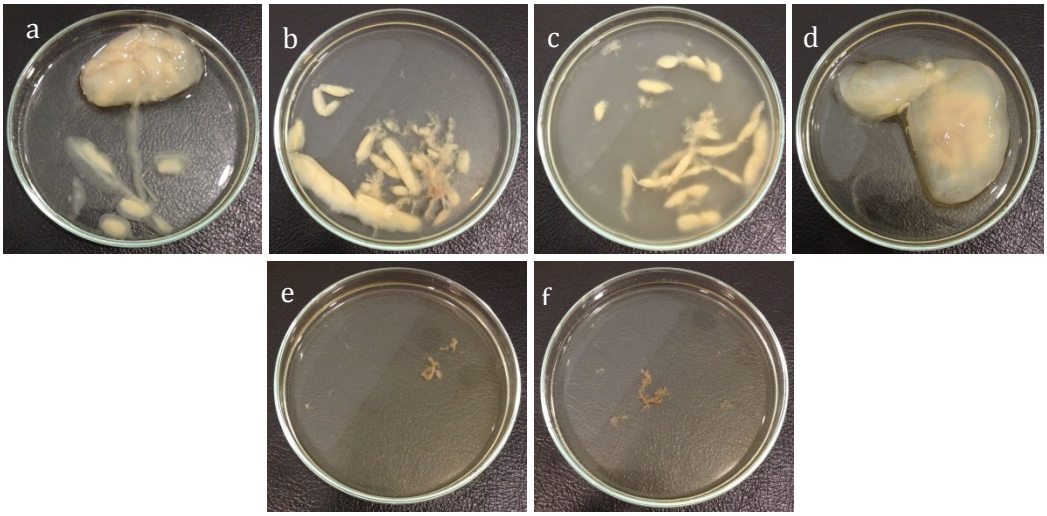

Figure 3. Fermentation of culture medium at rotation speed of (a-b) 150 rpm in incubator shaker, (c-d) 200 rpm in incubator shaker and (e-f) 150 and 200 rpm in controlled room

There was no BC formation at pH 4.5 and pH 5.5 after 7 days fermentation in controlled room. The culture was unable to produce any BC even though the growth of bacteria did occur (reduction of pH). This might result from unstable temperature of controlled room during this fermentation process where the temperature kept fluctuate up to 37 °C.

Some factors can cause temperature fluctuation was often opening of controlled room as it was free access to anyone. When the door was open, more heat and humidity to be released and it will take longer time to reach its normal temperature. Besides that, when the machines in the room were turned on, the internal heat sources released cause disturbance to the constant temperature. Hence, the heat must be compensated with a proper cooling system.

Table 2 summarized the dry weight of cellulose produced by *Acetobacter xylinum 0416* under different rotational speeds, initial pH, and incubation condition. Based on this data, an increase in the biomass yield in increasing cultivation rotational speed might due to improved aeration. Moreover, these results proposed that there was no relationship between cellulose yield and BC sizes for this strain.

Table 2. Bacterial production on various types of incubation, agitation speed and pH

| No. | Incubation Types | Rotational speed (rpm) | Initial pH | Dry Weight (g) |
|---|---|---|---|---|
| 1. | Incubator | 150 | 4.5 | 0.047 |
| 2. | | | 5.5 | 0.035 |
| 3. | | 200 | 4.5 | 0.098 |
| 4. | | | 5.5 | 0.137 |
| 5. | Controlled room | 150 | 4.5 | 0 |
| 6. | | | 5.5 | 0 |
| 7. | | 200 | 4.5 | 0 |
| 8. | | | 5.5 | 0 |

## Conclusion

Matured coconut water has potential as an economic medium which can serve as carbon substrates for BC production. Choosing the right incubation process is important to maximize the yield of BC synthesis. Besides that, more study should be done on different rotational speed to have high yield in short duration of fermentation.

**Abstract**

The growing threat of terrorism activities has caused an urgent need of improved forensic explosive analysis. Complex matrices, limited samples, and ambiguous interpretations serve as challenges for a forensic chemist in order to link the evidence to the perpetrator of the crime. This review focuses on three aspects namely screening techniques, extraction techniques, and instrumental techniques. For the screening techniques, this review focuses on fast detection based on chemical respond for pre- and post-explosion residues. Different types of extraction methods including swabbing technique, solid phase extraction, and solid phase microextraction were discussed. Instrumental techniques covered in this review included gas chromatography, high performance liquid chromatography, ion chromatography and capillary electrophoresis.

**Keywords**: explosive residue, forensic chemistry, screening techniques, extraction techniques, instrumental techniques

**Abstrak**

Peningkatan ancaman aktiviti keganasan telah membawa kesedaran akan perlunya penambahbaikan dalam analisis forensik. Matriks sampel yang kompleks, sampel terhad dan penafsiran yang tidak jelas menjadi satu cabaran dalam bidang kimia forensik untuk mengaitkan antara bahan bukti dan pelaku jenayah. Ulasan ini akan memberi tumpuan kepada tiga bahagian iaitu teknik saringan, teknik pengekstrakan dan teknik instrumen. Untuk kaedah saringan, kajian ini akan memberi tumpuan kepada pengesanan pantas residu letupan berdasarkan tindak balas kimia untuk sebelum dan selepas letupan. Pelbagai jenis kaedah pengekstrakan dibincangkan termasuk teknik sapuan, pengekstrakan fasa pepejal, dan pengekstrakan fasa pepejal mikro. Teknik peralatan yang akan dibincangkan dalam ulasan ini pula melibatkan kromatografi gas, kromatografi cecair berprestasi tinggi, kromatografi ion dan elektroforesis rerambut.

**Kata kunci**: residu letupan, kimia forensik, teknik saringan, teknik pengekstrakan, teknik instrumentasi

## Introduction

Terrorism is often portrayed as unlawful acts of violence, disregarding the safety of civilians with intent to create fear for their senseless ideology [1]. Terrorism brings harm not only to structural or physical injury, but the victims will sustain the damage from the aspect of psychological, economic and social damage [2]. Based on Global Terrorism Database (GTD) from the year 2000 until 2010, 57% of terrorism method (Figure 1) used by terrorists is

from bombing terrorism [3]. The distribution comprises of armed assault (31%), hostage taking (9%) and, unknown (2%), unarmed assault (1%) and hijacking (<1%).

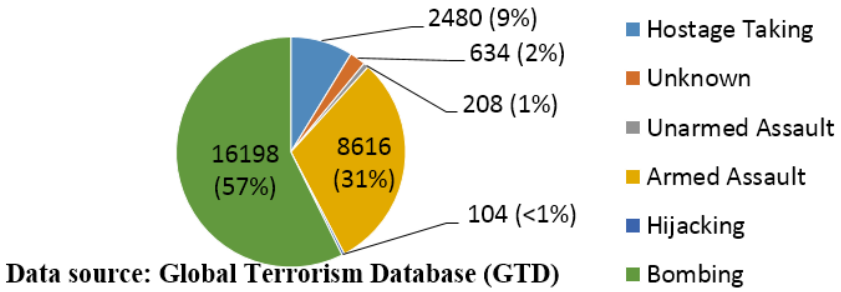

Figure 1. Distribution of terrorism method used by terrorist (2000 – 2010)

Bombing served as the preferred method of terrorism and this callous act of terrorism often happens in public spaces and cost innocent lives to be taken in their target [4-6]. Yavuz et al. [7] in their study on the terrorist bombing in Istanbul reported that 85% of deaths occurred at public spaces such as in the street, school, post-office, hotel lobby, university or campus and many others that involved non-combatant civilians. According to Bosnar et al. [8], suicidal deaths involving explosives have always been connected to terrorism instead of the unusual method of committing suicide.

The expanding threat, unlawful behavior and illicit activities utilizing energetic explosive materials for criminal and terrorism activities have urged the need for a reliable, rapid but also an accurate investigation technique for analyzing crucial puzzles left at the scene of the crime. Analysis of explosive residues become more difficult since the residues of origin material from post-blast samples are usually trapped and fused into surrounding. To identify unknown explosive samples, it demands a competency technique to determine an extensive number of organic and inorganic explosive material. It is of great importance for the explosive and their post-blast residues analysis to assist forensic scientist in determining the origin of explosive material used in the bombing and eventually help the law enforcement in narrowing down the investigation. Therefore, the review emphasizes on steps to track traces of evidence, method of extraction and the use of analytical instrumentation for explosive residue analysis.

**Sample collection**

The forensic scientist needs to analyze and gather information on the physical evidence collected to link the crime scene with the crime perpetrator. The results of laboratory analysis are important to deter terrorist activities and to reduce the occurrences of crime [9-12]. There are many challenges faced by investigating officers and forensic scientist before the results can be taken to court for the prosecution [13].

Numerous studies were reported regarding explosive by performing fields experiments to investigate the properties of explosive, pattern of post-blast sample distribution, or potential source of evidence. Chemical explosive is classified as low or high explosives according to their rates of decomposition [14]. Varga and Ubrich studied the chemical properties of high explosive dynamite via gas chromatography with electron capture detector (GC-ECD) and ion chromatography (IC), by using solid phase extraction (SPE) as the extraction method [15]. Their study revealed that other than dinitrotoluene (DNT) and ethylene glycol dinitrate (EGDN), inorganic components of post-explosion products ($Na^+$, $NH_4^+$, and $NO_3^-$) were also found in dynamite post-blast residues.

The knowledge on explosive residue distribution is important for comparison analysis with real samples. Various approaches were made on the study of explosive residues distribution by using trays [16, 17] or witness plates [18-20] placed at different distances from the epicenter of the explosion. The impact from the detonation process resulting in the fragment or residue from the explosive device will be ejected outward from the epicenter of the

explosion. However, almost all studies showed no clear relationship between the amount of explosive detected with the distance from the detonation or amount of explosive used for the detonation process [21, 22]. Many factors contribute to this lack of correlation between the explosive residues distribution with the amount of explosive detected from post-blast explosive residues including efficiency of the detonation, non-homogenous fragment residual dispersal, and influence of wind direction during detonation process.

Determining potential source of evidence is a very crucial step to track traces the explosive residues. Numerous efforts have been made by researchers to study on variety possible source of evidence so that it can become references for the future cases. These sources can exist in the form of solid [23] or porous material [24]. Since the bombing terrorism cases always involve human either as the perpetrator or as the casualty, human skin and hair having a potential of becoming a reliable source for retrieving explosive residues [25-28]. Clothes also have a potential becoming a positive source of evidence since clothes are always intact with the human body [29]. Considering bombing incident also happens in open areas, the possibilities of explosive residues seeping into the ground and making the soil become a potential source to track the explosive residues [30, 31]. Since the properties of water as a universal solvent to contain explosive residues, numerous studies were also done to detect the explosive in water [32-34].

Numerous challenges are often confronted during the process of collecting and analyzing the physical evidence. At the crime scene explosion, the evidence tends to blend into the background thus making the collection process difficult. The fraction, residue or unexploded material that usually blend with surrounding include soil, water, rubble, debris, fabric or any physical material involved in the explosion and the amount of material remains from the devices were usually of limited quantity [33, 35-37]. Shankill Road explosion incident in 1993 is an example when the evidence were mixed with 15 tons of rubble and needed painstaking examination before the remains of the explosive device were discovered among the rubbles [35]. The perpetrator in this incident used short relay electronic explosive device using high explosive as the main component.

Massive explosions usually leave traces when compared to small explosions. Because of that reason, it is not extraordinary if only a small fraction of the samples remains after detonation and combustion processes. For example, the Bali bombing on 12 October 2002 involved three explosions at three different places with different explosion damage [4]. The first explosion took place at Paddy's Bar before the second and the largest explosion exploded a moment later outside the Sari nightclub. Approximately 45 seconds after the blast at Sari nightclub, a third bomb exploded 10 km away near to the United States and Australian Consulates. Compared to the second and largest explosion that used vehicle-borne improvised explosive device (VBIED), the third and the smallest explosion outside the consulate provided more promising physical evidence as compared to the other two explosions.

The blast location or center of the blast must be discovered and approached with extreme steps of precaution. If any portion of the device is visible to the naked eyes during approaching the seat of the explosion most likely to contain, it must be packaged and labeled because it will make an excellent source of recovering of explosive residue. In Boston marathon bombing in 2013, the remaining pieces from a pressure cooker bomb were successfully discovered at the scene of explosion [38]. The explosion killed three peoples and injured more than 200 people.

Post blast samples collected are often placed in a sealed container, with the appropriate size. Soil or soft material in the form of powder can be stored in ziplock plastic bags. Metal, debris or any sharp object should be wrapped with protective material to prevent the samples from piercing the container. Other good sources of explosive residues are soil or any solid object that could be penetrated such as wood, insulation, plastics and metals [9]. Physical evidence that is attached to the victims or deceases must be taken into account and recovered in steps and precautions. In the Bali bombing of 2005, the bearing and electrical connectors were recovered from wounded victims and TNT explosive compound was successfully identified [39].

**Screening: On-site detection of explosive devices and residues**

Screening test for explosive trace residues in a post-blast forensic investigation is one of the important strategies for the on-site detection of explosives [40, 41]. The sensing methodology of optical and non-optical methods has been

widely applied by law enforcement and transportation security [42-46]. Trained canine team, metal detector, X-ray imaging, ion mobility spectrometry, and portable gas chromatography mass spectrometry (GC-MS) are among the examples of non-optical sensing methods. Spot test kit and thin layer chromatography are examples of preliminary colour tests often employed in laboratory screening of explosive residues.

Trained canine team, is a common and effective method for detection of explosives by training the dog to identify the explosives through vapour sniffing [9]. This approach is still widely practiced in airports or in crime scenes to locate evidence or any prohibited items including drugs and explosives. The abilities between humans and dogs were differentiated by the effectiveness of the olfactory system of the dog that can sniff the vapour much better when compared to human [47, 48]. However, the disadvantages of the canine teams are high maintenance, tendency for environmental distraction, physiological boredom and only the trainer can handle the sniffer dog limit the method for every operation [11].

X-ray imaging are widely used in security post, airports or border control to detect any prohibited items from passing the security line [49-51]. The recent system of the dual-view system is replacing a single view system which allows the image to be viewed at 360° and in pseudo-colors [49]. However, it has some weaknesses because the x-ray cannot penetrate high-density material such as a machine. Various items jumbled in the baggage, including organic materials, bottles, battery, electronic device together with cables and wire, increases the complexity of the image thus causing the possibilities of overlooking the existence of the explosive device.

Numerous reports were made on the development of spectroscopic sensors for detection of explosives [11, 52-55]. The principle of spectroscopy is the interaction between matter and the electromagnetic radiation, whereby samples from the explosive vapour are drawn from the surface or air into the drift region [56]. The ionized samples are then separated through the electric field, according to the mobility of ions or mass to charge ratio before being detected by the spectrometer detector. A few separation techniques combined with mass spectrometry have been developed for real-time detection of explosives (Table 1). Ion mobility spectrometry (IMS) [57] is an example of spectroscopic method that has been used on the field for detection of explosives [58-61]. The method has high selectivity and sensitivities, but until now, numerous efforts were made for miniaturization of the instruments and each instrument itself is very expensive.

Table 1. Example of explosive detection via spectrometry method

| Spectrometry Method | Explosive Analytes | Detection Limit | References |
|---|---|---|---|
| AFT-MS | PETN[1], tetryl, RDX[2], NG[3] | 10 ppq | [62] |
| DBDI-MS | RDX, TNT[4], PETN | 0.01-0.1 ng | [59] |
| ESI-IMS | TNT, 2,4-DNT[5], 2-ADNT[6], 4-NT[7], TNB[8], RDX, HMX[9], EGDN[10], NG | 0.015-0.190 ppm | [60] |
| NCD-IMS | RDX,TNT, PETN | 0.07-0.3 ng | [61] |

[1]PETN: pentaerythritol tetranitrate
[2]RDX: cyclo-1,3,5-trimethylene-2,4,6-trinitramine
[3]NG: nitroglycerin
[4]TNT: trinitrotoluene
[5]2,4-DNT: 2,4-dinitrotoluene
[6]2-ADNT: 2-amino-4,6-dinitrotoluene
[7]4-NT: 4-nitrotoluene
[8]TNB: trinitrobenzene
[9]HMX: cyclo-tetramethylene-tetranitramine
[10]EGDN: dinitro-ethyleneglycol

Most portable kits utilized classical screening tests based on optical and colorimetric analyzes. They are usually high in portability, low in price, and provide rapid and reliable explosives detection. Fisco, in 1975 developed a portable thin layer chromatography (TLC) analysis for the detection of explosives [44]. The kit requires 20-30 minutes for the TLC development prior to visualization using portable UV lamp at 254 nm. Longer analysis time,

the need to prepare various amounts of chemical reagent in the developer chamber, and low portability were major weaknesses of this method. Another approach for detection of explosive is from colorimetric reaction via spot test analysis named as ELIT [40], *Detection Kit Detex* [43], and *FORANEX* [63] spot test kit were among the rapid and reliable colorimetric analytical methods for detection of explosives. However, the techniques needed subsequent instrumental analysis in order to confirm the presence of certain components of the explosive. Recent advanced techniques utilized the capabilities of hexaazamacrocycle-capped [64]. Mohan and Chand reported on the rapid colour formation from red to blue with a detection limit at femtomolar ($10^{-15}$ mol/dm$^3$) concentration level. Table 2 shows the specific chemical reagents for the detection of certain explosives based on their respective color formation.

Table 2. Reference reagents for detection of explosive via colorimetric reaction [4, 37, 43, 63, 65]

| Reagent | Composition | Explosive Analytes | Color Formation |
|---|---|---|---|
| Griess reagents | alphanaphtylamine and sulfanilic in acetic acid with zinc dust as reducing agent | RDX, PETN, Nitrate ion | Pink color |
| Nessler reagent | potassium iodide and mercury (II) chloride in deionized water | TNT, Ammonium ion | Red-orange color |
| Chloride reagent | concentrated silver nitrate in deionized water | Chloride ion | White precipitate |
| Sulfate reagent | 10% barium chloride in deionized water | Sulfate ion | White precipitate |
| Perchlorate reagent | 0.3% methylene blue in deionized water | Perchlorate ion | Purple color |
| Peroxides reagent | diphenylamine in concentrated sulphuric acid | Peroxides | Dark blue color |

**Sample extraction**

Detection of explosive residues after a bombing incident is possible because not all the explosive materials are consumed during an explosion. Furthermore, characteristic by-products may be formed by the chemical reactions that take place during an explosion. Several methods of extraction techniques were employed to extract the explosive from the matrices, including swabbing technique solid phase extraction (SPE) and solid phase microextraction (SPME) [19, 25, 66]. The method of extraction is crucial to collect the analytes of interest effectively. Furthermore, a variety of the physical evidence will be recovered at the crime scene including soil, water, hair or debris need to be analyzed afterwards [24, 28, 33].

The swabbing technique is commonly used for collecting residues from solid surfaces such as metal, plastics, human skin, and cloth. The efficiency of swabbing technique not only depends on the area being swabbed but also other factors such as the type of solvent used, interval of time between explosion and analysis and the nature of the target sample [19, 26, 67, 68]. Song et al. in their study reported that polyester swabs were superior compared to the cotton swabs [68]. Their studies also indicated that dry swabbing was not an efficient technique as compared to wet swabbing. Wipes using alcohol was also found as a compromising solvent for its efficiency to transfer most of the target analyte from the surfaces to the polyester swab. However, the porosity, thickness and the nature of the surfaces may also reduce the effectiveness of swabbing technique [29].

The most challenging extraction process comes from matrices such as sand and soil. These matrices are found with many interferences from the surrounding such as fertilizers or waste product from home cleaning appliances that may be dissipated into the ground. Sample control from surrounding areas around the crime scene with the same physical properties of the soil at the seat of blast must be collected and taken to the laboratory before being analyzed

and compared with the questioned soil to remove the possibilities of background interferences. Most reported studies used EPA Method 8330 or a modified version of the EPA method to extract the target analytes from the soil [69, 70]. Halasz et al. [71] conducted their study on detection of explosives and degradation products in soil environment. Acetonitrile was used as the solvent to extract the analytes of interest. The sample was subjected to a sonication process for 18 hours prior to analysis by using HPLC-UV at 254 nm. Their study also revealed that from the training sites and former explosives manufacturing plants, the explosives compounds can be transferred from ground surfaces to groundwater and plant tissues.

Solid phase extraction (SPE) is a popular method for removing impurities and pre-concentration of target analytes [72]. This method mainly consists of four steps; conditioning, loading, washing and elution process. Warren et al. [73] applied a combined swab and SPE in their sample preparation. The sample was swabbed with a wetted ethanol cotton swab before the extract was passed through a Chromosorb-104 adsorbent column (washed with one-time acetone and three times of ethyl acetate). The loading sample was washed with ethanol/water fraction (50:50) for the collection of inorganic compound and the adsorbent was further washed using methyl tert-butyl ether/pentane before ethyl acetate fraction was used to elute the organic compound. The percentage recoveries of the selected inorganic ions (sodium, ammonium, potassium, magnesium, calcium, fluoride, chloride, nitrite, bromide, chlorate, nitrate, phosphate, sulphate, perchlorate, glucose, fructose and sucrose) were varied from 45.9% to 96.8%. However, it showed low percentage recoveries of selected organic explosive (nitroglycerin (NG), 2,4-dinitrotoluence (2,4-DNT), 2,6-dinitrotoluene (2,6-DNT), 3,4-dinitrotoluene (3,4-DNT), 2,4,6-trinitrotoluene (TNT), PETN and RDX) from 31.4% to 56%. Ahmad et al. [16] applied the SPE method on the post-blast water samples. For the optimization process, five nitro explosive compounds namely as HMX, 2,4-DNT, RDX, TNT and PETN was selected and undergoes pre-concentration process via SPE before being analyzed by using micellar electrokinetic chromatography (MEKC) and GC-ECD. They used LiChrolut EN SPE cartridges as their SPE adsorbent and used 10 mL of methanol followed by 20 mL distilled water for the conditioning process. The samples (200 mL) were allowed to pass through the SPE cartridge at the flow rate of 3 mL/min before the analytes were collected with three portions of 3 mL acetonitrile. From the optimization process, the SPE pre-concentration technique had succeeded to lower the detection limit by more than 1000 times and gave a good percentage recovery (>87%). From the post-blast water sampling, both RDX and PETN were detected in the range of 0.05 – 0.17 ppm and 0.0124 – 0.039 ppm respectively.

Solid phase microextraction (SPME) is an innovative approach of green technology to reduce the amount of solvent use for the extraction process, cutting the cost and chemical exposure to the human body [66]. Several factors affecting extraction process included the type of fiber use, nature of target analytes, the complexity of the matrices, temperature and desorption times. A study of solid phase microextraction combined with GC-ECD has been made on organic explosive samples [74]. Four types of fiber namely, polydimethylsiloxane (PDMS), polydimethylsiloxane/divinylbenzene (PDMS/DVB), Carboxen$^{TM}$/ polydimethylsiloxane (CAR/PDMS), and polyacrylate were used to study the relationship between the water solubility and the fibers. PDMS/DVB fiber with 30 minutes stirring showed a better result as compared to other fibers. Another study by Ahmad and Heng [75] demonstrated the effect of salting out procedure with 10% NaCl gave the best extraction of their target analytes of 2,6-dinitrotoluene (2,6-DNT), trinitrotoluene (TNT) and pentaerythritol tetranitrate (PETN).

**Instrumental techniques**

Instrumentation plays an important role in the detection of target compounds from various matrices. They are often combined with specific detectors for sensitive and selected detection of the explosive target compounds (Figure 2).

An extensive review on instrumental techniques for the detection of explosive was reported by Kolla [76]. The review covers the instrumental techniques pertaining to organic and inorganic analytes. However, the review was limited to gas chromatography (GC), high performance liquid chromatography (HPLC), capillary electrophoresis (CE), and ion chromatography (IC) analysis of explosive residues up to 1994. For chromatographic separation, a survey was done on articles searched using the keywords of *explosive* and selected instruments, GC, HPLC, IC and CE (Figure 3). Analysis of explosive using GC appeared to be the most popular followed by HPLC, IC and CE. The interest of explosive study had significantly increased between 2003 to 2005, but display a decreasing trend from 2005 to 2007 before showing an increasing pattern from 2008 to 2015 (Figure 3). This trend was obtained

following media reports of series bombing terrorism attacks such as Bali Bombing (2002), Delhi Bombing 2008, Mumbai Bombing (2008) Jakarta Bombing (2009), Moscow Bombing (2010), Norways Attack (2011) and Boston Marathon Bombings (2013).

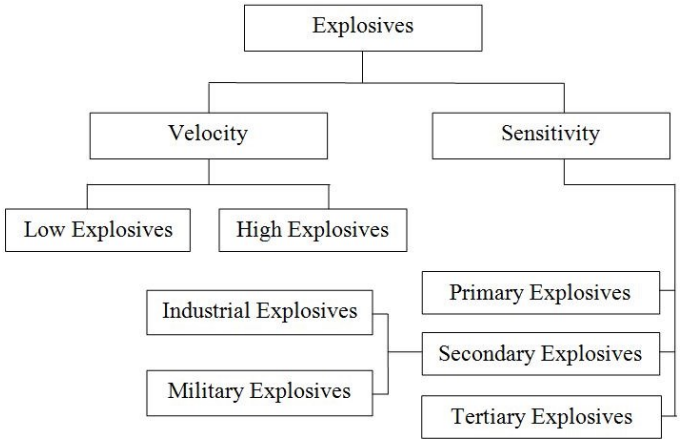

Figure 2. Classification of chemical explosives [14]

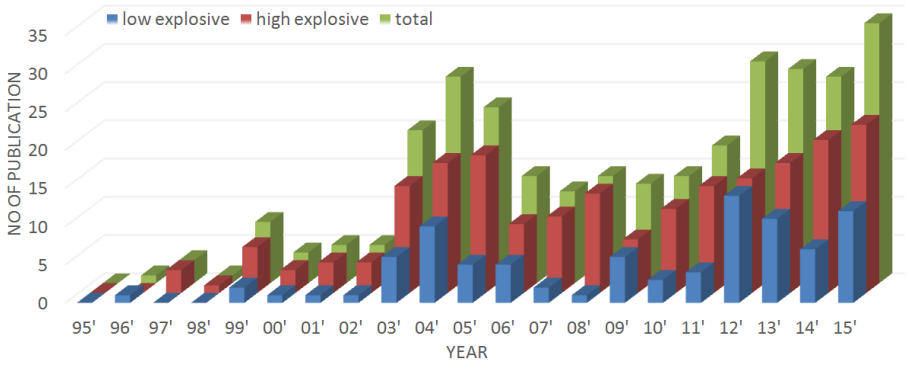

Figure 3. Distribution of journal publications on selected instrumentation based on SCOPUS database from year 2000 – 2015

**Gas chromatography**

Gas chromatography (GC) is frequently used for the identification of organic explosive compounds since the technique has high selectivity and sensitivity towards organic constituent analysis. However, the GC instruments prohibit non-volatile, mixture water samples and sparked samples to prevent the column from bearing the damage. Because of that, extra precaution on sample preparation is needed for every process. The detectors used combined with GC are electron capture detection (ECD) [30,74,77], thermal energy analyzer (TEA) [78,79], mass spectrometry (MS) [71, 80, 81], and tandem mass spectrometry (MS/MS) [82, 83]. Although ECD is less selective than TEA or MS, it is a sensitive means of detecting nitroaromatic base explosives [55]. ECD devices operate by passing a beam of electrons between two electrodes. When a sample elutes from the GC column, organic nitrate groups and the other electronegative moieties 'capture' these electrons, interrupting the current and thereby producing a signal. Varga and Ulbrich [15] successfully extracted TNT and PETN by using water as the medium of extraction and subsequent separation by using GC-ECD. However, nitrate ester based explosive compound such as ethylene glycol dinitrate (EGDN) and nitroglycerin (NG) were difficult to extract using water due to their hydrolysis

process. Ahmad et al. [27] had succeeded in detecting both PETN and RDX from the C4 explosive residues on hair samples by using GC-ECD. Three hair samples were located at 2.5 m, 5.0 m, and 7.5 m from the point of the blast. Their studies concluded that the human head hair has the potential to become a reliable source for explosive residues to be deposited and the concentration of residue deposited on the hair decreased with distance.

Gas chromatography-tandem mass spectrometry (GC-MS/MS) has become an alternative to gas chromatography-mass spectrometry (GC/MS). GC/MS/MS is an analytical tool of choice as the technique is more superior on the selectivity and sensitivity besides its powerful capabilities for detecting compounds in complex matrices. Perr et al. [82] have developed a GC/MS/MS method by using positive chemical ionization (GC/PCI/MS/MS) approach to analyze organic high explosives of nitrobenzene, 2-nitrotoluene, 3-nitroltoluene, 4-nitrotoluene, 1,3-dinitrobenzene, 2,6-dinitrotoluene, 2,4-dinitrotoluene, 1,3,5-trinitrobenzene, 2,4,6-trinitrotoluene, RDX, 4-amino-2,6 dinitrotoluene, 2-amino-4,6-dinitrotoluene, tetryl and HMX with low LOD (0.0006- 0.0414 ng/mL). This method successfully reduced sample preparation steps as the samples can be analyzed without any sample pre-concentration as well as reducing sample loss or sample contamination.

**High performance liquid chromatography**

High performance liquid chromatography is commonly used to detect the organic explosive compounds that are non-volatile. HPLC is often used as the instrument for analysis of explosives as it is amenable for the analysis compounds that have low volatility, high sensitive to heat and high molecular weight [55]. This will overcome the problem of detection of explosives that are thermally unstable and resulting in decomposition products in the vapors [76]. The common detector for HPLC is ultraviolet detector (HPLC-UV). The wide range of HPLC detection between 190-800 nm provides an excellent range of separation. Miller et al. [24] employed HPLC-UV for the identification of explosives from porous materials. By changing the temperature and methanol-water mobile phase ratio in HPLC system, separation of RDX, TNT and PETN was successfully achieved within 20 minutes. At a temperature of 30°C and methanol-water mixture of 50:50 was found as the optimum condition for the isocratic separation of target analytes. There was another study applying HPLC-UV for the analysis of organic high explosive on the analysis of nitroglycerin (NG) in post-blast samples [84]. By using reversed-phase C18 column employing acetonitrile-water (60:40) mixture and UV wavelength detection at 210 nm, the LOD of NG detection was obtained at very low concentration (20 ng).

Ultra-high performance liquid chromatography (UHPLC) has recently been a favorite among the researchers because of its effectiveness for compound separation. Makarov et al. used UHPLC equipped with photodiode array detector to study the hydrolysis kinetics of 2,4,6,8,10,12-hexanitro-2,4,6,8,10,12 hexaazaisowurtzitane (CL-20), octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX), and hexahydro-1,3,5- trinitro-1,3,5-triazine (RDX) [85]. By using liophilic salts (KPF6) as mobile-phase additives, the study obtained a good range detection limit of CL-20, HMX and RDX at range of 0.04-0.05 mg/L. UHPLC, when combined with mass spectrometry (MS) or tandem mass spectrometry (MS/MS), makes the instrument a powerful tool regarding selectivity and sensitivity. Schramm et al. [86] developed a hyphenated method of ultra-high performance liquid chromatography-atmospheric pressure chemical ionization-tandem mass spectrometry (UHPLC-APCI-MS/MS). Fifteen nitro explosives were successfully detected at very low concentration (0.3-0.5 ppb) and their degradation products in environmental water samples.

**Ion chromatography**

Ion chromatography (IC) method was used to separate inorganic anions and cations found in post blast residues from homemade inorganic explosives as one of the types that was frequently used in terrorism attacks. Johns et al. [18] conducted an analysis of inorganic explosives on pipe bomb and soil samples via IC using suppressed IC on a Dionex column with potassium hydroxide as eluent for anions. For cations analysis, a Dionex SCS 1 column was employed using oxalic acid/acetonitrile as eluent for detection. Both anions ($Cl^-$, $ClO_4^-$, $ClO_3^-$, $NO_3^-$ and $SO_4^{2-}$) and cations ($NH_4^+$, $Na^+$ and $K^+$) were successfully separated and detected.

Simultaneous determination of inorganic ions is very important to meet the need of real field determination. However, in most cases, anions and cations are usually determined separately using different separation systems with different types of columns and conditions. Meng et al. [87] developed a non-suppressed ion chromatographic method by connecting anion and cation exchange columns directly in series for the separation and determination of

five inorganic anions ($Cl^-$, $NO_2^-$, $NO_3^-$, $SO_4^{2-}$, and $ClO_3^-$) and three cations ($NH_4^+$, $K^+$, and $Na^+$) simultaneously in explosive residues. The method was successfully applied to the analysis of the inorganic explosive residues samples from the explosion site with satisfactory results.

**Capillary electrophoresis**

In the explosive analysis, capillary electrophoresis (CE) serves as a complimentary technique to ion chromatography (IC) in the analysis of inorganic low explosives residues. CE components require narrow-bore capillary, a controllable high voltage power supply, two electrode, two buffer reservoirs and a detector. In CE, the targeted analytes elute from one end of the capillary under the influence of electric field and the analytes are separated according to ionic mobility. The requirement of sample site is low and can be applied to both anions and cations. It gives shorter time of analysis but sacrificing the separation of analytes [88].

Hopper et al. [89] conducted simultaneous separation of anions and cations to analyze a variety of low explosives in post-blast residues. Both anions ($Cl^-$, $NO_2^-$, $NO_3^-$, $SO_4^{2-}$, $ClO_4^-$, $SCN^-$, $ClO_3^-$, and $OCN^-$) and cations ($NH_4^+$, $K^+$, $Na^+$, $Ca^{2+,}$ and $Mg^{2+}$) were successfully separated under 7 minutes. The major disadvantages of CE over IC are poor reproducibility and sensitivity. It gave lower sensitivity because of the low amount of analytes that could be injected resulting in tiny peak volumes [90]. Ahmad et al. [91] have developed a CE method by using 25 mM 2,6-pyridinedicarboxylic acid (PDC) as a background electrolyte (BGE) and the addition of 0.5 mM cetyltrimethylammonium hydroxide (CTAH) to reverse the direction of electroosmotic flow (EOF). This method was successfully used to determine four anions ($Cl^-$, $NO_3^{2-}$ and $SO_4^{2-}$, and $SCN^-$) and three cations ($Ca^{2+}$, $Fe^{2+,}$ and $Fe^{3+}$) simultaneously under 7 minutes at pH 4.7. This method was also successfully applied to the analysis of post-blast explosive residues of black powder and ammonium nitrate-fuel oil (ANFO).

**Other techniques**

There are other instrumental techniques, most of which were upgraded version of the conventional instrumental techniques for the analysis of explosive. Infrared spectroscopy was developed for detection of explosive in 1960. Pristera et al. [92] successfully compiled 68 infrared spectrograms including high explosive compound and other ingredients of explosive by using conventional dispersive IR spectroscopic method. Fourier transform infrared spectroscopy (FTIR) was discovered at the end of 1970. However, the application of FTIR on the explosive analysis began in 1990 with the analysis of HMX explosive compound [93]. Compared to conventional IR, FTIR gave more benefits in terms of speed of analysis and sensitivity. Primera-Pedrozo et al. [94] developed an advanced technique for qualitative and quantitative analysis of explosives on metallic surfaces using fibre optic coupled reflection/absorption infrared spectroscopy (RAIRS). Their study revealed low detection limit of 2,6-DNT (200 $ng/cm^3$), TNT (160 $ng/cm^3$), PETN (200 $ng/cm^3$), HMX (400 $ng/cm^3$), and Tetryl (200 $ng/cm^3$). However, the study was only limited to highly reflective metallic surfaces.

X-ray powder diffraction (XRD) and X-ray fluorescence (XRF) are non-destructive methods for the composition analysis of the crystalline materials. Both of the methods are different but complementary to each other whereby XRD is used to analyze the phases or compounds meanwhile XRF is utilized for the analysis of the elemental composition of the crystalline material [95, 96]. The analysis of explosive using XRD begun in 1947 with 18 organic explosives were chosen to study their X-ray diffraction pattern [97]. O'Flynn et al. [98] developed a pixellated X-ray diffraction (PixD) system by combining both angular and energy dispersive X-ray diffraction into one system. By integrating principal component and discrimination analysis into the PixD system, a model was developed which can be used to identify explosive and inert samples.

There are many difficulties involved in the identification of materials and devices after an explosion. Thus, a wide range of analytical techniques or instrumentations are currently available and applicable for analysis of explosive residues. The choices of method used are dependent upon the type of sample collected and the types of analytes to be examined and studied. Table 3 shows some of the survey of explosive residue analysis with various instrumentation technique and types of explosive samples.

Table 3. Survey of explosive residue analysis

| Analytes | Sample | Instrument | References |
|---|---|---|---|
| Urea nitrate (UN) | Post-blast debris | Gas chromatography mass spectrometry (GC/MS) | [99] |
| NB, 2-NT, 3-NT, 4-NT, 1,3-DNB, 2,6-DNT, 2,4-DNT, 3,4-DNT, 1,3,5-TNB, 2,4,6-TNT, AMDNT, Tetryl, HMX | - | Gas chromatography positive chemical ionization and tandem mass (GC/PCI/MS/MS) spectrometry | [82] |
| NG, 2,6-DNT, 2,4-DNT, TNT, PETN | Soil | Solvating gas chromatography with thermal energy analyzer (SGC/TEA) | [78] |
| TNT , DNT | TNT, dynamite | Gas chromatography with electron captured detector (GC/ECD) and Ion chromatography (IC) | [15] |
| PETN, RDX, TNT | Hair | Gas chromatography with electron captured detector (GC/ECD) | [28] |
| RDX, PETN | Semtex plastic explosive | Fourier transform-infrared spectroscopy (FTIR) | [14] |
| C-4, TNT, PETN | Improvised explosive devices (IED) | Fourier transform-infrared spectroscopy (FTIR) | [100] |

| TNT, 2,4-DNT, 2-ADNT, 4-NT, HMX, EGDN,NG | | explosives using electrospray ionization/ion mobility spectrometry (ESI-IMS) | [60] |

## Conclusion

The screening process from the usage of trained canine team to portable detection instrument either as sensors or a portable kit as an improvement on classical biological olfactory system shows the capabilities of new technology to be directly applied in fieldwork. Extraction process has evolved from year to year towards a green technology and has demonstrated a significant impact on the total cost, time consumption and decreased amount on chemical usage. Combined with the right instrumentation, research study allowed the constituent or element of interest to be analyzed with high selectivity and sensitivity. Simultaneous detection of anions and cations in inorganic explosive showed promise for the reduction of analysis time and chemical consumption. Developments of SPME techniques has become a trending method when compared to the conventional liquid extraction that consumed more chemicals and cause risk to researcher's health. The development of an explosive database in the future will become a great tool for researcher reference for lab-to-lab comparison.

Much research work can be improved in order to cope with the advancement in terrorism. For the sake of global security, other than enhancement of law enforcement and military strength, attention should be paid to the importance of research and development on the analysis of scientific evidence, particularly on explosive residue analysis.

## Acknowledgement

Thanks are due to the Department of Chemistry, Faculty of Science, Universiti Teknologi Malaysia, Johor, for research facilities as well as to Malaysian Ministry of Higher Education (MOHE) for financial assistance through FRGS grant no R.J130000.7826.4F200 (4F200). Collaboration assistance from Science & Technology Research Institute of Defense (STRIDE) is also greatly acknowledged.

**Abstract**

This study proposed lignocellulosic oil palm trunk (OPT) biomass can be used as alternative substrate for glucose emanation *via* enzymatic saccharification route. The OPT biomass was pre-treated using steam-alkali-chemical (SAC) method prior to enzymatic saccharification process for glucose formation. Three basic physiochemical parameters such as enzyme concentration (20 – 100 FPU.mL$^{-1}$), pH (4.0 – 8.0) and reaction temperature (30 – 60 °C) were intensively studied. Results revealed that all parameters gave significant effect on glucose production. By setting the enzyme hydrolysis conditions at pre-determined parameters points, i.e. enzyme concentration, 60 FPU.mL$^{-1}$; pH, 6.0 and reaction temperature, 50 °C, respectively; 4.27 g.L$^{-1}$ of glucose was attained at 72 hours hydrolysis. There is 4.49-fold of glucose increment in SAC-treated OPT substrate compared to untreated ones. This research also indicates enzyme digestibility can be enhanced by using treated OPT as substrate.

**Keywords:** oil palm trunk biomass, steam-alkali-chemical pre-treatment, enzymatic saccharification, cellulase enzyme

**Abstrak**

Kajian ini mencadangkan lignoselulosa biomas batang kelapa sawit (OPT) boleh digunakan sebagai alternatif substrat bagi penghasilan glukosa melalui kaedah enzim sakarifikasi. Biomas OPT terlebih dahulu dirawat dengan wap-kimia-alkali (SAC) sebelum proses sakarifikasi enzimatik bagi pembentukan glukosa. Tiga fizikokimia parameter asas seperti kepekatan enzim (20 – 100 FPU.mL$^{-1}$), pH (4.0 – 8.0) dan suhu tindak-balas (30 – 60 °C) telah dikaji secara intensif. Hasil kajian menunjukkan bahawa semua parameter memberi kesan ke atas pengeluaran glukosa. Dengan menetapkan syarat enzim hidrolisis pada parameter yang telah ditentukan, iaitu masing-masing; kepekatan enzim, 60 FPU.mL$^{-1}$; pH, 6.0 dan suhu tindak-balas, 50 °C; 4.27 g.L$^{-1}$ glukosa telah dicapai pada 72 jam hidrolisis. Glukosa meningkat sebanyak 4.49 kali ganda dalam SAC-rawatan OPT substrat berbanding yang tidak dirawat. Kajian ini juga membuktikan penghadaman enzim boleh dipertingkatkan dengan menggunakan OPT terawat sebagai substrat.

**Kata kunci:** biomas batang kelapa sawit, pra-rawatan wap-kimia-alkali, sakarifikasi enzimatik, enzim selulase

## Introduction

Glucose is one of the most important monosaccharide with the chemical formula of $C_6H_{12}O_6$ and a molar mass of 180.16 g.mol$^{-1}$. It is the simplest form of sugar and serves as a main carbon source to living organisms including animals, human, plants and microbes for energy and metabolic requirement. Recently, glucose is produced from

lignocellulosic biomass waste such as sugarcane bagasse [1], corn stover [2] and oil palm [3]. This is because lignocellulosic biomass waste contains a higher amount of cellulose and hemicellulose which are able to be converted into sugars (mainly glucose). The produced glucose can be used as a cheaper alternative to feedstock for industrial applications particularly in fermentation industry. Usually, cellulase enzyme is required and employed to achieve the convertible goal. The efficiency of enzyme conversion towards its substrate depends on the enzymatic saccharification system. This means that the system has to provide optimal conditions for enzyme to digest its substrate in order for maximum product formation to occur. In line with this, fundamental physiochemical parameters such as enzyme concentration, pH and reaction temperature must be well manipulated [4].

However, the native behavior of recalcitrant lignocellulosic biomass makes the enzyme hydrolysis more challenging. In order to maximize sugar formation from lignocellulosic substrate, pretreatment on lignocellulosic biomass is inevitable. Apparent objectives of the pretreatment are i) to alter the structure of lignocellulose so as to make cellulose more accessible to cellulase and ii) to shatter the lignin seal and disrupt the crystalline structure of cellulose [5]. Therefore, the pretreatment step is crucial as it can maximize cellulose recovery from lignocellulosic substrate into usable form. Previous study has shown that microwave-alkali (Mw-A) pretreatment is capable of reducing lignin in small quantity. In contrast, steam-alkali-chemical (SAC) which is a double-step pretreatment method has proven to be more efficient in terms of lignin removal. According to Lai et al. [6], a significant decrease in the amount of lignin i.e. 87.07% was seen when using SAC method; whereas reduction of lignin using Mw-A pretreatment method was recorded to be only 15.33%. Lignin removal is essential since the presence of lignin will act as a shield that prevents cellulose from being hydrolyzed by cellulolytic enzymes. Thus, the double-step pretreatment (i.e. SAC method) was selected and used to pre-treat the OPT substrate in this study.

Currently, Malaysia is recognized as the world's second largest palm oil producers after Indonesia [7]. The oil palm biomass waste has amounted to 59 million tons annually which include (dry weight): oil palm empty fruit brunches (OPEFB), oil palm frond (OPF) and oil palm trunk (OPT), respectively. To eliminate bulk oil palm biomass in a more economic way; one of the method is to convert the oil palm biomass into fermentable sugars. The formed sugars (mainly glucose) can be utilized as carbon feedstock by microbes to produce the desired fermentative products such as organic acids, bio-ethanol and so on. The present study has chosen oil palm trunk (OPT) biomass as the substrate candidate. This is due to limited research data that focused on oil palm trunk studies compared to other parts of oil palm such as oil palm frond, oil palm empty fruit bunch and palm kernel shell. [8]. In order to maximize lignin removal and cellulose recovery, steam-alkali-chemical (SAC) pre-treatment method is used to accomplish the objectives. There are three important parameters to be considered for glucose conversion under enzymatic saccharification process, namely: enzyme concentration, pH and reaction temperature and all was investigated thoroughly. Apart from that, the findings of this research can provide complementary research data to oil palm study.

## Materials and Methods

### Raw materials

The pulverized oil palm trunk (OPT) biomass was provided by Concept Renewable Energy Sdn. Bhd., Malaysia. It was sieved to a particle size of less than 1.0 mm and dried at 45 °C for 3 days [7].The OPT samples were kept in 4 °C chiller prior to pre-treatment and enzymatic hydrolysis.

### Chemical reagents and enzymes

The chemicals used in the experiment were of analytical grade with highest purity, i.e. 96 – 99% and purchased from Merck (M) Sdn. Bhd. namely: sodium hydroxide (NaOH), acetic acid ($CH_3COOH$), potassium sodium tartrate ($KNaC_4H_4O_6{\cdot}4H_2O$), sodium metabisulfite ($Na_2S_2O_5$), phenol ($C_6H_6O$), sodium azide ($NaN_3$) and 3,5-dinitrosalicylic acids. The household bleach (sodium hypochlorite solution, 5.75% active chlorine) was bought from Tesco hypermarket. Meanwhile, the cellulase enzyme produced from *Trichodermareesei*, citric acid monohydrate ($C_6H_{10}O_8$) and trisodium citrate dehydrate ($C_6H_9Na_3O_9$) were obtained from Sigma-Aldrich (M) Sdn. Bhd.

### Steam-alkali-chemical (SAC) pre-treatment method

Ten grams of oil palm trunk (OPT) sample was soaked in a beaker containing 200 mL of 2.5 M NaOH solution for 1 hour. The mixture was brought to autoclave at temperature, 121 °C; reaction time, 20 min and pressure, 1.224 kg-

force.cm$^{-2}$, respectively [6]. Upon completion, the aqueous NaOH solution was discarded and the OPT slurry was washed with tap water (4 x 1000 mL) followed by distilled water (4 x 1000 mL). The steam alkaline slurry was then added with 200 mL of NaClO. The pH of the mixture was adjusted to acidic condition at pH 3.5 using $CH_3COOH$ [9]. The acid solution was then filtered-off and washed again with tap water (4 x 1000 mL) followed by distilled water (4 x 1000 mL). The SAC treated oil palm trunk sample was freeze-dried and kept at 4 °C for enzymatic saccharification reaction. The content of the chemical constituents such as cellulose, hemicellulose, lignin and extractives of raw and treated OPT substrate is presented in Table 1.

Table 1. Chemical composition of raw and treated oil palm trunk biomass (g per 100 g biomass)

| Pretreatment | (g per 100 g biomass) | | | |
|---|---|---|---|---|
| Type | Cellulose | Hemicellulose | Lignin | Extractives |
| Raw[7] | 50.78 ± 1.05 | 30.36 ± 1.10 | 17.87 ± 1.68 | 0.99 ± 1.73 |
| Mw-A[7] | 71.88 ± 2.55 | 11.77 ± 2.30 | 15.13 ± 0.40 | 1.22 ± 0.16 |
| SAC[9] | 42.70 ± 0.57 | 52.80 ± 1.36 | 1.90 ± 0.04 | 2.60 ± 0.76 |

All measurements were duplicated and fall within the relative percentage difference below 5% [10].
Mw-A: Microwave-alkali, SAC: Steam-alkali-chemical

**Cellulase enzyme activity**

The cellulase enzyme activity was measured according to Ghose's protocol [11]. One unit of filter paper unit (FPU) was defined as the amount of enzyme which produced 2.0 mg of glucose from 50 mg of filter paper at temperature, 50 °C; pH, 4.8 and reaction time, 60 min, respectively. The cellulase activity obtained from this assay was 104.42 FPU.ml$^{-1}$.

**Enzymatic hydrolysis and glucose analysis**

The enzymatic saccharification reaction was performed in a glass jar and the reaction temperature was manipulated using water bath. 1 % (w/v) of SAC-treated OPT was discharged into a glass jar containing 20 mL of 50 mM sodium citrate buffer and 100 µL of 2 % of $NaN_3$. In the enzymatic hydrolysis study, physiochemical parameters such as enzyme concentration (20 – 100 FPU.mL$^{-1}$), pH (4.0 – 8.0) and reaction temperature (30 – 60 °C) were tested using one-a-time variable method. For instance, when enzyme concentration analysis was carried out, both pH and temperature were set to 4.8 and 50 °C, respectively. The pre-set constant values were set according to the manufacturer's recommendation [12]. Once the optimal conditions such as enzyme concentration, pH and temperature were pre-determined; these selected conditions were used to re-run the enzymatic saccharification on untreated and SAC-treated OPT.

For all enzymatic study, exactly 200 µL of enzyme hydrolysate was withdrawn and deposited into microtube at specific intervals. The sample was mixed with DNS reagent (ratio of sample and DNS = 1:1), heated and agitated at 100 °C and 400 rpm, respectively for 15 min on a thermoblock. The brown color solution was used to determine glucose concentration at 540 nm using spectrophotometer (Thermo, Genesys 20). The reducing sugars derived from enzyme hydrolysis were considered as glucose equivalent [13]. All hydrolysis experiment was performed in triplicate and error was within ± 5% [14].

## Results and Discussion

**Effect of different enzyme concentration on glucose production**

In this study, cellulase concentrations (20 – 100 FPU.mL$^{-1}$) were tested at fixed pH, 4.8; reaction temperature, 50 °C and substrate mass, 1% (w/v), respectively. Figure 1 illustrates the 72 hours' time profile of glucose formation derived from saccharification process.

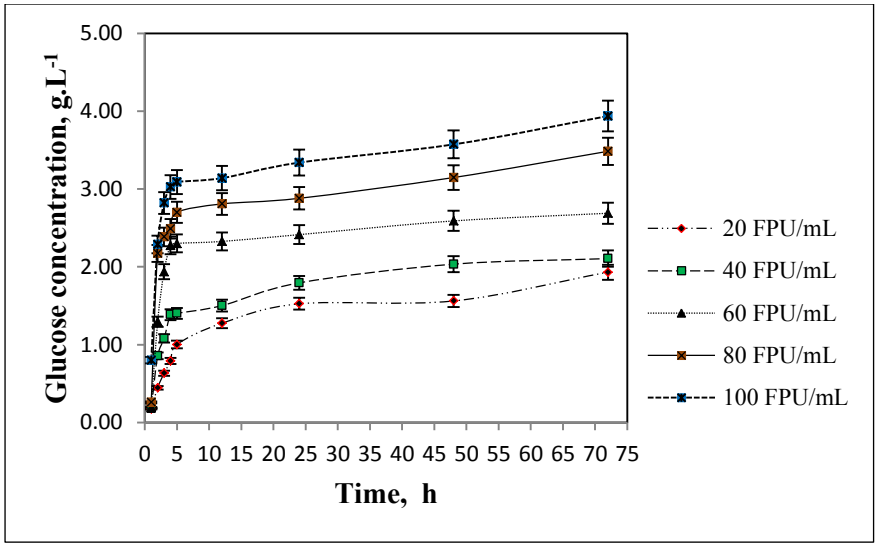

Figure 1. Effect of different enzyme concentration (20 – 100 FPU/mL) on glucose production

After the 72 hours enzyme saccharification, a glucose concentration of 1.93 $g.L^{-1}$ was recorded at 20 $FPU.mL^{-1}$ enzyme concentrations. When the enzyme amount increases from 40 – 100 FPU/mL, glucose concentration also increased to 2.11 – 3.94 $g.L^{-1}$ with an increment value of 9.32 – 104.15%. This indicates that formation of glucose amount in the present study could be enhanced by supplying a higher dose of cellulase enzyme. When more cellulase is supplied, there will be extra active sites available for substrate (present study: substrate is SAC-treated OPT). Hence, it will be easier for substrate to bind to the enzymes' active sites to form enzyme-substrate complex. This will eventually accelerate the enzymatic reaction and thus more glucose is released.

Although, the maximum glucose concentration was attained at 100 $FPU.mL^{-1}$; 60 $FPU.mL^{-1}$ of cellulase concentration was selected for the subsequent enzymatic study. This is because the cellulase enzyme cannot be recycled and a higher dose of enzyme usage will contribute to higher operation cost. Moreover, previous studies which demonstrated the usage of cellulase enzyme in enzymatic saccharification on lignocellulosic biomass for glucose production, utilized enzyme concentrations within the range of 20 – 60 $FPU.mL^{-1}$ [15-17]. Based on these views, enzyme concentration at 60 $FPU.mL^{-1}$ was selected and used for the next experiment.

**Effect of different pH on glucose production**

In this investigation, different pH values (pH 4.0 – 8.0) were tested on pre-selected enzyme concentration (60 $FPU.mL^{-1}$), reaction temperature (50 °C) and 1% (w/v) of SAC-treated OPT substrate for glucose production. Figure 2 depicts glucose concentration increased from strong to weak acidic condition (pH 4.0 – 6.0), i.e. 1.27 to 4.03 $g.L^{-1}$. There is about 3.17-fold of glucose increment when compared to pH 6.0 and pH 4.0. On the other hand, at neutral and weak alkaline pH conditions (i.e. pH 7.0 and pH 8.0), the glucose concentration slightly declined compared to pH 6.0, *viz.*10.92 – 11.66 % or equivalent to 3.56 and 3.59 $g.L^{-1}$, respectively. In general, the ionic group of enzyme reacts well within suitable pH ranges either in acidic or alkaline conditions. The variation of pH causes modification on enzymes' ionic groups and its three-dimensional structure [18]. The changing of enzyme structure or shape makes substrate unfit to enzymes' active sites and thus reduces the chances of enzyme-substrate complex formation. This can directly impede the rate of enzymatic reaction.

Current study revealed that cellulase enzyme is active in weak acidic and weak alkaline pH range (pH 6.0 – 8.0). The stronger acidic pH conditions (< pH 6.0) did not favour the cellulase hydrolysis. This is the reason for getting lower glucose content at pH 4.0 – 5.0 compared to pH 6.0 – 8.0. It is obvious that the optimal pH point is pH 6.0 and it was chosen for subsequent study.

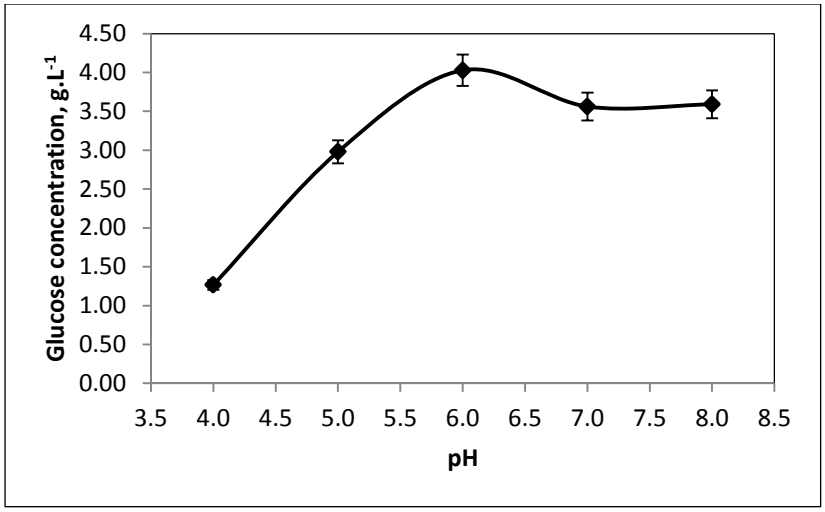

Figure 2. Effect of different pH (4.0 – 8.0) on glucose production

**Effect of different temperature on glucose production**

The range of temperatures, 30 to 60 °C was tested for glucose production by using 1% (w/v) of SAC-treated OPT sample. Other parameters such as enzyme concentration and pH were pre-set according to previous studies, i.e. 60 $FPU.mL^{-1}$ and pH 6.0, respectively.

Figure 3 demonstrates the glucose production from cellulase-SAC OPT hydrolysis at different temperature points. It is observed that glucose amount increased from 2.01 to 3.68 $g.L^{-1}$ when reaction temperatures rise from 30 to 50 °C. The total increment is up to 83.08%. The possible explanation is that the enzyme-catalysed reaction like most chemical reactions; proceeds at a faster velocity when temperature is increased. The temperature rise during enzymatic saccharification process imparts more kinetic energy to reactant molecules, resulting in more productive collision per unit time [19]. Consequently, more glucose is released when the system temperature was boosted from 30 to 50 °C.

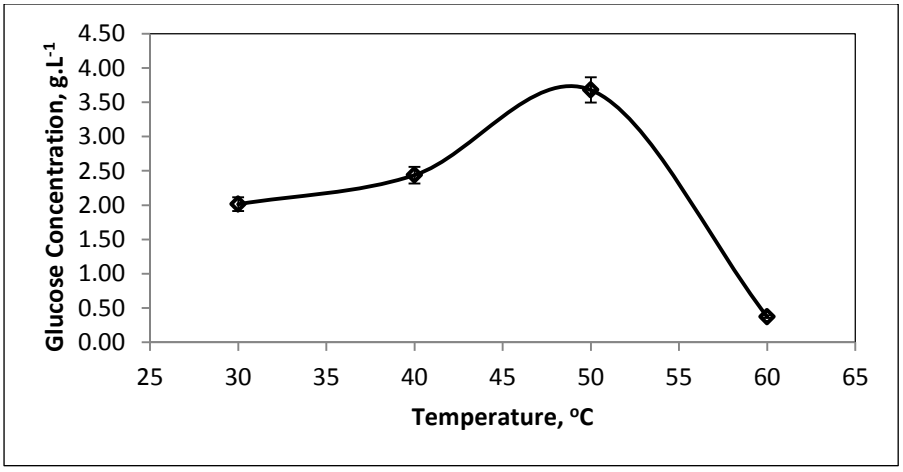

Figure 3. Effect of different temperature (30 – 60 °C) for glucose production

On the other hand, only 0.37 $g.L^{-1}$ of glucose concentration was obtained at 60 °C. This is in line with the fact that enzyme molecules possess delicate structure. The disruption of enzyme tertiary structure can occur when enzyme is exposed to temperature beyond its optimal point (present study; temperature optimal point = 50 °C). Similar phenomenon is observed in hydrolysis of cellulase-Mw-A treated OPEFB substrate where cellulase displayed deactivation when the reaction temperature is beyond 50 °C [20]. As shown in Figure 3, enzyme is considered to be partially denatured as it lose its catalytic power when temperature > 50 °C. This explains why reaction temperature of 60 °C gained less glucose amount compared to reaction temperature of 30 and 40 °C, respectively. Based on Figure 3, the optimal hydrolysis temperature point is 50 °C and it was selected for subsequent enzymatic experiment.

**Comparison of untreated and SAC-treated OPT under pre-determined enzymatic conditions**

The comparison of untreated and SAC-treated OPT sample was performed under pre-determined enzymatic conditions where enzyme concentration, pH and reaction temperature were set to 60 $FPU.mL^{-1}$, 6.0 and 50 °C, respectively. The amount of both substrates used in this study was 1% (w/v). After the 72 hours enzyme hydrolysis, up to 4.27 $g.L^{-1}$ glucose concentration was obtained in SAC-treated OPT; whereas the untreated OPT sample only produced 0.95 $g.L^{-1}$ of glucose (as shown in Figure 4). The glucose increased 4.49-fold when using the SAC-treated OPT biomass as a substrate.

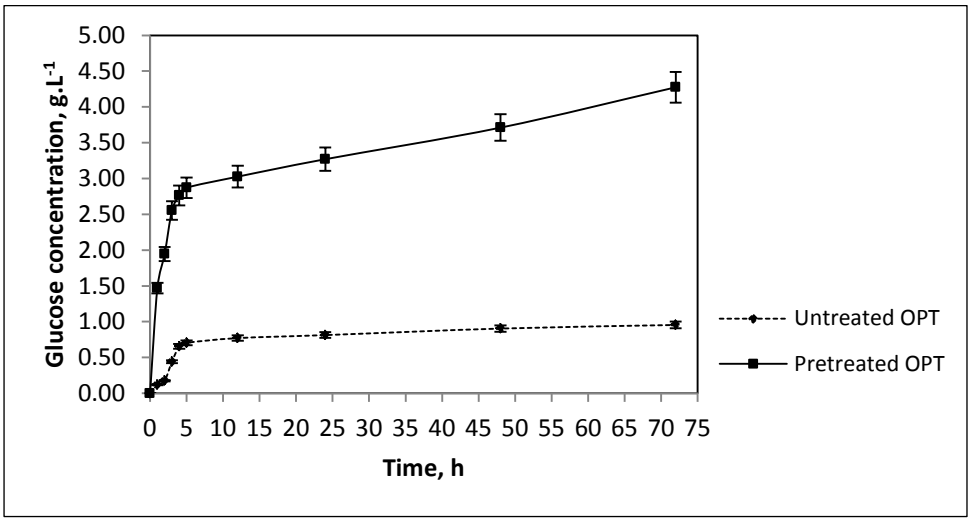

Figure 4. Glucose production for untreated and SAC-treated OPT under pre-selected enzyme hydrolysis conditions

The SAC pre-treatment process has enhanced the enzyme digestibility towards its substrate. This is attributed to disruption of encrusted lignocellulosic OPT structure by loosening the complex linkage among the cellulose, hemicellulose and lignin. Hence, more amorphous cellulose is released and readily available for cellulase enzyme. Binod et al. stated that treated lignocellulosic biomass contain more amorphous cellulose whereas untreated biomass contain more crystalline cellulose and the former is easily digested by cellulose [21]. In short, SAC pre-treatment process can effectively enhance the enzymatic saccharification rate in this study.

A recent report revealed that 72 hours enzymatic hydrolysis on SAC treated oil palm trunk biomass produced 16.59 $g.L^{-1}$ of glucose [9]. In contrast, the present study which had used a single enzyme (cellulase) to accomplish the hydrolysis process only produced 4.27 $g.L^{-1}$ of glucose at 72 hours. The main reason for the significant difference (glucose concentration) between these works is the use of an additional enzyme, i.e. addition of β-glucosidase in hydrolysis reaction. The existence of β-glucosidase not only improves enzymatic hydrolysis performance but also expedites the enzymatic saccharification rate. Therefore, more glucose is formed in the former study. However,

when using two enzymes in hydrolysis reaction, the glucose production cost will dramatically increase. Moreover, the cellulolytic enzymes cannot be recycled. Since one of the objective is to reduce the operational cost, this study only employed cellulase enzyme in the saccharification reaction for glucose production.

In another study, Hamzah et al. had conducted 24 hours' enzyme hydrolysis on Mw-A treated OPEFB [20]. The glucose amount of 0.49 $g.L^{-1}$ and 0.72 $g.L^{-1}$ were recorded for single enzyme (cellulase) and two enzymes (cellulase + β-glucosidase), respectively. Comparatively, 3.27 $g.L^{-1}$ amount of glucose was formed at 24 hours (see Fig. 4); which is 4.51 to 6.67-fold higher than previous study. This explains that SAC-treated substrate with its lower lignin content has more advantage compared to Mw-A treated substrate. The double-step pre-treatment outperformed single-step pretreatment in lignin removal. Lignin behaves like a protected shield and avoids cellulose from being hydrolyzed by cellulase. Through harsher pre-treatment method (like SAC conditions), lignin is removed effortlessly and more amorphous cellulose is exposed. Consequently, enzyme digestibility towards SAC OPT substrate is enhanced and resulted in more glucose formation.

## Conclusion

Three physiochemical parameters namely: enzyme concentration, pH and reaction temperature were tested in this investigation. Results divulged that optimal conditions for enzyme hydrolysis on steam-alkali-chemical (SAC) treated OPT were 100 $FPU.mL^{-1}$ of enzyme concentration, pH 6.0 and reaction temperature at 50 °C, respectively. However, 60 $FPU.mL^{-1}$ of cellulase was chosen in the subsequent enzymatic study as to reduce the operational cost for glucose production. A 4.49-fold of glucose increment was attained in enzymatic saccharification on SAC-treated OPT compared to untreated ones. In conclusion, SAC pretreatment can be potentially scaled up for industrial applications. The study also suggested that oil palm trunk biomass can be a cheaper alternative of substrate for high value added products such as glucose.

## Acknowledgement

The authors would like to thank to Concept Energy Resources (M), Sdn. Bhd. and Faculty of Engineering and Life Sciences, Universiti Selangor for providing the oil palm trunk sample, facilities and chemical reagents, respectively during this investigation.

# THE CHEMICAL CONSTITUENTS FROM YOUNG TUBERS of *Hydnophytum formicarum*

## (Juzuk Kimia Daripada Tuber Muda *Hydnophytum formicarum*)

Nur Shafiqa Abdullah, Wan Yaacob Wan Ahmad*, Noor Aziiraa Sabri

Received: 6 December 2016; Accepted: 16 January 2017

**Abstract**

The fine powders of young tubers of *Hydnophytum formicarum* was extracted by Soxhlet methanol extraction for 18 hours in three days continuously. The filtrate then was evaporated by rotary evaporator until it became concentrated solution. The fractionation and purification of the extract by vacuum liquid chromatography and radial chromatography has led to the discovery of four compounds namely sinapinic acid, β-sitosterol acetate, β-sitosterol and stigmasterol. Structures of the compounds were established by interpreting mass spectral data, $^{1}$H and $^{13}$C-APT NMR, Infrared and by comparison with literature data.

**Keywords**: *Hydnophytum formicarum*, sinapinic acid, β-sitosterol acetate, β-sitosterol, stigmasterol

**Abstrak**

Serbuk halus tuber muda *Hydnophytum formicarum* telah diekstrak melalui pengekstrakan Soxhlet selama 18 jam dalam tiga hari secara berturutan. Hasil penurasan kemudian telah disejat menggunakan penyejat berputar sehingga menjadi larutan yang likat. Pemfraksian dan penulenan ekstrak menggunakan kromatografi cecair vakum dan kromatografi radial membawa kepada penemuan empat sebatian yang bernama asid sinapinik, β-sitosterol asetat, β-sitosterol dan stigmasterol. Struktur sebatian ini telah ditentukan dengan mentafsirkan data spektrum jisim, RMN $^{1}$H dan $^{13}$C-APT, Inframerah serta secara membandingkannya dengan data kepustakaan.

**Kata kunci:** *Hydnophytum formicarum*, asid sinapinik, β-sitosterol asetat, β-sitosterol, stigmasterol

## Introduction

Rubiaceae is the largest plant family containing 10,700 species and 637 genera that consists mainly of tropical woody plants with great pharmacological potential [1]. The previous phytochemical study of all Rubiaceae species, published from 1990 to 2014, stated that the most common secondary metabolites of this family were iridoids, anthraquinones, triterpenes and indole alkaloids as well as other varying alkaloid subclasses [2]. One of the species, *Hydnophytum formicarum* or ant plant, is a tuberous ephyphytic of medicinal plant known in Malaysia as Raja Satong or Kepala Beruk or Sarang Semut. It is commonly found in Southeast Asia (Malaysia and Indonesia), Papua New Guinea and Pacific Islands [3].

The objectives of this study are to isolate compounds from the young tubers of *Hydnophytum formicarum* by extraction and fractionation using several chromatographic techniques as well as to elucidate structures of pure

compounds. Traditionally, the decoction of *Hydnophytum formicarum* tubers was used as a drink for liver and intestinal complaints. Soxhlet extraction with methanol was employed in this study in view of the use of the tubers by local people for medicinal purposes by boiling in water . Moreover, more constituents can be extracted by Soxhlet compared to maceration. Darwis et al. reported flavonoid, phenolic, aldehydes, ketones, terpenoids and tannin in the ethanol *Hydnophytum formicarum* extract [4]. Previous studies reported several compounds from *Hydnophytum formicarum* such as β-sitosterol [5], 7,3′,5′-trihydroxyflavanone [6], stigmasterol, protocatechualdehyde, butin, butein, and isoliquiritigenin [3]. Figure 1 below shows a young tuber of *Hydnophytum formicarum*. The tubers of *Hydnophytum formicarum* have been scientifically proven to contain bioactive constituents such as antioxidant and antimicrobial [3] and antiproliferative [7].

Figure 1. Young tuber of *Hydnophytum formicarum*

## Materials and Methods

### General

The $^{1}H$ and $^{13}C$-APT NMR spectra were recorded with Avance III 700 MHz Bruker in $CDCl_3$ with the chemical shifts, δ, in ppm and the values of coupling constants, *J*, in Hz. LC-MSToF spectra were taken on the Dionex/Bruker Micro ToFQ and FTIR spectra were recorded on the Perkin-Elmer Spectrum 400 FT-IR/FT-NIR.

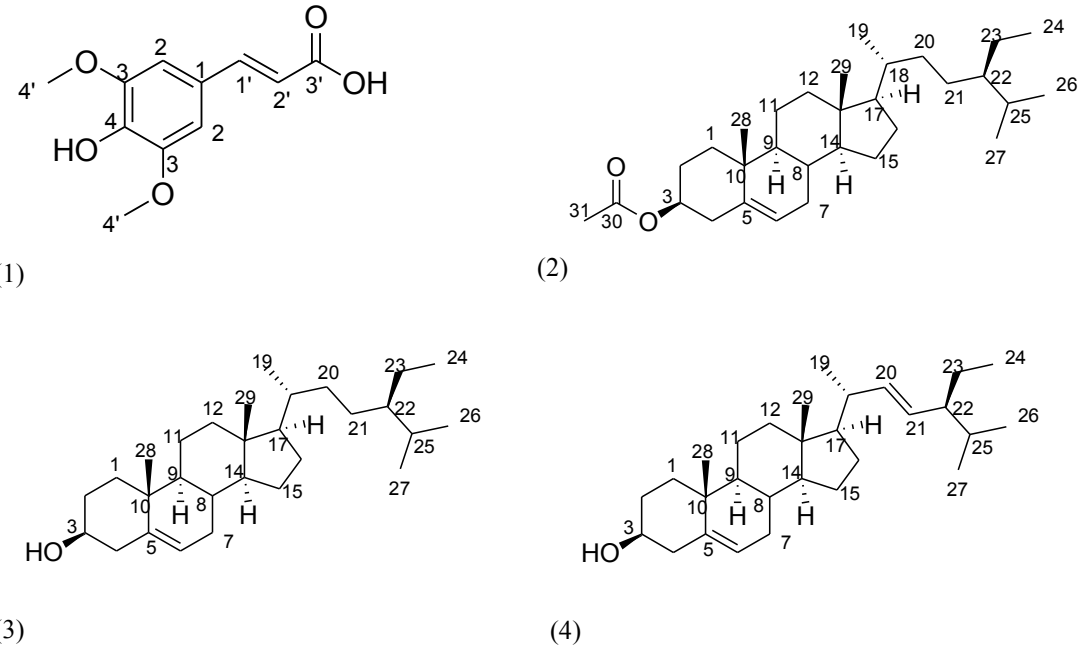
### Plant material

Young tubers of *Hydnophytum formicarum* were bought in April 2015 from a seller at Kampung Lak Lok, Jertih, Besut, Terengganu. A voucher specimen (UKMB 40312) was deposited at the Herbarium of Universiti Kebangsaan Malaysia Bangi (UKMB).

### Extraction and isolation

The air-dried young tubers of *Hydnophytum formicarum* were cut into small pieces and ground into fine powder by using grinding machine. The powder (1.04 kg) was then extracted with methanol by using Soxhlet for 6 hours in three days to give 15.0 g (1.44 %) of dark-brown extract after solvent removal by rotary evaporator. The extract was subjected to vacuum liquid chromatography (VLC) by using silica gel 7747 (Merck) eluted with increasing polarity of *n*-hexane and ethyl acetate. The eluents were combined based on their silica gel thin layer chromatography (TLC) (Merck 5554) profile to give seven fractions (A-G). Fraction A and B was washed with *n*-hexane to give stigmasterol (37.0 mg) and β-sitosterol (22.0 mg). Fraction E (0.84 g) was further purified by column chromatography (CC) using *n*-hexane-ethyl acetate (7:3) to yield six fractions (E1-E6). The E6 was pure to give sinapinic acid (29.0 mg). Fraction C (1.2 g) was further purified by radial chromatography (RC) using *n*-hexane-ethyl acetate (7:3) to produce β-sitosterol acetate (23.7 mg).

## Results and Discussion



### Characterization study

Sinapinic acid (29.0 mg): white powder; Rf = 0.70 (*n*-hexane-ethyl acetate, 7:3); ESI-MS (m/z): 247.2077 $[M+Na]^+$, $C_{11}H_{12}O_5$; FTIR (ATR) $cm^{-1}$: 3412 (O-H), 2916 and 2849 ($Csp^3$-H), 1711 (C=O carboxylic acid), 1268 and 1158 (C-O), 1463-1632 (C-C aromatic), 718-1032 ($Csp^2$-H).

β-Sitosterol acetate (23.7 mg): white needles; Rf = 0.81 (*n*-hexane-ethyl acetate, 7:3); ESI-MS (m/z): 479.3404 $[M+Na]^+$, $C_{31}H_{52}O_2$; FTIR (ATR) $cm^{-1}$: 2928 and 2868 (C*sp*$^3$-H), 1674 (C=O), 1458, 1378 (C*sp*$^3$-H).

β-Sitosterol (22.0 mg): white needles; Rf = 0.94 (*n*-hexane-ethyl acetate, 8:2); ESI-MS (m/z): 437.6012 $[M+Na]^+$, $C_{29}H_{50}O$; FTIR (ATR) $cm^{-1}$: 3374 (O-H), 2933 and 2866 (C*sp*$^3$-H), 1052 (C-O), 801 (O-H), 1463 and 1378 (C*sp*$^3$-H), 801-957 (C*sp*$^2$-H).

Stigmasterol (37.0 mg): white needles; Rf = 0.90 (*n*-hexane-ethyl acetate, 9:1); ESI-MS (m/z): 435.4306 $[M+Na]^+$, $C_{29}H_{48}O$; FTIR (ATR) $cm^{-1}$: 3330 (O-H), 2931 and 2869 (C*sp*$^3$-H), 1052 (C-O), 800 (O-H), 1644 (C=C), 1463, 1376 (C*sp*$^3$-H).

Source: *[8]

Comparison of $^{1}H$ and $^{13}C$-APT NMR spectral data of sinapinic acid (Table 1) with those literature data confirmed that both are of the same compound [8]. The ESI-MS gave molecular ion at m/z 247.2077 $[M+Na]^+$, which corresponded to the molecular formula $C_{11}H_{12}O_5$. Sinapinic acid and its ester had been isolated from Rubiaceae family such as *Gardenia jasminoides* [12] and *Mussaenda incana* [13] supports its existence in *Hydnophytum formicarum*.

Similarity of $^{1}H$ and $^{13}C$-APT NMR spectral data of β-sitosterol acetate (Table 2) with those of Gohari et al. and Ran et al. confirmed that they are of the same structure. The ESI-MS showed molecular ion at m/z 479.3404 $[M+Na]^+$, which is in accordance with the molecular formula $C_{31}H_{50}O_2$. To the best of our knowledge, this is the first time β-sitosterol acetate has been isolated from *Hydnophytum formicarum*, and this sterol has never been reported before from any other genus of Rubiaceae.

The NMR spectral data ($^{1}H$ and $^{13}C$-APT) of β-sitosterol and stigmasterol (Table 3) in agreement with those of literature data [11]. The ESI-MS exhibited respective molecular ions at m/z 437.6012 $[M+Na]^+$ and 435.4306 $[M+Na]^+$, which matched the molecular formulas of $C_{29}H_{50}O$ (β-sitosterol) and $C_{29}H_{48}O$ (stigmasterol). Besides frequent identification of these sterols as common compounds in many plants species, they are also found in the Rubiaceae family such as *Fadogia homblei* [14] and *Rudgea jasminoides* [15].

## Conclusion

Chromatographic separation of Soxhlet methanol extract of *Hydnophytum formicarum* young tubers yielded four compounds namely sinapinic acid, β-sitosterol acetate, β-sitosterol and stigmasterol. Sinapinic acid and β-sitosterol acetate can be used to evaluate their biological activities such as antimicrobial, antioxidant, anti-cancer and anti-inflammatory properties.

## Acknowledgement

We would like to thank the Ministry of Education, Malaysia and Univeristi Kebangsaan Malaysia (UKM) for financial support under the DLP-2013-018 grant. Special thanks to School of Chemical Sciences and Food Technology, Faculty of Science and Technology, UKM and Centre for Research and Innovation Management (CRIM) UKM for the technical support on NMR, LC-MSToF and FTIR instrumentation.

**Abstract**

Isolation of compounds from methanol extract from the leaves of *Adiantum latifolium* Lam. had been conducted by using radial chromatography and thin layer chromatography (TLC) techniques. Their structures were elucidated by ultraviolet-visible (UV), infrared (IR), nuclear magnetic resonance (NMR) and mass spectroscopy (MS) and by comparison with the previous literatures. Four steroids compound were isolated namely the Stigmast-4-en-3-one (**1**), Stigmasta-4,22-dien-3-on (**2**), Stigmasterol (**3**) and *β*-Sitosterol (**4**).

**Keywords:** *Adiantum latifolium*, adiantaceae, steroid

**Abstrak**

Pengasingan sebatian daripada ekstrak metanol daripada daun *Adiantum latifolium* Lam. telah dilakukan dengan menggunakan teknik kromatografi pepejal dan teknik kromatografi lapisan nipis (TLC). Struktur semua sebatian dicirikan dengan menggunakan ultra lembayung (UV), inframerah (IR), resonans magnet nukleus (NMR) dan spektroskopi jisim (MS), dan secara perbandingan dengan data kepustakaan. Empat sebatian steroid telah diasingkan iaitu, Stigmasta-4-en-3-on (**1**), Stigmasta-4,22-dien-3-on (**2**), Stigmasterol (**3**) and *β*-Sitosterol (**4**).

**Kata kunci:** *Adiantum latifolium*, adiantaceae, steroid

## Introduction

*Adiantum* is a genus belonging to the Adiantaceae family that consists of nearly 150 species and are widely distributed all over the world [1]. This species is indigenous to the central of America and northern South America and known as the common weed species in plantation [2]. It was introduced into Malaysia and became naturalized especially in palm plantation as weed. *Adiantum* is known in different names between countries. In some countries, this species is known as Maidenhair fern (English), Hansraj (India) and Tie Xian Jue Shu (China). Traditionally, most of the *Adiantum* species are used for treatments of chest complaints, cough, increase of lactation, colds, aid-kidney function, antiphrastic and to treat dandruff [3]. In Chinese medicinal practice, they also use *Adiantum* species to cure human and animal diseases including relief of internal heat or fever, enhancement of urination, removal of urinary calculus, relief of cough, cure of diarrhea and bleeding stoppage [4]. Concerning the phytochemical studies, most of *Adiantum* species have produced sterols [5, 6], any classes of flavonoid triterpenoids [7, 8, 9] and any classes of triterpenoids [10]. According to Nonato et al., *Adiantum latifolium* Lam can be used to

treat anxiolytic and analgesic [11]. So far, the chemical structures from *Adiantum latifolium* Lam have not reported. The main objective of this paper is to describe the isolation and structure characterization from the frond part of *Adiantum latifolium* Lam.

## Materials and Methods

### Plant materials

In July 2014, the leaves part of *Adiantum latifolium* Lam were collected from Tasik Chini Research Center, Pahang, Malaysia. Herbarium specimen of NMK091 was deposited at the Universiti Kebangsaan Malaysia Herbarium (UKMB).

### Extraction and isolation

Dried ground of the leaves of *Adiantum latifolium* Lam (120 g) was macerated with methanol at room temperature. The filtrate was concentrated using a rotary evaporator to yield a dark green extract (4 g, 4%). A 3-g portion of the extract was fractionated by using radial chromatography (RC) with 4 mm thickness silica gel on a round glass plate eluted with increasing polarity of *n*-hexane-EtOAc. The eluents that showed the same profile on thin layer chromatography (TLC) chromatogram were combined to give three fractions (I-III). Purification of fraction I (600 mg) was carried out using RC with a silica gel plate of 1 mm thickness eluted with 95:5 *n*-hexane-EtOAc in 5% polarity increment to yield compounds **1** (3 mg). Purification of fraction II (410 mg) was conducted, utilizing another RC with silica gel plate of 1 mm thickness. Elution with 9:1 *n*-hexane-EtOAc produced compound **2** (5 mg) and **3** (20 mg). Purification of fraction III (430 mg) was then performed using RC with the silica gel plate of 1 mm. Elution with 7:2:1 *n*-hexane-EtOAc-$CHCl_3$ resulted in compound **4** (8 mg).

### Compound identification

Structure elucidation of pure compound was determined based on the spectral data recorded on Shimadzu UV-260 spectrophotometer, Frontier Perkin-Elmer FTIR/NIR spectrophotometer and Bruker NMR 700 MHz Cryo-Probe instrument that included 1-D and 2-D NMR. Mass of compounds was recorded by using LCMS-Ultra Performance Liquid Chromatography (UPLC), Brand Waters. The isolation was then carried out by radial chromatography using round glass plates of the Merck Kieselgel 60 PF254 (art. no. 7749) and the profile was analyzed using smaller pieces from aluminum sheets of 20 x 20 cm of the Merck TLC silica gel 60 F254 of 0.25 mm thickness (art. no. 5554) and then detected under UV light (254 nm) or by a $CeSO_4$ spraying reagent test.

## Results and Discussion

### Stigmast-4-en-3-one (1)

White crystal; m.p: 82-84$^o$C. ESI-MS *m/z* 413 $[M+H]^+$ (calc. for $C_{29}H_{49}O$). UV (MeOH) $\lambda_{max}$: 241 nm. IR $v_{max}$ (ATR) $cm^{-1}$: 2926-2868 (C$sp^3$-H), 1708 (-C=O), 1678-1414 (-C=C-), 1243-1125 (C-O), 969 (-$CH_3$). $^1$H-NMR (700 MHz, $CDCl_3$) and $^{13}$C-NMR (175 MHz, $CDCl_3$) are tabulated in Table 1.

### Stigmasta-4, 22-dien-3-on (2)

Colorless crystal; m.p: 80-82$^o$C. ESI-MS *m/z* 411.3627 $[M+H]^+$ (calcd for $C_{29}H_{47}O$). IR $v_{max}$ (ATR) $cm^{-1}$: 2929-2867 (C$sp^3$-H), 1708 (-C=O), 1453 (-C=C-), 1376-1307 (-C-O), 958-907 (-$CH_3$). $^1$H-NMR (700 MHz, $CDCl_3$) and $^{13}$C-NMR (175 MHz, $CDCl_3$) are tabulated in Table 1.

### Stigmasterol (3)

Colorless crystal; m.p: 168–170$^o$C. ESI-MS *m/z* 413 $[M+H]^+$ (calcd for $C_{29}H_{49}O$). IR $v_{max}$ (ATR) $cm^{-1}$: 3423 (*br*-OH), 2936 (C$sp^3$-H), 1642-1449 (C=C), 1112 (C-OH), 910 (-$CH_3$). $^1$H-NMR (700 MHz, $CDCl_3$) and $^{13}$C-NMR (175 MHz, $CDCl_3$) is tabulated in Table 1.

### *β*-Sitosterol (4)

Colorless crystal; m.p: 144–146$^o$C. ESI-MS *m/z* 415 $[M+H]^+$ (calcd for $C_{29}H_{51}O$). IR $v_{max}$ (ATR) $cm^{-1}$: 3346 (*br*-OH), 2987-2831 (C$sp^3$-H), 1449 (-C=C-), 1022 (C-OH), 910 (-$CH_3$). $^1$H-NMR (700 MHz, $CDCl_3$) and $^{13}$C-NMR (175 MHz, $CDCl_3$) is tabulated in Table 1.

*APT (experiment for $^{13}$C NMR).

Four steroid compounds were successfully isolated from the methanol extract of the frond part of *A. latifolium*. The known compounds were elucidated based on the FTIR, MS and NMR ($^1$H and $^{13}$C) techniques and by comparison of physical and spectroscopic data with values found in the literature. Table 1 displays $^1$H and $^{13}$C NMR data of the isolated compounds. Stigmast-4-en-3-one (**1**) was isolated as a white amorphous. FT-IR (ATR) $v_{max}$ cm$^{-1}$: 2926-2868 (cyclic aliphatic), 1731 (-C=O) and 1647-1459 (-C=C-). The mass spectrum showed a molecular ion peak ESI-MS $[M]^+$ at *m/z* 412 which was analyzed for the molecular formula $C_{29}H_{48}O$. The $^{13}$C-NMR data showed the presence of 29 carbon signals representing six methyl carbons at $\delta_C$ of 11.9, 12.0, 17.4, 19.0, 19.8 and 21.2 ppm; eleven methylene carbons at $\delta_C$ of 35.7, 33.9, 33.0, 32.0, 21.0, 39.6, 24.2, 28.8, 34.0, 26.1 and 23.0 ppm; eight methine carbons at $\delta_C$ of 123.7, 36.1, 53.8, 55.9, 56.0, 36.1, 51.2 and 29.1 ppm; and four quaternary carbons at $\delta_C$ of 199.7, 171.8, 38.6, and 42.3 ppm. Based on the data, compound 1 can be assigned as a cyclic aliphatic triterpenoid where a double bond is formed between C-4 and C-5, while carbonyl is formed at C-3. Meanwhile, a total of 46 protons appeared in the $^1$H-NMR spectrum as shown in Table 1. Two singlet methyls bound directly to the rings, $\delta_H$ 0.75 (H-18) and 1.20 (H-19). Three doublet methyls at $\delta_H$ 1.03 (H-21), 0.86 (H-26) and 0.86 (H-27), and one triplet methyl at $\delta_H$ 0.82 (H-29) are located at the side chain outside the rings of the main skeleton. The occurrence of one highly-deshielded proton at $\delta_H$ 5.74 (H-4) indicated the presence of one pair of double bond. The typical signal for the olefinic H-6 of the steroidal skeleton was evident from a proton at $\delta_C$ 5.74, integrating for one-proton.

Stigmasta-4,22-dien-3-on (**2**) is a white amorphous with m.p. 80-82 °C. Its IR spectrum showed $v_{max}$ absorption peaks at 2929-2867 (C$sp^3$-H), 1708 (-C=O), 1453 (-C=C-), 1376-1307 (-C-O) and 958-907 (-$CH_3$). Compound **2** gave positive responses to the Liebermann-Burchard spray reagent, which indicated the presence of a triterpenoid nucleus**.** This assumption was reinforced by the $^{13}$C-NMR data that indicated the presence of 29 carbons as tabulated in Table 1 which included three olefinic carbon signals at $\delta_C$ 123.7 (C-4), 138.1 (C-22) and 129.4 (C-23) and one carbonyl at δc 199.7 (C-3). The $^1$H-NMR spectra showed the presence of 46 protons. Compound **2** had very similar NMR data with those of compound **1** except for the presence of two olefinic protons instead of two methylenes. Two olefinic protons were determined to be H-22 and H-23 based on its HMBC spectrum. Consequently, a molecular ion peak $[M + H]^+$ at *m/z* 411 was exhibited in its mass spectrum data, which gave a possible molecular formula of $C_{29}H_{47}O$. The combined spectral data of $^{13}$C NMR suggested that the triterpenoid was stigmasta-4.22-dien-3-on, which was further supported by comparison with the literature as tabulated in Table 1.

Stigmasterol (**3**) was obtained as colourless needle crystals. The mass spectral data indicated the molecular formula of this compound to be $C_{29}H_{48}O$ with *m/z* of 412. The FTIR spectral data showed a broad absorbance peak at 3423 cm$^{-1}$, illustrating the stretching vibration of O-H bond, and the peak at 1112 cm$^{-1}$ indicated the vibration band of C-O bend. The peak of C$sp^3$-H stretch appeared at 2936 cm$^{-1}$. An absorbance peak of symmetrical C=C stretching at 1642 cm$^{-1}$ indicated the existence of olefinic group in this compound. The $^1$H NMR experiment of (**3**) displays information of the presence of two singlet methyls bound directly to the rings, $\delta_H$ 0.68 (H-18) and 0.99 (H-19). Three doublet methyls at $\delta_H$ 0.91 (H-21), 0.81 (H-26) and 0.79 (H-27), and one triplet methyl at $\delta_H$ 0.84 (H-29) are located at the side chain outside the rings of the main skeleton. A proton at $\delta_H$ 3.51 (H-3) is attached to the oxygen-binding carbon (C-3). The occurrence of three highly-deshielded protons at $\delta_H$ 5.34 (H-6), 4.99 (H-22), and 5.14 (H-23) indicated the presence of two pairs of double bond. The typical signal for the olefinic H-6 of the steroidal skeleton was evident from a proton at $\delta_C$5.34 integrating for one-proton. The other olefinic protons, H-22 and H-23, are neighbours and are in *trans* position as indicated by their large coupling constants (*J*=15.2). The APT experiment showed that this compound contained 29 carbons consisting of 6 methyls, 9 methylenes, 11 methines, and 3 quarternary carbons. A methine carbon at $\delta_C$ 71.5 (C-3) indicated a carbon attached to an oxygen atom (oxymethine) which revealed the existence of a hydroxyl group. The presence of two double bonds in the molecule was confirmed by two pairs of highly deshielded carbons at $\delta_C$ 140.7 (C-5), 121.7 (C-6), 138.3 (C-22), and 129.2 (C-23). The DBE (Double Bond Equivalent) value is six, which means that this compound is a tetracyclic compound containing two double bonds. Therefore, compound **3** is identified as stigmasterol.

*β*-Sitosterol (**4**) was obtained in the form of colorless needle crystals. The mass spectrum showed a molecular ion peak EI-MS $[M+H]^+$ at *m/z* 212 which was analyzed for the molecular formula $C_{29}H_{51}O$. Compound **4** also identified as steroid with a DBE value of five, one for a double bond and the other three as a tetracyclic chain. The differences between compound **3** and **4** lay on C-22 and C-23, where compound **4** had a double bond (Figure 1).

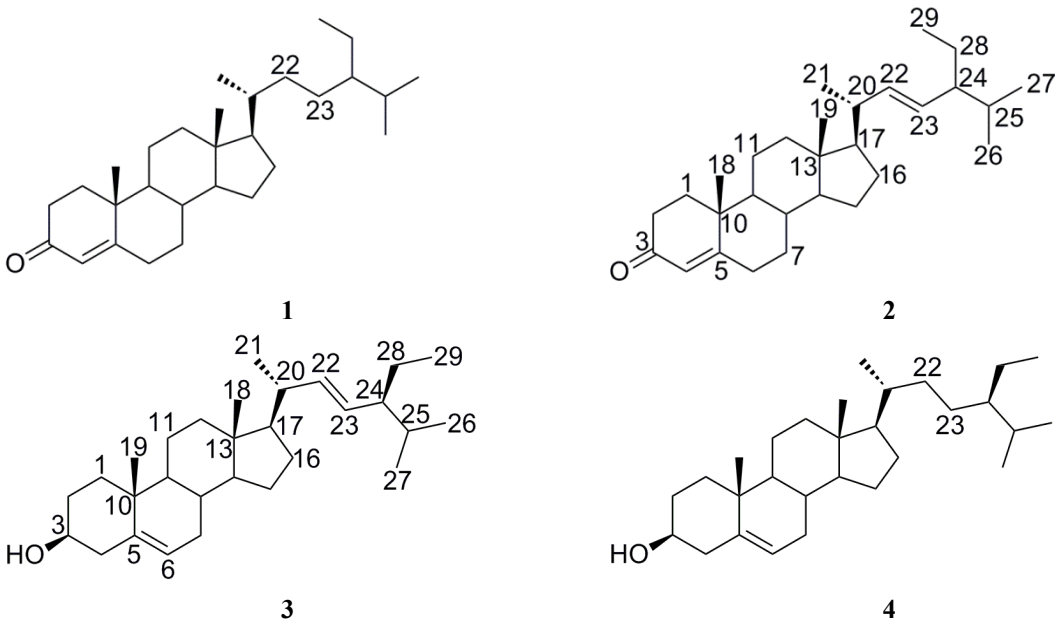

Figure 1. Chemical structures of **1**, **2**, **3** and **4**

## Conclusion

Four steroids namely Stigmast-4-en-3-one (**1**), stigmasta-4,22-dien-3-on (**2**), Stigmasterol (**3**) and *β*-Sitosterol (**4)** were successfully isolated from the leaves of *Adiantum latifolium* Lam. This is the first reported phytochemical study from this plant.

**Abstract**

Isolation on the hexane extract of the fruits of *Johannesteijsmannia altifrons* by vacuum liquid and radial chromatography yielded three known compounds namely β-sitosterol, γ-taraxasterol and stigmasterol. Their structures were determined using one-dimensional and two-dimensional nuclear magnetic resonance spectroscopy, fourier transform infra-red spectroscopy and mass spectrometry. All the isolated compounds were tested for their antibacterial activity using disc diffusion and minimum inhibitory concentration (MIC). All three compounds showed weak and moderate activities against all nine tested bacteria. This is the first report on the isolation of compounds from this species and on the antibacterial activity of γ-taraxasterol.

**Keywords**: *Johannesteijsmannia altifrons*, β-sitosterol, γ-taraxasterol, stigmasterol, antibacterial

**Abstrak**

Pemencilan ke atas ekstrak heksana bagi buah *Johannesteijsmannia altifrons* dengan kromatografi cecair vakum dan radial menghasilkan tiga sebatian yang pernah ditemui bernama β-sitosterol, γ-taraksasterol dan stigmasterol. Strukturnya ditentukan dengan spektroskopi resonans magnet nukleus satu-dimensi dan dua-dimensi, spektroskopi infra-merah transformasi Fourier dan spektrosmetri jisim. Kesemua sebatian yang dipencilkan diuji aktiviti bakterianya dengan kaedah peresapan cakera dan kepekatan perencatan minimum (KPM). Kesemua tiga sebatian menunjukkan aktiviti yang lemah dan sederhana terhadap kesemua sembilan bakteria yang diuji. Ini merupakan laporan pertama mengenai pemencilan sebatian daripada spesies ini dan mengenai aktiviti antibakteria bagi γ-taraksasterol.

**Kata kunci**: *Johannesteijsmannia altifrons*, β-sitosterol, γ-taraksasterol, stigmasterol, antibakteria

## Introduction

*Johannesteijsmannia* belonging to the Arecaceae family contains four species which are *J. altifrons, J. lanceolata, J. magnifica* and *J. perakensis. Johannesteijsmannia altifrons* which is also known as "Daun Sang" (Malay) and Joey Palm (English) commonly found in Kelantan, Perak, Terengganu, Pahang, Johor and Kedah [1]. No chemical constituents have ever been isolated or characterized from *Johannesteijsmannia altifrons*. The family of Arecaceae has been reported to contain flavonoids [2], alkaloids [3], terpenoids, steroids, fatty acids and tannins [4].Thus, conducting a phytochemical study on *Johannesteijsmannia altifrons* is vital to further enrich our knowledge on the species. In this study, the hexane extract from fruits of *Johannesteijsmannia altifrons* was purified and led to the discovery of known β-sitosterol, γ-taraxasterol and stigmasterol. Previously, Singh and Ghanapriya [5] reported β-sitosterol and stigmasterol inhibited at low levels (1+) against *Staphylococcus aureus*, *Bacillus subtilis* and

*Escherichia coli*. According to previous study by Manriquez et al. [6], both β - sitosterol and stigmasterol gives MIC value at 16.5 µg/mL against Staphylococcus aureus. Previous study discovered no inhibition of β-sitosterol and stigmasterol reported on *Escherichia coli, Bacillus subtilis* and *Salmonella thyphimurium* [6]. There are three types of extracts in this study which are hexane, chloroform and methanol but hexane extract was chosen to be purified further. This is because compounds from hexane extract are easily separated and purified compared to the other two extracts.

## Materials and Methods

### General

Different spectroscopic methods were used to elucidate the structures of β-sitosterol, γ-taraxasterol and stigmasterol including ultraviolet–visible spectroscopy, mass spectroscopy, fourier transform infra-red spectroscopy, one-dimensional, two-dimensional and carbon-13 nuclear magnetic resonance spectroscopy. The one-dimensional, two-dimensional and carbon-13 nuclear magnetic resonance spectroscopy spectra were recorded using Avance III 600 MHz Bruker. Deuterated chloroform ($CDCl_3$) was used as the NMR solvent with the chemical shifts, $\delta_H$, in ppm and the values of coupling constants, *J*, in Hz. Mass spectra were recorded by using the LC-mass spectrometry (LC-MS) on the Dionex/Bruker Micro ToFQ. The infra-red spectra were recorded on the Perkin-Elmer Spectrum 400 and the UV-VIS spectra were obtained in chloroform using UV-2400PC. Vacuum liquid chromatography (VLC) was prepared by using silica gel of Merck 7747. For radial chromatography (RC), silica gel with $PF_{254}$ containing gypsum (Merck 7749) was used. Thin layer chromatography (TLC) was performed on commercially pre-coated aluminum silica gel 60 $F_{254}$ of Merck 5554.

### Plant materials

The fruits of *Johannesteijsmannia altifrons* were collected at Pelagat Forest Reserve, Besut, Terengganu in February 2015. A voucher specimen (UKMB 40309) was deposited at the Herbarium of Universiti Kebangsaan Malaysia, Bangi (UKMB).

### Extraction and isolation

The air-dried, fruits of *Johannesteijsmannia altifrons* (786 g) were extracted for 3 days in methanol at room temperature, followed by filtration to give methanol solution. They were then extracted with *n*-hexane three times, combined and rotary evaporated to afford 4.42 g (0.56%) of greenish brown fruit *n*-hexane extract. The extract was fractionated by VLC, eluted with increasing polarity of *n*-hexane-ethyl acetate to collect the less polar and more polar fractions. The fractions were combined based on their silica gel TLC profiles. The VLC gave 16 fractions ($F_1$- $F_{16}$). Since fractions $F_4$ to $F_7$ have similar components, they were combined and further fractionated using RC to produce four combined fractions ($F_{41}$-$F_{44}$). The third fraction ($F_{43}$) contained β-sitosterol (32 mg). Then, fractions $F_9$-$F_{12}$ were combined and purified by RC to yield 7 combined fractions ($F_{91}$-$F_{97}$); fractions $F_{94}$ and $F_{96}$ contained γ-taraxasterol (25 mg) and stigmasterol (0.55 g), respectively.

### Bioassay

The pure compounds were assayed for antibacterial activity by using two methods which are disc diffusion and minimum inhibitory concentration (MIC) as described by Mamman et al. [7], Mukhtar and Ghori [8], and Yap et al. [9] with some modification, against nine bacteria; *Staphylococcus aureus,* Methicillin-resistant *Staphylococcus aureus (MRSA), Bacillus subtilis*, *Bacillus thruriengiensis*, *Escherichia coli*, *Salmonella thyphimurium, Serratia marcescens, Vibrio fluvialis* and *Vibrio cholera*. The pure compounds were prepared at 30 µg/mL in DMSO.

### Disc diffusion

Disc diffusion method for antibacterial testing was carried out to determine antibacterial activity of the pure compounds. The nine bacteria were spread on the Mueller-Hinton agar surface by using a sterile swab and the plates were dried for 15 minutes. Then, 100 µL of each dilution of the pure compounds was impregnated into sterile, blank disc of 6 mm in diameter and placed on the Mueller-Hinton agar surface. The positive control used was chloramphenicol 30 µg/disc which is a standard commercial antibiotic. The negative control used was DMSO (100%). The plates were then incubated at 37 $^oC$ for 24 hours. After the incubation, the plates were examined for inhibition zone and the results were recorded. The diameter of inhibition zones were measured in millimeter (mm).The test was repeated three times to ensure reliability.

**Minimum inhibition concentration**

Minimum Inhibition Concentration (MIC) was carried out to determine the lowest concentration of the compounds that could inhibit the visible growth of tested bacteria by using 96 microwell plate. An amount 100 µL of pure compounds undergo dilutions from 30 to 0.117 µg/mL. 50 µL of nine bacteria were added into wells containing compounds. The 96 microwell plate was incubated at 37 $^{o}$C for 24 hours. The positive and negative controls used were 100 µL of respective chloramphenicol antibiotic and DMSO. Then, 50 µL of 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT) was added to each single well and the plate was incubated at 37 $^{o}$C for 2 hour. The colour development was observed and the results were recorded. The test was repeated three times to ensure reliability.

## Results and Discussion

The ESI-MS gave molecular ion at $[M+Na]^+$ m/z 437.3381 which β-Sitosterol appeared as colourless needles. The ESI-MS gave molecular ion at $[M+Na]^+$ m/z 437.3381 which corresponded to the molecular formula $C_{29}H_{50}O$ (414.3862 + 22.9898 = 437.3759; Δ 0.40513). The IR spectrum showed absorption peaks at 3385 cm$^{-1}$ which is characteristic of O-H stretching, peaks at 2936 and 2868 cm$^{-1}$ due to aliphatic or C-H stretching ($CH_3$). Other absorption frequencies include peak at 1708 cm$^{-1}$ due to absorption of C=C stretching. The $^1$H NMR spectrum of β-sitosterol showed a multiplet signal at $\delta_H$ 3.53 (H-3), indicates the presence of a hydroxyl methine proton. The occurrence of a highly-deshielded signal at $\delta_H$ 5.36 (H-6) indicates the presence of a vinylic proton. On the other hand, a singlet signal at $\delta_H$ 1.02 indicates a methyl group at H-29. Two doublet signals at $\delta_H$ 0.86 and 0.91 are due to the two non-equivalent methyls at H-26 and H-27 of an isopropyl group. The $^{13}$C NMR spectrum showed that β-sitosterol contains 29 different carbon atoms consisting of six methyls, 11 methylenes, nine methines, and three quaternary carbons. Signal of methine carbon at $\delta_C$ 71.8 ppm indicates a carbon attached to an oxygen atom which showed the existence of a hydroxyl group at C-3. Two highly deshielded signals at $\delta_C$ 140.8 and 121.7 ppm, which are assigned to C-5 and C-6 indicates there is one carbon double bond in the molecule. According to the available data as well as comparison with the literature [10], the compound is confirmed to be β-sitosterol.

γ-Taraxasterol was obtained as colourless needle crystal. The ESI-MS showed a molecular ion peak at $[M+Na]^+$ m/z 449.2842 which corresponded to the molecular formula $C_{30}H_{50}O$ (426.3862 + 22.9898 = 449.3759; Δ 0.09176). The IR spectrum displayed a broad absorbance peak at 3385 cm$^{-1}$ which characteristic of O-H stretching. Absorptions at 2927 and 2871 cm$^{-1}$ represent the C$sp^3$-H stretching. The $^1$H NMR spectrum showed signal of a proton at $\delta_H$ 3.51 (H-3) is attached to the oxygen-binding carbon (C-3). This is deshielded proton which is hydroxyl methine proton. Seven singlet methyls at signals $\delta_H$ 1.61 (H-23), 1.10 (H-24), 0.82 (H-25), 0.81 (H-26), 1.29 (H-27), 0.80 (H-28) and 1.05 (H-30) indicating that they are attached to quaternary carbons and bound directly to the ring system. There is only one highly deshielded proton at $\delta_H$ 5.37 (H-21) indicating the olefinic proton that attaches to a double bond carbon (C-21). The $^{13}$C NMR spectrum showed γ-taraxasterol is formed by 30 carbon atoms consisting of eight methyls, nine methylenes, seven methines, and six quarternary carbons. A methine carbon at $\delta_C$ 80.7 indicates a carbon attached to an oxygen atom which showed the existence of a hydroxyl group at C-3. There are two highly deshielded olefinic carbon signals at $\delta_C$ 141.0 (C-20) and 121.7 (C-21) suggests that there is one double bond contained in the molecule. Through comparison of the observed data with literature [11], the compound is identified as γ-taraxasterol.

Stigmasterol was isolated as colourless needles. The ESI-MS gave molecular ion at $[M+Na]^+$ *m/z* 435.3279 which corresponded to the molecular formula $C_{29}H_{48}O$ (412.3705 + 22.9898 = 435.3603; Δ 0.0324). The IR spectrum displayed stretching band for O-H at 3354 cm$^{-1}$. Peaks at 2934 and 2866 cm$^{-1}$ indicate the presence of aliphatic or C-H stretching ($CH_3$). A band at 1667 cm$^{-1}$ appears due to the existence of olefinic group in this compound. The $^1$H NMR spectrum displayed signals for six methyls. Two singlet methyls at signals $\delta_H$ 0.69 (H-18) and 1.02 (H-19) indicating that they are bound directly to the ring system. Three doublet methyls at $\delta_H$ 0.93 (H-21), 0.84 (H-26) and 0.7 (H-27), and one *triplet* methyl at $\delta_H$ 0.83 (H-29) are located at the side chain outside the rings of the main skeleton. Hydroxyl methine proton appeared at $\delta_H$ 3.54 (H-3) which attached to the oxygen-binding carbon (C-3). Three highly-deshielded protons presence at $\delta_H$ 5.36, 5.03, and 5.09 due to the presence of two pairs of double bond which assigned at H-6, H-22 and H-23. The $^{13}$C NMR spectrum showed stigmasterol contained 29 carbon atoms consisting of six methyls, nine methylenes, 11 methines, and three quaternary carbons. Signal at $\delta_C$ 71.8 indicates a

methine carbon attached to an oxygen atom which showed the existence of a hydroxyl group at C-3. There are four olefinic carbon signals that appear downfield and highly deshielded at $\delta_C$ 140.8 (C-5), 121.7 (C-6), 138.3 (C-22) and 129.3 (C-23) suggests that there are two double bonds in the molecule. Based on the discussion above and data comparison with literature [10], the compound is identified as stigmasterol. The spectra of β-sitosterol, γ-taraxasterol and stigmasterol are shown in Figures 1, 2 and 3, respectively.

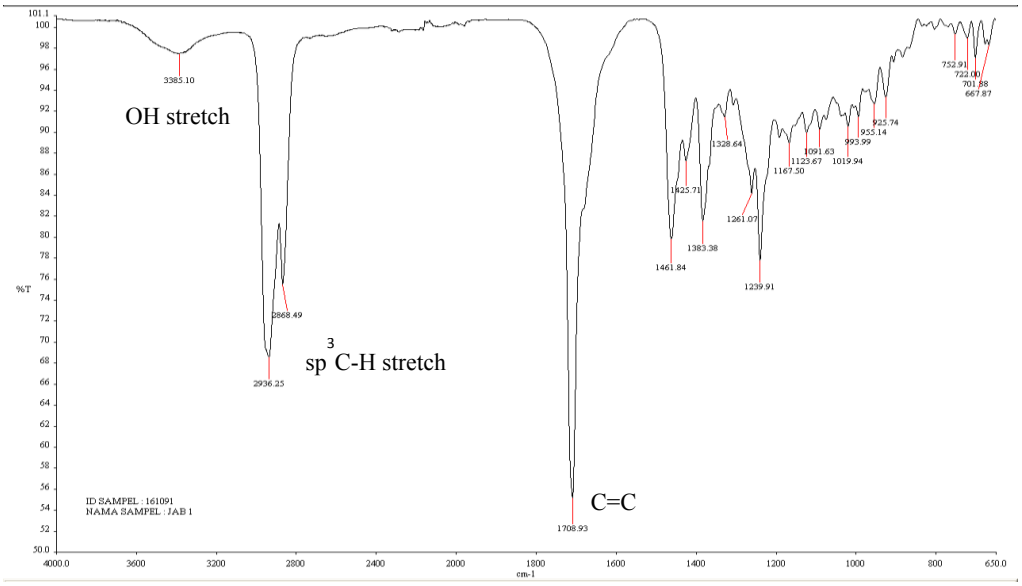

Figure 1. The infra-red spectrum of β-sitosterol

γ-Taraxasterol

Stigmasterol

Figure 4. Structures of the pure compounds

**Antibacterial activity**

The pure compounds isolated from the fruits of *Johannesteijsmannia altifrons* were tested for antibacterial activity. In disc diffusion method, β-sitosterol showed low inhibition which is 7.0 ± 0.00 mm against *Vibrio fluvialis*, MRSA and *Bacillus subtilis* whereas γ-taraxasterol and stigmasterol exhibited moderate activities against *Escherichia coli*, *Serratia marcescens*, *MRSA* and *Bacillus subtilis*. Based on the results, it was observed that β-sitosterol has inhibition against one gram negative bacteria and two gram positive bacteria. This may probably due to the morphological differences between gram negative and gram positive bacteria in terms of their cell wall composition. The gram positive bacteria only have an outer peptidoglycan which is not effective permeability barrier compared to gram negative bacteria that have both outer membrane and peptidoglycan. This makes the gram negative bacteria cell wall impermeable to most of the drugs [12]. For stigmasterol, the inhibition occurs at low level (1+) against *Staphylococcus aureus*, *Bacillus subtilis* and *Escherichia coli* which is similar as reported by Singh dan Ghanapriya [5]. Besides, γ-taraxasterol showed moderate (2+) inhibition against *Serratia marcescens* and *Bacillus subtilis.* Kanamysin and vancomysin used as positive controls and the results showed all compounds have lower inhibitory activity against all tested bacteria compared to the antibiotics. DMSO as negative control did not show any antibacterial activity against tested bacteria. The inhibitory zone values for all compounds are shown in Table 1.

Table 1. Antibacterial activity of the pure compounds in disc diffusion method

| **Pure Compounds** | **β-Sitosterol** | **γ-Taraxasterol** | **Stigmasterol** | **Kanamysin (K)*/ Vancomysin (V)**** |
|---|---|---|---|---|
| | **Inhibitory Zone (mm)** | | | |
| *Escherichia coli* * | - | 7.0 ± 0.53 | 7.0 ± 0.00 | 20 ± 1.00 (K) |
| *Vibrio fluvialis* * | 7.0 ± 0.00 | 7.0 ± 0.00 | 7.0 ± 0.00 | 35 ± 1.04 (K) |
| *Salmonella thyphimurium* * | - | 7.0 ± 0.00 | 7.0 ± 0.00 | 26 ± 0.00 (K) |
| *Vibrio cholera* * | - | - | - | 10 ± 0.00 (K) |
| *Serratia marcescens* * | - | 11.0 ± 0.00 | 11.0 ± 0.00 | 23 ± 1.52 (K) |
| Methicillin-resistant *Staphylococcus aureus (MRSA)* ** | 7.0 ± 0.00 | 7.0 ± 0.00 | 8.0 ± 0.5 | 20 ± 0.00 (V) |

| *Bacillus subtilis* ** | 7.0 ± 0.00 | 10.0 ± 0.5 | 7.0 ± 0.00 | 28 ± 0.00 (V) |
| *Staphylococcus aureus* ** | - | 7.0 ± 0.53 | 7.0 ± 0.00 | 25 ± 0.00 (V) |

Mean measurement: SD (n = 3), * Gram negative, ** Gram positive

In minimum inhibition concentration (MIC) method, all compounds gave value of 7.5 µg/mL against *Staphylococcus aureus*, *Escherichia coli*, *Vibrio cholera*, *Serratia marcescens*, *Bacillus thruriengiensis* and *Bacillus subtilis* whereas previous report showed both β-sitosterol and stigmasterol have higher MIC value of 16.5 µg/mL and no inhibition against *Escherichia coli* and *Bacillus subtilis*. No explanation can be given on the difference. First report on antibacterial activity of γ-taraxasterol provides new knowledge for the compound. The MIC values are shown in Table 2.

Table 2. Antibacterial activity of the pure compounds in minimum inhibitory concentration (MIC) method

| *Staphylococcus aureus* | 7.5 | 7.5 | 7.5 |

## Conclusion

The investigation on the chemical constituents from fruits of *Johannesteijsmannia altifrons* resulted in the isolation of three known compounds which are β-sitosterol, γ-taraxasterol and stigmasterol. In disc diffusion method, the isolated compounds showed no inhibition against *Vibrio cholera* and *Bacillus thruriengiensis*, and weak or moderate activities against other seven bacteria. In MIC method, the lowest and highest MIC values were at respective 7.5 and 30 µg/mL. All the compounds have been reported for the first time from this plant.

**Abstract**

Surface sediments from tropical coastal settings of Southwestern Johor, Malaysia, were analyzed for grain size, major element content and clay minerals using particle size analyzer, scanning electron microscope-energy dispersive spectrometer (SEM-EDS) and X-ray Diffractometer (XRD). This work is aimed at investigating the geochemical composition of surface sediments and possible anthropogenic inputs from urban settlements. Sediment texture was found to be clayey with an average of 45.15%. The abundance of major elements in decreasing order is $SiO_2$ > $Al_2O_3$ > $K_2O$ ≥ $ClO_2$ ≥ $Na_2O$ > MgO > MnO > ZnO. The dominance of $SiO_2$ appears to be linked with the draining of Sungai Pulai to the study area. The concentration of ZnO registered a hundred times higher than the average natural level of zinc in the earth's crust. Higher levels of Zn might be derived from the combination of anthropogenic input and natural geochemical processes. Mineral abundance follows the order of quartz > kaolinite > muscovite > smectite > calcite> illite. Smectite was detected in the upper river sediment, but was not present in the estuarine sediment. This is likely due to the accumulation and intensity of weathering products. The dominance of quartz in the coastal sediments is due to the intense weathering process.

**Abstrak**

Sedimen permukaan dari pesisiran pantai tropika di Barat Daya Johor, Malaysia, telah dianalisis untuk saiz butiran, kandungan unsur utama dan mineral liat dengan menggunakan penganalisa saiz partikal, imbasan elektron mikroskop-spektrometer serakan tenaga (SEM-EDS) and pembelauan sinaran-X (XRD). Kajian ini bertujuan untuk mengkaji komposisi geokimia enapan permukaan dan input antropogenik yang mungkin hadir dari penempatan bandar. Tekstur enapan adalah terdiri daripada liat dengan purata pecahan saiz liat sebanyak 45.15%. Kelimpahan elemen utama secara tertib menurun adalah seperti berikut $SiO_2$ > $Al_2O_3$ > $K_2O$ ≥ $ClO_2$ ≥ $Na_2O$ > MgO > MnO > ZnO. Dominasi $SiO_2$ membayangkan terdapat perkaitan dengan aliran Sungai Pulai ke kawasan kajian. Kepekatan ZnO direkodkan beratus kali lebih tinggi daripada tahap semula jadi purata zink di dalam kerak bumi. Tahap Zn yang lebih tinggi mungkin diperolehi daripada gabungan input antropogenik dan proses geokimia semula jadi. Kelimpahan mineral mengikuti urutan berikut kuarza> kaolinit> muskovit> smektit> kalsit> ilit. Smektit dikesan pada enapan di bahagian hulu sungai namun tiada di dalam enapan muara. Keadaan ini mungkin disebabkan oleh pengumpulan dan keamatan produk luluhawa. Dominasi kuarza di dalam sedimen pantai adalah disebabkan oleh proses luluhawa.

**Kata kunci:** tropika, enapan, elemen-elemen, mineral liat, Malaysia

## Introduction

Southwestern Johor has a unique environment due to the combination of different ecosystems (i.e. river, mangrove, estuary and beaches) and rapid development zone (i.e. Tanjung Pelepas Port, industrial area, oil terminal and urbanization). A report by ASEAN/US CRMP [1] stated that ~ 80% of Johor land is formed by sedimentary, metasedimentary and igneous rocks of pre-quaternary while the remaining 20% is covered by unconsolidated to semi consolidated quaternary sediments. Rapid development in this area over the past two decades might have caused changes in elemental composition. Thus, there is a possibility that the sediment deposits in coastal areas of Southwestern Johor are derived from natural and/ or anthropogenic sources. In certain conditions, the elements in surface sediment are governed by their concentration, relative proportions from various sources, components and forcing mechanisms. Some reports indicated the significant role of grain size sediments in controlling the element's content in coastal area [2-4], and the enrichment of elements in fine-grained sediments is attributed to their adsorption capabilities and low contents of quartz [5]. Based on the previous reports, we consequently presume that the relationship between elements and grain size can be applied as the environmental indicator in the coastal area of Southwestern Johor. Recently, several environmental studies have been conducted in the coastal area of Southwestern Johor [6-10]. However, there have been no reports that focus on the distribution of sediment mineral contents and geochemical composition in surface sediment. Thus, this paper presented and discussed the abundance and distribution of major elements and clay minerals composition in surface sediment of the Southwestern Johor.

## Materials and Methods

### Sample collection and preservation

Table 1 shows the coordinates of sampling points in the study area. The surface sediment samples were collected from 20 stations at different ecosystems of the coastal area of Southwestern Johor (Figure 1) using the ponar grab. The samples were then put in labelled plastic bags and brought back to the laboratory for further analysis.

Table 1. Latitude and longitude of the sampling points in the study area

| Station | Latitude | Longitude |

**Analytical techniques**

Approximately 5g of sediment samples were used in determining particle size. Homogenized samples were treated with 10ml calgon solution overnight and injected into the particle size analyzer MALVERN Mastersizer 2000. All data collected were subjected to statistical analysis using moment statistical method. The relative proportion of sand, silt and clay were determined using the textural triangle proposed by USDA [11]. The major oxide elements in sediment were analyzed by using scanning electron microscope-energy dispersive spectrometer (SEM-EDS). The samples were placed on the stub using double sided tape and coated with gold by Auto Fine Coater JFC 1600. The selected major oxide elements ($SiO_2$, $Al_2O_3$, $Na_2O$, MgO, CaO, $K_2O$, MnO, ZnO) were observed by using SEM model 6360 LA JOEL. Sediment samples for clay mineral analysis were dried in the oven (< 50 °C) and powdered using pestle mortar. The type of clay minerals present in the samples was analyzed using X-ray Diffractometer (XRD). The sample was placed on a glass slide and scanned for certain degrees using radiation of Cu-Kα equipped with automatic divergent tilt. The Joint Committee on Powder Diffraction Standards (JCPDS) was used as a reference. Peaks produced from X-Ray Diffractogram enabled the determination of d-spacing which associated with the types of mineral.

## Results and Discussion

Table 2 shows the percentage of sand, silt, clay and the textural class of sediments in the study area. The distribution patterns of sand, silt and clay are shown in Figure 2, 3 and 4, respectively. Most of the sediments in the study area can be classified as cohesive sediments where the size of sediments is less than 125 μm in diameter and large surface area in relation to its mass. The high percentage of clay particles with the value > 50% was recorded at ST1, ST2, ST3, ST4, ST7, ST11, ST13 and ST17. The high percentage of sand with the value > 50% was found at ST6, ST10, ST12, ST15, ST16 and ST18. Only ST5 registered silt content more than 50%.

Table 2. Percentage of sand, silt and clay and textural classes of sediments in the study area

| Station | Sand (%) | Silt (%) | Clay (%) | Textural class |
|---|---|---|---|---|
| 1 | 22.73 | 10.69 | 66.56 | Clay |
| 2 | 27.83 | 8.16 | 63.98 | Clay |
| 3 | 34.92 | 7.91 | 57.83 | Clay |
| 4 | 37.98 | 6.50 | 55.52 | Clay |
| 5 | 36.14 | 55.86 | 8.01 | Silt loam |
| 6 | 54.09 | 6.91 | 39.02 | Sandy clay |
| 7 | 32.07 | 7.90 | 60 | Clay |
| 8 | 49.4 | 6.53 | 44.08 | Sandy clay |
| 9 | 42.14 | 7.42 | 48.98 | Sandy clay |
| 10 | 73.88 | 24.50 | 23.66 | Sandy clay loam |
| 11 | 21.81 | 15.40 | 62.8 | Clay |
| 12 | 61.1 | 4.15 | 37.74 | Sandy clay loam |
| 13 | 21.09 | 15.83 | 63.09 | Clay |
| 14 | 44.26 | 6.91 | 48.86 | Clay |
| 15 | 51.02 | 5.89 | 43.1 | Sandy clay |
| 16 | 63.47 | 7.87 | 28.67 | Sandy clay loam |
| 17 | 36.9 | 8.01 | 55.1 | Clay |
| 18 | 79.86 | 4.24 | 15.9 | Sandy Loam |
| 19 | 48.52 | 5.94 | 45.55 | Sandy clay |
| 20 | 37.22 | 8.63 | 54.18 | Clay |

The relative proportion of textural classes of sediment was based on the percentage of sand, silt and clay (Table 2). Generally, the southwestern coastal area of Johor is dominated with clay (ST1, ST2, ST3, ST4, ST7, ST11, ST13, ST14, ST17 and ST20), sandy clay (ST6, ST8, ST9, ST15 and ST19), sandy clay loam (ST10, ST12 and ST16), sandy loam (ST18) and silt loam (ST5). Coarse sediment is dominant in two areas namely Tanjung Pelepas Port (ST10 and ST16), and the coastal area between south Pulau Kukup (ST 5) and Tanjung Piai National Park (ST18). The prevalence of coarse sediment in Tanjung Pelepas Port might be due to the wave action created by shipping activities and the deepening process of the port through dredging activities. Both processes will destabilize the composition of sediment in the port area and it will be much easier for them to be transported out in any condition involving increasing water forces. Meanwhile, finer sediment tends to accumulate in the upstream of Sungai Pulai (ST11 and ST13), northern part of Pulau Kukup (ST1, ST3 and ST7) and in front of Tanjung Piai town (ST19 and ST20). We assume that the accumulation of finer sediment had occurred due to the low energy environment. This will offer a suitable condition for the deposition of fine-grain sediment in those three areas compared to Tanjung Pelapas Port and the coastal area between south Pulau Kukup and Tanjung Piai National Park. Consequently, it is hypothesized that the different distribution pattern of sand, silt, clay and textural classes of sediment are relatively due to the different forces of water energy in this environment.

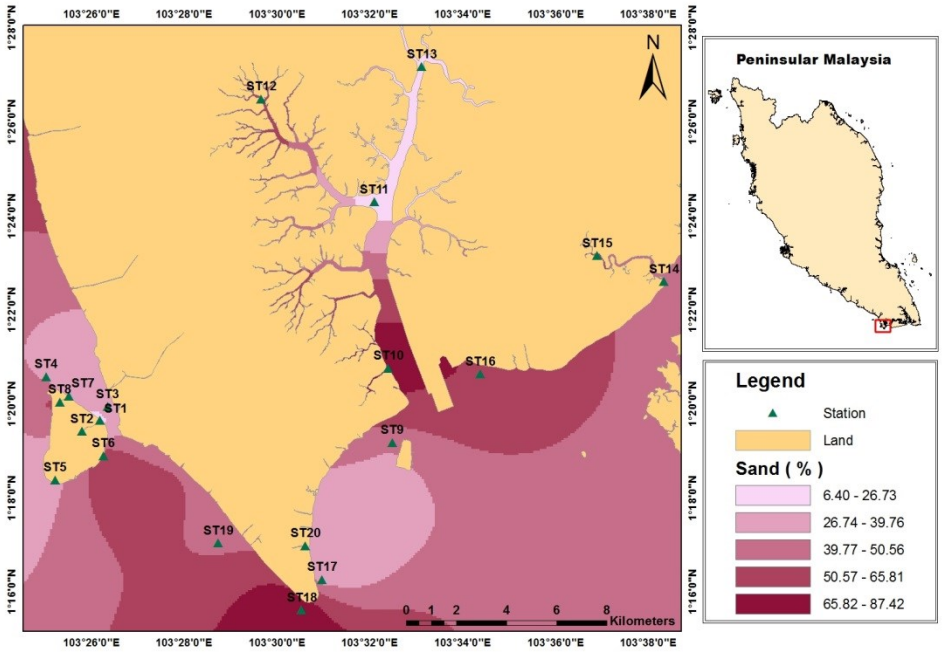

Figure 2. Distribution patterns of sand in the study area

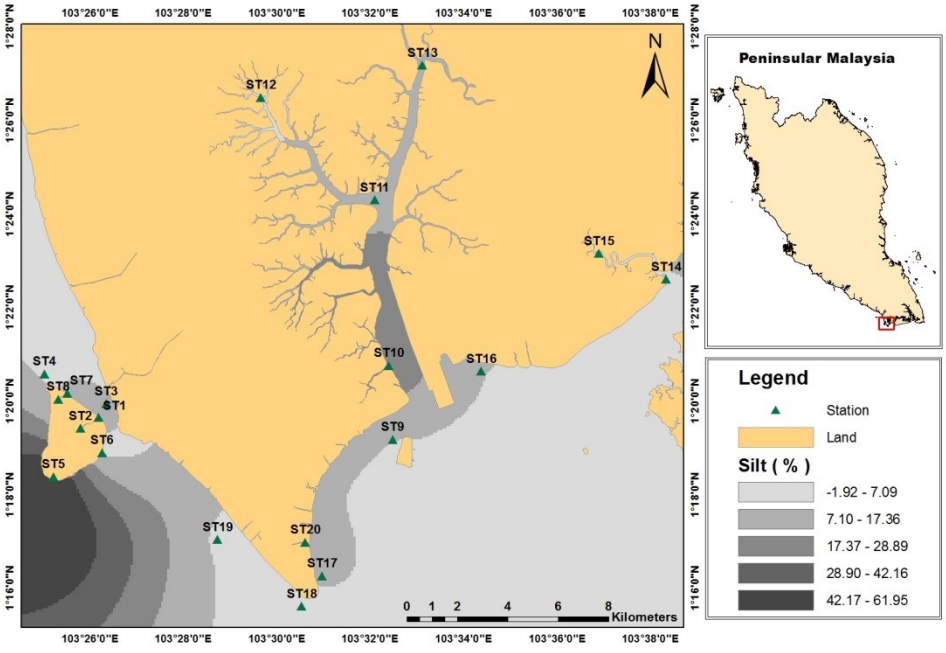

Figure 3. Distribution patterns of silt in the study area

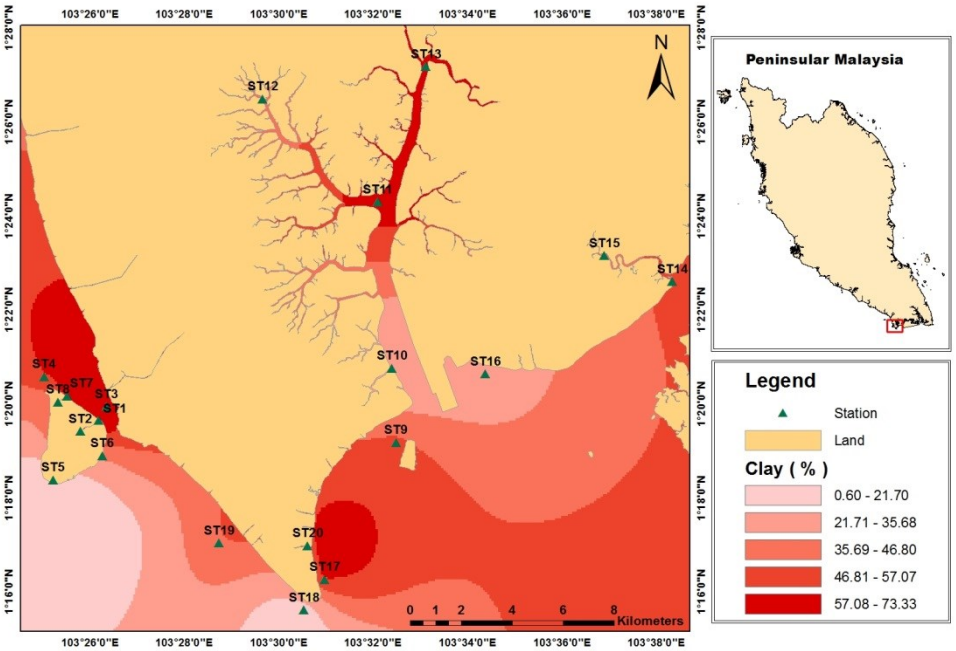

Figure 4. Distribution patterns of % clay in the study area

**Element oxides**

Table 3 shows the percentage of element oxides in the study area. The dominant element oxides found in the study area are $SiO_2$ (59.62%) followed by $Al_2O_3$ (12.49%). The rest of the element oxides such as $K_2O$, $ClO_2$, $MgO_2$, $MnO_2$ and $ZnO_2$ are present in trace amounts. The dominance of $SiO_2$ indicates that the area is highly siliceous [12]. The higher percentages of $SiO_2$ are found at ST6 (75.43%) and ST5 (72.47%), which show that these stations are most siliceous compared to the other of stations. The dominance of quartz might be due to the weathering product of granite, which is the dominant rock discovered in southern Peninsular Malaysia [13]. It is assumed that the quartz becomes the most resistant mineral in the coastal area of Southwestern Johor due to high temperatures and annual rainfall of tropical climatic conditions thus leading to the presence of high $SiO_2$ content.

The second most abundant element oxide is $Al_2O_3$ (corundrum) formed from igneous rock. The high content of this element at ST12 might be due to high-energy of water in upstream that erodes, transports and deposits sediments into the mangrove area. Wayne et al. [14] suggest that $Al_2O_3$ in certain environments are strongly influenced by aeolian input driven by wind activity and higher energy transport. The formation of corundum also occurs during hydrothermal alteration of volcanic and ultramafic rocks, under regional metamorphism of alumina-rich clays and bauxites, and in alkaline magmas that are alumina-supersaturated and silica-undersaturated [15].

The other oxide elements present in surface sediments of the study area were $K_2O$ (2.19%), $ClO_2$ (2.12%), $Na_2O$ (2.11%) and MgO (1.90%). $K_2O$ is a major element oxide present in trace amounts in the study area. This might be due to the sediment deposits originating from the dissolution of K-feldspar and mica [16]. Manganese oxide is a minor component of sediment with a value below 0.5% of dry weight and exists in the sediment as carbonate phase and oxi-hydroxide phase. The average content of MnO in the study area was 0.96 %. This value is about one-fold lower than $K_2O$, $ClO_2$, $Na_2O$ and MgO.

Table 3. Percentage of element oxides in sediments of the study area

| Station | $SiO_2$ | $Al_2O_3$ | $K_2O$ | $ClO_2$ | $Na_2O$ | MgO | MnO | ZnO |
|---|---|---|---|---|---|---|---|---|
| 1 | 55.16 | 8.64 | 1.67 | 2.64 | 1.15 | 1.2 | 0.9 | 1.43 |
| 2 | 56.26 | 9.63 | 1.62 | 2.7 | 5.2 | 1.02 | 0.84 | 0.6 |
| 3 | 57.18 | 8.91 | 3.14 | 1.65 | 1.25 | 1.14 | 1.23 | 0.37 |
| 4 | 59.27 | 9.23 | 3.22 | 2.07 | 1.64 | 1.26 | 0.64 | 0.54 |
| 5 | 72.47 | 8.71 | 2.51 | 2.72 | 7.31 | 1.43 | 0.4 | 1.07 |
| 6 | 75.43 | 19.51 | 1.74 | 1.67 | 4.12 | 2.46 | 0.87 | 0.51 |

| 16 | 62.04 | 8.73 | 2.47 | 1.92 | 1.79 | 2.01 | 0.79 | 0.50 |
| 17 | 57.3 | 8.31 | 2.91 | 1.11 | 0.61 | 2.35 | 1.29 | 1.35 |
| 18 | 57.84 | 5.04 | 2.46 | 2.38 | 1.64 | 2.45 | 1.83 | 0.99 |
| 19 | 60.15 | 10.3 | 1.57 | 2.26 | 1.43 | 2.37 | 0.63 | 0.82 |
| 20 | 53.72 | 8.33 | 1.86 | 1.43 | 1.65 | 2.11 | 0.76 | 0.46 |
| Average | 59.62 | 12.49 | 2.19 | 2.12 | 2.11 | 1.90 | 0.96 | 0.70 |
| SD (±) | 5.48 | 5.68 | 0.58 | 0.51 | 1.70 | 0.53 | 0.32 | 0.32 |

The lowest abundant element oxide in this environment is ZnO. However, the content of this element oxide is relatively higher compared to the earth's crustal values. The concentration of ZnO (~ 0.7%) registered a hundred times higher value than the average natural zinc in the earth's crust (70 ppm). In the manufacturing industry, ZnO is widely used as an additive in numerous materials and products including rubbers, plastics, ceramics, glass, cement and lubricants [17]. Thus, it is plausible that the anthropogenic input might be mixed with the natural zinc-origin products, causing an enrichment of ZnO in this environment.

SEM imagery and major element peaks clearly show the differences in grain particle shapes and element contents between downstream (Figure 5a) and upstream (Figure 5b) areas. Downstream sediments are characterized with sorted and more rounded angularity grain, higher content of silicon and aluminum. On the other hand, the upstream sediment recorded was poorly sorted and angular type of grain. There is a possibility that high-energy water especially during monsoon season sorted and smoothed the edges of grain particle in the transportation process of sediment from upstream to downstream.

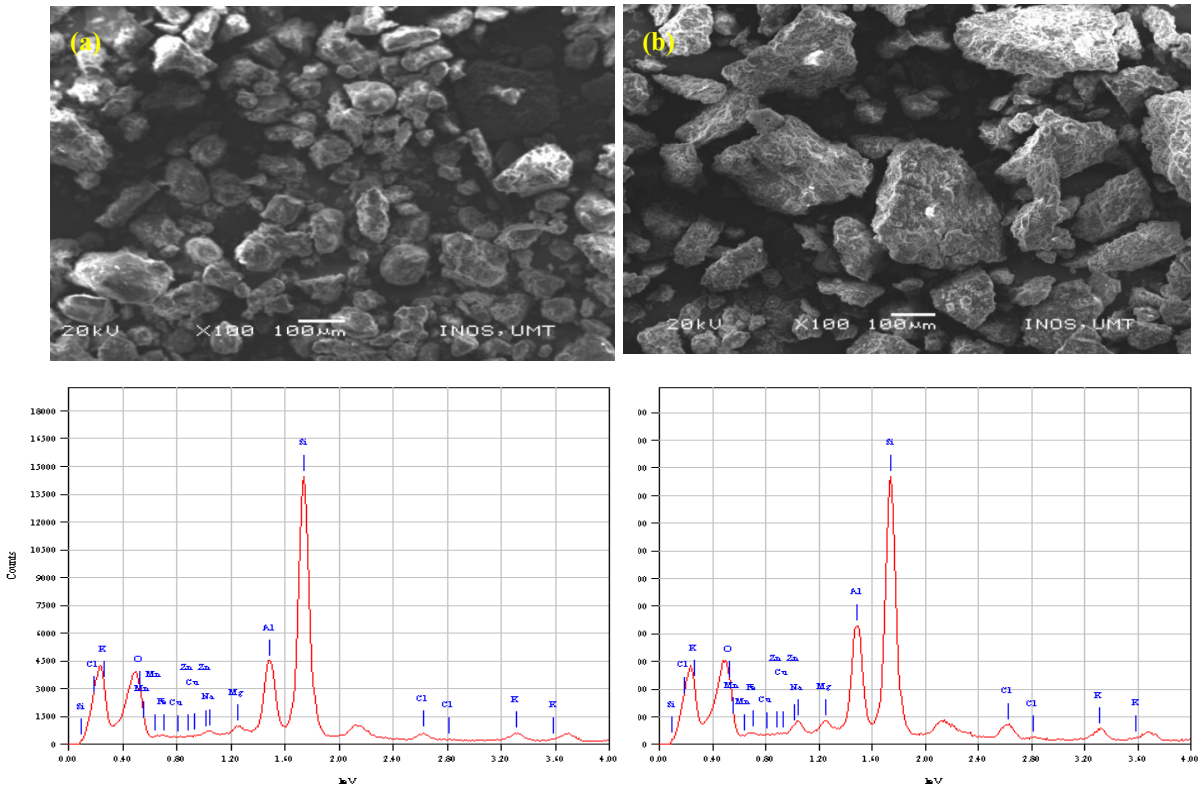

Figure 5. An example of SEM-EDS imagery and major element peaks of (a) downstream and (b) upstream area

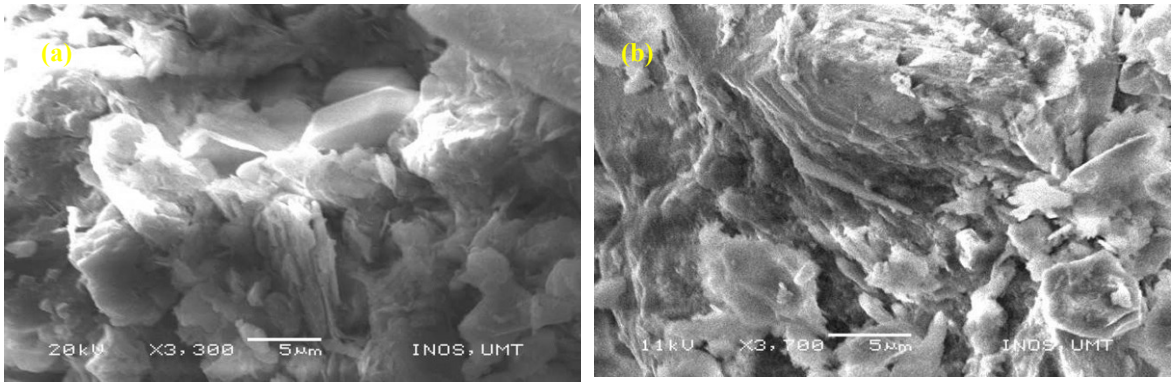
**Clay minerals**

Table 4 shows the clay minerals present in the study area. Quartz (Figure 6a) is the dominant mineral found in most of the stations (ST1, ST2, ST3, ST8, ST10, ST11, ST12, ST14, ST15, ST19 and ST20) and frequent at ST4, ST6, ST7, ST13, ST16, and ST17, while few at ST5, ST9 and ST18. The second most abundant clay mineral is kaolinite (Figure 6b) which is dominant at ST1 and ST13. Kaolinite is present at station ST3 and ST6, in moderate amounts whereas exists in small amounts at other remaining station. Hurst [18] proposed that the distribution of kaolinite is often associated with the exfoliation and change in content of mica minerals in sediments. This might be due to the influence of weathering. Pehlivanoglou et al. [4] suggested that low distribution of kaolinite was due to unfavorable climatic conditions as well as physicochemical factors including sediment origin, rapid transportation and deposition process at the sampling station. Presence of kaolinite as a dominant clay mineral indicated maturity of the sediments and the weathering stage. The predominance of kaolinite indicated humid periods that lead to intensive leaching and chemical weathering [19].

The third abundant mineral in the surface sediment is muscovite (Figure 6c). This clay mineral is present at ST10 and ST11 in moderate amount, while ST1, ST8, ST12 and ST13 show the presence of muscovite in small amounts. High content of muscovite can be found at Sungai Pulai (ST10 and ST11), respectively. According to Rothwell [20], muscovite was the second most stable primary mineral after quartz. Muscovite is usually found in coarse-grained igneous rock and intermediate metamorphic rock [21]. The existence of this clay mineral in the sediments indicated that the sediments are still young [22].



Only four stations had shown the presence of illite with ST13 showing moderate amounts while ST8, ST15 and ST20 show small amounts of illite. On the other hand, ST15 is the only station showing moderate content of smectite in the study area. The presence of smectite in small amounts at ST1, ST2 and ST13 might be influenced by

the accumulation and intensity of weathering products. El-Attar et al. [23] found that smectite exists on the surface layer of sediment by the mixing of aeolian inputs from the plateau.

Table 4. The presence of clay minerals in sediments of the study area

| Station | Clay Minerals | | | | | |
|---|---|---|---|---|---|---|
| | Quartz | Calcite | Smectite | Illite | Kaolinite | Muscovite |
| 1 | +++ | + | + | - | +++ | + |
| 2 | +++ | - | + | - | + | - |

## Conclusion

The mean concentrations of studied element oxides in decreasing order is as follows $SiO_2 > Al_2O_3 > K_2O \geq ClO_2 \geq Na_2O > MgO > MnO > ZnO$. The presence of quartz as the dominant mineral in this tropical environment is consistent with $SiO_2$ as the most abundant major element oxide. The abundance of kaolinite compared to other clay minerals indicated the advance-weathering stage and reflection of granite as the major rock type in the area. The higher level of ZnO as compared to the earth's crustal value is associated with the combination of anthropogenic input, and natural geological and geochemical processes. The change in grain surface morphology and sorting from the upstream to the downstream show the intensity of sediment transport processes.

## Acknowledgement

This research was funded by the Ministry of Science, Technology and Innovation through e-science grants no 04-01-12-SF0113. The authors wish to express their gratitude to the staff of Oceanography Laboratory, School of Marine and Environmental Science and Institute of Oceanography and Environment (INOS) for their assistance and hospitality throughout the sampling and analytical period.

**Abstract**

Zinc oxide (ZnO)/carbon spheres (CS) nanocomposites were successfully synthesised using waste engine oil as precursor for the CS production. ZnO nanorods were grown using sol-gel immersion method with MgZnO as the seeded catalyst and thermal chemical vapour deposition was used to synthesise CS. Different configurations of ZnO/CS structures were prepared i.e. CS-coated ZnO and ZnO-coated CS. The structures of composite samples were analysed using field emission scanning electron microscopy (FESEM), Energy-Dispersive X-ray (EDX), micro-Raman and X-ray Diffraction Spectroscopy (XRD). FESEM observations revealed the structural changes of pristine ZnO and CS in composite structures. The as-present of ZnO or CS was believed to affect the subsequent growth of another structure. Field electron emission (FEE) properties of both nanocomposites were also investigated. It was found that ZnO-coated CS sample has better FEE properties with lower turn-on (3.48 $V\mu m^{-1}$) and threshold field (6.35 $V\mu m^{-1}$) obtained at current density of 0.1 and 1 $\mu Acm^{-2}$, respectively. This study highlighted that nanocomposites of ZnO and CS have successfully enhanced the field emission performances of materials compared with pristine ZnO or CS due to the structural changes of material emitter.

**Keywords:** zinc oxide, carbon spheres, waste engine oil, field electron emission

**Abstrak**

Nanokomposit zink oksida (ZnO)/sfera karbon (SK) telah berjaya disintesis menggunakan minyak enjin terpakai sebagai pelopor untuk penghasilan SK. Nanorod ZnO telah ditumbuhkan menggunakan kaedah rendaman sol-gel dengan MgZnO sebagai pemangkin berbenih dan pemendapan wap kimia terma telah digunakan untuk mensintesis SK. Konfigurasi yang berlainan bagi struktur ZnO/SK telah disediakan iaitu SK bersalut ZnO dan ZnO bersalut SK. Struktur sampel komposit dianalisis menggunakan *Mikroskop* Imbasan *Elektron* Pancaran *Medan* (FESEM), penyerakan tenaga sinar-X (EDX), spektroskopi mikro-Raman dan pembelauan sinar-X (XRD). Pemerhatian FESEM menunjukkan perubahan struktur ZnO dan CS tulen dalam struktur komposit. ZnO atau CS sedia ada dipercayai memberi kesan kepada pertumbuhan seterusnya struktur lain. Sifat pemancaran elektron medan (PEM) bagi kedua-dua nanokomposit juga turut dikaji. Kajian mendapati bahawa sampel ZnO bersalut SK mempunyai ciri-ciri PEM yang lebih baik dengan nilai medan permulaan (3.48 $V\mu m^{-1}$) dan ambang (6.35 $V\mu m^{-1}$) yang lebih rendah diperolehi pada ketumpatan arus 0.1 dan 1 $\mu Acm^{-2}$. Kajian ini menekankan nanokomposit ZnO dan SK telah berjaya meningkatkan prestasi pemancaran medan bahan berbanding dengan ZnO atau CS tulen disebabkan oleh perubahan struktur bahan pemancar.

**Kata kunci:** zink oksida, sfera karbon, minyak enjin terpakai, pemancaran elektron medan

## Introduction

Field emission is a quantum process of electron emission from a material where the electrons in Fermi level tunnel the energy barrier to vacuum level under high applied electric field [1]. Emission characteristics of a material are based on the Fowler-Nordheim (F-N) theory as followed in Eq. 1 [2]:

$$J = \frac{A(\beta E)^2}{\varphi} exp\left(\frac{B\varphi^{3/2}}{\beta E}\right) \quad (1)$$

The current emission density (J) at applied electric field (E) can be calculated from the above equation. A and B are constants of 1.54 x $10^{-6}$ $AV^{-2}eV$ and 6.83 x $10^{9}$ $eV^{-3/2}Vm^{-1}$, respectively. Field enhancement factor of emitter (β) is an important FEE characteristic and can be calculated from the slope of ln ($J/E^2$) vs 1/E curve using the equation $\beta = -B\varphi^{3/2}/slope$. A typical benchmark that have been reported in the literature for FEE characterization comparison are the turn-on and threshold field, maximum current obtained (before the destruction of the emitter) as well as emission stability. Turn-on field for FEE is the field required to emit current density which is greater than the electrical noise-floor [3]. There is no agreement on the value of current density to be specified and the definition of turn-on and threshold field, it is determined by the group research themselves. For example, Ghosh et al. [4, 5] and Srivastava et al. [6] defined turn-on and threshold field to be the field required by the film to produce current density of 10 $\mu Acm^{-2}$ and 1 $mAcm^{-2}$ respectively. While Bonard and co-worker [90] specified the current density of 10 $\mu Acm^{-2}$ and 10 $mAcm^{-2}$ respectively. Since there is no specific definition of both turn-on and threshold field and as current density does not increase linearly with applied field, the result cannot be accurately compared. The comparisons between the results were only a rough estimation to claim that theirs is better than others. In this study, they are defined as the current density at applied field of 0.1 and 1 $\mu Acm^{-2}$, respectively for turn-on and threshold field.

To increase the FEE performance of the materials, it can be composited to further enhance the electron emission performance of those nanocomposites. Take carbon material such as carbon nanotubes (CNTs) as example, in view of its potential application as good electron emitters, however it can be easily degraded and damaged by the following factors [7-10], therefore the improvement of the FEE can be achieved by fabricating CNTs and zinc-oxide (ZnO) as nanocomposites [11-13]. The order of the configuration of CNTs/ZnO composites is the crucial component that lead to the enhancement of field emission ability, where it frequently occurs that the materials fabricated at the top is more likely to help the FEE performances. ZnO/CNTs nanocomposites structure have been reported to improve the FEE performance of material [1, 11-14]. In our recently published work [11], the investigation was done on the composite configuration to enhance the FEE performance by using two different configurations of ZnO/vertically aligned CNTs (VACNTs) where the order of the nanocomposites plays an important role in improving the FEE properties of pristine VACNTs.

The work revealed that the VACNTs-coated ZnO nanocomposites configuration showed a lower turn-on and threshold field at only 0.49 and 1.41 $V\mu m^{-1}$ as compared to the ZnO-coated VACNTs of 1.60 (turn-on) and 2.03 (threshold field) $V\mu m^{-1}$ respectively. The presence of different ZnO nanostructures including nanorods, nanoflowers and nanorods-nanoflakes for ZnO-coated CNTs configuration were seen to play significant role towards enhancing FEE performances [13]. Among the ZnO nanostructured used the growth of CNTs on ZnO nanoflower demonstrated the highest FEE performance of 0.8 $V\mu m^{-1}$ at 1 $uAcm^{-2}$ of turn-on field. ZnO is a semiconducting material with wide direct band gap (3.37 eV), large binding energy of 60 meV and and work function of 5.3 eV [1]. It has been applied in many electronic devices due to its unique and versatile properties [15-17]. ZnO nanostructures also showed promising application in field emission devices due to its high mechanical strength, chemical stability and good optical properties [18, 19]. On the other hand, carbon materials are well known as a conducting material which is good for electron emission application. One type of carbon materials namely carbon spheres (CS) has been reported to have a comparable field emission properties as compared to other materials [20].

Here we presented the composite structures of ZnO/CS and their FEE properties. To the best of our knowledge, this is the first report on the FEE of the CS synthesised from waste engine oil (WEO) with two different configurations of nanocomposite; CS-coated aligned ZnO nanorod and ZnO nanorod-coated CS sample. Recently, we reported the use of WEO for the production of another carbon material namely CNTs [21] and amorphous Al-Cu alloy nanowires decorated with CS [22]. The use of waste [23-27] and natural precursors [28-36] to produce carbon materials may not only be beneficial for nanotechnology research field but also preserve the environmental sustainability at the same time. The CS were synthesised using thermal chemical vapour deposition (TCVD) method while the ZnO were synthesised using the sol-gel method. The structural and field emission properties of ZnO/CS nanocomposites samples were then systematically investigated.

## Materials and Methods

The production of ZnO/CS was performed in two different synthesis processes which were (i) the synthesis of ZnO nanorods using sol-gel immersion process and (ii) the synthesis of CS via thermal chemical vapour deposition (TCVD) method. Two different configurations were prepared as illustrated in Figure 1. For the CS-coated ZnO sample, ZnO nanorods were initially grown followed by the synthesis of CS and vice versa for the ZnO-coated CS sample.

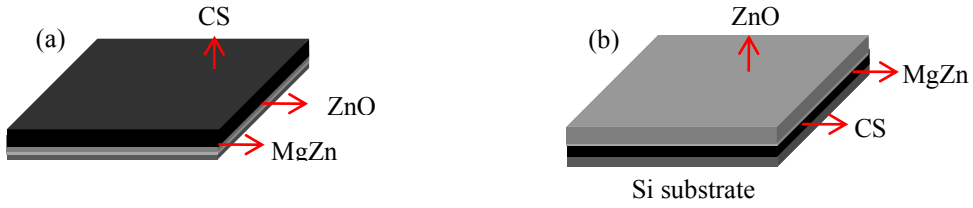

Figure 1. Different configurations of composite materials (a) CS-coated ZnO and (b) ZnO-coated CS

The synthesis procedures of CS from WEO precursor was similar to previous report [21, 22]. However, different synthesis parameters were used. An amount 3 ml of WEO mixed with 5.33 wt% ferrocene catalyst was heated at 450 °C in precursor zone and deposited onto Si substrate in 800 °C synthesis furnace. The synthesis process was carried out for 30 min under Ar gas flow at the rate of 0.25 $Lmin^{-1}$. Meanwhile, the synthesis of ZnO nanorods was adopted from [37]. MgZnO was initially deposited as the seeded catalyst. Collected samples were characterized using field emission scanning electron microscopy (FESEM-Hitachi SU8020), energy-dispersive X-ray (EDX), micro-Raman spectroscopy (Horiba Jobin Yvon-DU420A-OE-325) and X-ray diffraction (XRD) instrument (Bruker AXS D9). Field emission properties of the samples were measured using FEE equipment (Hewlett-Packard 34401A multimeter) at emission area of 0.1 $cm^2$ and distance between two electrodes was 100 µm.

## Results and Discussion

Figure 2(a) – (f) present the FESEM images of the prepared ZnO nanorods, CS and their nanocomposites with different configurations. It was observed in Figure 2 (a) that the ZnO nanorods were vertically aligned with length up to 1.6 µm. Wide diameter distribution of the rods in the range of 42.8 – 285.7 nm were measured. This was due to the non-unifom MgZnO particles size as the template for the ZnO nanorods growth. The growth of ZnO nanorods was also believed occurred on the collection of agglomerated MgZnO particles. High density of CS was obtained with diameter of the spheres were ranged from 0.17 to 2.57 µm as seen in Figure 2(b). The morphology of CS was modified after grown on ZnO nanorods as seen in Figure 2(c) and (d). Most of the spheres were decorated with short tube-like particles and grains which seemed to grow covering the CS. This was believed due to the adsorption of ZnO particles on the surface of CS which further become the catalyst for the secondary growth of short tube-like carbon structure. Somehow, the perfectly round shape of CS was still observed with diameter range from 1.1 to 2.7 µm.

Figure 2(e) and (f) show the FESEM observation of ZnO-coated CS sample. High density and uniformly grown ZnO nanorods on CS were observed. Slightly different to the pristine aligned ZnO nanorods, flower-like ZnO

nanostructures consisted of many hexagonal rods were also produced on the top of ZnO nanorods. The diameter of the rods was observed to be between 31.3 to 187.5 nm, in the smaller range as compared to pristine ZnO. This indicated the important presence of CS as the nucleation site for the growth of ZnO nanostructures. MgZnO particles were believed to be well deposited with uniform size on the CS, thus produced a better growth of ZnO nanostructures. Only small amount of CS was still observed as seen in the inset of Figure 2(f). The perfect alignment of ZnO nanorods cannot be observed due to the spherical shape of CS template. ZnO nanorods were initially grown on the uneven surface of MgZnO-coated CS template. Once the saturated condition was achieved, nucleation of aligned ZnO nanorods got slower. There was no more space for the growth of nanorods on the MgZnO-coated CS template, hence the ZnO particles started to nuclei on the top of the rods. Then, the aggregated ZnO particles formed the flower-like structure as can be observed in Figure 2(e)-(f).

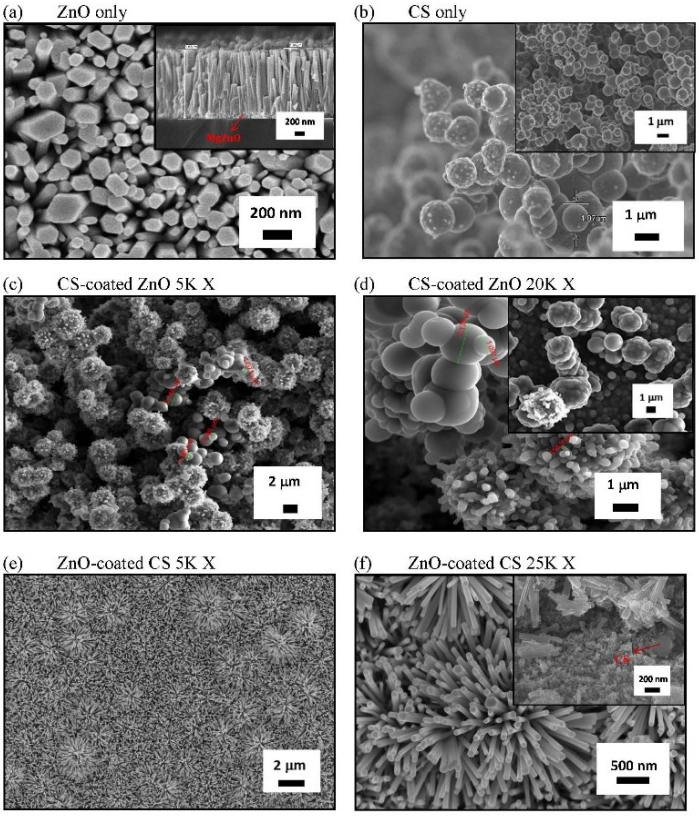

Figure 2. FESEM images of (a) ZnO nanorods, (b) CS, (c-d) CS-coated ZnO and (e-f) ZnO-coated CS nanocomposites

EDX analysis was performed to investigate the elemental compositions of the composite materials. Figure 3 show the EDX spectrum of both ZnO-coated CS and CS-coated ZnO samples. Carbon, oxygen, and Zn elements were detected from overall structure. The Si peaks was believed to come from the substrate used. The average atomic of zinc and oxygen was found to be 1:1 which indicated a good stoichiometric ratio of ZnO. Moreover, low amount of Mg element can be detected in this sample. The concentration of Zn atoms decreased in the CS-coated ZnO sample. This was in line with FESEM observation where during the synthesis of CS at high temperature of 800°C, the ZnO nanorods were fully etched and turned to be ZnO flakes structure. In the meantime, Zn and oxygen atoms were also suspected to be adsorbed on the surface of CS.

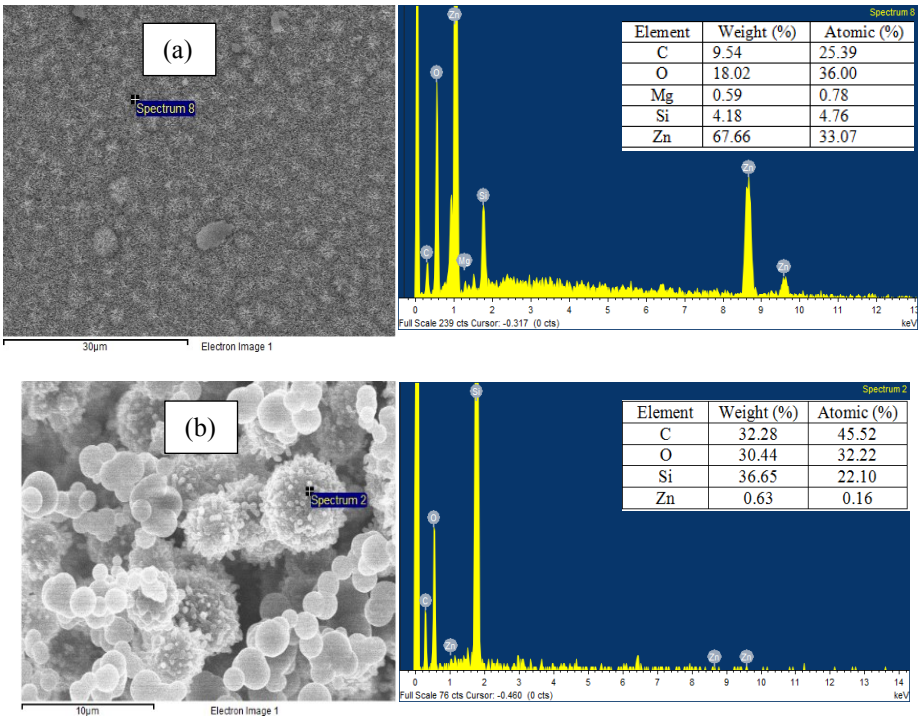

Figure 3. EDX analysis showing elemental compositions of ZnO/CS nanocomposites (a) ZnO-coated CS and (b) CS-coated ZnO

Micro-Raman spectra of the as-prepared samples are presented in Figure 4. The micro-Raman spectrum of pristine CS shows the *D* (disorder) and *G* (graphitic) band at 1357.70 and 1598.2 $cm^{-1}$, respectively with the intensity ratio of *D* and *G* band ($I_D/I_G$) ratio was found to be 0.79. Micro-Raman spectrum of ZnO nanorods only shows one typical ZnO characteristics at 438.18 $cm^{-1}$ attributed to the $E_2$ (high) modes. It also confirmed wurtzite hexagonal phase of ZnO nanorods. Peak at 303.76 $cm^{-1}$ was derived from the use of Si as the substrate. Micro-Raman spectra of ZnO/CS nanocomposites present both characteristic peaks of materials. ZnO-coated CS remained show the wurtzite hexagonal phase of ZnO characteristic at 438.18 $cm^{-1}$ which presented by a clear $E_2$ (high) mode.

Only CS characteristics can be observed from the Raman spectrum of CS-coated ZnO sample. However, micro-Raman spectrum at lower shift range Figure 4(b) showed a sharp low intense peak at 444.13 $cm^{-1}$ which corresponded to Raman active mode of wurtzite ZnO structure ($E_2$ high). This mode was shifted to a higher number. It might due to the increase of the stress or defect in the ZnO crystal [38]. Moreover, $I_D/I_G$ ratio of the CS increased to be 0.91 (ZnO-coated CS) and 0.88 (CS-coated ZnO) after being composited with ZnO. These indicated the lower crystallinity of CS in both composite structures as compared to the pristine CS. The reasonable explanation to these occurrences was due to the changes of CS structure after being combined with ZnO. In case of ZnO-coated CS sample, annealing process of MgZnO thin layer and ZnO nanorods alter the structure of CS where it introduced more defect of C–C bonding in the spheres. The highest ratio of 0.91 was obtained from this structure. In addition, for the growth of CS on ZnO nanostructures, defect-induced from the bonding of carbon from CS and oxygen from the ZnO nanostructures was responsible to the higher defect of CS [13].

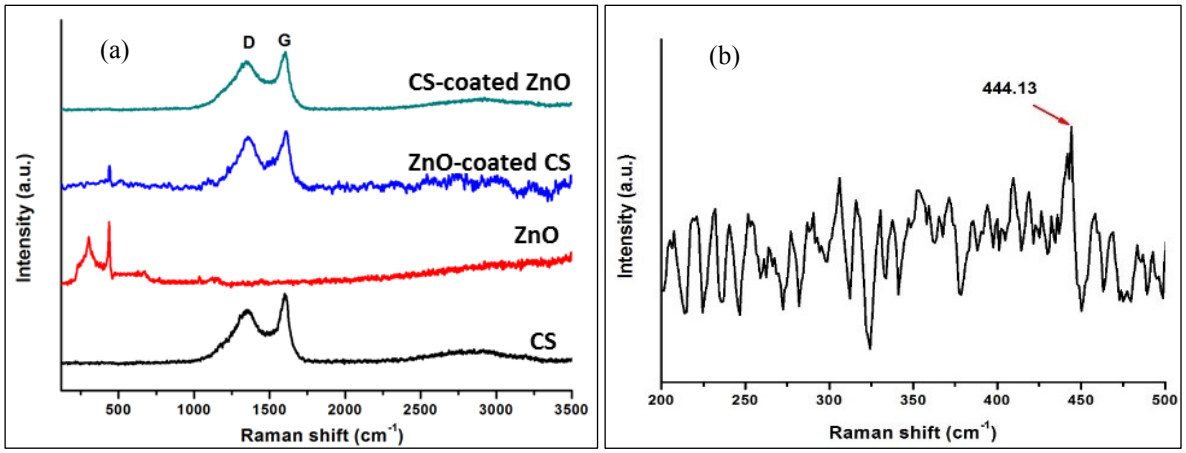

Figure 4. (a) Micro-Raman spectra of ZnO/CS nanostructures and (b) Raman profile at lower wavenumber of CS-coated ZnO structure shows the shift of $E_2$ high mode due to the compressive stress

Typical XRD patterns of ZnO/CS nanostructures are presented in Figure 5. Both samples show the characteristic peaks of ZnO and carbon. Similar to the pristine ZnO nanorods, the most intense peak was observed at ~34° along the (002) orientation [19]. ZnO-coated CS sample presents a broad and low intense peak at 43.40° which attributed to carbon phase from CS. Another ZnO peak was shown by a low intense peak at 47.49° along the (102) orientation. Diffraction peaks of ZnO in CS-coated ZnO sample are located at 2θ of 34.49, 36.15, 47.60 and 56.20° which are in good agreement with the standard of hexagonal ZnO crystal (PDF-01-080-0075). Meanwhile, carbon phase at 44.67 and 52.3° are well matched with the standard of cubic carbon crystal (PDF-01-080-0017) with the lattice parameter of 3.539 Å.

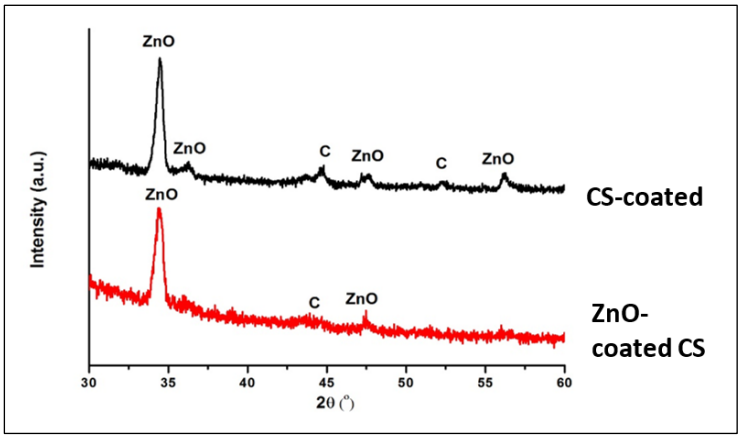

Figure 5. XRD patterns of CS/ZnO nanostructures composites

Figures 6 and 7 present the J-E and F-N plot of different ZnO and ZnO/CS nanocomposites materials. The measurements were taken at fixed electrodes separation of 100 µm and applied voltage was increased from 0 to 1000 V. Table 1 presents the summary of FEE characteristics of the as-prepared samples. Several repeated measurements have been conducted on the CS sample, but the current emission was still not observed. Due to its spherical structure, CS are less suitable to be applied as electron emitter. ZnO nanorods possessed moderate turn on

and threshold fields at 5.65 and 7.34 V/µm, respectively with maximum current density of 3.46 µA/cm$^2$. Composite structures of ZnO/CS successfully enhanced the FEE properties. Turn on and threshold values of CS-coated ZnO sample were founded to be at 6.83 and 7.88 V/µm and maximum current density of 2.51 µA/cm$^2$. Modification of CS structure with the presence of short tube-like carbon structure which covered the CS was believed promoted a better emission site as compared to pristine CS. Interestingly, ZnO-coated CS structure where the ZnO nanostructures were grown on CS as the template exhibited an obvious decrement in the turn on value to be as low as 3.48 V/µm and the threshold field was also decreased to be 6.35 V/µm. This structure presented a better FEE performance compared with the pristine ZnO nanorods as well as CS-coated ZnO composite structure. In addition, highest $\beta$ value up to 5485 and maximum current density of 3.78 µA/cm$^2$ were obtained. Higher conductivity of CS compared to ZnO nanorods promoted a better electron transfer from the CS through ZnO nanorods structures to the vacuum level at high applied voltage. Moreover, the high aspect ratio of ZnO nanostructures with a good crystallinity and uniform rods diameter were also responsible for the high $\beta$ value of ZnO-coated CS composite material [6].

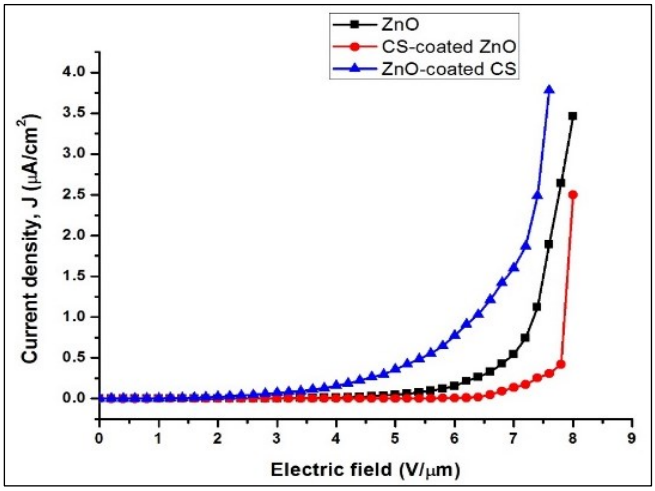

Figure 6. The J-E curves of the ZnO and ZnO/CS nanocomposites materials

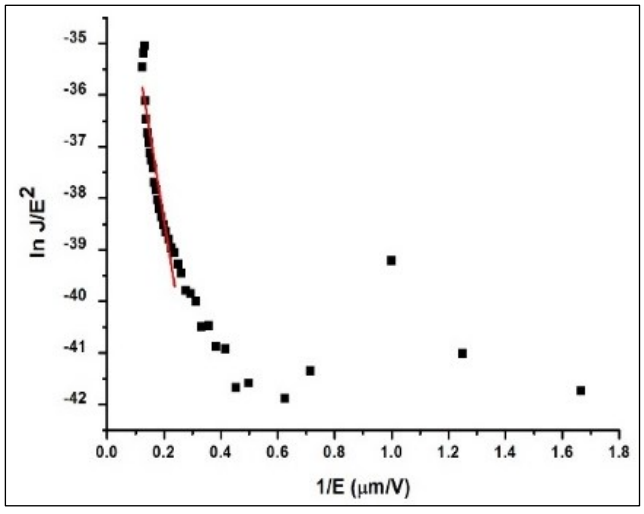

Figure 7. F-N plots of ZnO and ZnO/CS nanocomposites materials (a) ZnO, (b) CS-coated ZnO and (c) ZnO-coated CS

Table 1. FEE characteristics of CS, ZnO nanorods and their composite materials

| Sample | Turn on Field at 0.1 µA (V/µm) | Threshold Field at 1 µA (V/µm) | *J* Max (µA/cm$^2$) | $\beta$ |
|---|---|---|---|---|
| ZnO | 5.65 | 7.34 | 3.46 | 2452 |
| ZnO-coated CS | 3.48 | 6.35 | 3.78 | 5879 |
| CS-coated ZnO | 6.83 | 7.88 | 2.51 | 755 |

To study the emission current stability, a constant electric field was applied to the ZnO nanorods and ZnO/CS nanocomposites materials for one hour duration time. The current vs time graphs for both samples are presented in Figure 8 and the detail of their current emission fluctuation order is given in Table 2. The current emission of ZnO nanorods was moderately stable since frequent fluctuations to a high current value were observed. This was due to the wide diameter range of ZnO nanorods. Smaller diameter rods proportional with the length and rods spacing is preferable for a better FEE performance. Although ZnO nanorods current emission was less stable, the emission of ZnO nanorods was found to be higher in the order of $10^{-6}$ A than the CNTs which was in the order of $10^{-7}$ A [11]. ZnO nanomaterials have negative electron affinity [18] which can support the current emission due to their ability to emit electrons to the vacuum with little energy loss.

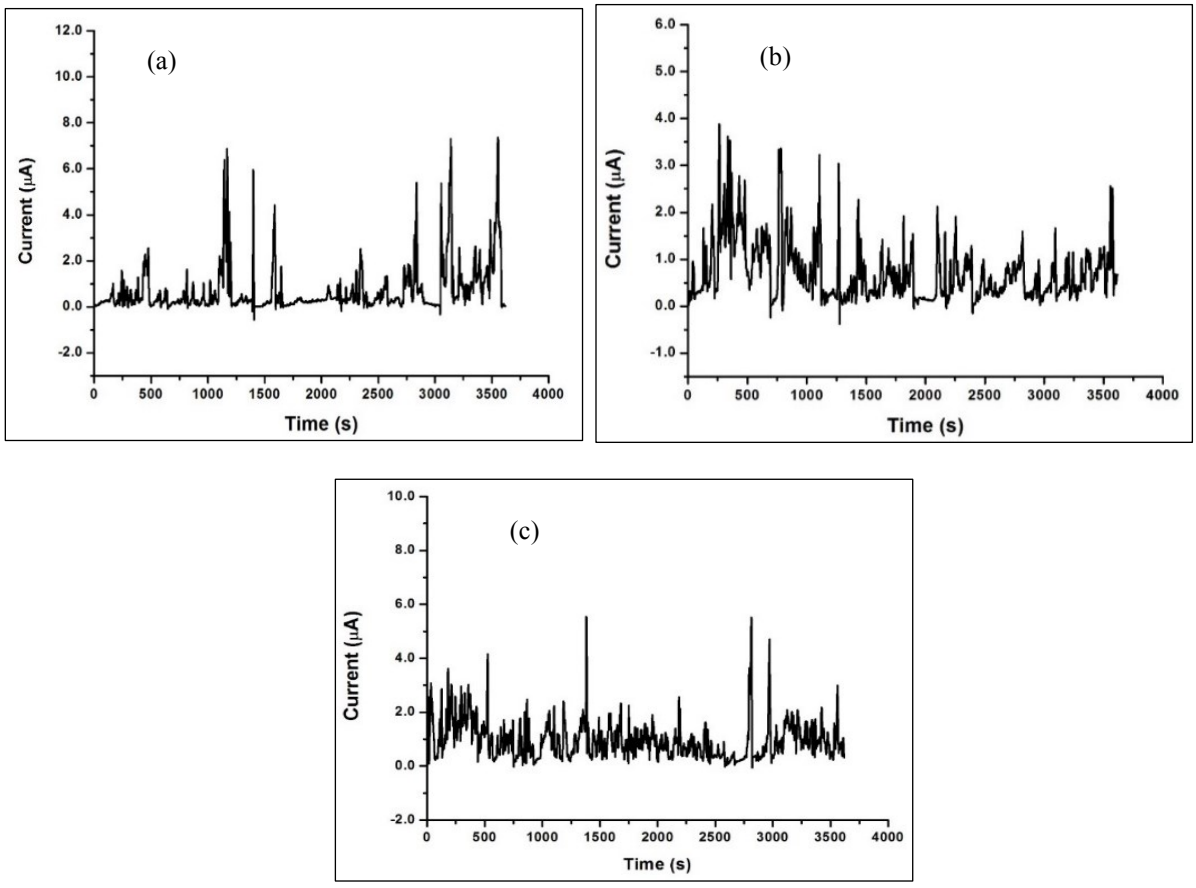

Figure 8. Current stability measurement of (a) ZnO and (b)-(c) ZnO/CS nanostructures composites

Table 2. Current emission fluctuation order of carbon material, ZnO nanorods and their composite structures

| Sample | Current Fluctuation Order (Ampere) |
|---|---|
| ZnO | $10^{-8} – 10^{-6}$ |
| ZnO-coated CS | $10^{-9} – 10^{-6}$ |
| CS-coated ZnO | $10^{-7} – 10^{-6}$ |

The growth of ZnO nanorods on CS sample gave better emission stability as compared to pristine ZnO and CS-coated ZnO samples. This was believed due to the presence of as-grown CS and high uniformity with smaller ZnO nanorods, flower-like ZnO nanostructures size which is more favourable for electron emission application. High conductivity of carbon materials promoted better electrons transfer and led to the enhancement of field emission. Moreover, the carbon materials acted as the additional catalyst which improved the uniformity and crystal quality of ZnO nanostructures.

## Conclusion

ZnO/CS nanocomposites were successfully synthesised using the combination of sol-gel immersion and TCVD method. Waste material precursor namely WEO was used to produce CS in this study. The structure of ZnO and CS were modified after being composited. In case of CS-coated ZnO, the structural change of CS was believed due to the adsorption of ZnO particles on the surface of CS. Meanwhile, the as-presence of CS in ZnO-coated CS sample has promoted a better growth ZnO nanostructure. This structure also presented the best FEE performances with the lowest turn on (3.48 V/μm) and threshold field (6.35 V/μm) as well as highest maximum current density (3.78 $\mu A/cm^2$) and field enhancement factor up to 5879 with better emission current stability. The presence of conductive carbon material which is CS promoted the well electron transfer from the CS through the ZnO nanostructures to vacuum level at high electric field. A better structure of ZnO nanorods with uniform diameter size was also responsible to the better FEE properties of this nanocomposites structure. It can be concluded that the ZnO-coated CS nanocomposites has great future applications in field emission devices such as flat panel displays and flat lamps.

**Abstract**

This paper reports on the experimental work using batch process conducted to determine the adsorption capacity of dissolved hydrogen sulfide in the synthetic wastewater onto the activated carbon which is derived from the eggshell. Fourier Transform Infrared Spectroscopy (FTIR), Energy-Dispersive X-ray Spectroscopy (EDX), Scanning Electron Microscopy (SEM), and particle size distribution have been used to characterize the prepared material. The raw materials of chicken eggshell are adopted to retrieve the carbon content which is then activated using KOH as the activation agent. The examined concentration of dissolved hydrogen sulfide is ranging from 100 to 500 ppm. The maximum adsorption capacity of the dissolved $H_2S$ onto the activated carbon is 289.3 mg/g and the equilibrium time is 6 hours. The examined pH value in this study is ranging from 4.5 to 5.5. The two well-known equilibrium adsorption isotherm models, i.e. the Langmuir and the Freundlich models, are employed. It is found that the adsorption isotherm capacity agrees very well to the Freundlich isotherm model. This paper attempts to show the difficulties of converting $CaCO_3$ to carbon due to the fact that the raw material contains higher calcium (Ca) content instead of carbon. It is concluded that the carbon derived from the chickens' eggshells is very beneficial for treatment of dissolved $H_2S$ in waste water.

**Keywords**: adsorption, hydrogen sulfide, chicken eggshells, activated carbon, isotherm

**Abstrak**

Kajian ini melaporkan mengenai kerja eksperimen menggunakan proses kelompok yang dijalankan untuk menentukan kapasiti penjerapan hidrogen sulfida terlarut dalam air sisa sintetik ke dalam karbon yang diaktifkan dihasilkan daripada kulit telur. Spektroskopi Inframerah Fourier (FTIR), Spektroskopi X-ray Tenaga Serakan (EDX), Mikroskop Imbasan Elektron (SEM), dan taburan saiz zarah telah digunakan untuk mencirikan bahan yang disediakan. Kulit telur ayam sebagai bahan mentah telah digunakan untuk mendapatkan semula kandungan karbon yang kemudiannya diaktifkan dengan menggunakan KOH sebagai agen pengaktifan. Julat kepekatan hidrogen sulfida yang diperiksa adalah di antara 100 hingga 500 ppm. Kapasiti penjerapan maksimum $H_2S$ terlarut ke dalam karbon diaktifkan adalah 289.3 mg/g dan masa keseimbangan selama 6 jam. Julat nilai pH yang diperiksa dalam kajian ini di antara 4.5 hingga 5.5. Kedua-dua model penjerapan isoterma keseimbangan terkenal seperti model Freundlich dan Langmuir telah dilaksanakan. Kapasiti penjerapan isoterma didapati selari dengan model isoterma Langmuir. Kajian ini cuba menunjukkan kesukaran untuk menukar $CaCO_3$ kepada karbon disebabkan oleh bahan mentah

mengandungi kandungan kalsium (Ca) yang tinggi dan bukannya karbon. Ini dapat disimpulkan bahawa karbon yang diperolehi daripada kulit telur ayam adalah sangat bermanfaat untuk rawatan $H_2S$ terlarut dalam air sisa.

**Kata Kunci**: penjerapan, hidrogen sulfida, kulit telur ayam, karbon diaktifkan, isoterma

## Introduction

Hydrogen sulfide ($H_2S$) is a very toxic, corrosive and flammable gas. It is a colorless gas, best known for its strong smell, much like the strong nauseating smell of rotten eggs. The $H_2S$ is volatile in water and soluble in some polar organic solvents [1]. It is also a reducing agent and oxidizes easily when the conditions are right and corrodes metals and even concrete. For example, $H_2S$ will oxidize gradually to elemental sulfur and over time oxidize to sulfuric acid and eventually damage the sewer [2]. Under specific conditions such as at a low concentration (1.36 mg/L) pH between 3 to 5 and immersion time of more than two hours, $H_2S$ has been found to have an inhibiting effect on iron corrosion [3, 4]. Moreover, $H_2S$ is also a harmful and putrid gaseous compound. It can create health problems, like coma, irritated eyes, and respiratory system irritation. Furthermore, the human nose can detect $H_2S$ at concentrations as low as 0.5 part-per-billion-volume (ppbv) [5]. Therefore, excess exposure to $H_2S$ can cause both chronic and acute ramifications [6]. Surprisingly, the allowable limit of $H_2S$ in drinking water is not specified by the World Health Organization (WHO) [7]. Most of the sulfide found in water may be expected to exist as molecular $H_2S$ at pH less than 4 [8]. Bisulfide and sulfide ions can be found when $H_2S$ is dissolved in water as per the following reaction:

$$H_2S_{(g)} \leftrightarrow H_2S_{(aq)} \quad (1)$$

$$H_2S_{(aq)} \leftrightarrow H^+ + HS^- \quad (2)$$

$$HS^- \leftrightarrow H^+ + S^{2-} \quad (3)$$

Reaction 2 (reverse direction) occurs at pH <4.5 [9] and reaction 3 (forward direction) happens at pH ≥ 9 [10]. In a natural environment, acid rain is precipitated through the oxidation of $H_2S$ to sulfuric acid. $H_2S$ dissolves easily in water (4-6 g/L) and it is poisonous to almost all types of life forms [11]. Owing to the above reasons, various agencies have been consistently developing solutions to remove $H_2S$. It could be removed in three different ways such as adsorption, oxidation, and scrubbing. Recently, there is a renewed interest in using adsorption process as an effective method to remove the pollutant e.g. $H_2S$ from wastewater. Adsorption is a physio-chemical technique, involving mass transfer between the liquid and the solid phase [12]. A considerable amount of literatures detailing on the removal of $H_2S$ have been published [13-15]. These studies have reported that the adsorption rate of $H_2S$ is affected by many factors such as surface area of adsorbent, pore size, moisture content, pH, and surface chemistry (oxygen containing functionalities). The experimental and simulation study detailing on $H_2S$ adsorption on impregnated activated carbon under an anaerobic condition has been carried out by Xiao et al. [13]. They have applied a sodium carbonate impregnated activated carbon as the adsorbent for low concentration $H_2S$ in nitrogen under the anaerobic condition in a fixed bed [13]. Moreover, sludge-derived $H_2S$ adsorbents have received considerable attentions from the galvanizing industry [14].

Other study has been conducted by Guo et al. [15], whereby they have studied activated carbons derived from oil-palm shell as an adsorption of $H_2S$ [15]. In addition, study on ferric and alum water treatment residuals has been conducted by Wang and Pei [16]. Possible materials to be used as adsorbents of $H_2S$ such as Fine Rubber Particle Media (FRPM) and crushed oyster shell have been tested by Wang [17] and Asaoka [18], respectively. Recently, the low-cost carbon-based materials such as agricultural wastes have been used as pollutant adsorbent such as rice husks [19], banana and orange peels [20], coconut shell [21], macadamia nut shells [22], fibers of oil palm empty fruit bunches [23], rice straw [24]. Several studies have documented that activated carbon has been widely used as an adsorbent for achieving high water purification. So far, very little attention has been paid to remove $H_2S$ from wastewater in liquid phase.

Therefore, this paper addresses on the use of eggshells as the source of activated carbon to adsorb dissolved $H_2S$ as liquid form out of wastewaters. It is important to note that eggshells are abundant and environmental friendly [25]. In this paper, our objective is to assess the effectiveness of activated carbon derived from eggshell waste as an adsorbent of dissolved $H_2S$ from waste water. Also, we aim to characterize this adsorbent and find the suitable isotherm adsorption model to be fitted with this adsorption process.

## Materials and Methods

### Preparation of activated carbon

In this study, the activated carbon derived from eggshells has been used as an adsorbent of $H_2S$ appeared in the petroleum refinery synthetic waste water. Firstly, the eggshells (around 100 pieces) were collected from restaurants around Kajang, Selangor, Malaysia. A sample of the eggshells was then carefully rinsed several times with deionized water and acidic solvent to remove impurities and pollutants. After that, the sample was gradually dried under 105 °C for eight hours. Then the dried eggshell was grinded into powder form. The powder (10 g) was placed in a furnace and gradually heated up to 700 °C [26], at constant heating rate of 10 °C/min with nitrogen ($N_2$) flow rate of 150 mL/min. Then the result product was soaked in concentrated solution of KOH for 24 hours. After that, it is filtered and dried under 105℃. Finally, the activation process is done in a horizontal tubular furnace at temperature of 750℃, which is subjected to constant heating rate of 10℃/min with $N_2$ flow rate of 150 mL/min. The prepared material was coded as ACES.

### Characterization of activated carbon

In this study, the pH value of the carbon surface was measured by taking a sample of 0.4 g of dry carbon powder added to 20 mL of water and the suspension was stirred overnight to reach equilibrium. Then, the pH value of the suspension was measured. Moreover, the surface morphology of the sample was examined using a Scanning Electron Microscope (SEM). Elemental analysis on the chemical composition of the sample was conducted using the energy-dispersive X-ray spectroscopy (EDX). The particle size distribution was also measured. The Fourier Transform Infrared Spectroscopy (FTIR) analysis has been used for the examination of functional groups on the surface of adsorbent.

### Hydrogen sulfide solution

In this study, the synthetic waste water was prepared according to the procedure reported by Asaoka et al. [18]. A portion of $Na_2S.9H_2O$ was dissolved in 500 mL solution of 0.01 M KCl purged with $N_2$ gas. Thereafter, the pH of the solution was adjusted to 4.5 – 5.5 using 0.2 M HCl [18]. The concentration of dissolved $H_2S$ in water is 4 – 6 g/L [11]. All forms of $H_2S$ are harmful to organisms, and they can exist in a solution in three forms, i.e. hydrogen sulfide ($H_2S$), bisulfide ($HS^-$) and sulfide ($S^{2-}$) [27].

### Batch equilibrium studies

The adsorption capacity of the ACES has been carefully studied by examining its ability in removing $H_2S$ from synthetic wastewater. The pollutant concentration was initially measured. The pH of the solution was controlled to 4.5 – 5.5 using NaOH and HCl. The experiments of the adsorption process of $H_2S$ were conducted using a batch mode process. For each experiment, the adsorption was carried out using 0.1 g of adsorbent after degassing at 105℃ for 24 hours in the oven. The solution was rotated at 160 rpm with an electric shaker for 9 hours to test their adsorption capacities. Upon the filtration of the suspensions, the initial and final concentration were measured. The adsorption capacity of the pollutants was calculated using equation 4 below:

$$q_e = \frac{(C_0 - C_e)V}{m} \tag{4}$$

where $V$ is the solution volume ($L$), $m$ is the adsorbent amount ($g$), $C_o$ and $C_e$ are the initial and final concentrations of the pollutants, and ($q_e$) is adsorption capacity in mg/g. All adsorption experiments were repeated and the maximum deviation was within 5%. All the measurements were done at fume hood as $H_2S$ is a very dangerous gas. The adsorbent sample yield can be calculated using the following equation 5 below:

$$Yield(\%) = \frac{W_c}{W_o} \times 100\% \tag{5}$$

where $W_c$ and $W_o$ are the dry weight of the final sample ($g$) and the dry weight of precursor ($g$), respectively. The equilibrium data were then fitted using the adsorption isotherm models, namely the Langmuir and the Freundlich models.

**Adsorption isotherm models**

The adsorption isotherm models explained the connection between the amounts of adsorbate adsorbed per unit mass of adsorbent (equilibrium adsorption capacity, $q_e$) at constant temperature and adsorbate's concentration at equilibrium conditions ($C_e$). Langmuir and Freundlich models are considered the well-known equilibrium adsorption isotherm models, and they were employed in the current study. Langmuir isotherm assumes monolayer adsorption onto a surface containing a finite number of adsorption sites of uniform strategies of adsorption with no transmigration of adsorbate in the plane of surface [28]. The linear form of Langmuir's isotherm model is given by the following equation 6 below:

$$\frac{C_e}{q_e} = \frac{1}{Q_{max}\, K_l} + \left(\frac{1}{Q_{max}}\right) C_e \tag{6}$$

where $C_e$ is the equilibrium concentration of the adsorbate ($H_2S$) (mg/L), $q_e$ is the amount of adsorbate adsorbed per unit mass of adsorbent (mg/g), and parameters such as $Q_{max}$ and $b$ are Langmuir constants related to monolayer adsorption capacity and affinity of adsorbent towards adsorbate, respectively. The essential characteristics of the Langmuir isotherm can be expressed in terms of a dimensionless equilibrium parameter ($R_L$), which is defined by:

$$R_L = \frac{1}{1+bC_0} \tag{7}$$

where $C_o$ is the $H_2S$ initial concentration (in mg/L). The value of $R_L$ indicates the type of the isotherm to be either unfavorable, linear, favorable, or irreversible as reported in Table 1.

Table 1. The range values of $R_L$

| **Value of $R_L$** | **Type of isotherm** |
|---|---|
| $R_L > 1$ | Unfavorable |
| $R_L = 1$ | Linear |
| $0 < R_L < 1$ | Favorable |
| $R_L = 0$ | Irreversible |

The Freundlich isotherm is another adsorption isotherm model which assumes heterogeneous surface energies, in which the energy term in Langmuir equation varies as a function of the surface coverage [29]. The correlation coefficients ($R^2$) is used to judge the applicability of an isotherm model. The well-known logarithmic form of the Freundlich model is given by the following equation 8 below:

$$\log q_e = \log K_F + \frac{1}{n} \log C_e \tag{8}$$

where $q_e$ is the adsorption capacity at equilibrium (mg/g), $C_e$ is the equilibrium concentration of the adsorbate ($H_2S$) and $K_F$ and n are Freundlich constants.

**Adsorption kinetic models**

Normally, the pseudo-first-order, pseudo-second-order and other kinetic models are used to simulate adsorption kinetics and determine the reaction rates. The mathematical relations of pseudo-first-order and pseudo-second-order are as given in equations 9 and 10, respectively [30,31]:

$$\log(q_e - q_t) = \log q_e - \frac{k_1}{2.303}\, t \tag{9}$$

$$\frac{1}{q_t} = \frac{1}{k_2 q_e^2} + \frac{1}{q_e}\, t \tag{10}$$

where $q_e$ and $q_t$ are the $H_2S$ adsorbed (mg/g) at equilibrium and at time t (h), respectively. $k_1$ ($h^{-1}$) and $k_2$ (g/mg h) are the rate constants for pseudo-first-order and pseudo-second-order, respectively.

## Results and Discussion

### Textural characterization of prepared activated carbon

Table 2 shows the composition of eggshell after the carbonization process. As seen, the prepared materials showed a high of carbon and oxygen of 30.36% and 50.27%, respectively. Indicating the carbon structure of the prepared material. Calcium is lower as compared to carbon and oxygen, which is could be attributed to remaining component of eggshells. Furthermore, the morphology of the adsorbent surface was tested using SEM, it is interesting to find that the extural structure of the ACES particles has porous structure with fine pores and cracks as shown in Figure 1. The porous materials is preferable for the adsorption processes as it will discussed in the coming sections.

Table 2. The elemental composition of ACES

| Element | Weight % | Weight Error (±) |
|---|---|---|
| Carbon (C) | 30.36 | 0.47 |
| Oxygen (O) | 50.27 | 0.86 |
| Molybdenum (Mo) | 6.16 | 0.31 |
| Calcium (Ca) | 12.48 | 0.31 |
| Potassium (K) | 0.40 | 0.07 |
| Magnesium (Mg) | 0.33 | 0.07 |
| Total | 100.00 | |

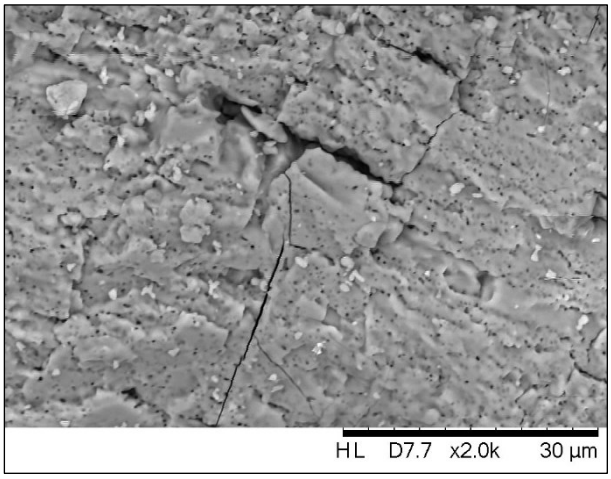

Figure 1. SEM image of ACES

Figure 2 shows the particle size distribution of adsorbent and Figure 3 shows another analytical test which is reporting on the FTIR structure of ACES particle. From Figure 3, it is obvious that the FTIR spectrum of ACES reveals three peaks. Each peak represents different functional group which might play an important role in the adsorption process. This corresponds to the presence of OH (hydroxyl), C=C (alkynes), and C–O (anhydrides) derivatives. Therefore, these surface functional groups could enhance the adsorption capacity of acidic pollutant (dissolved $H_2S$) in the waste water. Apart from that, at lower pH, the $H^+$ component which is high in concentration

may increase the positively charged $CaOH^{2+}$. It has been indicated that some reactions might occur during the adsorption process on the surface of adsorbent. Hence, reaction outlined in equation (11) might happen due to the oxygen content supporting the carbonization process of raw material. However, the dissociation of calcium oxide in water outlined in equation (12) forms calcium hydroxide ($Ca(OH)_2$) on the surface of ACES adsorbent which might help the adsorbent to attract via active site the acidic pollutant such as $H_2S$. Moreover, in equation (13) the $OH^-$ from $Ca(OH)_2$ reacts with $H_2S$ to form $Ca(HS)_2$ which is then converted to element sulfur as demonstrated in equation (14).

$$CaCO_3 \rightarrow CaO + CO_2 \quad (11)$$
$$CaO + H_2O \rightarrow Ca(OH)_2 \quad (12)$$
$$Ca(OH)_2 + H_2S \rightarrow Ca(HS)_2 + 2H_2O \quad (13)$$
$$Ca(HS)_2 + O_2 \rightarrow Ca(OH)_2 + 2S \quad (14)$$

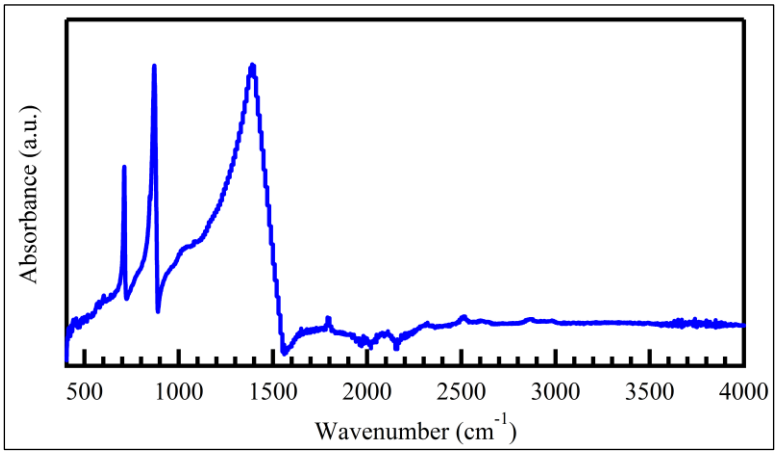

Figure 3. FTIR spectra of the ACES

**Effect of contact time and initial hydrogen sulfide concentration on adsorption equilibrium**

A series of contact time experiments for $H_2S$ have been carried out at different initial concentrations (100 – 500 mg/L) and at temperature of 30 ˚C. Figure 4 shows that the equilibrium time of 6 hours is required for $H_2S$ removal with the higher range of initial concentration (300 – 500 mg/L). However, with lower initial concentrations range (100 – 200 mg/L), a equilibrium time of 5 hours is required. As can be clearly seen from Figure 4, the amount of adsorbed $H_2S$ onto the modified adsorbent (ACES) increases with time and it reaches an asymptote as time progresses. The results reveals that the $H_2S$ adsorption rate is high at the initial stage of the contact period, and it becomes slower thereafter. This phenomenon happens due to the activity of functional group on the surface of adsorbent. It has been noted that vacant surface sites are vastly available for adsorption during the initial stage. However, as time elapses, it is difficult to occupy the remaining vacant surface sites due to the repulsive forces between the solute molecules on the solid and bulk phases. The results of this study indicate that the initial concentration has an important role in the adsorption capacity. Similarly, Choo et al. has found that higher concentration yields enhanced driving force along the pores, resulting in higher adsorption capacity [32]. However, Xiao et al. have shown that the effect of concentration is lower [13]. The contact time affects the adsorption capacity as well. From the current study, the effects of driving force and mass transfer are minimal in the dynamic adsorption. Moreover, it is limited by the rate of molecular diffusion into deeper pores and the adsorption process. The percentage of removal of $H_2S$ is 43%, which is calculated using equation 15 below:

$$Removal\ (\%) = \frac{C_0 - C_e}{C_0} \times 100 \tag{15}$$

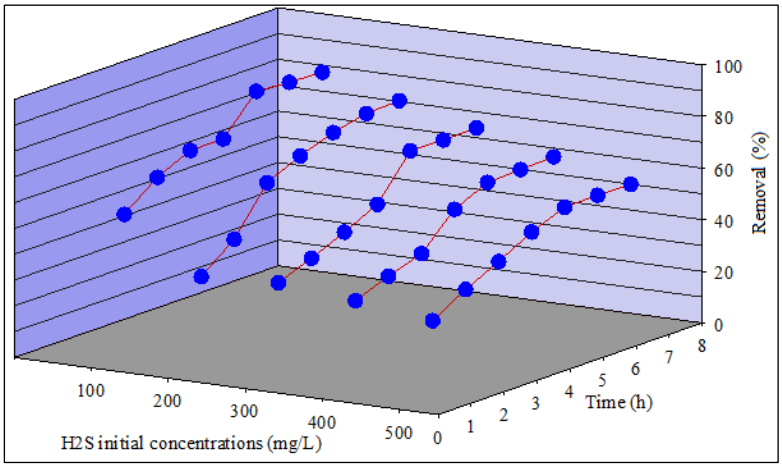

Figure 4. Effect of agitation time on $H_2S$ adsorption onto ACES at various initial concentrations (100 – 500 mg/L)

**Adsorption isotherms**

The adsorption isotherm demonstrates the adsorption process when it reaches an equilibrium state. It reveals on how the adsorption molecules are distributed between the solid phase and the liquid phase. The analysis of the isotherm data, which is performed by fitting the data on different isotherm models, is an important step to find the suitable model that can be used for design purposes [33]. Basically, adsorption isotherm is important to describe how solutes interact with adsorbents, and is critical in optimizing the use of adsorbents. $R^2$ value is used to identify the appropriate model of the adsorption process. Figure 5 shows the Langmuir isotherm model, where $1/q_e$ changes linearly with $1/C_e$, at a slope of $1/Q_o b$. The Langmuir constants $b$ and $Q_o$ are shown in Table 3. $R^2$ is 0.9849, indicating that the fitting error is quite high compare with Freundlich isotherm model. To support that, the essential characteristics of the Langmuir isotherm can be expressed in terms of a dimensionless equilibrium parameter ($R_L$),

and the value of $R_L$ is 0.069. Indeed, this indicates that the Langmuir isotherm is favorable for the adsorption of $H_2S$ by the ACES under the working conditions considered in this study.

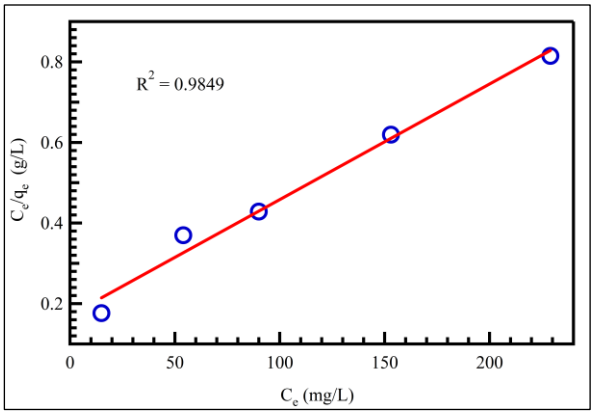

Figure 5. Langmuir adsorption isotherm of $H_2S$ adsorption onto ACES

Table 3. Parameters of Langmuir and Freundlich adsorption isotherm models of $H_2S$ adsorption onto ACES

| **Langmuir** | | | **Freundlich** | | |
|---|---|---|---|---|---|
| $Q_{max}$ (mg/g) | $K_L$ (L/mg) | $R^2$ | $K_F$ (mg/g (L/mg)$^{1/n}$) | 1/n | $R^2$ |
| 289.3 | 0.02704 | 0.9849 | 25.16 | 0.452 | 0.9874 |

According to Freundlich isotherm plot (log $q_e$ vs. log $C_e$), 1/$n$ of 0.452 could be obtained from the slope the straight line gives as shown in Figure 6, showing that the adsorption of $H_2S$ on the ACES is favorable. Accordingly, the Freundlich constants $K_F$ and $n$ are reported in Table 3. $R^2$ is 0.9874, indicating that the fitting error is lower than that of the Langmuir model. Table 4 compares the adsorption capacities of various adsorbents. It is interesting to see that the ACES has the highest adsorption capacity as compared to other adsorbents reported in the literature.

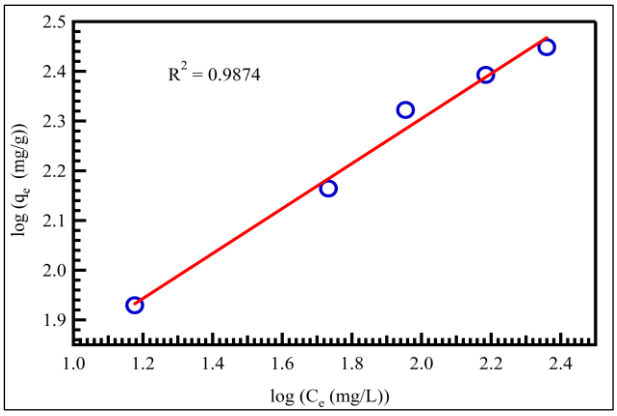

Figure 6. Freundlich adsorption isotherm of $H_2S$ adsorption onto ACES

| Red mud | $H_2S$ | 17 | [35] |
| Carbonated steel slag | $H_2S$ | 7.5 | [36] |
| Activated carbon from sawdust pellets | $H_2S$ | 6.2 | [37] |

**Adsorption kinetics**

The relation between $\log(q_e-q_t)$ and time showed straight lines as displayed in Figure 7a for the pseudo-first-order kinetic model. $R^2$ and $k_1$ values are listed in Table 5. On the other hand, linear relationships were obtained by plotting $t/q_t$ versus t (Figure 7b) for the pseudo-second-order kinetic model. Moreover, the $q_e$ and $k_2$ were determined from the slope and the intercept of the plot and listed in Table 5.

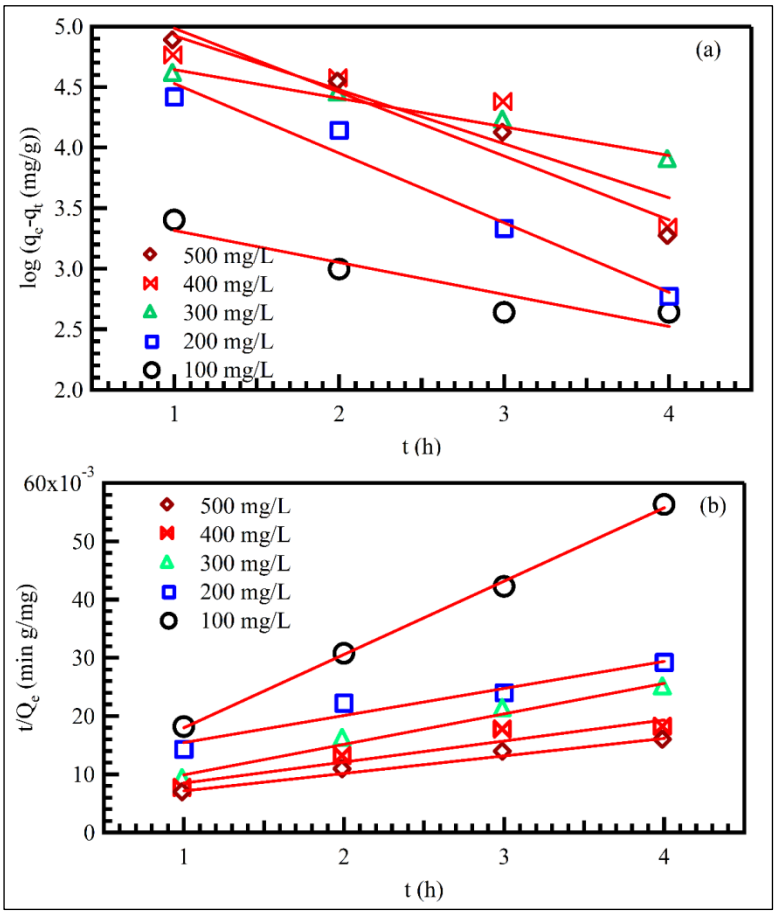

Figure 7. Pseudo-first-order (a) and pseudo-second-order (b) models of $H_2S$ adsorption onto ACES

Table 5. Pseudo-first-order and pseudo-second-order kinetic models' parameters for adsorption of $H_2S$ onto ACES

| Kinetic Model | Parameter | Initial $H_2S$ Concentration (mg/L) | | | | |
|---|---|---|---|---|---|---|
| | | 100 | 200 | 300 | 400 | 500 |
| Pseudo-first-order kinetic model | $K_1$ (1/h) | 0.264 | 0.574 | 0.236 | 0.445 | 0.527 |
| | $R^2$ | 0.884 | 0.970 | 0.820 | 0.950 | 0.970 |
| Pseudo-second-order kinetic model | $K_2$ (g/mg h) | 0.024 | 0.002 | 0.005 | 0.002 | 0.002 |
| | $R^2$ | 0.998 | 0.943 | 0.981 | 0.907 | 0.980 |

This procedure is more likely to predict the behavior over the whole range of adsorption. It shows a good agreement between the experimental and the calculated $q_e$ values (Table 5). It is found that, the correlation coefficients for the second-order kinetic model were higher than those for the pseudo-first-order model, indicating the applicability of the second-order kinetic model to describe the adsorption process of $H_2S$ onto the prepared ACES $R^2$ values obtained are shown in Table 5 and they are low compared to those obtained from pseudo-second-order. Table 5 lists the calculated parameters and it is found that the adsorption of $H_2S$ on ACES could be best described by the second-order kinetic model.

## Conclusion

The activated carbons have been prepared and analyzed to characterize their physical and chemical properties. The resulting solid samples have been used in the adsorption process of dissolved hydrogen sulfide from aqueous solution. From the current study, the activated carbon derived from the eggshell has the maximum adsorption capacity of 289.3 mg/g which is the highest amongst the other adsorbents reported earlier. The result indicate also that the initial concentration has an important role in the adsorption capacity. The adsorption isotherm fit very well to the well-known Freundlich isotherm model. In addition, the process followed the pseudo-second-order kinetic model. Thus, it can be concluded that eggshell is a very useful green and economic adsorbent due to its good accessibility and absence of any toxic and hazardous elements. Therefore, it is a very suitable candidate for removing $H_2S$ from wastewater.

**Abstract**

The inhibitive action of the extracts of three green inhibitors namely *Adathoda vasica, Eclipta alba and Centella asiatica* were investigated. Polarization method indicates that the plant extracts are under mixed control i.e promoting retardation of both anodic and cathodic reactions. The impedance method reveals that charge-transfer process controls the corrosion of mild steel. The plant-extracts obeys Langmuir adsorption isotherm. Kinetics and reason for the corrosion inhibition or the nature of adsorption is clearly shown. Physisorption mechanism has been proposed for the inhibition action of these plant extracts. The protective film formed on the surface was confirmed by Scanning Electron Microscopy (SEM). From hydrogen permeation method, all the plant extracts were able to reduce the permeation current. Results obtained in all the methods are very much in good agreement with increasing inhibition efficiency in the order: *Eclipta alba* > *Adathoda vasica* > *Centella asiatica*. Among the three plant extracts studied, the maximum inhibition efficiency was found in *Eclipta alba* which showed 99.6% inhibition efficiency at 8.0 % v/v concentration of the extract.

**Keywords**: mild steel, corrosion inhibition, plant-extracts, hydrochloric acid, physisorption

**Abstrak**

Tindakan perencatan oleh tiga ekstrak perencat hijau iaitu *Adathoda vasica, Eclipta alba dan Centella asiatica* telah dikaji. Kaedah polarisasi menunjukkan bahawa ekstrak tumbuhan di bawah kawalan campuran akan menghasilkan tindak balas perencatan bagi kedua–dua anod dan katod. Kaedah galangan mendedahkan bahawa proses pemindahan cas mengawal kakisan terhadap keluli lembut. Bahan ekstrak tumbuhan mematuhi penjerapan isoterma Langmuir. Kinetik dan sebab bagi perencatan kakisan atau sifat penjerapan jelas dapat ditunjukkan. Tindakan perencatan dari ekstrak tumbuhan adalah dicadangkan sebagai mekanisma serapan fizikal. Filem pelindung yang terbentuk di permukaan telah disahkan melalui mikroskopi elektron pengimbasan (SEM). Melalui kaedah penyerapan hidrogen, semua ekstrak tumbuhan dikenalpasti dapat mengurangkan penelapan arus. Keputusan yang diperolehi dalam semua kaedah amat bersetuju dengan peningkatan kecekapan rencatan adalah mengikut tertib iaitu *Eclipta alba* > *Adathoda vasica* > *Centella asiatica*. Di antara ketiga–tiga ekstrak tumbuhan yang dikaji, kecekapan rencatan maksimum diperolehi dari *Eclipta alba* iaitu 99.6% pada 8.0% v/v kepekatan ekstrak.

**Kata kunci**: keluli lembut, perencat kakisan, ekstrak tumbuhan, asid hidroklorik, serapan fizikal

## Introduction

Mild steel are widely used in boilers, motor car bodies, machines, gears, pipes, tanks and in most of the chemical industries. Hydrochloric acid and sulphuric acids are the medium generally used for pickling mild steel. About 90% of pickling problems can be solved by introducing appropriate pickling inhibitor to the medium. The recent and growing trend is using plant extracts as corrosion inhibitor on mild steel in acid medium due to their biodegradability, ecofriendliness, less toxicity, cost effectiveness, easy availability, environmentally safe, soluble and highly stable nature in acidic solutions. Owing to strict environmental legislation, emphasis is being focused on development of naturally occurring substances as corrosion inhibitors. Recently, many plant extracts have been reported to be very effective corrosion inhibitors for the protection of mild steel in acidic media [1 – 4]. In this study, the inhibition effect of the extracts of three green inhibitors namely *Adathoda vasica (Adathodai), Eclipta alba (Karisilankani) and Centella asiatica (Vallarai)* on the corrosion of mild steel in 1N hydrochloric acid was investigated using electrochemical and non-electrochemical methods.

## Materials and Methods

### Preparation of mild steel specimen

Mild steel strips were mechanically cut into strips of size 4.5 cm × 2 cm × 0.2 cm containing the composition of 0.14% C, 0.35% Mn, 0.17% Si, 0.025% S, 0.03% P and the remainder is Fe and provided with a hole of uniform diameter to facilitate suspension of the strips in the test solution for weight loss method. For electrochemical studies, mild steel strips of the same composition but with an exposed area of $1cm^2$ were used. Mild steel strips were mechanically polished with emery papers of 1/0 to 4/0 grades and subsequently degreased with trichloroethylene or acetone and finally with de-ionized water and stored in the desiccator. Accurate weight of the samples was taken using electronic balance.

### Preparation of the green inhibitors

The leaves of the *Adathoda vasica*, *Eclipta alba* and *Centella asiatica* were taken and cut into small pieces and they were dried in an air oven at 80 ºC for 2 hours and ground well into powder. An amount 10g of the sample was refluxed in 100 mL of distilled water for 1 hours. The refluxed solution was then filtered carefully and the filtrate volume was made up to 100 mL using double distilled water which is the stock solution and the concentration of the stock solution is expressed in terms of % (v/v). From the stock solution, 2% - 10% concentration of the extracts was prepared using 1N hydrochloric acid.

### Weight loss method

The pretreated specimens' initial weights were noted and were immersed in the experimental solution (in triplicate) with the help of glass hooks at 30 °C for a period of 3 hours. The experimental solution used was 1N HCl in the absence and presence of various concentrations of the plant extracts. After three hours, the specimens were taken out, washed thoroughly with distilled water, dried completely and their final weights were noted. From the initial and final weights of the specimen, the loss in weight was calculated and tabulated. From the weight loss, the corrosion rate (mmpy), inhibition efficiency (%) and surface coverage (θ) of plant extracts was calculated using the equation 1 – 3 as shown below:

$$\text{Corrosion rate (mmpy)} = KW / ATD \quad (1)$$

where $K = 8.76 \times 10^4$ (constant), W= weight loss in g, A=area in sq.cm, T= Time in hours and D=density in gm/ cu.cm (7.86).

$$\text{Inhibition efficiency (\%)} = (CR_B - CR_I) / CR_B \times 100 \quad (2)$$

$$\text{Surface coverage } (\theta) = CR_B - CR_I \ / CR_B \quad (3)$$

where $CR_B$ and $CR_I$ are Corrosion rates in the absence and presence of the inhibitors.

**Potentiodynamic polarization method**

Potentiodynamic polarization measurements were carried out using electrochemical analyzer. The polarization measurements were made to evaluate the corrosion current, corrosion potential and tafel slopes. Experiments were carried out in a conventional three-electrode cell assembly with a time interval of 10 – 15 minutes was given for each experiment to attain the steady state open circuit potential. The polarization was carried from a cathodic potential of – 800mV (vs SCE) to an anodic potential of – 200 mV (Vs SCE) at a sweep rate of 1 mV per second. The inhibitor efficiency was calculated using equation 4 below:

$$IE\ (\%) = \frac{I_{Corr} - I^*_{Corr}}{I_{Corr}} \times 100 \quad (4)$$

where $I_{corr}$ and $I^*_{corr}$ are corrosion current in the absence and presence of inhibitors.

**Electrochemical impedance method**

The electrochemical AC-impedance measurements were also performed using electrochemical analyzer. A sine wave with amplitude of 10 mV was superimposed on the steady open circuit potential. The real part (Z') and the imaginary part (Z") were measured at various frequencies in the range of 100 KHz to 10 MHz. A plot of Z' vs Z" was made. From the plot, the charge transfer resistance ($R_t$) was calculated and the double layer capacitance was then calculated using the equation 5 below:

$$C_{dl} = \frac{1}{2\pi} f_{max}\ R_t \quad (5)$$

The experiments were carried out in the absence and presence of different concentrations of inhibitors. The percentage of inhibition efficiency was calculated using the equation 6 below:

$$IE\ (\%) = \frac{R_t^* - R_t}{R_t^*} \times 100 \quad (6)$$

where $R_t^*$ and $R_t$ are the charge transfer resistance in the presence and absence of inhibitors.

**Hydrogen permeation method**

The permeation current was measured using hydrogen permeation apparatus in 1N HCl medium in the absence and presence of optimum concentration of extracts.

**Surface examination studies**

Surface examination of mild steel specimens in the absence and presence of the optimum concentration of the extracts immersed for 3 hours at 30 $^oC$ were studied with the magnification of 1000X specimens. The protective film formed on the surface of the mild steel was confirmed by scanning electron microscopy (SEM) studies.

## Results and Discussion

**Weight loss studies**

The various corrosion parameters were obtained from weight loss method in1N hydrochloric acid in the absence and presence of various concentrations of the plant extracts ranging from 2% to 10% v/v are listed in Table 1.

It was found that the optimum concentration for *Adathoda vasica* was found to be 6% v/v with maximum inhibition efficiency of 99.0%, *Eclipta alba* at 8% v/v with maximum inhibition efficiency of 99.6% and *Centella asiatica* at 10% v/v with maximum inhibition efficiency of 85.3% for a period of 3 hours of immersion time. This result indicated that the plant extracts could act as good corrosion inhibitors.

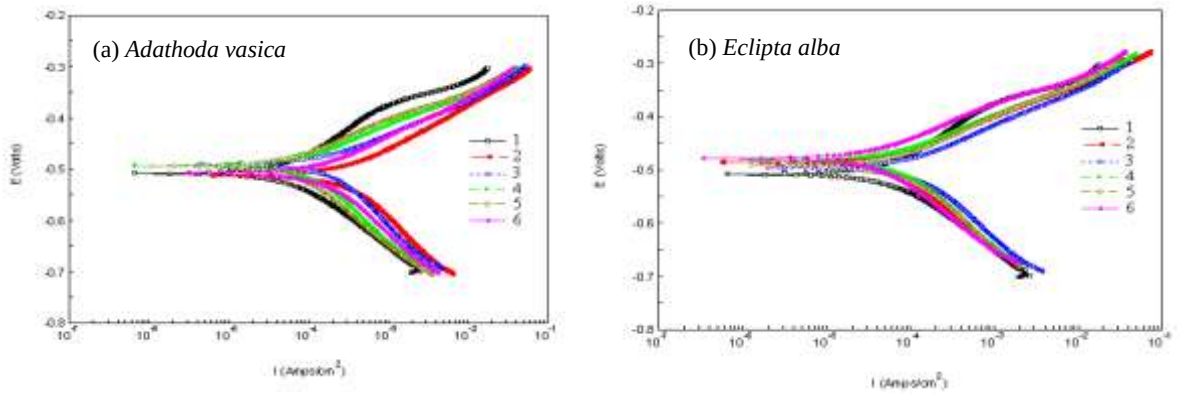

Table 1. Corrosion parameters obtained from weight loss measurements for mild steel in 1N HCl with various concentrations of the plant extracts

| Name of the Plant Extract | Conc. of Extract (% in v/v) | Corrosion Rate (mmpy) | Inhibition Efficiency (%) | Surface Coverage (θ) |
|---|---|---|---|---|
| *Adathoda vasica* | Blank | 30.67 | - | - |
| | 6.0 | 0.30 | 99.0 | 0.990* |
| | 8.0 | 0.35 | 98.8 | 0.988 |

**Maximum inhibition efficiency*

**Potentiodynamic polarization studies**

Potentiodynamic polarization studies as shown in Figures 1a – 1c revealed that the extracts act through mixed mode of inhibition as the polarization curves have not shifted towards more positive potential or more negative potential but has shifted towards less negative potential and lower current density values upon the addition of extract. It was observed that with increase in concentration of the plant extract from 2% to 10%, the maximum inhibition efficiency of 99.2% was observed for *Adathoda vasica* at an optimum concentration of 6% v/v, for *Eclipta alba* extract with 99.7% at 8% v/v and *Centella asiatica* with 85.7% at 10% v/v of the extract (Table 2).

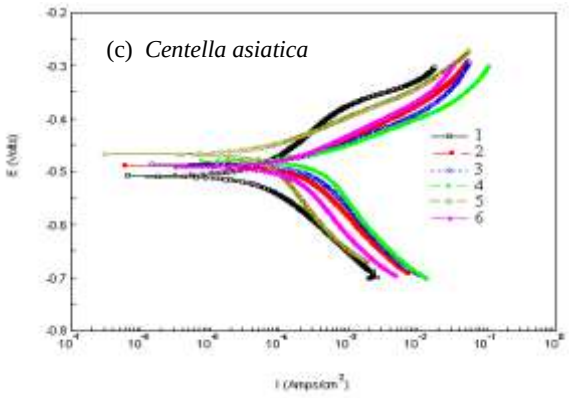

Figure 1. Potentiodynamic polarization curves for mild steel in 1N HCl solution in the absence and presence of various concentrations of the plant extracts (a) *Adathoda vasica, (b) Eclipta alba and (c) Centella asiatica* (Note legend information: 1 – blank, 2 – 2.0% v/v, 3 – 4.0% v/v, 4 – 6.0% v/v, 5 – 8.0% v/v and 6 – 10.0% v/v)

Table 2. Potentiodynamic polarization parameters for mild steel in 1N HCl at 30 $^{o}$C containing various concentrations of the plant extracts

**Electrochemical impedance studies**

Impedance measurements were studied to evaluate the charge transfer resistance ($R_t$) and double layer capacitance ($C_{dl}$) as shown in Table 3 and through these parameters the inhibition efficiency was calculated. From Figure 2, the obtained Impedance diagrams are almost in a semi-circular appearance, indicating that the charge - transfer process mainly controls the corrosion of mild steel. Deviations of perfect circular shape are often referred to the frequency dispersion of interfacial impedance. In fact, in the presence of the plant extracts the values of $R_t$ has enhanced and the values of double layer capacitance are also brought down to the maximum extent. The decrease in $C_{dl}$ shows that the adsorption of the inhibitors takes place on the metal surface in acidic solution. A good agreement is observed between the results of weight loss method and electrochemical methods (Potentiodynamic Polarization method and Impedance method) in the order: *Eclipta alba > Adathoda vasica > Centella asiatica.*

Table 3. Impedance parameters for the corrosion of mild steel in 1N HCl in the absence and presence of various concentrations of the plant extracts at 30 °C

| Name of the Plant Extract | Conc. of Extract (% in v/v) | $R_t$ ($\Omega$ cm$^2$) | $C_{dl}$ ($\mu$F/cm$^2$) | Inhibition Efficiency (%) |

| *Centella asiatica* | 10.0 | 54.32 | 39.88 | 86.0 |

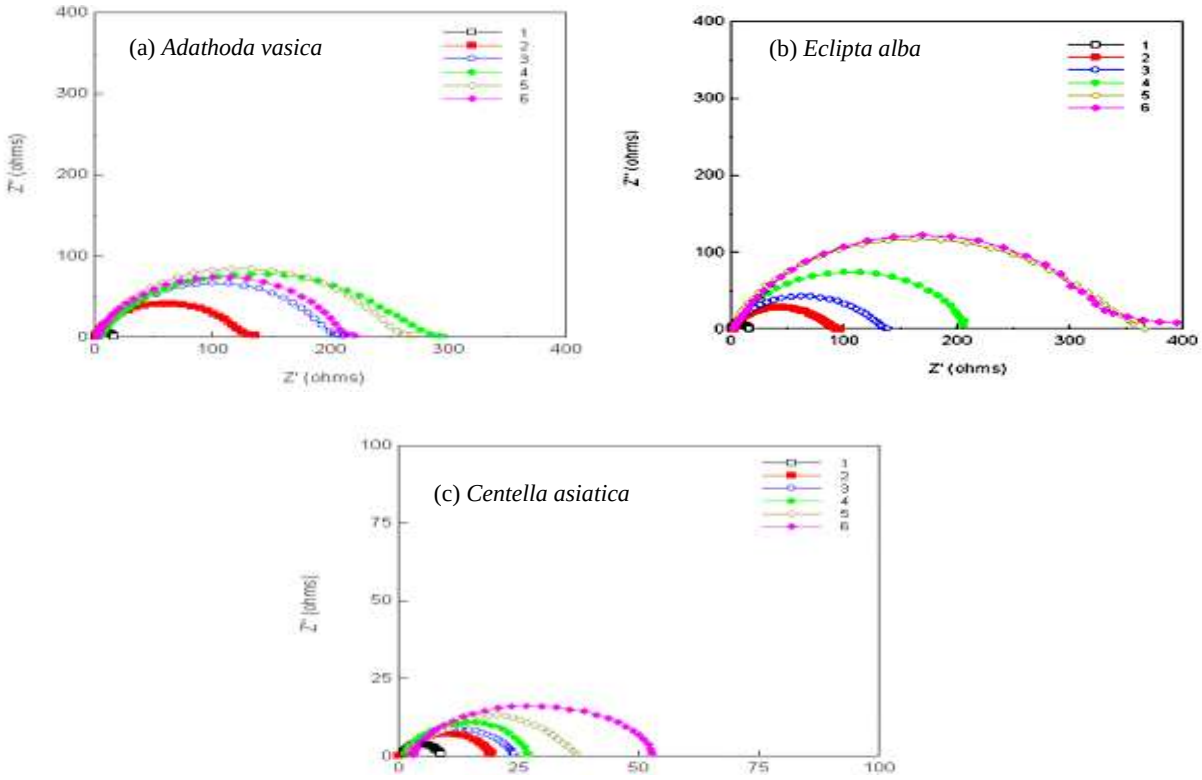

Figure 2. Impedance diagrams for mild steel in 1N HCl solution in the absence and presence of various concentrations of the plant extract: (a) *Adathoda vasica*, (b) *Eclipta alba* and (c) *Centella asiatica*. (Note legend information: 1 – blank, 2 – 2.0% v/v, 3 – 4.0% v/v, 4 – 6.0% v/v, 5 – 8.0% v/v and 6 – 10.0% v/v)

**Kinetics and reason for the corrosion inhibition**

The major phytochemical constituents present in *Adathoda vasica* are the alkaloids namely vasicine and vasicinone (Figure 3), in *Centella asiatica* is asiaticoside, a triterpene glycoside (Figure 4), and in *Eclipta alba* are wedelolactone, β-sitosterol, stigmasterol (Figure 5a – 5c) and also an alkaloid namely ecliptine [5, 6]. Inspection of the chemical structures of the phytochemical constituents reveals that the compounds can adsorb on the metal surface via the lone pair of electrons present on their oxygen atoms and make a barrier for charge and mass transfer leading to decrease the interaction of the metal with the corrosive environment. As a result, the corrosion rate of the

metal was decreased**.** The formation of film layer essentially blocks discharge of $H^+$ and dissolution of metal ions. Due to electrostatic interaction, the protonated constituent's molecules are adsorbed (physisorption) and high inhibition is expected [1]. Acid pickling inhibitors containing organic N, S and OH groups behave similarly to inhibit corrosion [7 – 10].

The adsorption of different concentrations of *Adathoda vasica*, *Eclipta alba* and *Centella asiatica* extracts on the surface of mild steel in 1N hydrochloric acid followed Langmuir adsorption isotherm as shown in Figure 6.

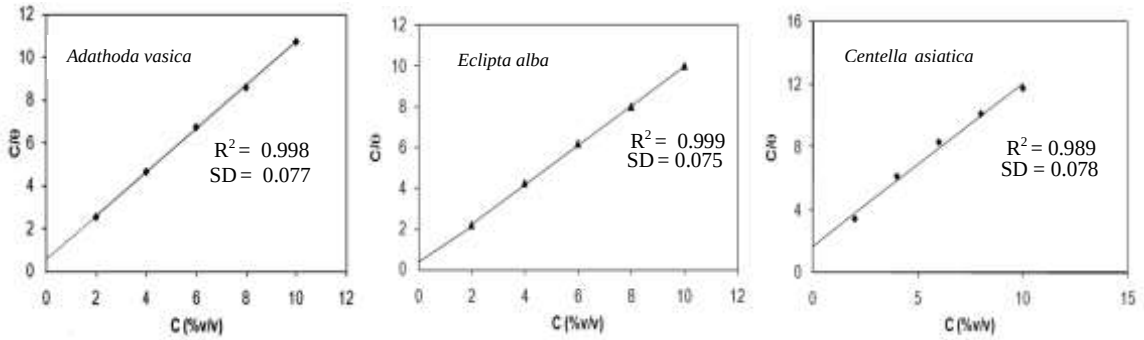

Figure 6. Langmuir adsorption isotherm plot for the adsorption of different concentrations of the green inhibitors on the surface of mild steel in 1N HCl solution

**Surface examination studies**

From the SEM images it shows the presence of a protective film over the surface of the mild steel in the presence of the inhibitors and the protective film is uniform in the order: *Eclipta alba* > *Adathoda vasica* > *Centella asiatica.* The SEM morphology of the adsorbed protective film on the mild steel surface has confirmed the high performance of inhibitive effect of the plant extracts as shown in Figures 7a to 7d, respectively.

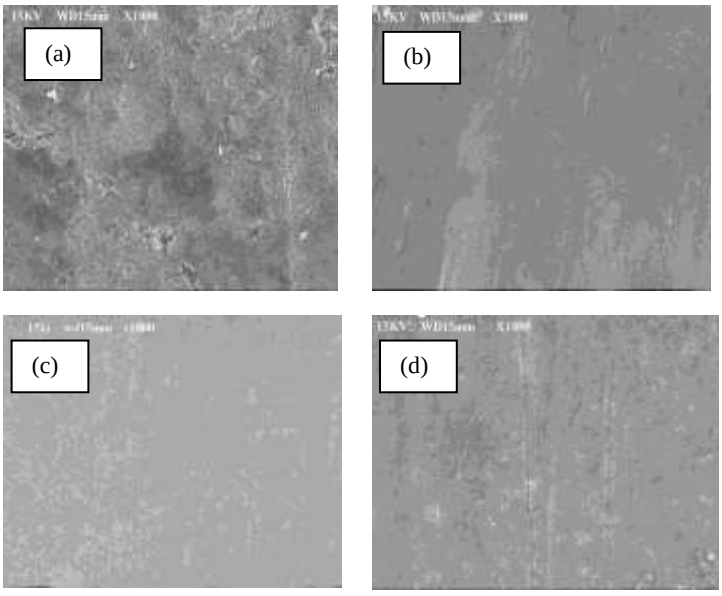

Figure 7. Mild steel immersed in 1N HCl solution (a) blank, (b) with optimum concentration (6% v/v) of *Adathoda vasica*, (c) optimum concentration (8% v/v) of *Eclipta alba* and optimum concentration (10% v/v) of *Centella asiatica*

From the hydrogen permeation studies on mild steel in 1N HCl in the absence and presence of inhibitors, it was observed that all the prepared extracts were able to reduce the permeation current compared to the control because

those inhibitors, which reduce the permeation current are good at inhibiting the entry of hydrogen into the metal concerned. The decrease in the permeation current follows the order: *Eclipta alba* > *Adathoda vasica* > *Centella asiatica.* Permeation current *vs*. time curves for mild steel in 1N HCl in the absence and presence of inhibitors are shown in Figure 8 and their corresponding permeation are given in Table 5.

Table 5. Hydrogen permeation current parameters in the absence and presence of inhibitors

| **Inhibitor** | **Conc. of the Extract (% in v/v)** | **Permeation Current (μA)** | **Reduction in Permeation Current (%)** |
|---|---|---|---|
| Blank | - | 23.0 | - |
| *Centella asiatica* | 10.0 | 19.4 | 15.65 |
| *Eclipta alba* | 8.0 | 2.2 | 90.43 |
| *Adathoda vasica* | 6.0 | 3.1 | 86.52 |

## Conclusion

Green inhibitors namely *Adathoda vasica*, *Eclipta alba* and *Centella asiatica* were proved to be good and efficient inhibitors for corrosion of mild steel in 1N hydrochloric acid. Potentiodynamic polarization studies revealed that the extracts act through mixed mode of inhibition. The impedance studies revealed that charge-transfer process mainly controls the corrosion of mild steel. The mechanism involved is the phytochemical constituents in the plant extracts have adsorbed on the metal surface forming a protective thin film layer preventing the discharge of $H^+$ ions and dissolution of metal ions and has prevented the small corrosion on the surface of the metal. The adsorption followed Langmuir adsorption isotherm. The SEM morphology confirmed the high performance of inhibitive effect of the green inhibitors. Results obtained in weight loss method were very much in good agreement with the electrochemical methods and hydrogen permeation method in the order: *Eclipta alba* > *Adathoda vasica* > *Centella asiatica* and among the three plant extracts studied, the maximum inhibition efficiency was found in *Eclipta alba* which showed 99.6% inhibition efficiency at 8.0% v/v concentration of the extract.

**Abstract**

Poly(vinylidene fluoride-co-tetrafluoroethylene) (PVDF-co-PTFE) flat sheet membranes were prepared via phase inversion process by means of immersion precipitation. The effects on the microstructure of prepared membranes by using different solvents and the effect of polymer solution composition (polymer concentration) on the membrane morphologies and the membrane porosity were studied. Three different solvents were employed, which were, N,N-dimethylacetamide (DMAc), N-methyl-2-pyrrolidone (NMP) and N,N-dimethylformamide (DMF). Different polymer concentrations were used; 20 wt.%, 25 wt.% and 30 wt.%. Brookfield viscometer was used to measure the viscosity for each polymer solution before the membrane was casting. The morphological study for the cross-sectional area of PVDF-co-PTFE membrane was carried out by using scanning electron microscope (SEM). The membrane porosity was determined by using the weight difference and density resulted from the immersing of dry membrane into octanol for 15 seconds. The results showed that the polymer concentration was a particularly important parameter. At different polymer concentration, the precipitant plays an important role and finally influence the prepared membrane microstructure. At higher concentration of PVDF-co-PTFE polymer, the prepared membrane possessed a sponge-like membrane structures, whereas at lower concentration, a finger-like structure was obtained. It was also found that, the membrane porosity decreases with the increasing of polymer concentration. The effect of different solvent reflected to different morphologies of the prepared flat sheet membranes. Prepared membrane with more sponge-like structure indicated a weak dissolution solvent was used. Hence, a small amount of water needed to induce precipitation and reduced the precipitation rate.

**Keywords**: PVDF-co-PTFE polymer, phase inversion, polymer concentration, membrane morphology

**Abstrak**

Membran kepingan rata poli (vinilidena fluorida-ko-tetrafluoridaetilena) (PVDF-ko-PTFE) telah disediakan dengan kaedah fasa penyongsangan menggunakan fasa pemisah bukan pelarut teraruh (FPBT). Kesan ke atas mikrostruktur membran tersedia dengan menggunakan pelarut yang berbeza dan kesan komposisi larutan penuangan (kepekatan polimer) ke atas morfologi membran dan keliangan membran telah dikaji. Tiga pelarut yang berbeza digunakan ialah N,N-dimetilasetamida (DMAs), N-metil-2-pirolidon (NMP) dan N,N-dimetilformamida (DMF). Kepekatan polimer yang berbeza akan digunakan, iaitu pada 20 wt.%, 25 wt.% dan 30 wt.%. Brookfield viskometer digunakan untuk mengukur kelikatan lasrutan polimer sebelum membran diacukan. Kajian morfologi bagi kawasan keratan rentas membran PVDF-co-PTFE telah dijalankan dengan menggunakan mikroskop elektron pengimbas (SEM). Analisis keputusan keliangan ditentukan dengan perendaman membran kering di dalam oktanol selama 15 saat. Keputusan menunjukkan bahawa kepekatan polimer adalah parameter penting. Pada kepekatan polimer yang berbeza, bahan pemendak memainkan peranan yang penting dan akhirnya mempengaruhi mikrostruktur membran tersedia. Pada kepekatan polimer PVDF-ko-PTFE yang lebih tinggi, membran tersedia memiliki struktur membran seperti span,

sedangkan pada kepekatan yang lebih rendah, struktur seperti-jejari telah diperolehi. Ia juga mendapati bahawa, keliangan membran menurun dengan peningkatan kepekatan polimer. Penggunaan pelarut yang berbeza terkesan kepada berlainan morfologi membran kepingan rata yang tersedia. Membran tersedia dengan struktur seperti span menunjukkan pelarut pelarutan lemah telah digunakan. Oleh itu, jumlah air yang sedikit diperlukan untuk mendorong mendakan dan mengurangkan kadar mendakan.

**Kata kunci**: PVDF-ko-PTFE polimer, fasa pemisah, kepekatan polimer, morfologi membran

## Introduction

The first commercial membrane was invented via phase inversion method by Loeb and Sourirajan in early 1960's [1]. Phase inversion is a demixing process whereby the initially homogenous polymer solution changed from a liquid to a solid state in a controlled manner. The process can be achieve in different ways, which are (a) non-solvent induced phase separation (NIPS) or known as immersion precipitation; (b) thermally induced phase separation (TIPS); and (c) vapour induced phase separation (VIPS). It is reported that among these techniques, NIPS is the most popular method for the membrane fabrication because it allows the preparation of many membrane morphologies [2, 3]. However, different variable of phase inversion parameters applied will give different morphological properties of the prepared membranes, and consequently on their properties [4]. These include the composition of polymer solution (polymer concentration, solvent, co-solvent, additives and their respective concentration) [5], the types of support materials (polymer, glass, metal, nonwovens, etc.) [6], the thickness of the casted polymer films [7], the temperature and evaporation time before immersion [8], as well as the temperature and composition of the coagulation bath [9]. Therefore, the preparation of membrane will exhibit different properties of the membranes and it is necessary to understand the factors contribute to the changes of membrane properties [10].

The membranes can be made from inorganic material and/or organic material. Fluoropolymers such as poly(vinylidene fluoride) (PVDF) is among attractive organic material that been used for commercial membrane fabrication. Usually, fluoropolymers possess a high thermal stability, chemical resistance and lower surface tension due to low polarizability and strong electronegativity of the fluorine atom, its small van Der Waals radius and the strong C-F bond [11-13]. The application fields of PVDF membrane had been reported by many researchers which include the application in pharmaceutical industry for removal of endotoxins from pharmaceutical grade-water system; application in membrane distillation for reverse osmosis pre-treatment for brackish water and seawater [14], application in waste water treatment for textile dye removal [15, 16], recovery of ethanol [17], application as a separator in lithium-ion rechargeable batteries [7], and absorption of $CO_2$ [18]. Despite the advantages of PVDF membrane mentioned in the previous work, there still a room for improvement to enhanced the hydrophobicity and mechanical properties of the prepared membrane [19, 20]. Poly(vinylidene fluoride-co-tetrafluoroethylene) (PVDF-co-PTFE) is a PVDF copolymer. The increase in the fluorine content results to more hydrophobic material than PVDF due to the incorporation of an amorphous phase of tetrafluoroethylene (TFE) into the main vinylidenefluoride (VDF) constituent blocks. The contact angle of PVDF membrane is around 70 to 80° can be increased up to 100° by using PVDF-co-PTFE polymer. In addition, Feng et al. (2004) in their study of preparation and properties of microporous membrane from PVDF-co-PTFE for membrane distillation reported that the addition of TFE in PVDF gave a superior mechanical strength compared to PVDF [21].

In this work, three different solvents (N,N-dimethylacetamide, N-methyl-2-pyrrolidone and N,N-dimethyl-foemamide) at different PVDF-co-PTFE polymer concentration (20 wt.%, 25 wt.% and 30 wt.%) was used to explore the effect on the prepared membrane properties. The polymer solution viscosity was measured by using Brookfield viscometer. Meanwhile, the morphologies of prepared membranes were characterized by using scanning electron microscope (SEM), whereas the membrane volume porosity was determined by gravimetric method.

## Materials and Methods

### Materials

Poly (vinylidene fluoride-co-tetrafluoroethylene) (PVDF-co-PTFE) was obtained from Arkema Pte Ltd, Singapore. Three solvents were used namely N,N-dimethylacetamide (DMAc), N-methyl-2-pyrrolidone (NMP) and N,N-dimethylfoemamide (DMF). DMAc (≥ 99.0% purity) was purchased from Merck Millipore Corporation, NMP (≥

99.5% purity) from Sigma Aldrichand DMF (≥ 95.0% purity) from Fisher Scientific. All solvents were used as a solvent without any purification.

**Polymer solution preparation**

PVDF-co-PTFE powder and its solvent (DMAc, NMP and DMF) were dissolved in a sealed conical flask under continuous rotation for 2 hours using an overhead stirrer. The rotation speed was constant at 200 rpm. Throughout the stirring process, the temperature of the mixture was maintained at 50 °C. A homogenous polymer solution was then degassed in an oven with a temperature of 45 to 50 °C for 24 hours [22].

**Phase inversion method**

The non-solvent induced phase separation (NIPS) was choosen to cast a flat sheet membrane. A PVDF-co-PTFE solution was casted onto a glass plate using a hand-casting knife with a knife gap set at 400±10 μm and followed by exposed to the surrounding air for 30 seconds. The cast film together with the glass plate was immersed into a coagulation bath immediately for 24 hours after the evaporation period come to an end. The coagulation bath medium consists of purely distilled water. Finally, the solidified membrane was taken out from the coagulation bath and dried at room temperature for 24 hours [22].

**Characterization of prepared membrane**

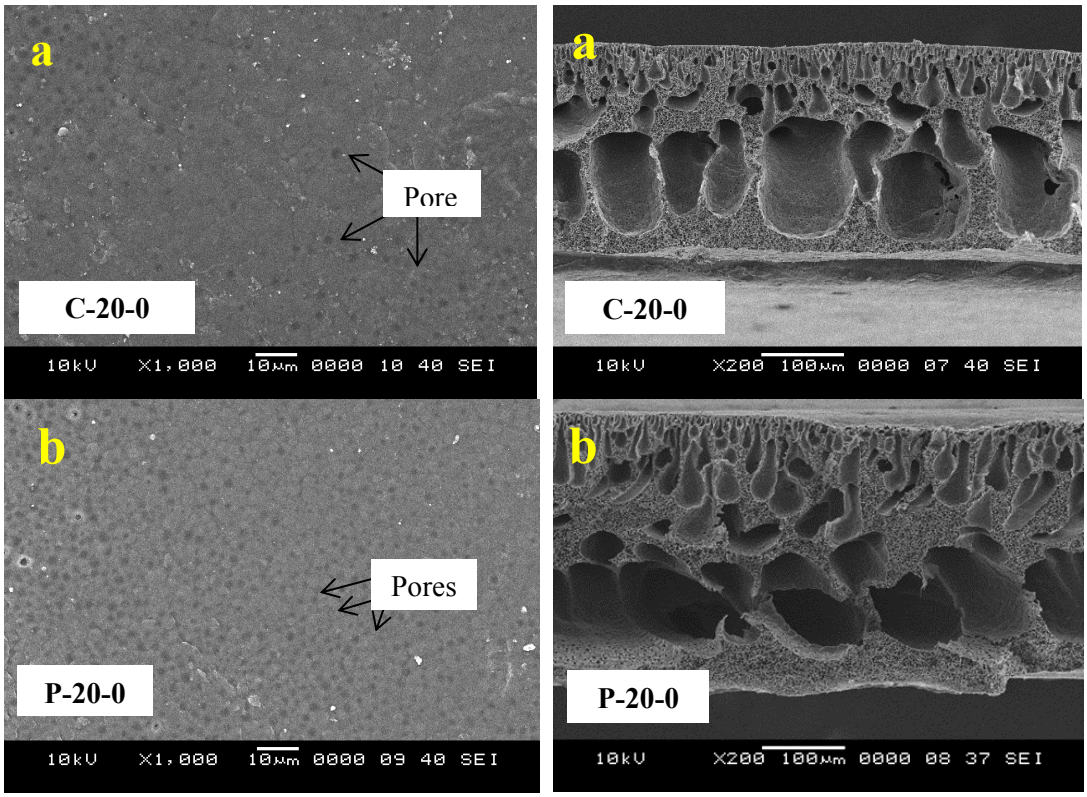
The polymer solution viscosity was measured by a Brookfield Dial Reading Viscometer (RVT Model) using a cylindrical sample container. The result of all measurement was taken from the mean of at least three single measurement at room temperature. Meanwhile, the prepared membrane surface and the cross section morphological studies was carried out by using a scanning electron microscope (SEM) model JSM 6260 LE JEOL. The pore sizes was observed through the SEM images and measured by using SEMAFORE software. Whereas, the porosity of the prepared membrane was analysed by using an octanol test. The membrane porosity, ω was defined as the volume of the membrane pores divided by the total volume of the porous membrane [21]. The sample was immersed into octanol for 15 seconds to improve the hydrophilicity. The sample was immersed into distilled water for 2 min before being dried using a filter paper. Mass of samples before and after soaked in both octanol and distilled water were recorded. Equation (1) was used to calculate the membrane porosity.

$$\omega = \frac{m_n/\rho_n}{m_n/_{p_n} + {}^{m_p}/_{\rho_p}} \quad (1)$$

where ω is the porosity of the membrane, $m_p$ is the mass of dry membrane (g), $m_n$ is the mass of absorbed octanol (g), $\rho_p$ is the density of the membrane (g/cm$^3$), and $\rho_n$ is the density of octanol (g/cm$^3$). This method is used to estimate the porosity by determined the weight of liquid contained in the membrane pores.

## Results and Discussion

**Effect of different solvent in polymer solution**



Three different solvents, DMAc, NMP and DMF were used to study the effect on the prepared membrane properties. The preparation of polymer solution was by adding 20 wt.% of PVDF-co-PTFE into 80 wt.% of solvent. Table 1 lists the formulation used to prepare the polymer membranes and the polymer solution viscosity reading.

Table 1. Fabrication conditions of flat sheet PVDF-co-PTFE membrane

| Membrane Code | Polymer Solution Composition | | Viscosity (cp) |
|---|---|---|---|
| | PVDF-co-PTFE (wt.%) | Solvent | |
| C-20-0 | 20 | 80 wt.% DMAc | 750 |
| P-20-0 | 20 | 80 wt.% NMP | 1000 |
| F-20-0 | 20 | 80 wt.% DMF | 2100 |

The viscosity of the polymer solution was an important parameter, which used to determine the inter-diffusion rate of solvent and non-solvent during the immersion precipitation process. Therefore, it affected the kinetics of the phase inversion throughout the membrane formation. As shown in Table 1, the viscosity of 20 wt.% PVDF-co-PTFE prepared with different solvents were found to be highest by using DMF and followed by NMP and DMAc respectively. According to Gracia-Fernandez, increasing of polymer solution viscosity reduced the coagulation rate of the polymer solution [23]. Hence, lower in coagulation rate hindered the formation of finger-like structure or even macro-voids.

Figure 1 shows the micrographs of the surface and cross sections of the flat sheet membranes. As can be seen from the figure, the cross sectional area of C-20-0, P-20-0 and F-20-0 membranes exhibited inhomogeneous structures due to the presence of large voids and cavities with different size and shape beneath the skin. It is observed that the number and size of interconnected macrovoids for the membrane casting with DMAc solvent was larger than the membrane casting with NMP and DMF solvents. This structure indicated a fast precipitation rate during the immersion process. Meanwhile, the least macrovoids formation can be seen from F-20-0 micrograph. The membrane microstructure exhibited a mixture of finger-like and a sponge-like structure throughout the membrane cross section. The elimination of macro-voids from the cross section structure along with the highest reading of polymer solution viscosity agree with each other. Similar result was obtained by Peng et al. where increasing the polymer solution viscosity was the main approach to suppress the macro-voids from the prepared membrane cross section [24].

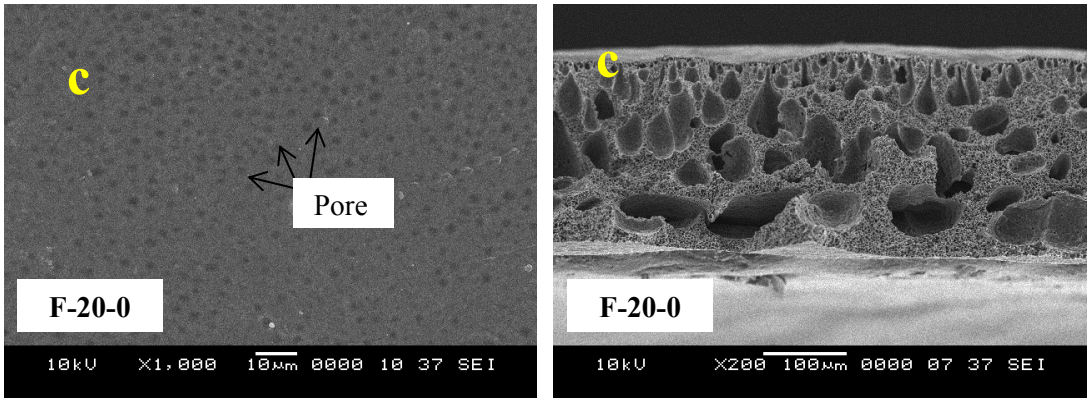


Figure 1. SEM micrographs of flat sheet membranes surface and cross sectional area prepared by using 20 wt.% PVDF-co-PTFE with different solvent; (a) DMAc, (b) NMP and (c) DMF

Table 2. Membrane pore size and porosity with different solvents

| Membrane Code | Solvent | Pore Size (µm) | | Porosity, ε (%) |
|---|---|---|---|---|
| | | Minimum | Maximum | |
| C-20-0 | DMAc | 4.3 ± 1.7 | 115.0 ± 35.1 | 47.6 |
| P-20-0 | NMP | 4.0 ± 1.6 | 153.8 ± 34.7 | 53.7 |
| F-20-0 | DMF | 4.3 ± 1.9 | 76.9 ± 20.6 | 35.8 |

It has been generally accepted that the morphology of prepared membrane affected by the precipitation rate which will then influences the membrane properties [19]. Table 2 represents the membrane properties of PVDF-co-PTFE membranes casted with different solvents in terms of pore sizes and porosity measured by using SEMAFORE software. It can be seen that the smallest pore size was contributed by F-20-0, followed by C-20-0 and P-20-0 respectively. The membrane used NMP as solvent obtained the maximum pore size of 153.8 µm, larger than those other membranes. The membrane prepared by NMP showed the highest porosity value which was 53.7%, which can be related to the pore sizes. This findings agreed with the research conducted by Li et al. in investigation of mixed solvents effect on the membrane performance [25]. Therefore, the growing of membrane macrovoids leads to higher porosity.

**Effect of polymer concentration**

Three different polymer concentrations were used (20 wt.%, 25 wt.% and 30 wt.%) to study their effects on the prepared flat sheet membrane. Table 3 summarizes the fabrication conditions of flat sheet PVDF-co-PTFE membrane along with their polymer solution viscosities. NMP was chosen to be a constant solvent for all three different polymer concentrations. Increasing the polymer concentration from 20 wt.% to 30 wt.% caused a greatly increasing of polymer solution viscosity from 1000 cp to 16500 cp.

Polymer concentration in polymer solution plays an important part in determining the membrane properties. Figure 2 represents the SEM micrographs of PVDF-co-PTFE flat sheet membrane using different polymer concentrations. It can be obviously seen that the increasing of polymer concentration in the casting solution changed the pore morphologies from large macrovoids to thin finger-like voids with combination of sponge-like elements. The number and size of maximum cavities were reduced with increasing of polymer concentration from 20 to 30 wt. %. The maximum cavities size was reduced from 153.8 µm at 20 wt.% to 46.2 µm at 30 wt. % of polymer concentration.

Table 3. Fabrication conditions of flat sheet PVDF-co-PTFE membrane

| Membrane Code | Polymer Solution Composition | | Viscosity (cp) |
|---|---|---|---|
| | PVDF-co-PTFE (wt.%) | Solvent | |
| P-20-0 | 20 | 80 wt.% NMP | 1000 |
| P-25-0 | 25 | 75 wt.% NMP | 3800 |
| P-30-0 | 30 | 70 wt.% NMP | 16500 |

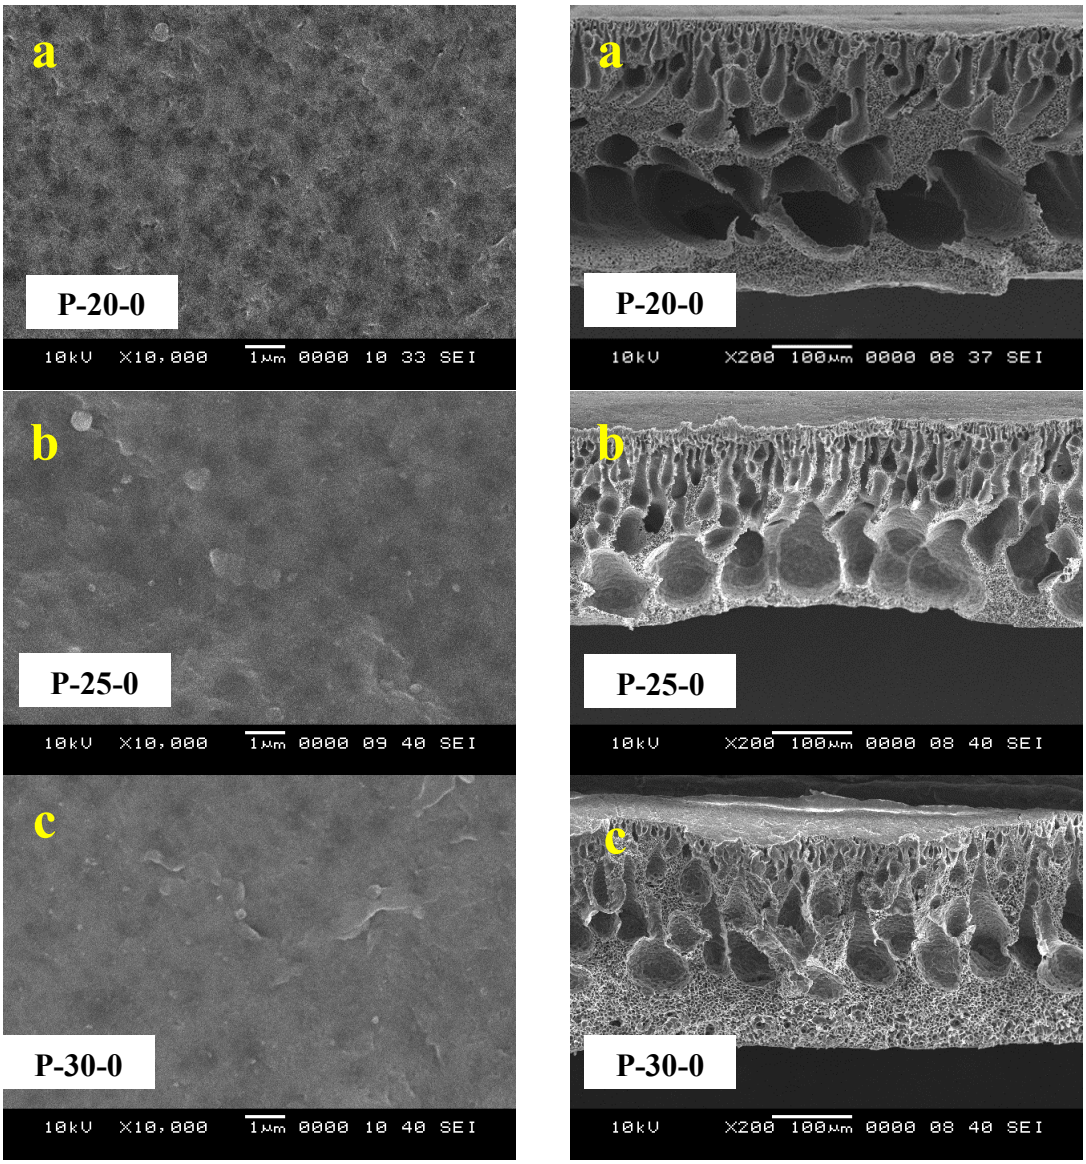

Figure 2. SEM micrographs of flat sheet membranes surface and cross sectional area using different polymer concentrations by using NMP as a solvent. (a) 20 wt.%, (b) 25 wt.% and (c) 30 wt.%

Increasing the polymer concentration resulted in higher polymer concentrations at the polymer/non-solvent interface prior the immersion in the non-solvent coagulation bath. This implied the volume fraction of polymer increases. Therefore, diffusion rate of solvent and non-solvent was slowed down, thus resulted in delay demixing. Consequently, the membrane morphology changes from macrovoids to a more spongy structure [3]. A similar result also found by Hołda et al. in the study of polysulfone concentration effects on the nanofiltration membranes. As the polysulfone concentration increased, the number of macrovoids decreases and their shape changes from a finger-like to pear-like structure [26]. The findings were also agreed in another research conducted by Marbelia et al. [8]. Formation of smaller pores as increasing of polymer concentration was due to the delayed liquid-liquid demixing between the solvent and non-solvent [8].

Figure 3 shows the effect of polymer concentration on porosity. The average porosity of membrane decreases with the increased of the polymer concentration. The increasing of polymer concentration in the polymer solution resulted in higher polymer concentration at the non-solvent interface. This implied that the volume fraction of polymer increased and consequently lower porosity was obtained [3].

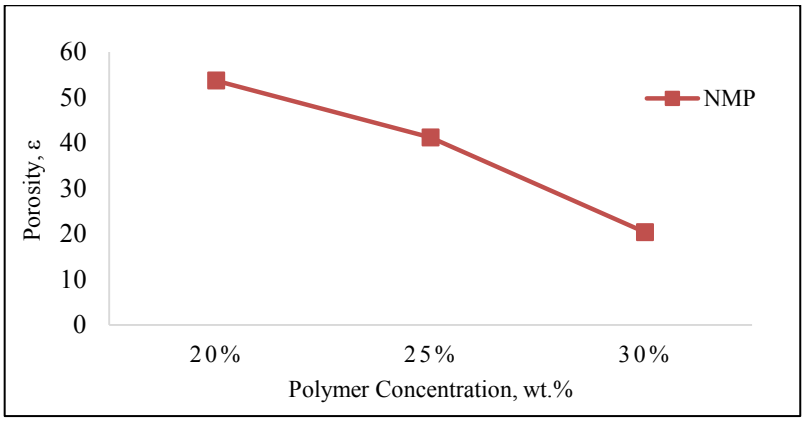

Figure 3. Effect of polymer concentration on PVDF-co-PTFE membrane porosity

## Conclusion

The PVDF-co-PTFE membranes were prepared by using phase inversion by means NIPS method. The membrane morphology, porosity and pore size obtained was greatly depends on the experimental parameters such as the selection of solvent and the concentration of polymer used. The results reveals that the types of solvents used in the casting solution considerably affected the membrane properties. From SEM micrographs, higher number of finger-like macrovoids formed when DMAC was used instead of DMF due to the rate of precipitation of polymer solution using DMAc is faster due to lower viscosity. On the other hand, sponge-like structure with lower porosity can be observed by using DMF as a solvent. With increasing polymer concentration lead to increasing in polymer solution viscosity, hence the precipitation rate becomes slower. The structure of the prepared membranes changes remarkably from finger-like macrovoids to sponge-like as the polymer concentration increased. In addition, the number of macrovoids also decreased. The alteration of the pore structure resulted in decreasing of pore sizes and consequently, the membrane porosity was reduced.

# PREPARATION AND CHARACTERIZATION OF DIFFERENT LOADING OF ZINC OXIDE ON ACTIVATED CARBON NANOFIBERS

## (Penyediaan dan Pencirian Gentian-Nano Karbon Teraktif Pada Kepekatan Zink Oksida Yang Berbeza)

**Abstract**

The study deals on the modified PAN-based activated carbon nanofibers (ACNFs) embedded with different amount of zinc oxides (ZnO) (0, 5, 10, and 15% relative to PAN wt.) to be used as adsorbents for natural gas adsorption. The nanofibers (NFs) were successfully fabricated via electrospinning process at optimize parameters. The resultant NFs underwent three steps of pyrolysis process which are stabilization, carbonization and activation at optimum parameters. The morphological structure and diameter of pure and modified ACNFs were characterized using SEM while the existences of chemical bonds were analyzed by FTIR analysis. XRD analysis was done to identify the crystallinity of the ACNFs. BET method was used to identify the specific surface area (SSA) and nitrogen adsorption isotherm of the samples. The results showed that the SSA of ACNF5 (163.04 $m^2/g$) is significantly higher compared to the pristine and other modified ACNFs, nevertheless the obtained results is much lower compared to average theoretical value. SEM micrograph depicted that all ACNF samples possessed average diameter of 300 – 500 nm with smooth and aligned structure. The presence of white spots as ZnO alongside the NFs has been confirmed with FTIR and XRD analysis. From these findings, it is believed that ACNFs/ZnO will become a new adsorbent with great potential for gas adsorption and storage in the near future applications.

**Keywords**: activated carbon nanofibers, zinc oxide, polyacrylonitrile, specific surface area

**Abstrak**

Kajian ini membincangkan tentang gentian-nano karbon teraktif (ACNFs) terubah suai berasaskan polimer PAN yang digabungkan dengan kandungan zink oksida (ZnO) yang berbeza (0, 5, 10, dan 15% berdasarkan berat PAN) untuk digunakan sebagai penjerap dalam penjerapan gas asli. Gentian-nano (NFs) telah berjaya direka melalui proses putaran elektro menggunakan parameter-paramter optimum daripada kajian terdahulu. Kemudian, NFs yang terbentuk akan melalui tiga peringkat proses pirolisis iaitu penstabilan, karbonisasi, dan pengaktifan menggunakan parameter optimum daripada kajian terdahulu. Struktur morfologi dan diameter ACNFs tulen dan yang telah diubahsuai dengan ZnO telah dicirikan menggunakan SEM manakala kewujudan ikatan kimia telah dianalisis menggunakan FTIR. Selain itu, untuk mengenalpasti penghabluran ACNFs yang terhasil, analisis yang dikenali sebagai XRD telah dijalankan. Kaedah BET pula dijalankan untuk mengenal pasti luas permukaan tertentu (SSA) dan isoterma penjerapan nitrogen. Hasil kajian menunjukkan bahawa SSA sampel ACNF5 (163,04 $m^2/g$) adalah lebih tinggi berbanding dengan ACNFs tulen atau ACNFs yang telah diubahsuai yang lain..Walau bagaimanapun, keputusan yang diperoleh menunjukkan SSA yang jauh lebih rendah berbanding dengan nilai teori purata. Melalui SEM mikrograf, semua sampel ACNFs yang dihasilkan melalui kajian ini memiliki diameter purata dari 300 hingga 500 nm dengan struktur licin dan sejajar. Kehadiran bintik putih sebagai ZnO telah disahkan melalui analisis FTIR dan XRD.

Penemuan ini membuktikan bahawa ACNFs/ZnO akan menjadi penjerap baru yang mempunyai potensi besar dalam aplikasi penjerapan dan penyimpanan gas pada masa hadapan.

**Kata kunci:** gentian karbon teraktif, zink oksida, poliakrilonitril, luas permukaan spesifik

## Introduction

Activated carbon (AC) has been widely utilized as adsorbent in various applications in recent years included in water or gas adsorption due to their porous structure, high specific area, and cost-friendly [1]. Currently, AC can be developed by using various types of precursors such as pitch, lignin, polymers, and also synthetic precursor, however polyacrylonitrile (PAN)-based adsorbents have become an attractive alternative as PAN precursor could produce high carbon yield up to 56% as compared to the other precursors [2]. However, a new enhanced material known as activated carbon nanofibers (ACNFs) with highly microporous structure with finer structure and greater specific surface area [3] have been developed in order to overcome the disadvantages of AC that possessed low SSA and limited the gas adsorption capabilities. Ascribed by its low resistance to bulk flow, high adsorption-desorption kinetics, heat stability, and high strength; PAN-based ACNFs have received major attention from researcher all over the globe and were studied for their potential as excellent gas adsorbents [4].

Nanofibers (NFs) can be fabricated by various techniques included template synthesis, phase separation, electrospinning, and self-assembly [5]. Out of those available techniques, electrospinning seems to produce NFs with smaller diameter with uniform distribution structures. Moreover, electrospinning offers more advantages than other techniques such as versatility, efficiency, and feasibility in large quantities production. Recently, in order to improvised the NFs structures, the electrospun NFs were subjected to activation process to create new macropores and micropores structures, with smaller fiber diameter and greater SSA. Furthermore, incorporation of additives such as metal oxide into the NFs was proven can enhance the structure of the NFs. Metal oxide nanoparticles such as magnesium oxide (MgO), manganese dioxide ($MnO_2$), zinc oxide (ZnO), and nickel oxide (NiO) have been profound to be as excellent candidate that could enhance the physicochemical properties of PAN-based ACNFs due to their catalytic effects [6]. These nanoparticles themselves are high in SSA and the addition of right amount of these nanoparticles into the NFs solution are believed could improve their structure as well as adsorption capabilities.

In this study, the ACNFs embedded with ZnO were produced through suitable electrospinning and activation method under optimum parameters obtained from previous studies [7]. The objective of this present study is to prepare the ACNFs incorporated with ZnO and to study their microstructural properties and surface area for suitable gas adsorbent materials.

## Materials and Methods

### Nanofibers fabrication

The polymer polyacrynitrile (PAN) and solvent N, N-dimethylformamide (DMF) were purchased from Sigma-Aldrich while zinc oxide (ZnO) powder was purchased from Alfa Aesar. Homogenous DMF solutions of PAN containing 0, 5, 10, and 15% (relative to PAN wt.) of ZnO were stirred gently for 24 hours at room temperature. The nanofibers (NFs) were prepared by using a lab-scale electrospinning machine NFOM1000-1503 supplied from Nfiber at optimum voltage of 12.4kV, the distance between the needle tip to collector of 20 cm, and flow rate of 1 ml/hour. The resultant NFs with 0, 5, 10, and 15% of ZnO were denoted as NF0, NF5, NF10, and NF15, respectively.

### Activation of nanofibers

The resultant NFs were underwent three stages of pyrolysis process. Start with stabilization with pure air until the temperature of 275 $^{\circ}$C, followed by carbonization under inert air condition until 600 $^{\circ}$C, and finally activation with activating gas such as carbon dioxide until 800 $^{\circ}$C, in order to improve the porous structure of the NFs and directly increasing the specific surface area with 30 minutes of resting time for each stage. After activation, the NFs were known as activated carbon nanofibers (ACNFs). In this study, ACNFs with 0, 5, 10, and 15% of ZnO were denoted as ACNF0, ACNF5, ACNF10, and ACNF15, individually.

**Characterization**

In order to better understanding of the PAN-based ACNF/ZnO produced, there are several characterization analyses have been conducted. The morphology and diameter of the NFs have been characterized using field emission scanning electron microscopy (FESEM) while the elemental analysis and chemical studies of the NFs were analyzed by using X-ray diffraction (XRD) analysis and Frontier Transform Infrared (FTIR) analysis, respectively. Moreover, Brunauer–Emmett–Teller (BET) analysis was used in order to study specific surface area and pore size distribution of all the resultant NFs. The surface area and microspore analysis of NFs and ACNFs were investigated using nitrogen gas ($N_2$) adsorption isotherm at 77 K (ASAP2020, Micromeritics, USA).

## Results and Discussion

**Morphological studies of nanofibers**

Figure 1 shows the SEM images of PAN-based ACNF/ZnO with different loading of ZnO prior activation. It can be seen that the all NFs possessed smooth, straight, and aligned structure with several white spots attached alongside the fibers (Figure 1b, c, d) that represent the existence of ZnO. The fibers diameter was varied in all concentrations. From the figure, it obviously can be seen that the pristine NFs possessed the largest fiber diameter as compared to NFs embedded with ZnO. It was found that addition of ZnO has reduced the diameter of the NFs up to 45%, with average diameter of NF0 is 576.8 ± 55.91 nm and was reduced to 325 ± 43.1 nm in all modified NFs (NFs embedded with ZnO).

After activation, the NFs were transformed into activated carbon nanofibers (ACNFs) and the SEM photographs of all pristine and modified ACNFs are shown in Figure 2. It can be seen that the ACNFs possessed rougher, irregular, and undulated structure compared to NFs prior activation. The average diameter of the all NFs also decreased up to 40% from 450 nm to 270 nm due to the removal of PAN and other molecules during the heat treatment resulting in weight loss and NFs' diameter reduction [8, 9]. As shown in Figure 2(b), ACNF5 possessed the finest fiber structure with well-dispersed and a few agglomeration of ZnO alongside/inside the ACNFs as compared to the others.

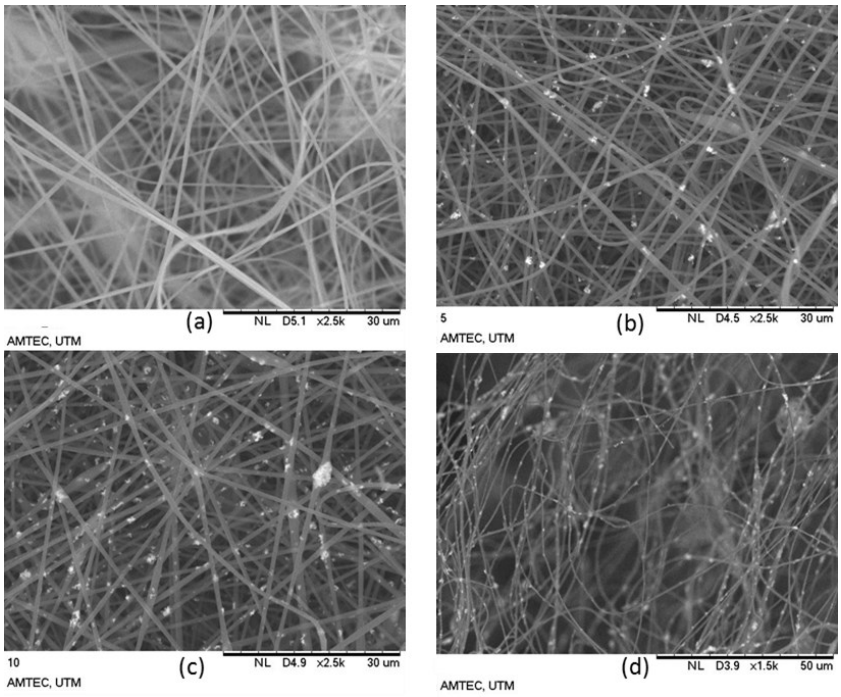

Figure 1. SEM micrograph of nanofibers with different loading of zinc oxide prior activation (a) NF0, (b) NF5, (c) NF10 at 2500x magnification and (d) NF15 at 1500x magnification

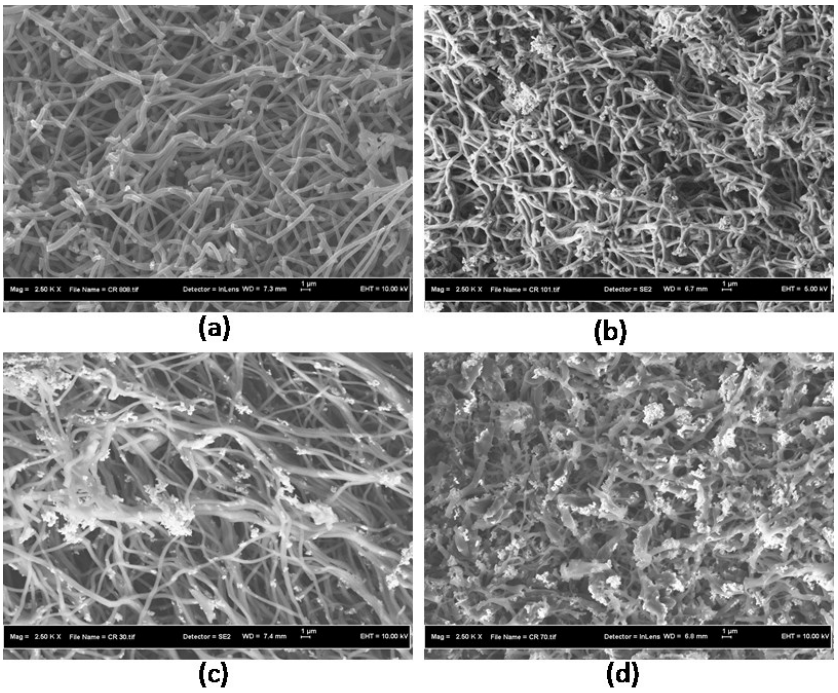

Figure 2. SEM micrograph of nanofibers with different loading of zinc oxide after activation (a) ACNF0, (b) ACNF5, (c) ACNF10, and (d) ACNF15 at 2500x magnification

Although this result counterback the result of previous research conducted by Dadvar et al. [6], as they said the increasing the amount of metal oxide loaded, the smaller the diameter of the NFs; this study has concluded that NFs were only affected by the amount of metal oxide, which is up to its maximum loading depends on the type of the metal oxide used in order to produce NFs with better structure. This phenomenon is believed could start as early as during the dope preparation and fiber preparation stages as the amount and types of the metal oxide used can affect the viscoelasticity of the solution and varies the ejection time of jet to arrive at the collector and these behaviors are believed to give impact to the diameter of the NFs [10].

**Chemical bond studies**

Figure 3 shows the FTIR spectra for NFs embedded with 0 and 5% of ZnO prior and after activation. As can be seen, there are various peaks appeared in the NFs prior activation (Figure 3a) and some of the peaks were removed after activation due to heat treatment (Figure 3b), and it is believed only carbon and hydrogen peaks were left. Theoretically, numerous new transition structures were formed during pyrolysis. As can be seen in Figure 3(a), there are five major peaks can be detected in both NF0 and NF5 that represent different vibrations existed in the NFs prior activation. However, there is one high peak was detected at wavenumber 445.7 $cm^{-1}$ in NF5 that represents Zn-O vibrations [11, 12]. Nevertheless, the appearance of unknown peak around wavenumber 400 – 700 $cm^{-1}$ in Figure 3 is believed due to the existence of other vibrations that overlapped at the same wavenumber range such as C-C, C-N, and C-O. After activation, there are only three major peaks were detected at 1285.5, 1433.1, and 1581.7 $cm^{-1}$ represent C=O, C-H, and C=C vibrations, respectively [13].

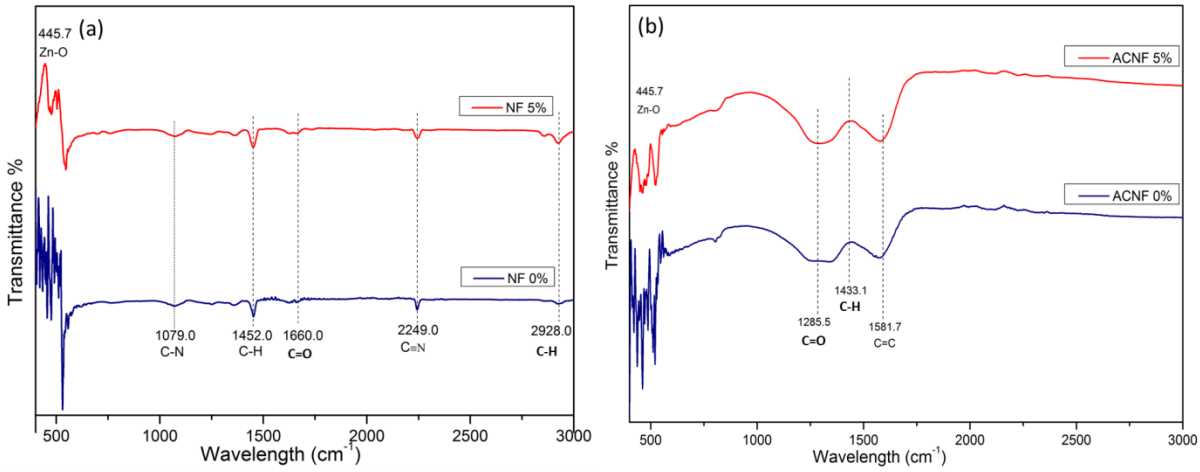

Figure 3. FTIR spectra of NF0 and NF5 (a) prior activation and (b) after activation

**Elemental analysis**

The crystallographical behaviors of both NF0 and NF5 prior and after activation have been analyzed by using X-ray diffraction analysis as shown in Figure 4. It can be seen that prior activation, the structure of the NFs is amorphous and after activation, the structure become more crystalline. As shown in Figure 4(a), the obvious peak detected at 16.7$^{o}$ in NF0 represents the polymer PAN peak [12] while the other two sharp peaks that only appeared in NF5 at 31.85 and 36.3$^{o}$ represents the ZnO peaks. However, in Figure 4(b), the polymer peak changed to carbon peak after activation and it was detected at 13.2$^{o}$ [13]. As detected in Figure 4(a), the same ZnO peaks were also observed in ACNF5 with addition of two other ZnO peaks at 34.6 and 47.55$^{o}$ [14 – 16]. It is believed these two peaks already appeared in the NF5; however it cannot be seen due to amorphous structure of the NFs.

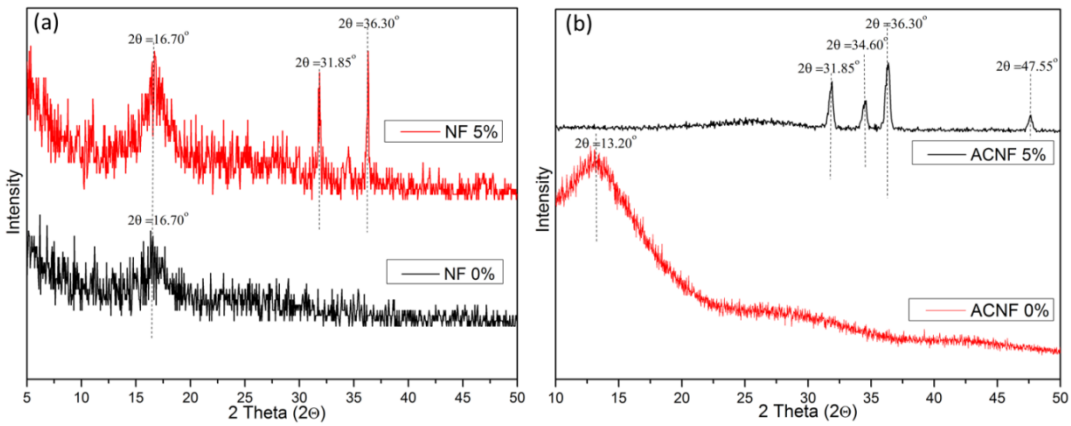

Figure 4. X-ray diffractogram of NF0 and NF5 (a) prior activation and (b) after activation

**BET surface area**

Brunauer–Emmett–Teller (BET) analysis was used to determine the specific surface area (SSA) of all resultant NFs as depicted in Table 1. Prior activation, the addition of low or high concentration of ZnO bring no effect to the enhancement of SSA of the NFs (see data in Table 1), in contrast it shows pristine NFs possessed the largest SSA.

However, after heat treatment was conducted to the NFs, there is significant increment in SSA of NFs especially for ACNF5 that possessed total SSA of 163.04 $m^2/g$. The result obtained was comparable to the previous study conducted by Kahjwal and friends (2016) [16] as they obtained BET results of 137 $m^2/g$ after the calcination of NFs embedded with ZnO at 700 $^oC$.

However, the addition of 10 and 15% of ZnO into the NFs showed no significant increment in SSA even after activation as compared to the ACNFs with 5% ZnO. This phenomenon occurred due to the higher amount of ZnO (more than 5%) could probably inhibited the catalytic effect of the ZnO that increasing the diameter of the resultant NFs and it also believed the fiber distribution became broader. As the diameter increases, the SSA are believed to reduce and it is important to note that the right amount of ZnO are the main concern in order to produce NFs with smaller diameter and high SSA. Higher specific surface area is believed could increase the adsorption performance due to increasing adsorption active sites [17].

Table 1. Comparison of specific surface area of nanofibers embedded with different concentration of ZnO prior and after activation

| Sample | Prior activation ($m^2/g$) | After activation ($m^2/g$) |
|---|---|---|
| NF0 | 9.1300 | 3.9446 |
| NF5 | 8.9070 | 163.0416 |
| NF10 | 5.3658 | 29.1523 |
| NF15 | 7.4454 | 24.9459 |

## Conclusion

Thorough chemical, physical and thermal characterizations that have been employed in this study, the effects of incorporating ZnO in PAN-based NFs have been investigated. Composite ACNF/ZnO after heat treatment possessed average diameter of 270 nm and SSA obtained ranging from 3.9446 to 163.0416 $m^2/g$. By using various type of characterization techniques like FE-SEM, BET, XRD, and FTIR, have provided better understanding on morphological and structural properties of PAN-based ACNFs embedded with various concentration of ZnO.

**Abstract**

Preparation and surface modification of PSF/$TiO_2$ membranes by DC Ar-plasma were conducted to improve membrane hydrophilicity and gas permeation efficiency. Using $TiO_2$ as a photocatalyst, photocatalysis could be induced upon the plasma exposure. Radicals from this process led to an increase in the membrane hydrophilicity. In order to improve the dispersion quality of $TiO_2$ in an organic membrane, methyltrimethoxysilane (TMMS) or ethyltrimethoxysilane (TEMS) was utilized as coupling agents to modify the $TiO_2$ surface prior to blending. The coupling agents caused organic silane bonds on the $TiO_2$ surface leading to a better dispersion of nanoparticle on the membrane matrix. The incorporation of modified-$TiO_2$ tended to decrease membrane water contact angles (WCA) to the lowest value when compared with PSF membranes with unmodified $TiO_2$ and neat PSF membranes. Results also showed that TMMS could produce better outcomes compared to TEMS. It was found that the modified-$TiO_2$ could decrease the WCA. More importantly, pressure normalized flux of $CO_2$ and $CH_4$ gases of PSF/modified-$TiO_2$ membrane was found to increase with slightly decrease in the selectivity of $CO_2/CH_4$.

**Keywords**: silane coupling agent, surface modification, gas separation membrane, low pressure DC-plasma, polysulfone

**Abstrak**

Penyediaan dan modifikasi permukaan membran PSF/$TiO_2$ oleh DC Ar-plasma telah dijalankan untuk meningkatkan kehidrofilikan membran dan kecekapan penyerapan gas. Menggunakan $TiO_2$ sebagai foto-pemangkin, fotopemangkinan dapat didorong apabila terdedah kepada plasma. Radikal daripada proses ini membawa kepada peningkatan dalam kehidrofilikan membran. Untuk meningkatkan kualiti penyebaran $TiO_2$ dalam membran organik, metiltrimetoksisilana (TMMS) atau etiltrimetoksisilana (TEMS) telah digunakan sebagai agen gandingan untuk mengubah suai permukaan $TiO_2$ sebelum campuran. Ejen-ejen gandingan menyebabkan ikatan silana organik di permukaan $TiO_2$ yang membawa kepada penyebaran nanopartikel yang lebih baik pada matriks membran. Penggabungan $TiO_2$ yang diubahsuai cenderung untuk mengurangkan sudut sentuhan air membran (WCA) kepada nilai yang paling rendah berbanding membran PSF dengan $TiO_2$ yang tidak diubahsuai dan membran PSF kawalan. Keputusan juga menunjukkan bahawa TMMS boleh menghasilkan hasil yang lebih baik berbanding PPSMI. Ia telah mendapati bahawa $TiO_2$ yang diubahsuai boleh mengurangkan WCA. Lebih penting lagi, tekanan fluks normal gas $CO_2$ dan $CH_4$ daripada membran PSF/$TiO_2$ yang diubahsuai didapati meningkat dengan sedikit penurunan kepilihan $CO_2/CH_4$.

## Introduction

Membrane technology is currently widely used in many industrial sectors and one of its important applications is for gas separation process. As $CO_2$ gas is the main causes of greenhouse effect that leads to global warming, many attempts were made to develop an ideal membrane for $CO_2$ adsorption and separation [1]. Polysulfone (PSF) is one of the high potential and widely used polymers because it has many advantages such as excellent stability and resistivity to high temperature and acid-base environments and easy to be used for membrane making [2, 3]. However, PSF is hydrophobic in nature [4]. For the PSF membranes to be used in the $CO_2/CH_4$ gas separation, the hydrophilicity of the membrane surface needs to be improved. This improvement is quite important due to the differences of the quadrupole moments of these two gases [5].

Konruang et al. [5] discussed differences of several gases that have small molecules and very little differences in size. Besides, electronic properties, polarizability and quadrupole moment, which we can be used for the extract gas, were also discussed. Table 1 shows the structure, polarizability and quadrupole moment of $CO_2$ and $CH_4$ gases [6]. Considering electronic properties of $CO_2$ and $CH_4$ gases, we can see that membrane surfaces, which have a higher polarity can absorb a higher polarizability and quadrupole moment gas more than of lower polarizability and quadrupole moment gas. Therefore, hydrophilic properties represent the polarity of membrane surfaces, which is the cause for $CO_2$ to permeate more through such a membrane than $CH_4$. The quadrupole moment affects the gas permeation through the membranes. For hydrophilic polymeric membranes, the permeability of $CO_2$, which has a quadrupole moment and polarizability of about $13.4 \times 10^{-40}$ $Cm^2$ and $2.93\times 10^{-40}$ $J^{-1}C^2m^2$, respectively, is higher than of $CH_4$, which has a quadrupole moment and polarizability of about zero and $2.89\ 10^{-40}$ $J^{-1}C^2m^2$, respectively [6]. Therefore, research and development are required to improve the hydrophilicity of membranes. [5].

Table 1. Structure, physical and electronic properties of gas molecules [6]

| **Molecule** | **Structure** | **Polarizability** ($10^{-40}$ **$J^{-1}$ $C^2$ $m^2$**) | **Quadrupole moment** ($10^{-40}$ **C $m^2$**) |
|---|---|---|---|
| $CO_2$ | Linear | 2.93 | 13.4 |
| $CH_4$ | Tetrahedral | 2.89 | 0 |

Titanium dioxide ($TiO_2$) can improve the hydrophilicity of membranes because of its photocatalytic property [7, 8]. Typically, electrons in the valence band of a photocatalytic material will jump to the conduction band when they are stimulated by a photon. The holes are created in the valence band and the electron from the donor molecule can move to this hole. At the same time, an electron from the valence band can be transferred to the acceptor [9, 10]. For this reason, the photo catalyst can take the interaction with the molecules at the material surface. Additionally, the stimulation of $TiO_2$ at the membrane surface can decrease the surface roughness and eventually, lead to the decrease in membrane contact angle [11].

However, the minimum energy for the stimulation of $TiO_2$ has to be equal with the band energy gap that is about 3.2 eV [12, 13]. Unlike PSF, $TiO_2$ is an inorganic material and the dispersion of $TiO_2$ particles in the PSF matrix is quite low. Madaeni et al. [14] studied the increase of $TiO_2$ loading in polyethersulfone (PES) support. Here, an increase in the $TiO_2$ content of the polydimethylsiloxane (PDMS) matrix lead to an increase in the self-condensation, polarity, and polar groups. Nevertheless, the $CO_2$ permeability in that work is reported to decrease. Chen and Yakovlev [15] studied the modification of $TiO_2$ nanoparticles by the interaction with organic silane. They found the creation of Si-O-Ti bonds and organic groups after $TiO_2$ was modified by 3-aminopropyltrimethoxysilane (APTES) and phenyltrimethoxysilane (PTMS).

This current work studied the modification of PSF membranes using dry/wet phase inversion method. $TiO_2$ nanoparticles were modified by silane-coupling agents, including trimethoxymethylsilane (TMMS) and triethoxymethylsilane (TEMS). The modified $TiO_2$ was then incorporated into the PSF membrane matrix to increase its hydrophilic properties and the permeance of $CO_2$. In order to further enhance the gas separation properties, the

obtained membranes were treated by DC Ar-plasma and then the permeance of the hydrophilicity of plasma treated membranes was studied.

## Materials and Methods

Pellets of PSF (UDEL P-1700) were supplied by Solvay (China). Polymer solvents included N,N-dimethylacetamide (DMAc) and tetrahydrofuran (THF) was purchased from Sigma-Aldrich (Singapore) and ACI Lab-scan (Australia), respectively. Titanium dioxide ($TiO_2$; 32 nm APS powder MW. 79.90) nanoparticles, methyltrimethoxysilane (TMMS) and ethyltrimethoxysilane (TEMS) were supplied by Alfa Aesar (China). The TMMS and TEMS were used as silane coupling agent while $TiO_2$ was used as an inorganic additive. Ethanol (EtOH) and methanol (MeOH) were supplied by J.T. Baker. All chemicals and materials were used as received.

In order to modify the surface of $TiO_2$ nanoparticles by a silane coupling agent, 1 g of $TiO_2$ was dispersed in 100 ml of RO water under vigorous stirring. The obtained solution was sonicated for 10 min before the addition of the silane coupling agent with a concentration of 12.5 wt.%. The reflux process was taking place for 5 hours at a temperature of 80 $^oC$. The as-modified $TiO_2$ was alternately cleaned by RO water and EtOH and collected by centrifugation at 10,000 rpm twice. The collected $TiO_2$ was then dried at 100 $^oC$ for 24 hours before use.

In the first step of membrane preparation, PSF pellets were dried at 80 $^oC$ for 24 hours to remove moisture. The dry/wet phase inversion method was used for membrane preparation in this research. Four types of membranes were prepared. They are pure PSF, PSF/$TiO_2$, PSF/($TiO_2$-TMMS) and PSF/($TiO_2$-TEMS) membranes. The PSF/($TiO_2$-TMMS) and PSF/($TiO_2$-TEMS) ones were PSF membranes incorporated with $TiO_2$ and further modified by TMMS and TEMS agent. The membrane designations before and after plasma treatment are shown in Table 2.

Table 2. Designation of the samples

| Sample | Plasma Treated | Untreated |
|---|---|---|
| PSF | A1 | B1 |
| PSF/$TiO_2$ | A2 | B2 |
| PSF/($TiO_2$-TEMS) | A3 | B3 |
| PSF/($TiO_2$-TMMS) | A4 | B4 |

During membrane preparations, PSF, DMAc, THF and $TiO_2$ (or $TiO_2$-TMMS or $TiO_2$-TEMS) were blended at a weight ratio of 22.5:38.25:38.25:1.0, respectively, at 50 – 60 $^oC$ for 24 hours. The completely dissolved solution was then cast on a smooth and clear glass plate with a wetting thickness of about 150 µm. The cast membrane was freely placed in ambient air (evaporation time, ET) for 90 and 120 s before immersed in RO-water for 15 min followed by in MeOH solution for another 2.5 hours. Subsequently, the membrane was dried under ambient conditions for 24 hours. Finally, the membrane was dried in an electric oven at 70 $^oC$ for 12 hours before usage.

The optimized membrane surface was further modified by DC glow discharge plasma generated from Ar gas. The membrane sample was placed on the anode electrode as shown in Figure 1. The inter-electrode gap was controlled at about 3 cm. Before Ar gas was fed into the plasma chamber, gas pressure in the chamber was controlled at $5.90\times10^{-2}$ mbar. Afterwards, Ar gas was fed into the chamber through a needle valve until the pressure reached $2.00\times10^{-1}$ mbar. The pressure was constant throughout the plasma treatment. Discharge power and treatment time were 20 W and 4 min, respectively.

After plasma treatment, membrane hydrophilicity was determined by measurements of water contact angle (WCA) at different ageing times. The spread tendency of a liquid that drops on a smooth surface of a solid. To measure the WCA, the contact angle measuring instrument (Model OCA 15 EC, Data Physics Instruments GmbH, Germany) was used. Membrane samples for WCA measurements were cut into rectangular shape with a dimension of 3 mm in width and 10 mm in length. The membrane was fixed on a clear and smooth glass slide. Liquid was dropped on the

membrane surface and the measured WCA was analyzed by using SCA software. The WCA was measured for at least three times per sample and the average was presented in Table 3. Fourier transform infra-red (FTIR) spectroscope was used to analyze the functional groups on the modified membrane surface. The distribution of $TiO_2$ particles in the membrane matrix was analyzed through the micrograph of the scanning electron microscope (SEM) while the skin layer thickness was measured by SEM micrograph combined with the computer software, Carnoy versions 2.0®. Atomic force microscope (AFM) was utilized to analyze the roughness of membrane surfaces. The separation properties of all resultant membranes were evaluated through gas permeation measurement.

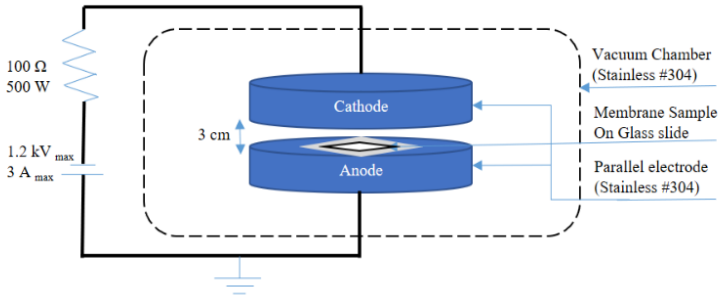

Figure 1. Schematic diagram of the membrane sample placed on the anode electrode in the DC plasma system used in this work.

Table 3. Water contact angle of membrane samples prepared at different conditions

| Samples | Water contact angle (θ) | |
|---|---|---|
| | Evaporation Time (ET) 90 s | Evaporation Time (ET) 120 s |
| B1 | 83.30 ± 5.19 | 83.80 ± 6.22 |
| B2 | 92.36 ± 2.09 | 81.89 ± 0.43 |
| B3 | 81.84 ± 2.30 | 89.86 ± 1.82 |
| B4 | 72.95 ± 1.83 | 70.07 ± 5.90 |

## Results and Discussion

### Water contact angle

As shown in Table 3, contact angles of membranes prepared at ET of 90 s, it was found that WCA of B2 increased to 92.36° whereas the WCA of B4 and B3 decreased to 72.95° and 81.84°, respectively. For membranes prepared at ET of 120 s, the highest WCA value was measured on the surface of B3 whereas the lowest WCA appeared on the surface of B4. WCA of B4 was 13° lower than of the pure B1 membrane. This indicated that modified $TiO_2$ by TMMS gave membranes with higher hydrophilic than by TEMS.

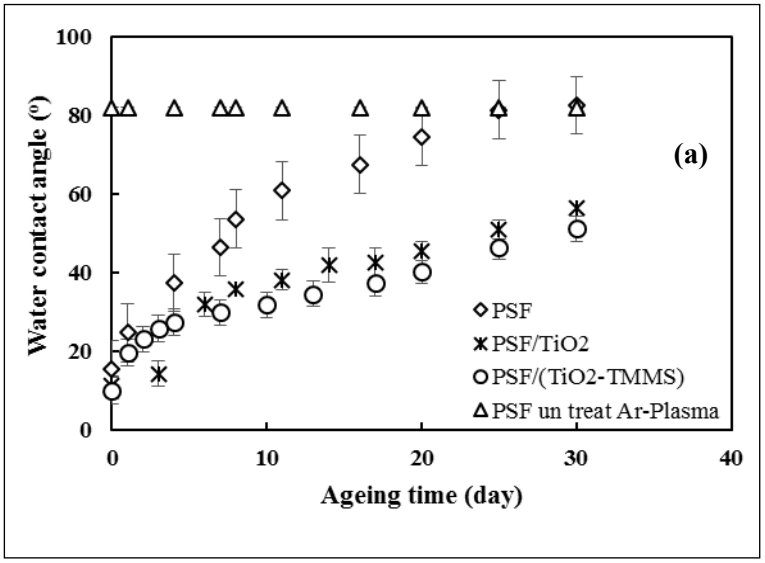

Table 4 shows the WCA of Ar-plasma treated membrane surfaces. It can be seen that WCA of PSF membranes that were plasma treated with a discharge power and exposure time of 20 W and 4 min, respectively, decreased clearly. From Table 4, WCA of A4 membrane prepared at ET of 90 and 120 s decreased about 60°. The lowest WCA (9.96 ± 5.32°) appeared on the surface of A4 membrane prepared at ET of 120 s. This phenomenon showed that TMMS affected the dispersion of $TiO_2$ in the matrix of PSF membranes. Furthermore, the photocatalytic property of $TiO_2$ in PSF membranes was stimulated by plasma radiation leading to an increase in hydrophilicity. TMMS showed an increase silane bonds on $TiO_2$ surface which enable it to improve functional groups of organic compounds capture, as explained by Zhao et al. [16].

Table 4. Water contact angle of Ar-plasma treated (20 W, 4 min) membranes

| Sample | Contact angle (θ) | |
|---|---|---|
| | Evaporation Time (ET) 90 s | Evaporation Time (ET) 120 s |
| A1 | 17.06 ± 2.35 | 15.34 ± 1.35 |
| A2 | 17.36 ± 2.51 | 11.11 ± 2.45 |
| A4 | 12.58 ± 3.57 | 9.96 ± 2.32 |

When the surface of $TiO_2$ was improved with TMMS, $TiO_2$ exhibited properties of organic material and was well dispersed in an organic membrane. Typically, $TiO_2$ showed the photocatalytic properties after it was activated by plasma. These phenomena represent the increase of hydrophilic properties. Similar to Hashimato et al. [11] suggestion, $TiO_2$ excited by ultraviolet (UV) light revealed hydrophilic properties. Besides, $TiO_2$ can induce the dissociation of water without the use of external voltage. Therefore, $TiO_2$ induced the surface of a membrane to be more hydrophilic. The glow discharge plasma consisted of several elements and a frequency range of UV. UV light encourages its photocatalytic properties. In this work, the permanency of hydrophilicity of plasma treated membrane was evaluated. We found that in the ageing time of 30 days, WCA of plasma treated membrane surface gradually retrieved to the WCA of pure and untreated PSF membrane. The WCA of pure and plasma treated membrane recovered faster when compared with A2 and A4 membranes. Importantly, the lowest recovery of WCA appeared on the surface of A4.

Figure 2 shows that the WCA of plasma treated PSF membranes was increased with ageing time. Using B1 as a reference, the WCA of A1 increased faster when compared with that of A2 and A4 membranes. However, WCA of A1 and became close to B1 membrane in the storage time of 25 days. The recovery rate of WCA in A2 was similar to the result obtained from A4 membrane. For A2 membranes prepared with ET of 120 s, WCA increased to 56.25 ± 1.96° after being stored at room temperature for 25 days, while the A4 at the same ageing time showed about 51.24 ± 1.47°. It was clear that WCA at ageing time of 30 days of A4 recovered slower than that of A2 membranes. Additionally, for the membrane prepared with ET 90 s, WCA of A2 and A4 membrane were about 70.33 ± 1.24° and 58.35 ± 1.64°, respectively. It was confirmed that modified $TiO_2$ can prolong the hydrophilicity of the plasma treated PSF membranes. Due to the fact that hydrophilicity of the membrane surface easily causes contamination by airborne smirch in ambient condition. This explained the temporary water-like property [6].

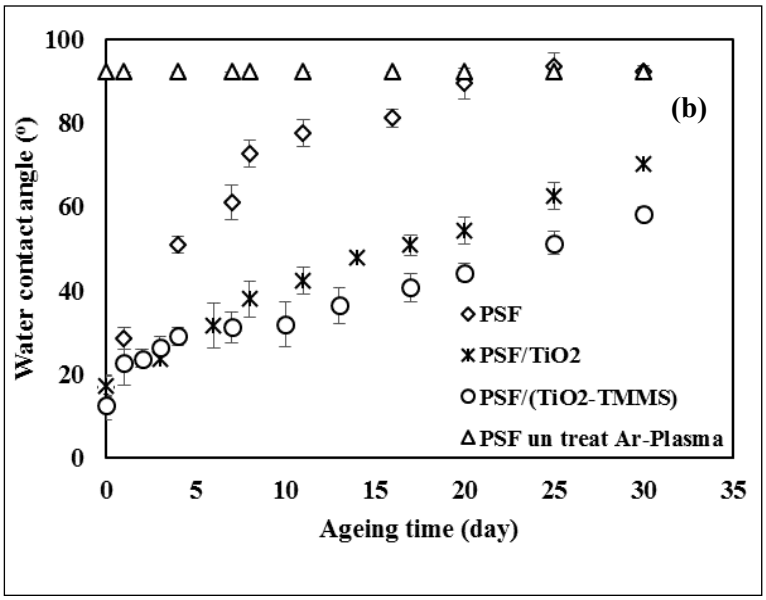

Figure 2. Variation of WCA with a storage time of 30 days of untreated and Ar-plasma treated membranes prepared at ET 120 s (a) and 90 s (b). PSF: A1, PSF/TiO2: A2, PSF/(TiO2-TMMS): A4 and PSF untreated Ar-Plasma: B1.

**Fourier transform infra-red spectroscopy**

Since PSF membranes are organic materials whereas $TiO_2$ is an inorganic material, the agglomeration of $TiO_2$ generally take place when it is blended in PSF membranes. To improve this problem, the modification of $TiO_2$ surfaces by a silane coupling agent was conducted. The objective of this modification was to introduce the organic functional group on the surface of $TiO_2$ nanoparticles. Introduction of organic groups on the surface of $TiO_2$ affected the dispersion of them in the polymer matrix. Figure 3 shows the FTIR spectrum of B2 and B4 membranes. It is shown that the Ti-O-Si bonds [17] appeared in a wavenumber range of 910 – 960 $cm^{-1}$. In the B4 system more Ti-O-Si bonds were created than in the B2 system. The number of Ti-O-Si bonds creations lead to an increase of the compatibility of the modified $TiO_2$ with the matrix of PSF membranes.

**Scanning electron microscope results**

Figure 4 shows an SEM micrograph at a magnification of 5,000x of a membrane cross section and Figure 4(a) shows the thick and dense selective layer and a large number of pores in the sub-structure of B1. The agglomeration and dispersion of $TiO_2$ particles in the membrane structure can be observed through the SEM micrograph. From Figure 4(a) and 4(b), the thicknesses of the skin layer membranes are 0.9 and 0.1 µm, respectively. $TiO_2$ was dispersed less in the PSF matrix compared to the modified ones with TMMS. This shows the enhancement of Ti-O-Si bonds in B4 membranes within 0.3 µm membrane thickness. The selective or skin layer of both B2 and B4 was thinner than of the B1 membrane. Additionally, the wall of pore of B2 and B4 membranes were thicker than of the B1 membrane. The variation of skin layer thickness affected the gas permeation rate of prepared membranes. According to these reasons, the plasma treated membrane showed greater gas permeation rate in A4 membrane compared to that of A1 and A2 membranes.

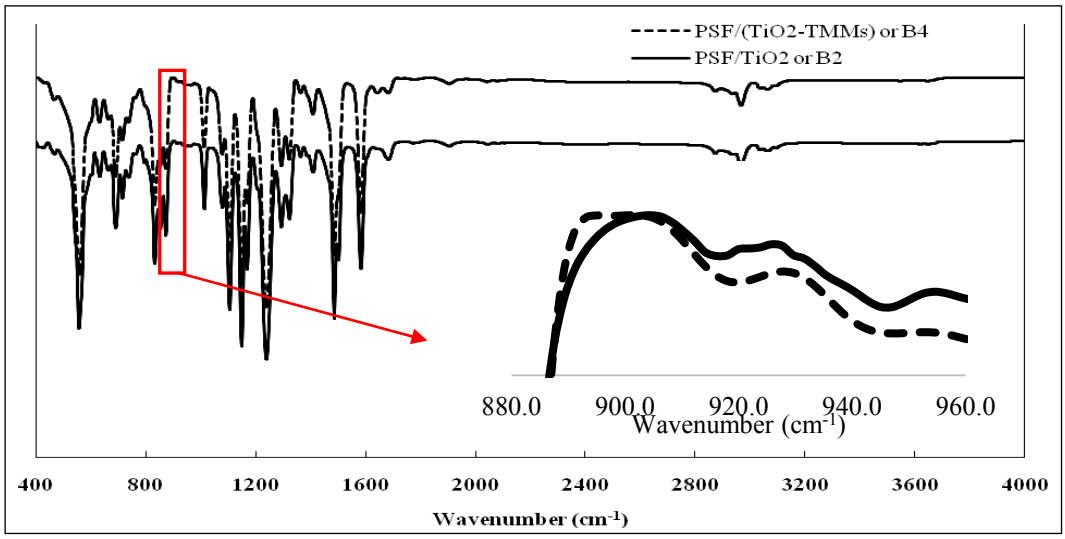

Figure 3. FTIR spectrum of B2 and B4 membranes.

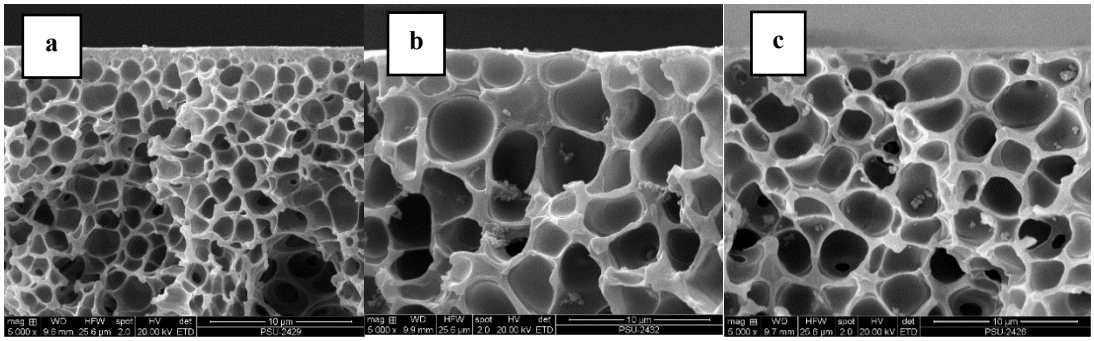

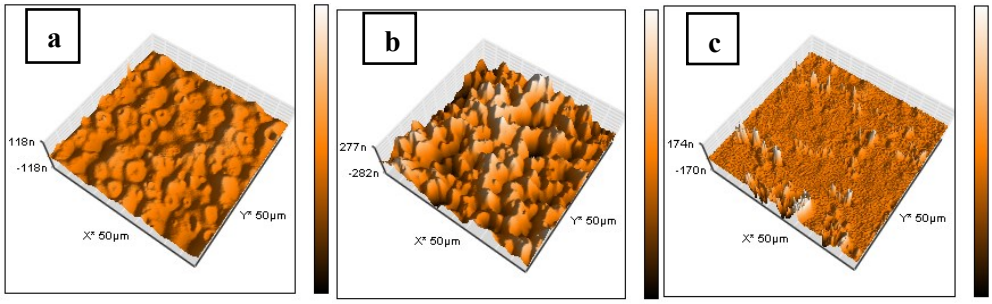

Figure 4. SEM micrographs (5,000x) of B1 (a), B2 (b) and B4 (c) membranes prepared with ET of 120 s

**Atomic force microscope**

Figure 5(a) to (c) show the surface morphology of B1, B2, and A4 membranes. An area of 50×50 $\mu m^2$ was scanned. It was shown that the highest roughness appeared on the surface of the B2 membrane prepared with ET of 120 s, whereas for plasma treated PSF/($TiO_2$-TMMS), A4 membranes, the lowest roughness appeared when compared with B2 membranes. AFM results, when PSF was adulterated by $TiO_2$ it creates more roughness on the membrane surface as shown in Figure 5b (roughness at nanometer scale). After plasma treatment, the membrane surface was reduced in its roughness, as shown in Figure 5c. It should be emphasized that the smoother surface does not reflect more hydrophilicity upon the decrease nanoscale roughness, which then reduces the probability of the lotus effect occurrence. This finding is useful and can be explored further.

Rms 11.359 nm Rms 92.013 nm Rms 29.875 nm

Figure 5. AFM micrographs of B1 (a), B2 (b), and A4(c) membranes after plasma treatment

**Gas permeation testing**

The maximum permeance of $CO_2$ was about 80.81±0.09 GPU measured with the A4 membrane, which was prepared with ET of 120 s. This result corresponded to the aim of this study. The $CO_2$ permeance of A4 membranes is higher than of A1 and A2 membranes prepared with the same ET. From Table 5, it can be seen that the $CO_2$ permeance of A1 and A2 membranes were about 18.36 ± 0.07 and 17.46 ± 0.05 GPU, respectively. Similarly, the permeance of $CH_4$ increased from 3.29 ± 0.05 to 18.59 ± 0.07 GPU for A1 and A4 membranes, respectively. In addition to the gas permeance, the maximum $CO_2/CH_4$ selectivity was about 6.84 ± 0.01 for A2 membranes prepared with ET of 120 s. It was shown that the selectivity of gas inversely varied with the gas permeance. Consequently, the minimum ideal $CO_2/CH_4$ selectivity of about 4.34 ± 0.01 determined for the A4 membranes because these membranes showed the maximum gas permeation. To enhance both the permeance and the selectivity of gases, further studies should be conducted with new aspects such as facilitated transport and refined mixed matrix membranes to be considered.

Table 5. Permeance (P/L) and ideal $CO_2/CH_4$ selectivity of plasma treated membranes (ET 120 s)

| Sample, ET 120 s | P/L (GPU) | | Selectivity of $CO_2/CH_4$ |
|---|---|---|---|
| | $CO_2$ | $CH_4$ | |
| A1 | 18.36(±0.07) | 3.29(±0.05) | 5.58(±0.02) |
| A2 | 17.46(±0.05) | 2.55(±0.02) | 6.84(±0.01) |
| A4 | 80.81(±0.09) | 18.59(±0.07) | 4.35(±0.01) |

## Conclusion

In summary, preparation of flat sheet asymmetric PSF membranes by incorporation with the modified $TiO_2$ at evaporation time (ET) of 90 and 120 s was conducted. PSF/($TiO_2$-TMMS) membrane prepared with ET at 120 s showed better results for $CO_2$ permeation by 340% and 363% compared with the PSF and PSF/$TiO_2$ membranes, respectively. Surface modification by DC Ar-plasma at indicated conditions showed improvement of membrane surface hydrophilicity. The maximum increase of the hydrophilic properties belonged to the plasma treated PSF/($TiO_2$-TMMS) membrane preparing with ET at 120 s. The plasma treatment decreased WCA by 85.78% in PSF/($TiO_2$-TMMS) membrane. Additionally, the permeance of the hydrophilic property created from Ar-plasma treatment for PSF/($TiO_2$-TMMS) membranes was reported to improve. The hydrophilic property could sustain for over 30 days. The study of chemical change through the FTIR spectrum found an increase of Ti-O-Si bonds in the wavenumber range of 910-960 $cm^{-1}$. This confirmed the bonding of $TiO_2$ with TMMS coupling agent and lead to the enhancement of dispersion of modified $TiO_2$ in the PSF membranes. The dispersion of $TiO_2$ was also confirmed

by SEM micrographs. This study also found that $TiO_2$ modified with TMMS leading to the enhancement of their hydrophilicity, although a slight decrease in $CO_2/CH_4$ selectivity was evidenced.

**Abstract**

With increasing industrial activities around the globe, water source had been severely polluted by various heavy metal substances that lead to adverse effect not only to the environment but also to human being. The content of heavy metal in wastewater especially cadmium was increasing in the recent years and can be attributed to the strong demand of cadmium in the battery and electroplating industry. In this study, the potential of novel nanocomposite mixed matrix membrane incorporated with manganese oxide ($MnO_2$) nanoparticle for cadmium removal was investigated. The membranes were fabricated using polyethersulfone (PES) by phase inversion technique with different manganese oxide nanoparticle loading. Prior to performance evaluation, the membranes were characterized by their structural morphology, surface chemistry and cadmium adsorption capability. The results suggested that PES membrane incorporated with 2.0 ratio of $MnO_2$/PES exhibited the best result in both cadmium adsorption (51.7 mg/g) and water permeability (1462 L/m$^2$.h.bar). This indicated the prospect of this membrane to be applied in wastewater treatment industry.

**Keywords**: mixed matrix membrane, polyethersulfone, cadmium, wastewater

**Abstrak**

Sumber air di seluruh dunia telah teruk tercemar dengan pelbagai bahan logam berat yang akan memberi kesan buruk kepada alam sekitar dan manusia. Pencemaran air ini adalah akibat daripada aktiviti-aktiviti perindustrian yang semakin pesat di dunia kita. Kandungan logam berat dalam air sisa terutamanya kadmium semakin meningkat dalam beberapa tahun ini disebabkan oleh permintaan kadmium yang tinggi terutamanya dalam industri bateri dan elektropenyaduran. Dalam kajian ini, potensi membran campuran matrik yang baharu dengan mangan oksida ($MnO_2$) dikajikan dalam sistem turas aliran lintang untuk penyingkiran kadmium. Membran ini dibuat daripada polietersulfona (PES) dengan teknik fasa berbalik dengan pelbagai berat zarah nano mangan oksida. Sebelum kajian dijalankan, membran dicirikan dengan kajian struktur dan permukaan morfologi, keliangan, sudut kenalan permukaan, kajian pembenaman $MnO_2$ dan kajian penjerapan kadmium. Hasil kerja kajian ini mencadangkan bahawa membran PES dengan nisbah 2.0 $MnO_2$ menunjukkan keputusan yang memberangsangkan dalam penjerapan kadmium (51.7 mg/g) dan fluks air tulen yang paling tinggi (1,462 L/m$^2$.h.bar). Keputusan kajian ini telah menunjukkan membran mempunyai potensi yang besar digunakan dalam industri rawatan air sisa.

**Kata kunci:** membran matriks campuran, polietersulfon, kadmium, air sisa

## Introduction

Since the industrial revolution in the human history, the environmental pollution by heavy metals has become more severe, leading to the catastrophic environmental and health problems. Cadmium (Cd) is a commonly used heavy metal in the industry, particularly in the battery, electroplating and pigment [1]. Nevertheless, Cd is a carcinogen to living organisms, where the presence of it will pose threat to the aquatic system and human health. Owing to strong industrial growth and increasing demand of Cd around the world, the wastewater containing Cd had increased drastically in the recent years [2].

Many wastewater treatment technologies had been developed for heavy metal removal. These include precipitation, ion exchange and solvent extraction. Although these methods are widely used in the industrial application, they possess disadvantages such as high capital cost, discharges of toxics solvent, disposal of sludge, and etc. [3]. One of the alternative methods to overcome these issues is membrane technology.

Membrane technology had been developed rapidly in the past two decades due to the advances in the membrane fabrication and characterization techniques. Several membrane separation techniques had been used in the seawater desalination and wastewater treatment, namely, reverse osmosis (RO), nanofiltration (NF) and ultrafiltration (UF) [4, 5]. Despite the successful application of membrane technology in the wastewater industry, the membrane performance as a function of filtration time is still a main concern as membrane is prone to fouling, especially in the treatment of wastewater containing heavy metals [6]. In this work, the potential of novel mixed matrix membrane embedded with manganese oxide ($MnO_2$) nanoparticles was evaluated for Cd removal. The membrane fabrication and characterization techniques, adsorption behavior and separation efficiency were investigated by performing static adsorption and cross flow filtration experiment under various experimental conditions.

## Materials and Methods

### Materials

The main polymeric material used for the membrane fabrication was polyethersulfone (Radel A300 PES) with a molecular weight of 58,000 g/mol purchased from Amoco Chemicals. Polyvinylpyrrolidone (PVP) and N-methylpyrrolidinone (NMP) obtained from Merck were used as additives and solvent, respectively. Ethanol and potassium permanganate were supplied by KLH Chemicals and used for nanoparticle synthesis. Cadmium chloride purchased from R & M Chemicals was used to prepare feed solution.

### Synthesis of manganese oxide particles

The synthesis method adopted in this study was similar to the literature reported by Subramanian et al. [7]. Potassium permanganate was first dissolved in distilled water followed by the addition of ethanol. The mixture was stirred until brownish black precipitate of manganese oxide was formed. The precipitate was filtered by Whitman filter paper and cleaned with distilled water to remove the unwanted impurities. Subsequently, the precipitate was dried in a vacuum oven at 60 $^{o}$C for 24 hours to remove the moisture content before use.

### Membrane preparation

The membrane fabrication technique employed in this study was phase inversion technique which has been discussed elsewhere in details [8]. A pre-determined amount of PES and additive ($MnO_2$ and PVP) were weighed and added to NMP solvent. The solution was stirred for 4 hours by magnetic stirrer followed by sonication at 60 $^{o}$C for 24 hours to produce homogenous dope solution. The viscosity of the dope solution was recorded by digital viscometer (98965-40, Cole-Parmer) to investigate the effect of the ratio of $MnO_2$ and PES.

In the flat sheet membrane fabrication, the dope solution was cast evenly onto a flat glass plate. A casting glass rod was used to cast the solution into a film with a thickness of 230 – 250 μm. The casted film was then immersed into distilled water at room temperature to induce phase inversion. The formed membrane was immersed in water for 3 days in order to removal residual trace of solvent. Finally, the membrane was dried in a vacuum oven at 60 $^{o}$C for 24 hours to completely remove the moisture content. Table 1 lists the composition of dope solution used in this study for membrane fabrication.

Table 1. Composition of dope solution

| Membrane | $MnO_2$/PES Ratio | PES (wt.%) | PVP (wt.%) | NMP (wt.%) | $MnO_2$ (wt.%) | Viscosity (Cp) |
|---|---|---|---|---|---|---|
| PES | 0 | 15.00 | 1.50 | 83.50 | - | 200 |
| $MnO_2$/PES-0.5 | 0.5 | 13.95 | 1.40 | 77.67 | 6.98 | 1,800 |
| $MnO_2$/PES-1.0 | 1.0 | 13.04 | 1.30 | 72.60 | 13.04 | 2,000 |
| $MnO_2$/PES-1.5 | 1.5 | 12.24 | 1.22 | 68.18 | 18.36 | 9,450 |
| $MnO_2$/PES-2.0 | 2.0 | 11.54 | 1.15 | 64.23 | 23.08 | 12,450 |
| $MnO_2$/PES-2.2 | 2.2 | 11.28 | 1.13 | 62.78 | 24.81 | 13,250 |

**Characterization**

The structure of the $MnO_2$ was identified by transmission electron microscopy (TEM). The $MnO_2$ sample was first reduced for 30 min by inducing hydrogen to remove any carbon deposit, and then carefully transferred to a porous carbon film supported on a metal grid at scale bar of 20 to 50 nm. The sample was then examined with an accelerating voltage at 400 KeV to obtain the electron micrographs.

Fourier transform infrared–attenuated total reflectance (FTIR–ATR) (Perkin Elmer) was used to investigate the functional group of $MnO_2$ before and after the cadmium adsorption test. Additionally, the functional groups of $MnO_2$ particles in the PES membranes were also identified by FTIR-ATR.

The membrane surface and cross sectional morphologies were examined using scanning electron microscope (SEM) (Hitachi TM3000). The samples were cryogenically fractured liquid nitrogen into a small strip. The membranes were then coated with a thin layer of platinum by sputter machine before SEM analysis.

Both membrane surface roughness and pore size of the flat sheet membranes were structurally characterized using atomic force microscopy (AFM) (Seiko SPA-300HV). The membrane samples were first washed using ethanol to remove any trace residual. The samples were cut into square pieces with area of approximately 1.0 $cm^2$ and attached to the sample holder in the scanner tube. The AFM images were obtained with tapping mode with a scanning size of 5 μm × 5 μm.

The contact angle of the flat sheet membrane was measured by sessile drop technique using contact angle goniometer (DataPhysics, OCA15Plus). Distilled water droplet was placed on 10 to 20 regions on the membrane surface and average contact angle was reported.

Membrane porosity was calculated by the gravitational method as explained in the literature [9]. The weight of the membrane samples were first weighted as dry weight and then immersed into water for 24 hours. The weight of the wetter membrane was measured as wet weight and the porosity ($P_r$) was determined using Equation 1.

$$P_r = \frac{W_w - W_d}{d_w \times s \times l} \quad (1)$$

where $W_w$ is the weight of wet membrane (g), $W_d$ is the weight of dry membrane (g), $s$ is the surface area of membrane ($cm^2$), $l$ is the thickness of wet membrane (cm) and $d_w$ is the density of water at room temperature.

**Experimental work**

The adsorption test of cadmium using the fabricated membrane was studied using batch adsorption technique. The Cd solution was prepared by dissolving cadmium chloride ($CdCl_2$) in distilled water. The batch adsorption was carried out in a 15 mL sample tube with 10 mL of Cd solution with a concentration of 30 ppm and membrane with mass of 0.01 g, and pH value remained as constant at 9. The sample tube was placed in incubation shaker at 250 rpm, 25 $^oC$ for 48 hours. Additionally, the effect of pH value on the Cd adsorption was investigated by mixing the

membrane with 10 mL of 100 ppm Cd solution at different pH values. The concentration of Cd residual was analyzed using inductively coupled plasma-optical emission spectrometry (ICP-OES). The analysis was repeated three times to yield average result. The equilibrium adsorption capacity ($q_e$) of the membrane was determined using Equation 2 [10].

$$q_e = \frac{(C_i - C_e)V}{M_m} \quad (2)$$

where $c_i$ (mg/g) is the initial Cd solution concentration, $c_e$ (mg/g) is the equilibrium Cd solution concentration, $v$ is the volume of Cd solution ($l$) and $M_m$ is the mass of the dry membrane which is added into the solution (g).

The Cd removal was also conducted by the cross flow filtration system as illustrated in Figure 1. Flat sheet membrane with an area of 14.5 $cm^2$ was installed in the membrane module. The feed stream consisting of Cd solution with a concentration of 100 ppm was pumped into the membrane module at 0.1 bar. The quality of permeate was determined at every 30 min interval by ICP-OES. The pure water flux is then determined by Equation 3 [10].

$$J_w = \frac{Q}{A\Delta t \Delta p} \quad (3)$$

where $J_w$ is pure water flux (l/$m^2$.h), $Q$ is the volume of permeate (l), $A$ is the effective membrane area ($m^2$), $\Delta t$ is the sampling time (h) and $\Delta p$ is the transmembrane pressure difference.

## Results and Discussion

### Characterization of $MnO_2$ nanoparticles and PES/$MnO_2$ MMMs

Figure 2 shows the images of six different membranes used in the experiment. It was observed that the color of membrane turned brownish when $MnO_2$ was added to PES. The color became darker with higher dosage of $MnO_2$. The results were consistent with the original colour of $MnO_2$.

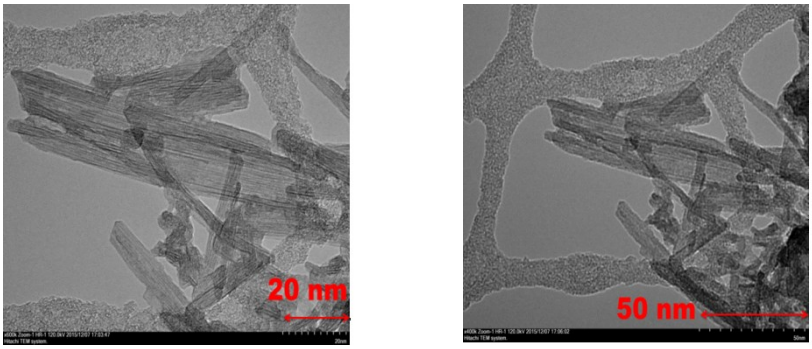

Figure 3 shows the TEM images of the synthesized $MnO_2$. The $MnO_2$ structure appeared to be rod-like structure with a dimension of 125 ± 30 nm. Such structure was achieved when the product of $MnO_2$ was formed as a result of addition of ethanol to aqueous solution of potassium permanganate ($KMnO_4$).

Figure 2. Images of six different membranes used (a) PES, (b) $MnO_2$/PES-0.5, (c) $MnO_2$/PES-1.0, (d) $MnO_2$/PES-1.5, (e) $MnO_2$/PES-2.0 and (f) $MnO_2$/PES-2.2

(a) (b)

Figure 3. TEM images of manufactured $MnO_2$ at different scale bars, (a) 20 nm and (b) 50 nm

Figure 4 depicts the FTIR spectra of $MnO_2$ particles and the membrane embedded with and without $MnO_2$. It is found that a sequence of adsorption bands for the $MnO_2$ was appeared at 3394.8, 1542.5 and 1412.2 $cm^{-1}$. Strong adsorption peak observed at 3394.8 $cm^{-1}$ was assigned to -OH stretching vibration because large amount of hydroxyl groups presented in $MnO_2$. The band at region of 1542.5 $cm^{-1}$ might be attributed to asymmetric N-O stretching vibration. On the other hand, the band at region of 1412.23 $cm^{-1}$ might be resulted by C-C stretching vibration.

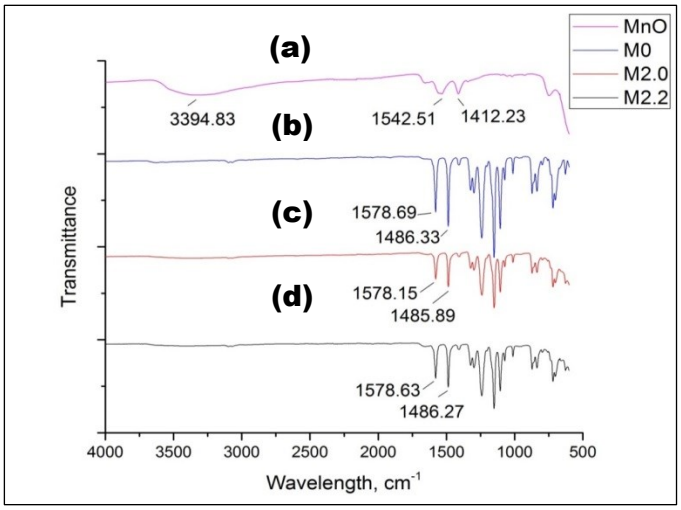

Figure 4. FTIR spectrums of (a) $MnO_2$ particles, (b) PES, (c) $MnO_2$/PES-2.0 and (d) $MnO_2$/PES-2.2

Table 2 summarizes the contact angle when water droplet placed onto the surface of six different membranes. It could be observed that the contact angle decreased significantly from 63.73° for the neat membrane to 18.13° for the $MnO_2$/PES-2.2 membrane. This indicated significant improvement in membrane surface hydrophilicity. Such improvement resulted from embedding $MnO_2$ particles in the PES membrane was most probably due to the presence of large amount of hydroxyl groups in $MnO_2$, which could be proved by FTIR result. A membrane with improved surface hydrophilicity generally would ameliorate membrane water permeability as shown in Table 2. It could also be noticed that the overall porosity values of all membranes were high (76 – 94.8%) (Table 2). This could be caused by low concentration of polymer used as well as addition of PVP (which acted as pore forming agent) in the casting solution. Moreover, the porosity appeared to increase from 76.81% in neat PES membrane to 94.81% in the $MnO_2$/PES-2.2 membrane. This was due to the addition of $MnO_2$, which was super-hydrophilic in nature as evidenced by the results of FTIR and contact angle.

Table 2. Pure water permeability, contact angle and overall porosity of various membranes

| **Membrane** | **PWF ($L/m^2h$)** | **Contact Angle (°)** | **Overall Porosity (%)** |
|---|---|---|---|
| PES | 22.74 (±0.39) | 63.73 (±2.96) | 76.81 (±0.65) |
| $MnO_2$/PES-0.5 | 234.93 (±1.68) | 46.89 (±4.45) | 77.11 (±-0.13) |
| $MnO_2$/PES-1.0 | 248.84 (±1.56) | 37.68 (±6.18) | 77.73 (±0.21) |
| $MnO_2$/PES-1.5 | 508.77 (±1.68) | 32.94 (±8.52) | 81.31 (±0.44) |
| $MnO_2$/PES-2.0 | 1461.99 (±3.93) | 20.82 (±4.52) | 85.89 (±0.36) |
| $MnO_2$/PES-2.2 | 1288.36 (±12.33) | 18.13 (±7.57) | 94.81 (±0.28) |

Figure 5 shows the AFM surface images of all the membrane samples provided in atomic-level resolution. *Ra* value is known as roughness value. It increased drastically from 17.34 nm in the neat membrane (M0) to >58 nm in the $MnO_2$/PES-2.0 membrane when the weight ratio of $MnO_2$/PES was increased from zero to 2.0. This could be resulted by the distribution of $MnO_2$ embedded in the membranes. A membrane with higher roughness value indicates better filtration performance. Hence, the M2.0 membrane was shown to have the best filtration performance compared with the M2.2 membrane.

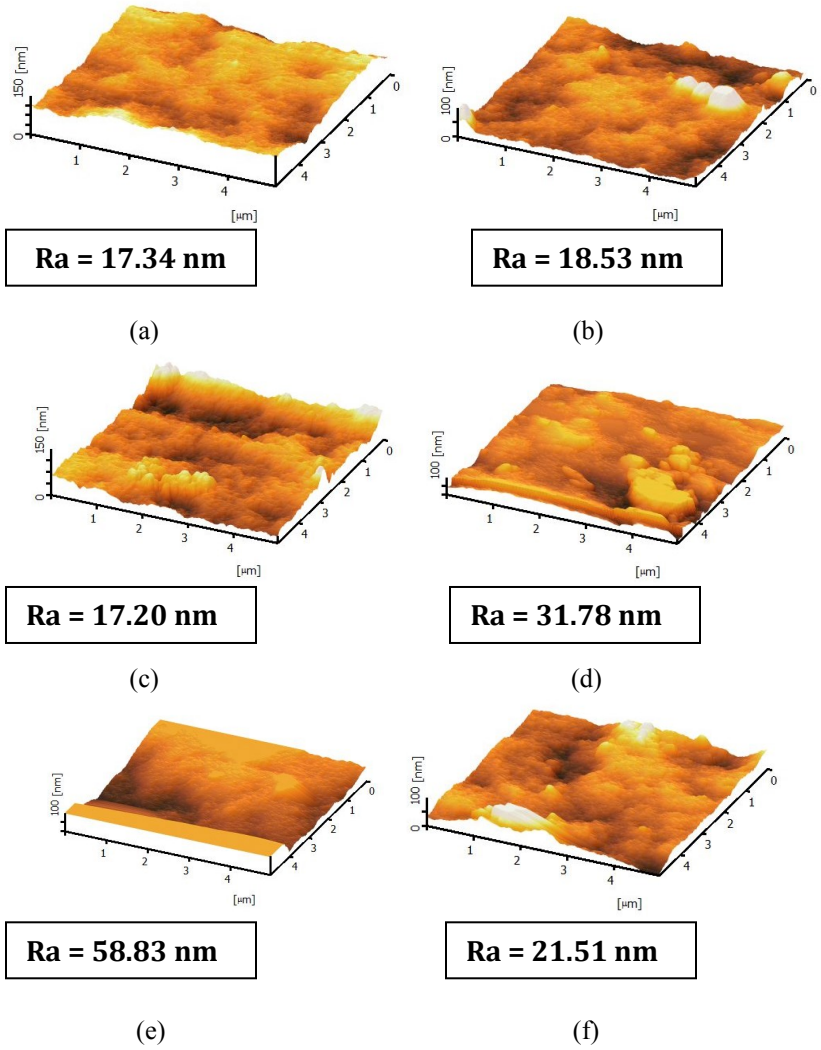

Figure 5. AFM images of various membranes with different $MnO_2$/PES ratios, (a) PES, (b) $MnO_2$/PES-0.5, (c) $MnO_2$/PES-1.0,(d) $MnO_2$/PES-1.5, (e) $MnO_2$/PES-2.0 and (f) $MnO_2$/PES-2.2

**Cadmium adsorption studies: Effect of adsorbent dosage and initial concentration (isotherm analysis)**

Both the effects of adsorbent dosage and initial concentration were studied at 25 $^{o}$C and pH = 9 by differing the Cd initial concentration of 10, 30, 50 and 100 ppm for various membranes with different PES/$MnO_2$ ratios. Neat membrane was not tested for this experiment because it had no adsorption capacity of Cd due to the absence of $MnO_2$ particles. Figure 6 shows that when the $MnO_2$/PES ratio increased, the Cd adsorption capacity increased accordingly. The maximum Cd adsorption capacity for $MnO_2$/PES-0.5, $MnO_2$/PES-1.0, $MnO_2$/PES-1.5, $MnO_2$/PES-2.0 and $MnO_2$/PES-2.2 were found to be 31.63, 35.29, 45.89, 51.71 and 49.82 mg/g, respectively. The enhancing adsorption capacity of prepared membranes was clearly attributed to the increasing dosage of $MnO_2$ adsorbents for Cd adsorption. In addition, the positive relationship between initial Cd concentration and Cd adsorption capacity was also obviously observed in Figure 6.

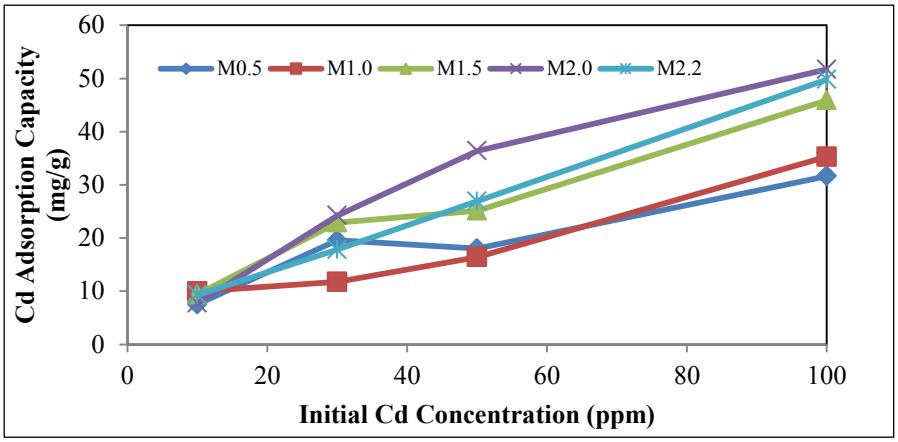

Figure 6. Adsorption isotherm of Cd using membranes with different $MnO_2$/PES ratios. (Operating Conditions: pH = 9, membrane dose = 1g/L, temperature = 25 $^oC$, contact time = 48 hours)

**Effect of pH**

The pH value is deemed to be a pivotal parameter in controlling Cd removal efficiency because of the strong aggressive bond between hydrogen ions and heavy metal ions in allocation of sites for adsorption. Figure 7 shows the removal efficiency of Cd under different pH values (i.e. pH 3, 5, 7, 9 and 11) during the adsorption studies. From the experiment, $MnO_2$/PES-2.0 membrane was chosen to be used because of its highest adsorption capacity among other membranes. As can be seen, better Cd removal efficiency was found to be in alkaline solution. The optimum Cd removal was observed between pH 9 to pH 11 for the $MnO_2$/PES-2.0 membrane attributed to the increase in the electrostatic attraction between the positively charge $Cd^{2+}$ ions and the negative charged binding sites of the functional group present on the cell surface which is similar to the reported by Al-Homaidan et al. and Adhiya et al [11, 12].

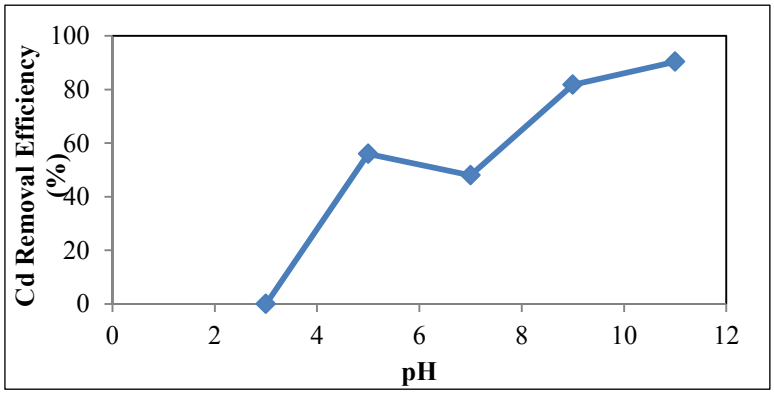

Figure 7. Effect of initial pH value on Cd removal by $MnO_2$/PES-2.0 (Operating Conditions: initial Cd concentration = 30 mg/L, membrane dose = 1g/L, temperature = 25$^oC$, contact time = 48 hours)

**Effect of contact time**

Effect of contact time (5, 10, 20, 30, 60, 120, 240, 360, 480 and 720 min) was investigated for the $MnO_2$/PES-2.0 membrane at initial Cd concentration of 30ppm. Figure 8 shows that Cd was more rapidly removed at the starting,

while the removal rate slowed down as the time passed. The higher rate of Cd removal initially might be due to larger surface area of the membrane embedded with $MnO_2$ for Cd adsorption. As time passed, the availability of surface area would become smaller, and hence the rate of Cd removal slowed down. The adsorption equilibrium was reached after 480 min.

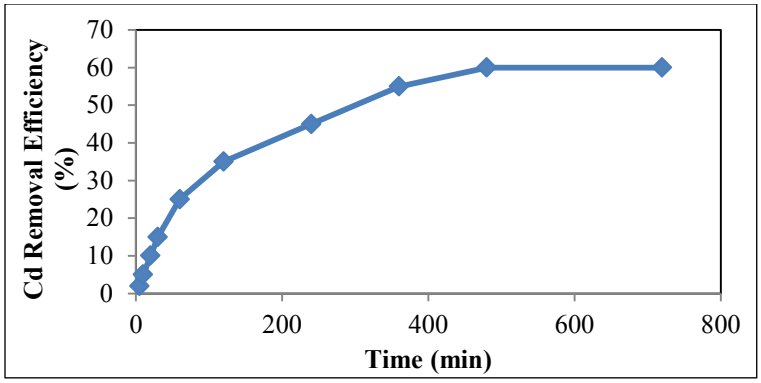

Figure 8. Effect of contact time on Cd removal by $MnO_2$/PES-2.0 (Operating Conditions: initial Cd concentration = 30 mg/L, membrane dose = 1g/L, temperature = 25 $^oC$, pH = 9)

**Continuous filtration**

The performance of optimum membrane, which was PES/ $MnO_2$-2.0 membrane, for Cd removal in the dead-end filtration process is depicted in Figure 9. According to the result, $MnO_2$/PES-2.0 membrane was capable of maintaining the Cd concentration below the maximum contamination level (MCL) of 10 ppb as stated by World Health Organization (WHO) for approximately 4000 $cm^3$ of permeate.

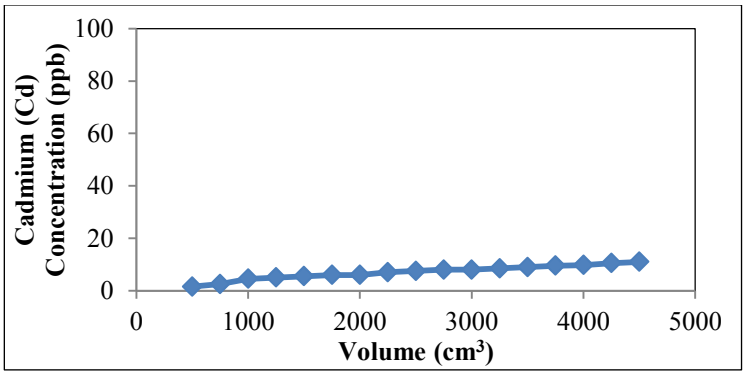

Figure 9. Adsorption of Cd from aqueous solution using $MnO_2$/PES-2.0 membrane (Operating conditions: initial Cd concentration = 100 ppb, pH = 9, temperature = 25 $^oC$, pressure = 5 bar)

## Conclusion

In this study, the $MnO_2$/PES mixed matrix membranes with different $MnO_2$ additives were successfully fabricated in laboratory scale. The fabricated membrane was characterized to understand the effect of the additives on the membrane morphology. The addition of $MnO_2$ in the membrane showed the increment of the surface roughness and better porosity. The $MnO_2$/PES membranes were found to have the highest Cd removal efficiency between pH 9 and 11 attributed to the electrostatic attraction between the positively charge $Cd^{2+}$ ions and the negative charged binding

sites of the functional group which lead to the possible application of Cd removal at broad pH range from pH 4 to 11. The filtration results showed that the $MnO_2$/PES-2.0 membrane was capable of producing permeate of good quality with Cd concentration below 10 ppb (the MCL set by WHO). This proved that the $MnO_2$/PES-2.0 membrane was very effective in removing Cd from aqueous solutions. In summary, the PES/$MnO_2$-2.0 membrane shows a great potential to be applied Cd removal from various wastewater treatment industry.

**Abstract**

The usage of ceramic membranes is gaining enormous attention due to their higher selectivity, permeation rate, and chemical and thermal stability as compared to the polymeric membrane. Owing to the fact of these superior properties, the search of a low-cost ceramic membrane is still in demand. To date, the fabrication of ceramic membrane using natural zeolite as the membrane ceramic loading has yet to be explored. Thus, this study aims to develop natural zeolite (Clinoptilolite) as the ceramic source in the fabrication of low-cost hollow fibre ceramic membrane (HFCM) via phase inversion and sintering techniques. Several fabrication parameters were also studied namely air gap distance, bore fluid flow rate and sintering temperature throughout this research. The best ceramic membrane was fabricated using 5 cm air – gap distance, 13 mL $min^{-1}$ of bore fluid flow rate and 1000 °C of sintering temperature. The acceptable strength and morphological behaviour of finger-like and sponge-like voids were found to be an advantageous characteristic of the fabricated membrane. The cheap and yet abundant raw ceramic material as well as low sintering temperature are eventually reduced the cost of membrane production.

**Keywords**: natural zeolite, ceramic membrane, phase inversion, sintering

**Abstrak**

Penggunaan membran seramik semakin mendapat perhatian ramai berasaskan sifat pemilihan yang tinggi, kadar keserapan, dan daya ketahanan yang tinggi terhadap suhu dan bahan kimia berbanding dengan membran polimer. Berdasarkan fakta tentang sifat-sifat yang hebat ini, maka pencarian terhadap membran seramik kos rendah masih lagi menjadi permintaan. Sehingga kini, fabrikasi membran seramik menggunakan zeolit semulajadi sebagai bahan seramik masih belum dikaji. Justeru itu, kajian ini memfokuskan kepada pembangunan zeolit semulajadi (Clinoptilolite) sebagai bahan sumber seramik dalam fabrikasi membran seramik gentian berongga (HFCM) berkos rendah melalui kaedah penyongsangan fasa dan sinteran. Beberapa parameter fabrikasi telah dikaji iaitu jarak ruang udara, kadar aliran cecair penebuk dan suhu sinteran. Membran seramik terbaik telah diperoleh menggunakan jarak ruang udara sebanyak 5 cm, kadar aliran cecair penebuk iaitu 13 mL $min^{-1}$ dan 1000 °C bagi suhu sinteran. Nilai kekuatan dan sifat morfologi yang memuaskan bagi stuktur span dan jejari dikenal pasti menjadi ciri - ciri kelebihan bagi membran yang difabrikasi. Harga yang murah dan sumber asli bahan seramik yang banyak serta suhu sinteran yang rendah justeru mengurangkan kos penghasilan membran ini.

**Kata kunci:** zeolit semulajadi, membran seramik, penyongsangan fasa, sinteran

## Introduction

In recent years, the development in hollow fibre membrane contactors has gained an enormous attention for the elimination of various volatile contaminants including ammonia [1]. A membrane contactor is a system that attains gas/liquid and liquid/liquid mass transfer without the dispersal of one phase within another. Usually, most of the hollow fibres used are commonly has microporous and hydrophobic properties. In the case of the gas/liquid separation, the penetration of aqueous solution into gas-filled pores is avoided since the hydrophobic properties of the membrane hindered the penetration of this high surface tension materials. Hence, the volatile compound will volatilize from the feed, diffuse through the gas-filled membrane pores, and then be removed by a sweep gas, sucked up by a vacuum or reacted with a stripping solution [2].

Hollow fibre membrane contactors have shown to be useful for eradicating low-concentration solutes from wastewater and they may verify to be a smart substitute for the present work. Hollow fibre membrane contactors, usually in a shell and tube configuration, offer many benefits over traditional contact operations. Membrane contactors provide a large and stable interfacial area. Two fluids flowing across the hollow fibre allow mass transfer to occur between the fluids. The hydrophobic microporous membrane provides the transfer area and restricts the permeation of water. The transfer takes place at the pore opening, inside the pore, or at the pore exit.

Currently, most of the commercially available and commonly used hollow fibre membranes are made from polymeric materials such as polyethylene, polypropylene, polyimide, etc., For instance, for gases in water, polypropylene (PP), polytetrafluoroethylene (PTFE), and polyvinylidene fluoride (PVDF) are normally used as hydrophobic polymers [3,4]. Most of these polymeric hollow fibres are vulnerable to chemical and thermal stresses, resulting in morphological changes and membrane swelling. These changes have weakening effects towards the membrane performance [5,6,7]. Therefore, polymeric membranes are limitedly applicable in mild operating conditions, namely low temperature and low acidity or alkalinity.

As a solution into this matter, a new approach has been developed in the invention of hollow fibre ceramic membranes (HFCM). Owing to the fact that their better thermal stability chemical resistance, ceramic membranes are superior over polymeric membranes in harsher environment. Numbers of studies have shown the achievement in the preparation of hollow fibre membranes of the ceramic materials such as aluminium oxide ($Al_2O_3$), $SrCe_{0.95}Yb_{0.05}O_{3-}\alpha$ (SCYb), $Ba_{0.5}Sr_{0.5}Co_{0.8}Fe_{0.2}O_{3-\delta}$ (BSCF), $La_{1-x}Sr_xCo_{1-y}Fe_{3-\alpha}$ (LSCF), etc. [8,9]. However, the production of a low cost ceramic membrane is still in search. Thus, zeolite is known to have a potential in producing a cheaper but effective HFCM.

Natural zeolites are raw materials can be found abundantly across the globe, and have been shown to possess interesting ceramic properties especially through high temperature (~1150 °C) phase transformations [10]. Natural zeolites are the principal inorganic cation exchangers that possesses high selectivity, ion exchange capacity and compatibility towards the natural environment. Currently, various different types of this mineral have been discovered. The most abundant natural zeolite that occurs in relatively large minerable sedimentary deposits in satisfactorily high purity in many parts across the globe is known as clinoptilolite [11].

The ion-exchange features of the zeolite minerals were first discovered in 1858 [12]. Clinoptilolite is also known to be as one of the ion exchanger with a high affinity for ammonium ion. Clinoptilolite possesses significant macroporosity since it shows a classical alumina silicate like structure. In nature, the cations present on clinoptilolite are sodium, potassium and calcium. The selectivity order of natural zeolite among cations shows that ammonium ion is one of the highest selected cations toward zeolite. Therefore, it is strongly believed that natural zeolite has an ability in the removal of ammonia from the solution concerning adsorption and ion exchange feature.

This work aims towards the development of low cost ceramic membrane in liquid-liquid membrane contactor system. It is known that most of the ceramic-typed membranes are made of metal oxides, which are normally hydrophilic in nature. This is due to the presence of hydroxyl ($OH^-$) groups on the surface. This property avoids them to be applicable in some applications which necessitate only hydrophobic membranes, such as non-polar solvent extraction, membrane contactor, vapour permeation and water ozonation [13]. However, the hydrophobicity properties of ceramic membranes can be enhanced by surface modification. More than a few types of surface

modifying agents can be used such as fluoroalkylsilanes (FAS), polydimethylsiloxane (PDMS), alcohol, chloroalkylsilanes, etc. [14]. Thus, the fabrication of zeolite-based HFCM for the liquid-liquid membrane contactor system is highly aimed to be realized. Consequently, the removal of ammonia in wastewater via ceramic membrane contactor system can be done.

## Materials and Methods

### Raw materials

The fine zeolite powder was prepared by grinding and sieving the zeolite stone purchased from Indonesia prior to the experiment. Polyethersulfone (PESf, Radel A300, Ameco Performance, USA), Arlacel P135 gel (CRODA), and N-methyl-pyrrolidone (NMP, QRëC™) were used as polymer binder, dispersant and solvent, respectively. The suspension composition (ceramic powder weight ratio of 35 wt.%) and the hollow fibre ceramic membrane (HFCM) fabrication parameters namely air-gap distance and bore fluid flow rate are listed in Table 1 and Table 2, respectively.

Table 1. The composition of zeolite based hollow fibre ceramic membrane

| Composition | Zeolite (g) | Arlacel P135 (g) | PESf (g) | NMP (g) |
|---|---|---|---|---|
| 35 wt.% | 35 | 1 | 5 | 59 |

Table 2. Zeolite based hollow fibre ceramic membrane spinning parameters used

| Fibre | Bore Fluid Flow Rate (mL/Min) | Air Gap (Cm) |
|---|---|---|
| 1 | 10 | 3 |
| 2 | 10 | 5 |
| 3 | 10 | 7 |
| 4 | 7 | 5 |
| 5 | 10 | 5 |
| 6 | 13 | 5 |

### Preparation of spinning suspension

The low-cost zeolite based hollow fibre ceramic membrane was prepared by immersion-induced phase inversion and sintering technique. Firstly, Arlacel P135 was dissolved in NMP solvent at vigorous stirring. After a homogeneous solution was formed, the pre-dried zeolite powder (the weight ratio specified in Table 1) was slowly added and projected into the ball milling process using NQM-2 planetary ball mill. After 48 hours of milling, PESf of desired weight was added into the dope and further milled for another 48 hours. The resulting suspension was degassed for 30 minutes at room temperature to eliminate the air bubbles.

### Fabrication of zeolite based hollow fibre ceramic membrane

After the degassing process, the spinning suspension was inserted into a syringe pump and extruded through a tube-in-orifice spinneret with internal diameter of 0.5 mm and external diameter of 2.8 mm. Tap water was used as the internal coagulant or also known as bore fluid solution. The fibre membrane precursor passed through a certain air-gap distance were immersed in a water coagulant (external coagulant) bath for 24 hours (Figure 1) to let the phase inversion process to be completed. Afterwards, the membrane precursors were dried at room temperature. Finally, the hollow fibre ceramic membrane precursors were calcined in air for 4 hours at various sintering temperatures in the range of 950 - 1050 °C by using a tubular furnace (XL - 1700). About 5 – 8 of membrane precursors were placed into the alumina boat and subjected into the furnace for stipulated time. The temperature was increased from room temperature to 600 °C at a rate of 2 °C $min^{-1}$ and held for 2 hours, then to target temperature at a rate of 5 °C

$min^{-1}$ and held for 4 hours. The temperature was later cooled down at a rate of of 5 °C $min^{-1}$ to room temperature. In this process, the polymer binder was burned off leaving only ceramic material in the HFCM.

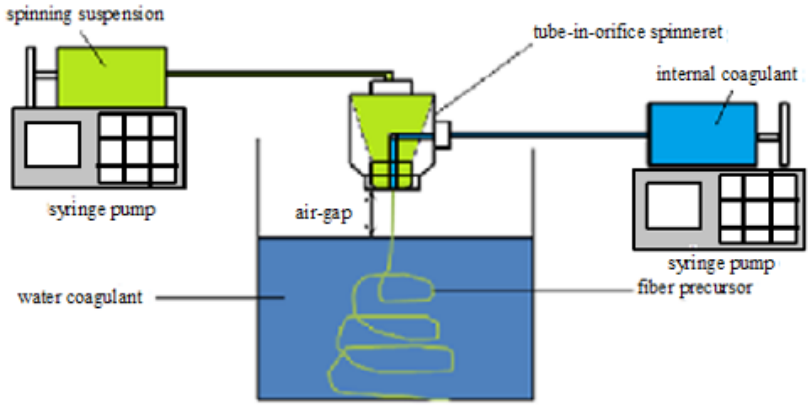

Figure 1. The schematic diagram of the phase inversion process set up for the fabrication of hollow fibre ceramic membrane

**Characterization**

The viscosity of the spinning suspension was measured instantly prior to the spinning process using viscometer (BROOK FIELD) at shear rate range between 1 $s^{-1}$ and 100 $s^{-1}$ at room temperature. The morphologies of the HFCM for all parameters studied were analyzed using scanning electron microscopy (SEM, Hitachi Model TM 3000) at different magnifications. Prior to the SEM analysis, the samples were gold coated under vacuum for 3 minutes. The morphological behavior as well as the wall thickness were examined through this analysis. In addition, the three-point bending tests were done in order to measure the mechanical strength of the zeolite HFCM using INSTRON 3342. The HFCMs about 5 cm in length were tested in three – point bending instrument and at least a triple set of test were done for each parameter studied. The mechanical strength (σF) was calculated using Equation (1) as follow [15];

$$\sigma F = \frac{8FLD_o}{\pi(D_o^4 - D_i^4)} \quad (1)$$

where F is the maximum load at which the fracture occurred while L, $D_o$, and $D_i$ are the length of span (43 mm), the outer diameter, and the inner diameter of the hollow fibres, respectively.

## Results and Discussion

**Rheology of ceramic suspension**

In this study, the presence of ceramic (35 wt.%) loading has affected the viscosity of the suspension. The viscosity of the ceramic suspension at shear rate of 1 – 100 $s^{-1}$ is shown in Figure 2. The rheological profile of this ceramic suspension containing Zeolite/NMP/Arlacel/PESf is found to conform the non-Newtonian behavior that has been previously reported by Kingsbury and Li [16]. The viscosity of Zeolite/NMP/Arlacel/PESf suspension was determined at a shear rate of 30 $s^{-1}$. The viscosity of this suspension was found to be 1.0308 Pa.s. From the SEM analysis, all HFCMs spun at this ceramic loading show the formation of the finger-like voids. According to Kingsbury and Li, the formation of finger-like structure is mainly dominated by the viscosity of the ceramic suspension [16]. A finger-like formation occurred when less viscous fluid (non-solvent) comes into contact with high viscous fluid (ceramic suspension) [17]. In addition, they have investigated that the critical viscosity value for their ceramic is 12.1 Pa.s at the shear rate of 30 $s^{-1}$. This value has been established as the threshold value for the formation of finger-like void in the membrane morphology. In other words, if the viscosity value obtained was beyond above this critical viscosity value, the formation of finger-like void is unfavorably to occur. In this study, the viscosity of the 35 wt.% ceramic loading suspension is far lesser than the critical viscosity value. Thus, the

formation of finger-like void is most likely to be attain. This theory is positively supported by the SEM analysis results which shown the presence of finger-like structure in most of the fabricated HFCMs.

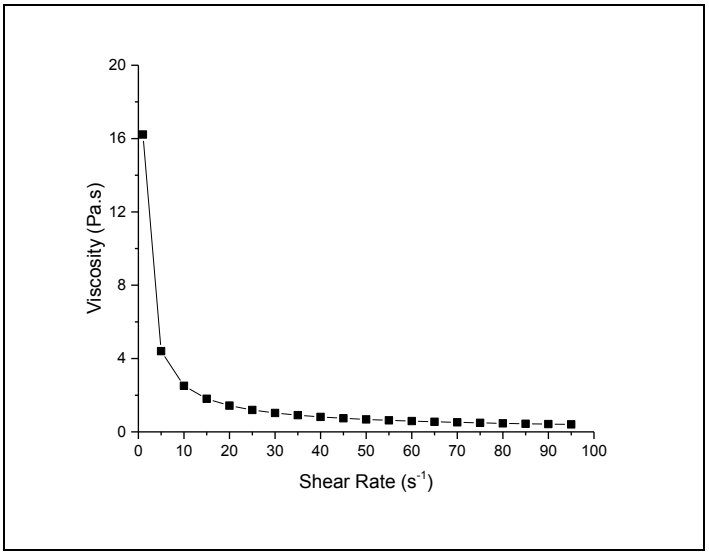

Figure 2. The rheological profile of ceramic suspension containing Zeolite/NMP/Arlacel/PESf with 35 wt. % of zeolite content

**Effect of air-gap distance**

The effect of air-gap distance on the structural behavior of zeolite based HFCM was studied at three different air-gap distances at a constant bore fluid flow rate of 10 mL $min^{-1}$. The obtained HFCM precursors were first sintered at 1000 °C prior to the morphological analysis through SEM. The SEM images of these HFCMs were depicted in Figure 3.

From Figure 3, it can be clearly seen that all three HFCMs showed the formation of finger-like void and sponge-like structures in all membranes. The finger-like void is significantly observed and obtained as the air-gap distance increased. The voids were elongated from the inner part towards the outer of the fibre as the air-gap distance enhanced. The best finger-like void was obtained by the air-gap of 5 cm (Figure 3b) since it gives the higher value in mechanical strength (Figure 4). In addition, the elongation of finger-like structure was not significantly enhanced as the air-gap increased from 5 to 7 cm. Furthermore, the formation of finger-like void were in good agreement with the viscosity analysis findings. According to Kingsbury and Li, the presence of water moisture in the air has encouraged a minor combination between non-solvent and solvent and thus amplified the viscosity at the outer surface. This phenomenon thus stifled the formation of outer finger-like void and preferred the formation of inner finger-like structure. In addition, 5 cm was selected as the best air-gap distance due to its mechanical strength (Figure 4). The lower value of mechanical strength possessed by air-gap 7 cm (Figure 3c) is due to the significant distortion suffered by the inner structure of the membrane. Similar phenomenon has been reported in Li et al. study [18].

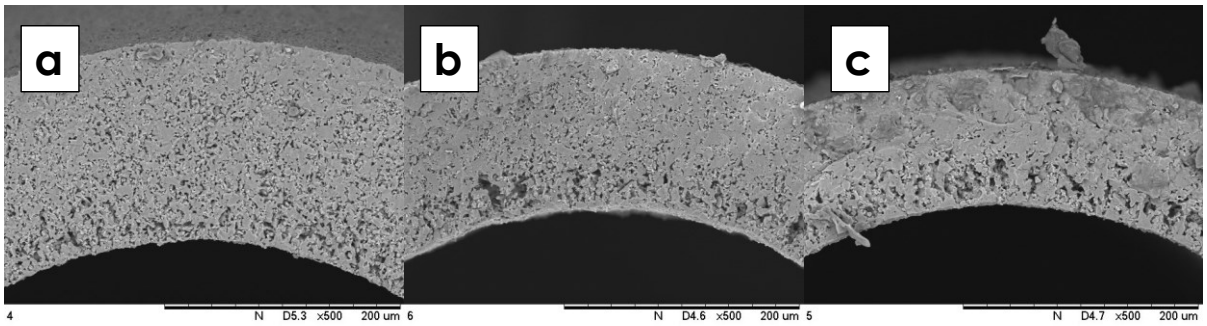

Figure 3. Cross-sectional SEM images of the zeolite based HFCMs spun at different air-gap distance: (a) fibre 1, 3 cm; (b) fibre 2, 5 cm; and (c) fibre 3, 7 cm, at a fixed bore fluid flow rate of 10 mL $min^{-1}$ and 35 wt.% of ceramic loading, respectively

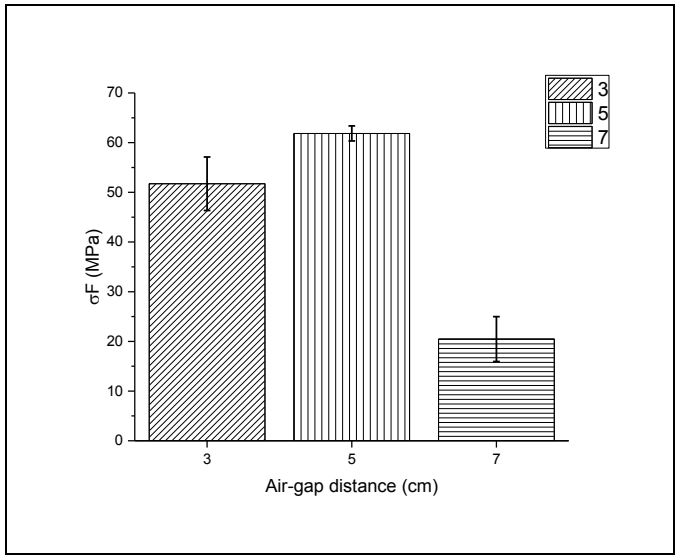

Figure 4. Flexural strength of the zeolite based HFCMs spun at different air-gap distance: (a) fibre 1, 3 cm; (b) fibre 2, 5 cm; and (c) fibre 3, 7 cm, respectively

**Effect of bore fluid flow rate**

The morphological behavior of zeolite based HFCM spun at different bore fluid flow rate were depicted in Figure 5. The studied bore fluid flow rate in this study namely 7 mL $min^{-1}$, 10 mL $min^{-1}$, and 13 mL $min^{-1}$, at a static air-gap distance of 5 cm and ceramic loading of 35 wt.% of zeolite. From the figure, it can be seen that the alteration of bore fluid flow rate has significantly change the morphologies of the HFCMs produced. The low flow rates (7 mL $min^{-1}$and 10 mL $min^{-1}$) is found to distort the bore shape formation of the fibre. However, the regular formation of the outer contours of the fibre was obtained by all fibres spun at different bore fluid flow rate without any distortion. The deformation of inner shape of the fibre can be clearly seen when the fibres spun at low bore fluid flow rates (7 mL $min^{-1}$and 10 mL $min^{-1}$), while a completely circular shape was obtained by the bore fluid of 13 mL $min^{-1}$.

The shrinkage of the HFCM was always obtained in the phase inversion process. This is due to the rate of solvent (NMP) diffusion from the suspension is always faster than the rate of diffusion of water into the suspension [19]. The shrinkage of the fibre was also attributed to the inward radial force which eventually resulted in the deformation of the inner shape of the fibre. There are two main reasons attributed into this phenomenon namely hydrodynamic

force and solidification rate. A low bore fluid flow rate (7 mL $min^{-1}$and 10 mL $min^{-1}$) could not generate a sufficient hydrodynamic force (outward) against the ceramic suspension which in turn resulting in the distortion of the bore shape.

The low bore fluid flow rates also produced a slow solidification rate. The slow solidification rate attributed to the incomplete solidification of polymer in the inner surface of the fibre which in turn is not durable enough to resist the inward radial force and thus distorted the formation of the circular contour of the fibre. The flow rate of 13 mL $min^{-1}$ is found to be the best bore fluid flow rate in order to produce the perfect circular shape of the inner contour of the zeolite based HFCM.

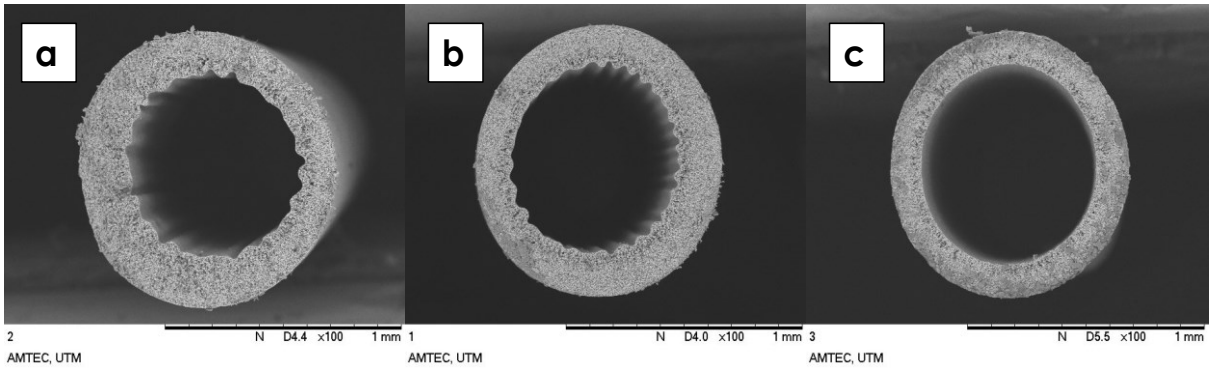

Figure 5. SEM images of the zeolite based HFCMs spun at different bore fluid flow rate: (a) fibre 4, 7 mL $min^{-1}$; (b) fibre 5, 10 mL $min^{-1}$; and (c) fibre 6, 13 mL $min^{-1}$, at a fixed 35 wt.% of ceramic loading and air-gap distance of 5 cm, respectively

**Effect of sintering temperature on zeolite based HFCM properties: Sintering shrinkage**

The zeolite based HFCM precursors were subjected into air calcination in order to remove the polymer binder and only ceramic would remain in the fibre. The sintering profile of the zeolite based HFCM is depicted in Figure 6. At first stage of the calcination, all polymer binders were eliminated at 600 °C. The grain growth of the ceramic particles is occurred at targeted sintering temperature (950 °C – 1100 °C). Figure 7 shows the cross-sectional images of the zeolite based HFCMs before and after calcination at varying sintering temperatures. From the images, it can be clearly seen that the fibre has shrunk when sintered as compared to the fibre precursor. The shrinkage of the fibre is further incremented as the temperature increased.

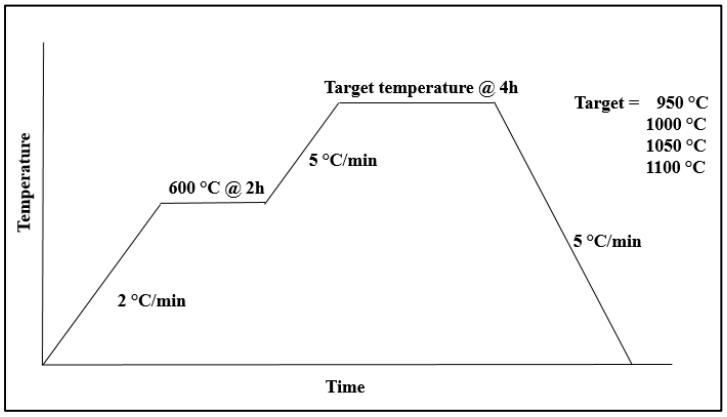

Figure 6. Sintering profile of the zeolite based HFCM

The radial shrinkage of the zeolite based HFCMs increased from 22% to 37% as the sintering temperature increased from 950 °C to 1100 °C. The increment in the shrinkage value suggested that the formation of sintering neck caused by the diffusion of the particles in the fibre [18]. Further enhance in sintering temperature has led to the destruction of the fibre due to the melting of the ceramic.

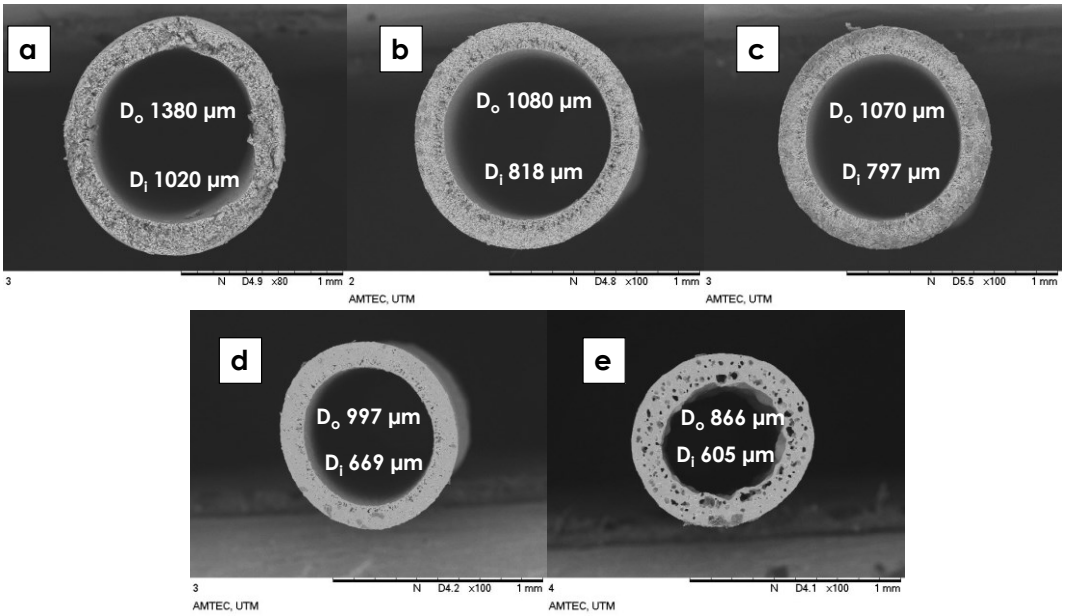

Figure 7. Cross-sectional SEM images of the zeolite based HFCMs (fibre 6) before (a) and after calcination at different sintering temperatures: (b) 950 °C; (c) 1000 °C; (d) 1050 °C; and (e) 1100 °C, fabricated at a fixed air-gap distance of 5 cm, bore fluid flow rate of 13 mL $min^{-1}$, and ceramic loading of 35 wt.% of zeolite, respectively.

**SEM microstructure of zeolite based HFCM**

Figure 8 depicts the microstructure of the cross-sectional zeolite based HFCMs before and after the sintering process has taken place at different temperature. The images of these membranes were taken at the magnification of 500 x in order to see the porous microstructure of the membranes.

From the images, it can be clearly seen that the sintering temperature had significantly affect the microstructure porosity of the inner and outer parts of the membranes. Before the sintering process has done, the particles of the ceramic altogether with the binder were freely distributed throughout the membrane and loosely packed in the membrane. As the sintering process has taken place, the polymer has been eliminated and left only the ceramic in the membrane. During this process, the grain growth of the particles occurred and the membrane is shrunk and densified. The formation of finger-like void is also significantly enhanced as the sintering temperature increased from 950 °C to 1000 °C. Similarly, Wang et al. [20] reported the densification of β-sialon ceramics at a temperature of 1650 °C, for the highest mechanical strength for the ceramic.

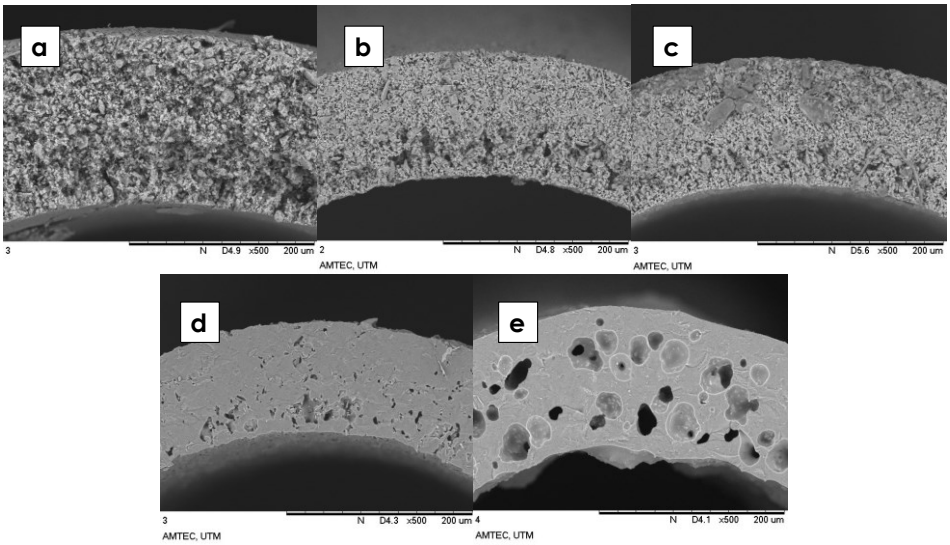

Figure 8. Cross-sectional SEM images (magnification 500x) of the zeolite based HFCMs (fibre 6) before (a) and after calcination at different sintering temperatures: (b) 950 °C; (c) 1000 °C; (d) 1050 °C; and (e) 1100 °C, respectively

As the temperature further increased to 1050 °C, the ceramic particle became densified both in inner and outer parts of the membrane. The destruction in finger-like voids and the formation of macro voids were significantly increased. At 1100 °C, the membrane became completely dense and compacted accompanied with the presence of macro voids all over the structure. At this stage, the ceramic material is approaching its melting point. The formation of macro voids could be attributed by the space left by the particles when it starts to closely packed to one another. The closed-up images of the particles is shown in Figure 9 where the images were taken at 3000 x magnification. Therefore, the best sintering temperature for the fabrication of zeolite based HFCM is 1000 °C. Although the most densified membrane could give the highest mechanical strength, but it is unfavorably desired since it will eventually give a lower permeation and flux.

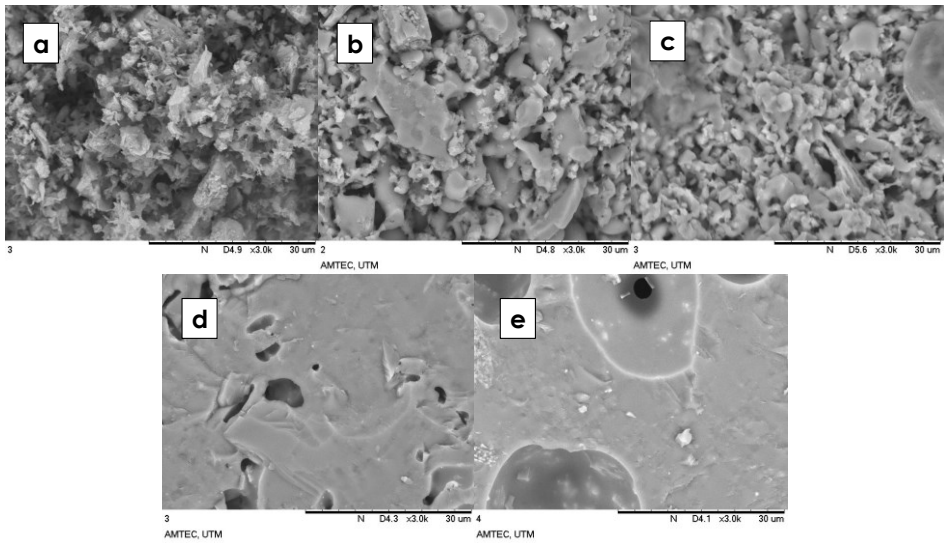

Figure 9. SEM images (magnification 3000x) of the cross-sectional zeolite based HFCMs (fibre 6) before (a) and after calcination at different sintering temperatures: (b) 950 °C; (c) 1000 °C; (d) 1050 °C; and (e) 1100

## Conclusion

A low-cost zeolite based hollow fibre ceramic membrane was successfully fabricated using phase inversion and sintering techniques. The best fabrication parameters were 5 cm air-gap distance, 13 mL $min^{-1}$ of bore fluid flow rate and sintering temperature of 1000 °C. The acceptable strength and morphological behavior of finger-like and sponge-like voids were found to be an advantageous characteristic of the fabricated membrane. Its pleasant structure with a separation layer from either inner and outer surface may be beneficial for applications in separation and filtration of volatile compounds such as ammonia in liquid-liquid membrane contactor system.

**Abstract**

In this study, thin film nanocomposite (TFN) membranes were prepared by incorporating multi-walled carbon nanotube-titania nanotube (MWCNT-TNT) hybrid into the polyamide layer via interfacial polymerization on the surface of PS35 commercial substrate. The study showed that in the neat thin film composite (TFC), the presence of PIP in polyamide layer increased the water permeability (from 0.54 to 2.25 L/m$^2$ h bar) but decreased the NaCl rejection (from 86.48 to 47.45%). Interestingly, the presence of MWCNT-TNT in MPD-PIP polyamide layer increased the NaCl rejection by 38.68% (47.45 to 86.13%) while giving a significant water permeability performance at 0.86 L/m$^2$ h bar. The incorporation of acid treated MWCNT-TNT has improved the water permeability from 0.86 to 0.89 L/m$^2$ h bar while decreasing the NaCl rejection from 86.13 to 77.51%. Further investigation of MWCNT-TNT loading at pH 2 revealed that the increase of its loading in polyamide layer decreased both water permeability and NaCl rejection performance of the membrane. Overall, it can be concluded that the addition of an appropriate loading of surface modified MWCNT-TNT into the polyamide layer can remarkably improve the performance of conventional TFC membranes for desalination applications. In addition, incorporating PIP in the polyamide layer reduces the capability of the membrane on NaCl rejection.

**Keywords**: water desalination, thin film nanocomposite membrane, MWCNT-TNT hybrid

**Abstrak**

Dalam kajian ini, filem nipis komposit nano (TFN) membran telah disediakan dengan menggabungkan karbon tiub nano pelbagai dinding-titania tiub nano (MWCNT-TNT) ke dalam lapisan poliamida melalui pempolimeran antara muka di permukaan substrat PS35 membran komersial. Kajian ini menunjukkan bahawa tanpa MWCNT-TNT, kehadiran PIP dalam lapisan poliamida meningkatkan kebolehtelapan air (daripada 0.54 kepada 2.25 L/m$^2$ h bar) tetapi mengurangkan penyingkiran NaCl (daripada 86.48 kepada 47.45%). Menariknya, kehadiran MWCNT-TNT dalam lapisan poliamida MPD-PIP meningkatkan penyingkiran NaCl pada 38.68% (47.45 kepada 86.13%) sambil memberi prestasi kebolehtelapan air yang besar pada 0.86 L/m$^2$ h bar. Penggabungan MWCNT-TNT ygng dirawat asid telah meningkat kebolehtelapan air dari 0.86 to 0.89 L/m$^2$ h bar namun mengurangkan penyingkiran NaCl (daripada 86.13 kepada 77.51%). Siasatan lanjut terhadap muatan MWCNT-TNT pada pH 2 mendedahkan bahawa peningkatan muatannya dalam lapisan poliamida menurun kedua-dua prestasi membran terhadap kebolehtelapan air dan penyingkiran NaCl. Secara keseluruhan, dapat disimpulkan bahawa penambahan muatan dan pH yang

sesuai bagi MWCNT-TNT ke dalam lapisan poliamida dapat meningkatkan lagi prestasi membran TFC konvensional untuk aplikasi pengenyahmasin. Di samping itu, menggabungkan PIP dalam lapisan poliamida mengurangkan keupayaan membran terhadap penyingkiran NaCl.

**Kata kunci:** pengenyahmasin air, membran filem nipis komposit nano, hibrid MWCNT-TNT

## Introduction

Nanofiltration (NF) which lies between ultrafiltration (UF) and reverse osmosis (RO) is a separation technique used in desalination process mostly to reject multivalent ions rather than monovalent ions. NF shows some advantages over RO such as greater water permeability and lower operating pressure [1]. The thin film composite (TFC) NF membrane is normally fabricated through interfacial polymerization (IP) process of two immiscible phases in the formation of thin and dense polyamide layer. Nowadays, TFC NF membrane has also been widely applied for water purification, wastewater treatment, food processing and bio-separation [2].

Recently, many efforts have been made to tailor the structural properties of polyamide-based TFC membrane to improve the separation performance of the membrane. The introduction of polymeric nanocomposites either by mixed matrix membrane or incorporated in polyamide layer of the membrane have gained interest of many researchers. Various nanomaterials such as silica, zeolite, graphite, metal oxide nanomaterials and carbon nanotubes (CNTs) have been introduced for membrane application due to their unique features including the ability to promote high permeability and decreased in fouling resistance [3]. Evidently, each nano-materials have their own unique properties, but a single material is unlikely to simultaneously offer several if not all, of these beneficial features for membrane fabrication. This has led to recent developments and application of hybrid nanomaterials capable of synergistically contributing the advantages of their individual components and thereby reducing their shortcoming [4].

The present work aims to evaluate the feasibility of using multi-walled carbon nanotubes-titania (MWCNT-TNT) hybrid as nanofillers of thin film nanocomposite (TFN) membrane. Even though many works on inorganic nanoscale particles have been studied, however, there is still no exploration on hybrid nanomaterials for water desalination membrane. In this study, a hybrid of MWCNT-TNT will be incorporated into the polyamide layer of TFN membrane to harness the unique characteristic of both MWCNTs and TNTs. The TFN membrane will be evaluated in term of their water permeability and NaCl rejection performance.

## Materials and Methods

### Materials

Commercial ultrafiltration (UF) membrane obtained from Sterlitech was used for membrane substrate. 1,3,5-benzenetricarboxylic acid chloride (TMC, Acros Organic) in n-hexane (Fisher Chemical), 1,3-phenylenediamine (MPD, Merck) and piperazine (PIP, Merck) in RO water were used in TFC membrane fabrication for PA layer. Titanium dioxide nanoparticles ($TiO_2$, Degussa P25 Evonik), multi-walled carbon nanotube (MWCNT, Aldrich), hydrochloric acid (HCl, Merck), sulfuric acid ($H_2SO_4$, Merck 95 – 97%), nitric acid ($HNO_3$, Merck 65%) and sodium hydroxide (NaOH, Merck) and sodium hydroxide (NaOH, Merck) were used to synthesize hybrid MWCNT-TNT. Sodium chloride (NaCl, Merck) was used in salt water preparation.

### Synthesis of MWCNT-TNT hybrid

MWCNT-TNT hybrid was synthesized by oxidization and hydrothermal method. Firstly, 1g of MWCNTs was acid refluxed in $H_2SO_4$:$HNO_3$ (each 3 M, 3:1, v/v) (250 ml) at 80 °C for 24 hours. The solution was filtered and washed to get pH neutral before oven-dried. 3 g of oxidized MWCNTs and $TiO_2$ (1:5) was undergone the hydrothermal process for 24 hours at 120 °C in 10M NaOH (100 ml). The MWCNT-TNT was washed until pH lower than 9 and was treated with HCl solution (0.1M) to obtain pH 3 – 4. The final product was washed to pH neutral and dried in an oven at 60 °C. To prepare the acid treated filler (a-MWCNT-TNT), the prepared MWCNT-TNT was treated with hydrochloric acid (HCl). Briefly, a 0.2g of MWCNT-TNT was added into a solution of pH 2 containing 0.05 HCl solution and was shake for 24 hours. All the solution were prepared with a specific gravity of 0.03M NaCl solutions as buffer solution. The precipitate of a-MWCNT-TNT was filtered and dried in the oven at 60 °C [5].

**Synthesis of polyamide layer**

Two types of polyamide layer were formed by (i) MPD (1.5wt) / TMC (0.05wt) which indicated as TFC A and (ii) MPD (1.13wt)-PIP (0.37wt) / TMC (0.05wt) indicated as TFC B. The polyamide layer for thin film composite (TFC) membrane was introduced via interfacial polymerization (IP) process on the surface of PS35 substrate membrane. The PS35 substrate was kept in RO water for at least 24 hours prior to interfacial polymerization (IP) process. Briefly, the MPD or MPD-PIP, was dissolved in RO water and the solution was covered by tissue paper to prevent from light oxidation [6]. In separated solution, TMC was dissolved in n-hexane. All the solutions were stirred at a minimum of 3 hours prior to use. To begin IP process, 40 ml of MPD aqueous solution (0.8 g MPD in 40 ml RO water) was poured and fully covered the PS35 substrate surface which was held horizontally for 1 min. The excess MPD solution and residual droplets were gently removed by using a soft rubber roller. Then, 40 ml of TMC solution (0.04 g TMC in 40 ml n-hexane) was also poured and fully covered on the substrate and was drained off after 50 s. The synthesized TFC membrane was dried for 1 min at ambient condition and 5 min later in the oven at 65 $^{o}$C. Finally, the TFC membrane was cooled for 1 min at ambient condition before continued to be rinsed with water and stored in RO water container [7]. The membrane (mentioned as MWCNT-TNT/TFC) were fabricated similarly to TFC membrane, except that during the interfacial polymerization, the MWCNT-TNT (0.05 wt.% or 0.1 wt.%) was dispersed and sonicated for 30 min in organic solution of TMC in n-hexane and was reacted with MPD or MPD-PIP immobilized on PS35 substrate commercial membrane

**Characterization of MWCNT-TNT, TFC and TFN membranes**

The crystal configuration of MWCNT-TNT hybrid was analyzed by X-ray diffraction (XRD) analysis. The tabular morphology of MWCNT-TNT hybrid was observed by transmission electron microscopy (TEM, HT 7700, Hitachi). The Zeta potential analysis (Malvern Zetasizer, Nano ZS) was utilized to determine the charge of the MWCNT-TNT and fabricated membrane. The hydrophilicity of membranes was measured by contact angle goniometer (OCA 15Pro, Dataphysics).

**Performance study of TFC and TFN membranes**

Pure water permeability and salt rejection performance by RO water and standard aqueous solution of NaCl (2000ppm) were conducted using dead end RO cell at an applied pressure of 15 bar. All permeation experiments were performed using circular membranes with an effective area of 14.6 cm$^2$. The membrane water permeability was evaluated by dividing the water flux value (Eq. 1) with operating pressure (15 bar).

$$J = \frac{V}{A \times t} \tag{1}$$

where $V$ is the permeate volume (L), $A$ is the membrane active area (m$^2$) and $t$ is the experiment time (h) to obtain $V$. The salt rejection was calculated based on following Equation 2:

$$R(\%) = \left(1 - \frac{C_p}{C_f}\right) \times 100 \tag{2}$$

where $C_p$ and $C_f$ are the concentration (ppm) of the permeate and feed solution, respectively.

## Results and Discussion

**XRD analysis**

The XRD analysis of MWCNT-TNT hybrid, MWCNTs and TNTs are represented in Figure 1. The self-synthesized TNTs sample shows an intense peak at 2-theta values of 10.48$^{o}$, 24.76 $^{o}$ and 48.58 $^{o}$. These patterns correspond to the crystal structure of TNTs. The peaks at a 2-theta values of 25.78 $^{o}$ and 43.13 $^{o}$ in XRD pattern of MWCNTs correspond to the cylindrical concentric tubular structure of MWCNTs and the sp$^3$ hybridization of the carbon atom. The characterization peak of MWCNTs at 25.78$^{o}$ can also be observed clearly in the formation peak at 26.18$^{o}$ in the patterns of MWCNT-TNT hybrid, which suggested the successful formation of MWCNT-TNTs [8]. Meanwhile, an intense peak at 2-theta values of 24.98$^{o}$, 26.18$^{o}$ and 48.72 $^{o}$ for MWCNT-TNT hybrid samples supported the

formation of TNTs nanotubes. The diffraction peak 10.48° and 11.1° showed by TNTs and MWCNT-TNT hybrid, respectively, a notable feature of the tubular structure of $TiO_2$ nanomaterials [8].

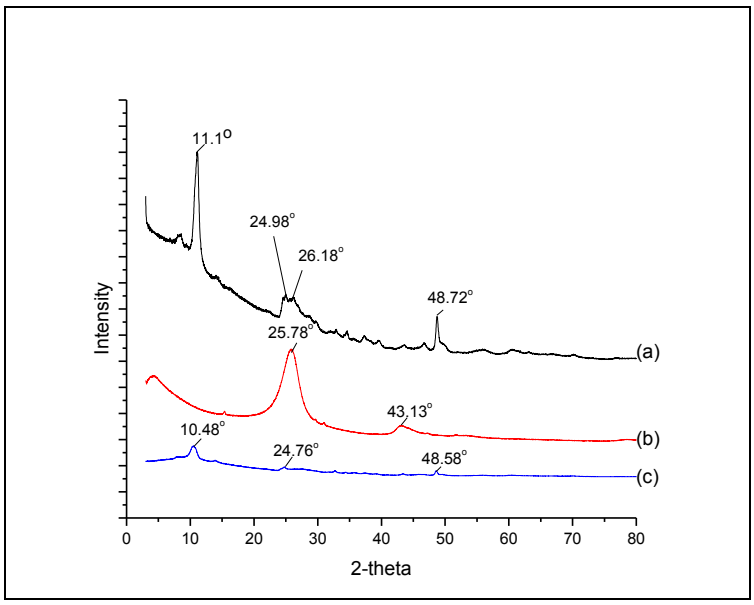

Figure 1. XRD patterns of (a) self-synthesized MWCNT-TNT hybrid, (b) commercial MWCNTs and (c) self-synthesized TNT

**TEM analysis**

TEM images (Figure 2) clearly demonstrate the tubular structure of MWCNT-TNT hybrid which depicted the open end of MWCNTs in the MWCNT-TNT hybrid. The MWCNT have the outer diameter in the range of 16 –20 nm while 71 – 141 nm for TNT, as indicated by TEM image. In addition, there were no $TiO_2$ nanoparticles (NPs) observed in TEM image of MWCNT-TNT hybrid, confirming that $TiO_2$ NPs was completely converted into TNTs after the hydrothermal treatment. These findings are consistent with the XRD results. Liu et al. [8],who applied the same hydrothermal method for the synthesized of MWCNT-TNT hybrid indicated the homogeneous mixture of nanotube was difficult to be achieved through the simple mechanical mixing.

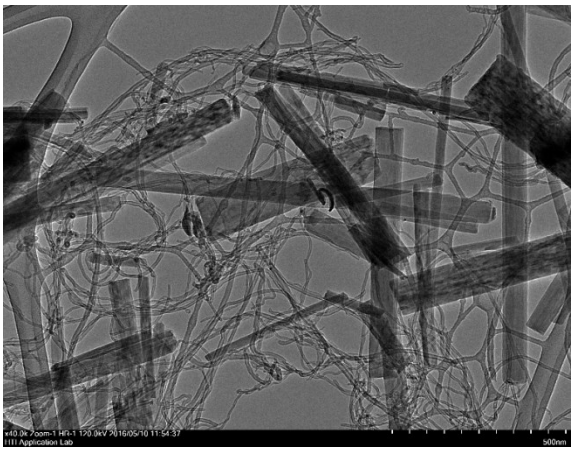

Figure 2. TEM image (magnification: 40K) of MWCNT-TNT hybrid

**Membrane performance**

Water permeability and NaCl rejection were evaluated for the membrane performance to determine the effect of the addition of MWCNT-TNT hybrid as nanofiller in polyamide layer of composite membrane. It was observed (Figure 3) that the water permeability of TFC membrane was increased from 0.54 to 2.25 L/m$^2$ h bar when piperazine as a co-monomer was used in polyamide selective layer (TFC B). The transport property that includes flux and rejection of nanofiltration membranes were greatly influenced by monomer type during polyamide layer formation which in accordance with that reported Saha and Joshi [9]. It was also believed that the addition of piperazine into PA layer will disturb the restricted chain flexibility of MPD-TMC PA, resulting in high water permeability in TFC B [9].

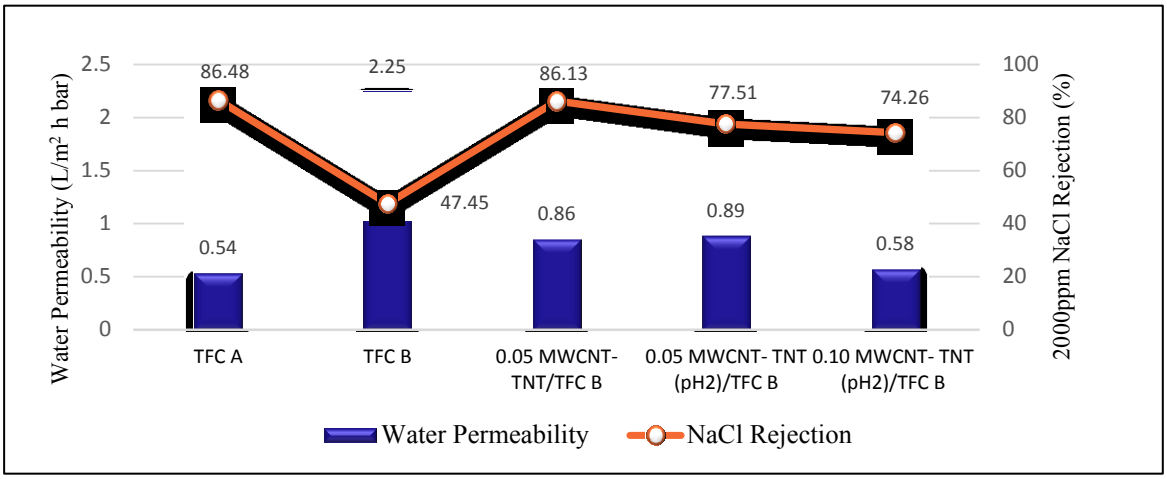

Figure 3. Water permeability and NaCl separation of thin film composite membranes (TFC) of TFC A [MPD (1.5wt) / TMC (0.05wt)] and TFC B [MPD (1.13wt)-PIP (0.37wt) / TMC (0.05wt)]. (Test conditions: 15 bar, 25 $^o$C, 2000 ppm NaCl aqueous solution)

However, the sharp increase in water permeability deteriorating the NaCl rejection from 86.48% to 47.45%. This observation is in agreement with that of reported by Wu et al. [1] where PIP was used as co-monomer. Uniquely, by incorporating the MWCNT-TNT hybrid in TFC B, the NaCl rejection increased from 47.45% to 86.13%, while the water permeability was higher compared to TFC A. The existence of hydrogen on MWCNT-TNT can enhance the hydrogen bonding formation in PA layer which in turn decreased the pore sizes in PA layer while later contributed to low water permeability and increase NaCl rejection [9]. Moreover, the successful synthesis of MWCNT-TNT as confirmed by XRD and TEM provides unique properties for the membrane which offers pore channels and high hydrophilicity of hybrid to increase water permeability while reject certain dissolved ions [10], [11]. Meanwhile, when the MWCNT-TNT was treated with acid (a-MWCNT-TNT) and was incorporated into the polyamide layer of TFC B, the water permeability was increased as indicated by decreasing contact angle from 72.92 to 61.71$^o$ of the membrane as shown in Table 1.

However, a-MWCNT-TNT/TFC B showed a slightly decreased in NaCl rejection. The polymer links formed from PIP and TMC, which occurs faster in polyamide layer of TFC B might compete with the bonding between a-MWCNT-TNT with the free –COCl groups of TMC [1]. Hence, contributed to the decreased in surface negative charge of the membrane as provided by the positive value of zeta potential (Table 1). The further increased of a-MWCNT-TNT in polyamide layer of TFC B deteriorated NaCl rejection of membrane performance. It is possibly due to the tendency of NaCl molecules to pass through some voids between a-MWCNT-TNT and polyamide at high loading of the hybrid nanotube [11]. Moreover, higher a-MWCNT-TNT loading (0.10 MWCNT-TNT) led to ineffectiveness on water permeability, which likely suggests the formation of thicker polyamide rejection layer under this a-MWCNT-TNT loading condition [12, 13].

Table 1. The properties of MWCNT-TNT hybrid and TFC/TFN membranes prepared in this work

| MWCNT-TNT / Membrane | Contact Angle ($^o$) | Surface Zeta Potential (mV) |
|---|---|---|
| MWCNT-TNT | - | -8.95 |
| a-MWCNT-TNT | - | 26.6 |
| TFC A | 90.22 ± 2.81 | - |
| TFC B | 52.66 ± 3.39 | -14.1 |
| 0.05 MWCNT-TNT/TFC B | 72.92 ± 3.56 | -10.6 |
| 0.05 a-MWCNT-TNT/TFC B | 61.71 ± 2.21 | 17.2 |
| 0.10 a-MWCNT-TNT/TFC B | 75.77 ± 2.97 | 14.3 |

## Conclusion

Novel TFN membranes for nanofiltration were fabricated by incorporating MWCNT-TNT hybrid. The MWCNT-TNT hybrid was successfully synthesized, which was confirmed by XRD and TEM analysis. The mixed cross-linking of MPD-PIP diamine monomer during interfacial polymerization in polyamide layer decreased the rejection of NaCl to an average of 39%. The unique properties of MWCNT-TNT hybrid such as tubular structure have improved the membrane performance in terms of water permeability and NaCl rejection. The acid treatment of MWCNT-TNT with HCl possibly provided external Cl group which help on PA layer formation. However, it might compete with the fast reaction of PIP monomer which decrease the negative charge of the membrane and decreased the salt rejection. Worth noting that the higher loading of a-MWCNT-TNT in MPD-PIP polyamide layer decreased both water permeability and NaCl rejection of membrane performance due to the dense PA layer formation.

**Abstract**

In this study, P84-based carbon tubular membranes were fabricated and characterized in terms of their structural morphology and gas permeation properties, by using Scanning Electron Microscopy (SEM) and pure gas permeation system, respectively. The polymer tubular membranes were then carbonized under nitrogen atmosphere at different carbonization temperatures of 600, 700, 800 and 900 °C, with heating rate of 3°C/min and thermal soak time of 30 minutes. The manipulation of carbonization temperatures was required to see if it could enhance the permeation properties as desired. Pure gas permeation tests were performed using $CO_2$ and $CH_4$ gases. The $CO_2/CH_4$ selectivity was found increasing as the carbonization temperature was increased from 600 to 800 °C. The carbon membrane carbonized at 800°C showed the most promising result for $CO_2/CH_4$ selectivity, rendering 69.48 and $CO_2$ permeance of 206.1 GPU.

**Keywords**: carbonization temperature, tubular support, P84 copolyimide, carbon membrane, gas separation

**Abstrak**

Dalam kajian ini, membran tiub karbon berasaskan P84 telah direka dan dicirikan dari segi morfologi dan penyerapan gas dengan menggunakan mikroskopi elektoron pengimbasan (SEM), dan sistem penyerapan gas tulen. Membran polimer tiub kemudian dikarbonisasi dalam kawalan gas nitrogen pada suhu karbonisasi berbeza iaitu 600, 700, 800 dan 900 °C dengan kadar pemanasan 3 °C/min dan kawalan haba selama 30 minit. Pengubahsuaian syarat karbonisasi diperlukan untuk mempertingkatkan ciri – ciri penyerapan gas. Ujian penyerapan gas tulen telah dilakukan dengan menggunakan gas $CO_2$ dan gas $CH_4$. Keterpilihan gas $CO_2/CH_4$ telah meningkat apabila suhu karbonisasi meningkat daripada 600 ke 800°C. Daripada kajian ini, membran karbon yang dikarbonisasi pada suhu 800 °C menunjukkan bacaan yang paling tinggi dengan nilai keterpilihan $CO_2$ /$CH_4$ sebanyak 69.48 dan nilai kebolehtelapan $CO_2$ ialah 206.1 GPU.

**Kata kunci:** suhu karbonisasi, sokongan tubul, P84 kopolimid, membran karbon, pemisahan gas

## Introduction

Membrane technology has gained interest as fluids separation media. Membrane is semi permeable barrier that allows only specific molecules to pass through, while discriminating others. Since there is no occurrence of phase

change during the separation [1], membranes technology offers minimal energy requirement [2]. Moreover, the membrane technology incorporating an efficient and straightforward separation approach with no moving parts makes it as preferable process. The membrane technology has shown a great industrial potential in seawater desalination, water filtration, wastewater treatment, dialysis and gas separation. Since the past decades, the depletion of natural gas quality, where the presence of impurities is prominent, has encouraged researches on membrane technology to focus on natural gas purification [3, 4]. There are several well-established processes such as adsorption, chemical absorption and cryogenic distillation which have been implemented in the purification process. These conventional processes, however, are known to suffer from high energy requirement, toxic refrigerant, unit corrosion, expensive maintenance and high operation cost. Membrane for gas separation offers a lot of advantages including space efficiency, requiring no complicated integration into the power plant, no regeneration, and chemical are not needed [5].

However, there is a trade-off suffered by polymeric membrane; which highly permeable membranes commonly accompanied by poor gas pair selectivity and vice versa [6, 7]. Since then, researches has highlights numerous strategies to overcome the limitation. Among them, new class of membrane known as carbon membrane was discovered. Carbon membrane is resulted from carbonized formed of polymeric precursor. During carbonization, polymeric precursor began to decompose, causing the functional group presence to breakage and form amorphous material. The resulted amorphous material having bimodal pore distribution having better thermal stability, chemically resistant towards various concentrations of acid, hot organic solvent and alkaline solution compared to their polymeric counterpart [8-9]. The gas separation performance of carbon membrane has been highlighted over the years. Owing to their bimodal pore distribution, carbon membrane performed well above the Robeson Upperbound. However, due to the fragility of carbon membrane structure, good handling is needed to avoid structural collapse [10]. To overcome the limitation, fabricating carbon membrane on ceramic substrate is among preferable approach [11]. In this study, supported carbon membrane was prepared via dip-coating method due to its straightforwardness approach and cost-effective [12, 13].

Since development of tubular supported carbon membrane is a relatively new approach, it is important to identify the most ideal carbonization temperature that could result in high performance carbon membrane. Therefore, this study aims to develop tubular supported carbon membrane for $CO_2/CH_4$ separation using different carbonization temperatures.

## Materials and Methods

A commercially available polyimide-type polymer was chosen as a precursor, which is a thermally stable co-polyimide BTDA-TDI/MDI (P84), procured from Sigma Aldrich (CAS#: 58698-66-1). The measured density of P84 was about 1.31g/cm$^3$ with glass transition temperature ($T_g$) of 315 $^oC$ [14]. N-Methyl-2-Pyrrolidone (NMP) was used as solvent; which is a strong, aprotic solvent with high solvency and low volatility, purchased from Merck (Germany). Porous tubular ceramic was purchased from Shanghai Gongtao Ceramics Co. Ltd. The dimension of the porous tubular ceramic was about 8 cm in length, 13 mm in outer diameter and 10 mm in inner diameter. The porosity of the support was 40 – 50% with an average pore size of 0.2 μm.

To begin, P84 was dissolved in NMP, stirred using mechanical stirrer and sonicated to remove trapped bubbles from the solution. The tubular support was immersed into the polymeric solution for 15 minutes and the process was repeated three times. The supported membrane was dried at temperature of 80 °C for 24 hours, followed by immersion in methanol for 2 hours. The sample was then placed in oven at temperature of 100 °C for 2 hours to remove the methanol prior to carbonization. Subsequently, the supported membrane was placed at the center of the Carbolite horizontal tubular furnace to undergo carbonization process. Heat treatment was performed at 300 °C for 30 minutes, followed by carbonization at temperatures of 600 °C, 700 °C, 800 °C and 900 °C, with heating rate of 3 °C /min under nitrogen gas (200 mL/min) as illustrated in Figure 1. The nomenclature of the resultant carbon tubular membrane was given in the form of CM-Carbonization Temperature and the resultant carbon membranes was given in the form (CM-Carbonization Temperature); denoted as CM-600, CM-700, CM-800, CM-900. All samples were cooled naturally at room temperature under air atmosphere after completing each heating cycle.

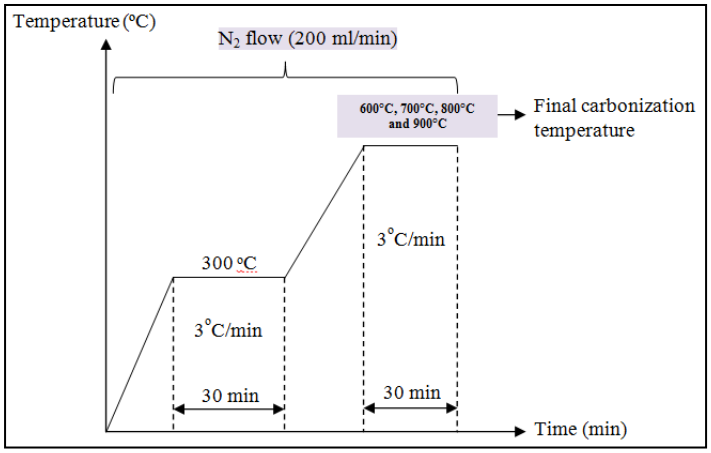

Figure 1. Heat treatment profile

The morphological structures of the P84-based membranes were viewed via scanning electron microscopy (SEM) model JEOL JSM-5610LV. In this study, free-standing carbon membrane in the form of flat sheet (without tubular support) was prepared for characterization purposes. The membrane was fabricated under the same condition as supported carbon membrane. A small piece of the tested membranes was cut and conditioned in liquid nitrogen to prepare an unreformed structure, which was then mounted on sample stubs. The sample was then coated with gold by sputter coating under vacuum. The performance of the carbon membrane was indicated by the gas permeance and gas selectivity. The carbon tubular membranes were tested using in-house gas permeation system. The system consists of flexible hose, permeation cell, valve, pressure regulator and soap bubble meter, which was fabricated to measure the pure gas permeation rate for tubular supported membranes. The 8 cm carbon tubular membrane was placed inside tubular stainless steel module, which was 14 cm in length. The membrane was fitted with rubber O-rings to allow the membrane to be housed in the module without leakages.

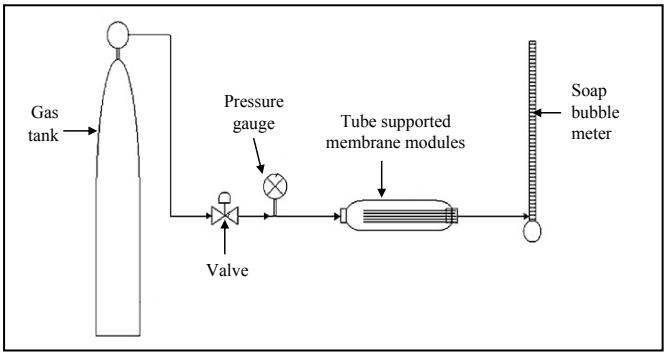

Figure 2. Gas permeation system [15]

Figure 2 shows the gas permeation system reported by a previous study [9]. Pure $CO_2$ (0.33nm) and $CH_4$ (0.38 nm) gases were fed separately into the module at a trans membrane pressure of 8 bars. The permeance, *P/l* (GPU) and selectivity, α of the membranes were calculated using the following equations:

Permeance, *P:*

$$(P/l)_i = \frac{Q_i}{\Delta p.A} = \frac{Q}{\pi D l \Delta P} \quad (1)$$

Selectivity, α:

$$\alpha_{A/B} = \frac{P_A}{P_B} = \frac{(P/l)_A}{(P/l)_B} \quad (2)$$

where *P/l* is the permeance of the membrane, *Qi* is the volumetric flow rate of gas *i* at standard temperature and pressure ($cm^3$ (STP/s), *p* is the pressure difference between the feed side and the permeation side of the membrane (cmHg), *A* is the membrane surface area ($cm^2$), *D* is an outer diameter of the membrane (cm), and *l* is an effective length of the membrane (cm).

The volumetric flow rate of gas permeate was measured by using the soap bubble flow meter. Similar gas permeation system had also been used in the previous study [13]. The feed pressure of 8 bars was applied throughout the experiment. This permeation test was repeated for at least three membrane samples.

## Results and Discussion

Scanning Electron Microscopy (SEM) was used to characterize the morphological structure of P84-based polymeric and carbon membranes prepared under different carbonization temperature. Figure 3(a) shows the cross section microphotographs of the P84-based polymeric membrane, while Figure 3(b) to 3(e) show the cross section microphotographs of P84-based carbon membranes prepared at 600, 700, 800 and 900 °C. It was observed that all P84 membranes tested under different carbonization temperature had porous structure. Compared between P84-based polymeric membrane and P84-based carbon membrane under different carbonization temperature, it was clearly seen that P84-based carbon membranes with high carbonization temperature had higher density, compactness structure and less thickness, as shown in Figures 3(b) to 3(e), than P84-based polymeric membranes, as shown in Figure 3(a). It was found that the formed polymer chains had increased the packing density of the membranes, and some of the pores had become narrow due to the densification of carbon structure. Similar findings had also been reported elsewhere [16]. As the final carbonization temperature was increased, the gas passed through the membrane structure according to their kinetic diameter. Thus, the increment of carbonization final temperature produced a carbon membrane with a higher permeability and selectivity.

As can be seen in Figures 3(b) to 3(e), the structure of the prepared membrane experienced increasing density when temperature was increased from CM-600 to CM-800. On the other hand, the morphological structure for CM 900 resulted in low packing density, as higher temperatures caused the pores to shrink and finally disappeared. At 700 to 800 °C, the pores started to enlarge up; however when the temperature reached around 1000 °C, the pores of the carbonized material were mainly closed [17].

The permeance and selectivity of the membranes were then measured using gas permeation test apparatus at room temperature (Table 1). From the gas permeation test, the performance of the P84-based tube supported carbon membrane was characterized by two important factors, which are permeance and selectivity. As shown by the gas permeation test results, the carbon membranes had presented an excellent performance compared to the polymeric membranes. In addition, the increment in smaller molecule permeance was more prominent compared to larger molecules, resulting in higher gas pair selectivity, according to the increment of carbonization temperature. Carbon membranes contain constrictions in its structure which are closer to molecular dimensions of gas molecules compared to polymeric membranes. The pore system generally consisted of extensive openings with narrow constrictions. The separation was caused by the passage of smaller gas molecules through the pores, while the larger gas molecules were blocked, as well as due to the transport mechanism. Thus, it exhibited high selectivity for the smaller gas molecules, which were $CO_2$. These findings are in agreement with the work done by Ismail and David [18]. For both precursor and carbon membranes, the best performance of the membranes was obtained at the pressure of 8 bars. This result could be endorsed to the combination of low porosity and the kinetic diameter of the

gases, which could result to the pore blocking and resistance of gas transport at higher feed pressure. Similar results were also reported by Hosseini and Chung [19].

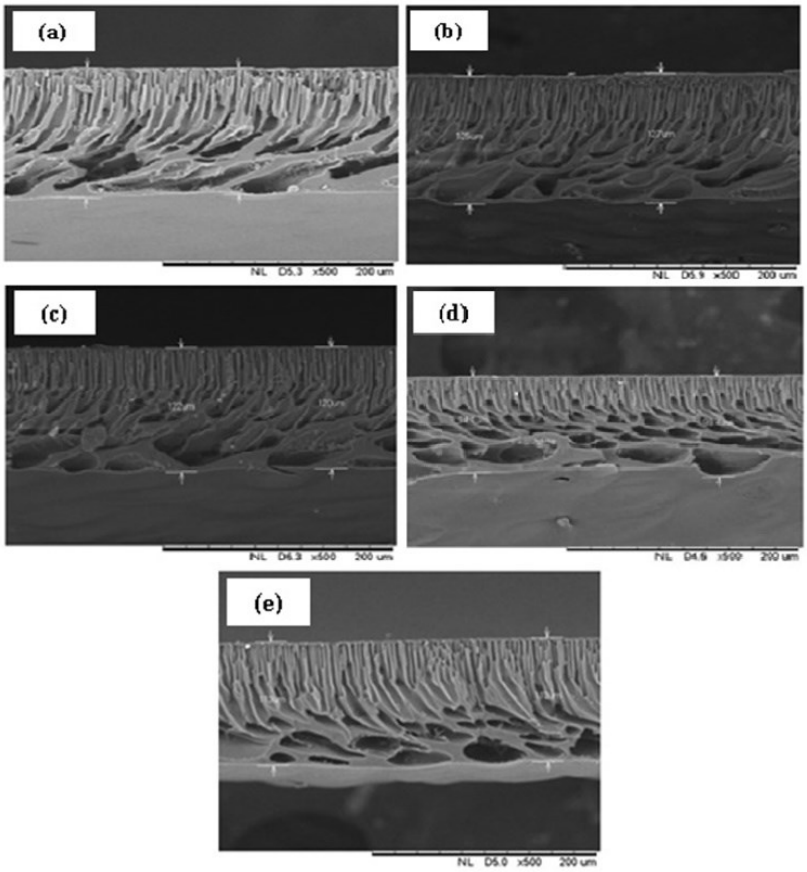

Figure 3. SEM images for (a) P84 Polymeric, (b) CM-600, (c) CM-700, (d) CM-800, and (e) CM-900

In general, low carbonization temperature would produce membrane with poor performances due to poor structural arrangements. On the other hand, at excessive high carbonization temperature, the structural of the carbon membrane would collapse and result in highly dense membrane. Accordingly, the permeability of two pure gases with different molecular sizes; $CO_2$ (3.30Å), and $CH_4$ (3.80Å), through the resulting carbon membranes were measured. The gas permeance of the prepared carbon membranes was found following the order of $CO_2 > CH_4$, according to their kinetic diameters. Consequently, the gas permeance was hindered while possessing poor gas pair selectivity. In addition, the micropores within the carbon membrane allowed smaller molecules (kinetic diameter of $CO_2$ is 3.3Å) to permeate easily across the membrane, while discriminating larger molecule (kinetic diameter of $CH_4$ is 3.8Å), or better known as molecular sieving effect. The molecular sieving effect, commonly reported as separation mechanism in carbon membrane, resulted from the breakage of benzene ring and other functional group, and created bimodal rigid pore distribution. Hence, the resulting membrane showed high $CO_2$permeance and $CO_2$/ $CH_4$ selectivity. The permeability of $CO_2$, and $CH_4$ gases increased due to increase of carbonization temperature from 600 to 800 °C.

Table 2. Gas Permeance and Selectivity of polymeric and carbon membranes.

| Sample | Permeance (GPU) | | Selectivity |
|---|---|---|---|
| | $CO_2$ | $CH_4$ | $\alpha_{CO2/CH4}$ |
| P84 Polymeric | 1.21 | 0.46 | 2.63 |
| CM-600 | 7.42 | 1.12 | 6.63 |
| CM-700 | 122.81 | 2.86 | 42.94 |
| CM-800 | 205.67 | 2.96 | 69.48 |
| CM-900 | 175.39 | 2.90 | 60.48 |

However, the gas permeance decreased when 900 °C of carbonization temperature was applied. This indicates that pores and carbon structure of the carbon membrane became rigid and compact; and some of the pores might change into closed pores during the carbonization. This phenomenon is often related to structure compaction and entanglement of polymer chain when polymer composition exceeds the ideal temperature. Consequently, poor structural arrangements induced higher mass transport resistance and hindered the permeation of all tested gases. In addition, significant reduction of $CO_2$ permeance compared to $CH_4$ further suggested severe structural arrangement for at macroscopic level at 900 °C carbonization temperature, leading to lesser $CO_2/CH_4$ selectivity.

Further carbonization temperature caused the pores to shrink and finally disappear. This pattern is in agreement with the fact that at high temperature, carbonized membranes will possess a microporous structure that is capable to recognize different kinetic diameter of gases, which then will increase the selectivity. Similar findings were also reported by Salleh and Ismail [16]. The increasing trend suggested that the micropores formation and the carbon structure of the carbon membrane became rigid and compact; and some of the pores might change into closed pores during the carbonization process. In general, high carbonization temperature will induce higher porosity. Polyimides are known to exhibit high permselectivity for various gas pairs; especially for $CO_2/CH_4$, and high chemical resistance, thermal stability and mechanical strength. Many researchers reported that P84 polyimide as one of the best materials for membrane-based $CO_2/CH_4$ separation, due to its attractive combination of gas permselectivity and permeability [20] .

## Conclusion

The gas permeation properties of prepared tubular supported carbon membrane are highly dependent on carbonization temperatures. Results in this study revealed that the ideal $CO_2/CH_4$ selectivity of 69.48 with $CO_2$ permeance of 206.10 GPU can be obtained by using carbon membranes at temperature of 800 °C. The study also shows that tubular supports possess higher membrane area per unit module volume, which results in high permeance.

**Abstract**

The presence of chromium in the natural water can be toxic to aquatic organism and is one of the major environmental problems. Therefore, the removal and recovery of chromium from industrial wastewater is very crucial to accomplish the standard discharge concentration limit. Supported liquid membrane is one of the processes which combines the extraction and recovery process in one single stage. This paper presents an experimental study on the removal and recovery of chromium ions from acidic aqueous solutions through a flat-sheet supported liquid membrane (FSSLM) system. Through this system, chromium ions were transported from feed phase into stripping phase via Tri-n-octyl-methylammoniumchloride (TOMAC)-kerosene-polypropylene supported liquid membrane (SLM). The liquid membrane phase was prepared by dissolving the corresponding volume of the carrier, TOMAC in organic diluent of kerosene. The stripping agent used was sodium hydroxide (NaOH) solution whereas the membrane support used was commercial Accurel polypropylene membrane with good features of 100 µm thickness, porosity of 72% and effective pore size of 0.10 µm. The chromium ion concentration in the feed and stripping phases as a function of time was analysed using an atomic absorption spectrometry (AAS). The effects of different operational variables such as TOMAC concentration in the membrane phase, NaOH concentration in the stripping phase and pH of the aqueous feed phase were investigated. The result demonstrated that about 90 and 98% of 150 ppm of chromium was removed and recovered, respectively at favorable condition of 1.0 M TOMAC, 0.5 M NaOH and pH 2 of the feed phase.

**Keywords**: supported liquid membrane, chromium, removal, recovery, acidic aqueous solution

**Abstrak**

Kehadiran kromium di dalam sumber air semula jadi adalah toksik kepada organisma akuatik dan salah satu masalah utama alam sekitar. Oleh itu, penyingkiran dan pemulihan semula kromium daripada air sisa industri adalah sangat perlu untuk memenuhi had kepekatan piawaian pelepasan. Membran cecair berpenyokong adalah salah satu proses yang menggabungkan penyingkiran dan pemulihan semula dalam satu peringkat proses. Kertas kerja ini membentangkan satu kajian eksperimen tentang penyingkiran dan pemulihan semula ion kromium dari larutan berasid melalui sistem helaian rata membran cecair berpenyokong (FSSLM). Melalui sistem ini, ion kromium dibawa dari fasa suapan ke fasa pelucutan melalui Tri-n-oktil-metilammonium klorida (TOMAC)–kerosin-polipropilena membran cecair berpenyokong (SLM). Fasa cecair membran telah disediakan dengan melarutkan sejumlah pembawa, TOMAC dalam pelarut organik kerosin. Ejen pelucutan yang digunakan adalah larutan sodium hidroksida (NaOH) manakala membran sokongan yang digunakan ialah Accurel polipropilena membran komersial yang mempunyai ciri-ciri yang baik dengan ketebalan 100µm, keliangan 72% dan saiz liang 0.10 µm. Kepekatan ion kromium dalam

fasa suapan dan fasa pelucutan terhadap fungsi masa dianalisis menggunakan spektrometri penyerapan atom (AAS). Kesan pembolehubah operasi yang berbeza seperti kepekatan TOMAC dalam fasa membran, kepekatan NaOH dalam fasa pelucutan dan pH fasa suapan telah dikaji. Keputusan menunjukkan bahawa sekitar 90 dan 98% daripada 150 ppm kromium telah disingkirkan dan dipulihkan semula pada 1.0 M TOMAC, 0.5 M NaOH dan pH 2 fasa luaran.

**Kata kunci:** membran cecair berpenyokong, kromium, penyingkiran, pemulihan semula, larutan berasid

## Introduction

Electroplating waste containing hazardous heavy metal of chromium is an environmental concern especially to the natural water system. Normally industrial electroplating waste contain both hexavalent and trivalent forms of chromium. According to Malaysia's environmental law, the standard discharge regulation of industrial effluent containing hexavalent and trivalent chromium is 0.05 and 1.0 ppm respectively [1]. Chromium(VI) is one of the most dangerous carcinogenic and mutagenic heavy metals as it is toxic for humans, animals, plants and microorganisms [2]. If these wastes are directly discharged into the natural water system, they will undoubtedly cause a lot of environmental problems. Thus, the removal and recovery of chromium is very crucial to bring down the concentration of such hazardous metal ions below the discharge standards. Hexavalent chromium is not precipitated as an insoluble hydroxide. Therefore hexavalent chromium need to be reduced to the trivalent state. The common reducing agent used include sulfur dioxide or bisulphite addition at low pH of 2 to 3. However this process suffers from high cost of sodium bisulphite. The use of inexpensive reducing agents such as ferrous sulphate significantly increase the volume of hydroxide sludge [3]. Besides, the solvent extraction method involves large amount of chemical consumption whereas electrodialysis provides high cost of operation [4, 5].

In order to overcome this problem, many researchers found that liquid membrane extraction technology has a great potential and has been reported as an advanced technique for separating solutes. Liquid membrane technology has attracted much interest for its potential impact in the fields of separation processes because the main advantage of liquid membrane configuration treatment is a single step process, in which removal and recovery processes occur simultaneously [6, 7]. This technique also provides high efficiency in separation and selectivity toward the desired solute as reported by Harrudin et al. [8]. Liquid membrane technologies have been commonly used to separate and recover many types of metals from diluted solutions. There are three types of liquid membrane technology namely bulk liquid membrane, emulsion liquid membrane and supported liquid membrane. Liquid membrane systems in which solvents containing carriers are placed in a porous support material are called supported liquid membrane (SLM). Supported liquid membrane has been extensively used for the recovery of organic matter, heavy metals and precious metals. The main advantages of SLM are the small amounts of organic phase and extractant used, one-step mass transfer, the possibility of achieving high separation factors, concentration of extracted compound during separation, and low separation costs [9, 10].

Carrier is one of the important components in the liquid membrane formulation. Carriers can be categorized as acidic, basic and solvating. For acidic type carrier, the metal extraction based on the cationic exchange reaction. The acidic carriers which are normally used for the extraction of various metal cations including chelating ( 5,8-diethyl-7-hydroxy- dodecan-6-oxime (LIX63), 2-hydroxy-5-nonylacetophenone oxime (LIX841) and etc) and phosphorus derivative (di-2-ethylhexyl phosphoric acid (D2EHPA), di-2,4,4-trimethylpentylmonothio phosphinic acid (Cyanex 302), di-2,4,4-trimethylpentyl phosphinic acid (Cyanex 272) and etc). On the other hand the basic type carrier tend to perform the extraction of anionic metal complexes through an anionic exchange reaction. Several basic carriers used for metal extraction are Trioctylamine (TOA), Tridodecylamine (TDA), Tri-octylmethylammonium chloride (TOMAC) and so forth. In order to achieve this exchange, the amine must be first converted to the amine salt to provide the anion to exchange with the metal species [11]. Besides, the solvating carrier are weakly basic in nature and thus they extract either neutral metal complexes or acids and suitable to extract the alkaline earth metals [12].

In this present work, Tri-n-octyl- methylammoniumchloride (TOMAC) is employed for the removal and recovery of chromium ion using supported liquid membrane process. To the best of our knowledge, the chromium compounds will release the anion complexes into the water. Hence, the best carrier for these anion complexes is the basic type carrier. Furthermore, TOMAC no need to be protonated because this compound in ionic complexes. Previously, TOMAC also have been reported as a good basic carrier for various anion complexes extraction with higher

efficiency [13]. The important parameters influencing the removal and recovery efficiency such as carrier and stripping agent concentration, and pH of the feed phase were investigated.

## Materials and Methods

### Materials

Potassium dichromate, $K_2Cr_2O_7$ as a feed solution was purchased from Sigma Aldrich. Tri-n-octyl methyl ammonium chloride (TOMAC) as a carrier and kerosene as diluent was procured from Fluka and Merck, respectively. The structure of TOMAC is illustrated in Figure 1. Sodium hydroxide, NaOH as a stripping agent was supplied from Qrec. All chemicals are analytical grade and were used without further purification as received. Stock Cr (VI) solutions were prepared by dissolving $K_2Cr_2O_7$ in distilled water. Polypropylene membrane of 100 µm thickness, 72% porosity and an effective pore size of 0.1 µm was obtained from Accurel Membrana was used as membrane support for the liquid membrane in supported liquid membrane process.

### Preparation of liquid membranes and rig set-up

The organic liquid membrane was prepared by dissolving a specified volume of TOMAC in the kerosene. Then, the polymeric hydrophobic microporous polypropylene membrane was impregnated with the liquid membrane for 24 h. After impregnation, the membrane support was let to drip for a few seconds and the excess liquid membrane was wiped from the membrane surface using the filter paper. The cleaning procedure was done gently in order to ensure that there is no liquid membrane was removed from the membrane pores. Then, the membrane was applied between the feed and strip cells as demonstrated in Figure 2. About 400 ml of feed and strip solutions were added into cell 1 and cell 2, respectively. The initial concentration of chromium in the feed phase was 150 ppm. NaOH solution was used as a stripping phase. The samples were taken from the feed and strip phase for each 30 minute and were analysed using Atomic Absorption Spectrometry (AAS) in order to observe the changes in the chromium concentration. The pH of feed phase and stripping phase was measured using a Metler Toledo pH meter. The new membrane support was used for each experiment. All experiment was carried out at ambient temperature (25±1 ºC).

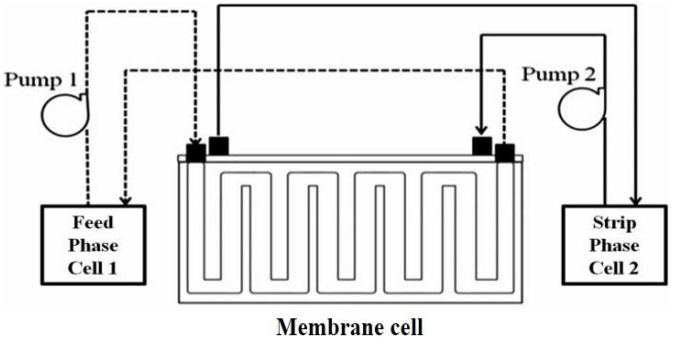

Figure 2. Schematic diagram of supported liquid membrane process [8]

**Determination of removal and recovery performance**

The determination of the removal and recovery percentages of chromium ion through SLM process were calculated using the following equations as below:

$$\text{Removal (\%)} = \frac{[Cr]_{f_o} - [Cr]_{f_t}}{[Cr]_{f_o}} \text{ x } 100\% \quad (1)$$

$$\text{Recovery (\%)} = \frac{[Cr]_s}{[Cr]_{f_o}} \text{ x } 100\% \quad (2)$$

where $[Cr]_{f_o}$ represents initial concentration of chromium in the feed phase; $[Cr]_{f_t}$ represents final concentration of chromium in the feed phase and $[Cr]_s$ represents a concentration of chromium in the strip phase.

**Determination of permeability value**

Membrane permeability is the ability of a membrane to allow the desired solute to pass through it. Permeability, p ($cms^{-1}$) of the chromium ions transferred from the feed phase to the strip phase can be determined by Equation (3) and (4) below:

$$\text{Permeability, } p = \frac{dC}{C} \cdot \frac{1}{dt} \cdot \frac{V}{A} \quad (3)$$

By integration Equation (3), Equation (4) was obtained,

$$\ln \frac{C}{C_{fi}} = - p \left(\frac{A}{V}\right) . t \quad (4)$$

where $C_{fi}$ is the initial concentration of metal ion in the feed phase, $c$ is the concentration of metal ion at given time, $p$ is permeability value ($cms^{-1}$), A is the effective area of membrane ($cm^2$), $v$ is the volume of aqueous feed phase ($cm^3$) and t is the time (s).

## Results and Discussion

**Mechanism of chromium ions transport across supported liquid membrane**

All stable complexes of hexavalent chromium are anionic species which exist in different forms in the aqueous phase depending on the pH. Under alkaline or neutral condition, chromium predominantly exist as chromate ions ($CrO_4^{2-}$) whereas at slightly acidic condition, hydrochromate ions ($HCrO_4^-$) take place as the dominant species. At very low pH and high total chromium (VI) concentration, the dichromate ion ($Cr_2O_7^{2-}$) predominates [14]. In that case, in this study, chromium ions exist as hydrochromate ions ($HCrO_4^-$) in the feed phase at low initial concentration of Cr (VI) solutions. The mechanism of removal and recovery on the chromium ion is shown in Figure 3. In SLM transport process, the diffusion of chromium ions takes place via the following steps:

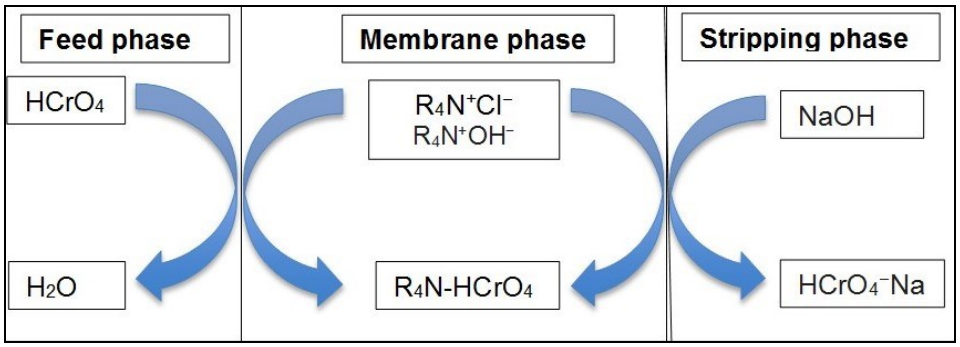

Figure 3. Removal and recovery mechanism of chromium ion by TOMAC

a) The carrier, TOMAC in the membrane phase react with the stripping agent, NaOH at the membrane-internal interface as represented in Equation (5) below:

$$[R_4N^+Cl^-]_{org} + [NaOH]_{aq} \longleftrightarrow [R_4N\text{-}OH]_{org} + [Cl^-]_{aq} + [Na^+]_{aq} \quad (5)$$

b) There are two types of carrier exists in the membrane phase which are $[R_4N^+Cl^-]$ and $[R_4N^+OH^-]$. Therefore, at the feed-membrane interface, hydrochromate ions chemically react with both types of carrier as shown in Equation (6) and (7) below:

$$[HCrO_4^-]_{aq} + [R_4N^+Cl^-]_{org} \longleftrightarrow [R_4N\text{-}HCrO_4]_{org} + [Cl^-]_{aq} \quad (6)$$
$$[HCrO_4^-]_{aq} + [R_4N^+OH^-]_{org} \longleftrightarrow [R_4N\text{-}HCrO_4]_{org} + [OH^-]_{aq} \quad (7)$$

c) The formation of $R_4N\text{-}HCrO_4$ complex diffuse across the membrane phase from feed-membrane interface to the membrane-internal interface reversibly, where the stripping reaction take place with stripping agent, NaOH as shown in Equation (8). The created complex $HCrO_4Na$ is insoluble in the membrane phase and will not diffuse back to the feed phase.

$$[R_4N\text{-}HCrO_4]_{org} + [NaOH]_{aq} \quad [HCrO_4Na]_{org} + [R_4N\text{-}OH]_{aq} \quad (8)$$

**Effect pH of feed phase**

One of the important variables for the removal and recovery performance of Cr(VI) in the supported liquid membrane process is pH of the feed solution. Basically, the stable anion complexes of chromium exist in different form depending on the pH. Figure 4(a) illustrates the effect of various pH on the removal of Cr(VI). The pH was adjusted using sulphuric acid and sodium hydroxide solution for acidic and basic range, respectively. On the other hand, the calculated permeability value at different pH is tabulated in Table 1. Based on the result obtained, the highest removal percentage was observed at pH 2 (89%) with the highest permeability value of 5.91 x $10^{-2}$ $cms^{-1}$. Further increase pH value up to 3, the removal percentage was slightly reduced to 80% with the permeability value of 4.32 x $10^{-2}$ $cms^{-1}$. In fact, at pH 2 and 3 which are acidic medium, hydrochromate ions ($HCrO_4^-$) are more predominant, thus showing the efficiency of TOMAC to chemically react with this type of anions. However, pH 2 which is more acidic, can induce higher ions dissociation from the chromium complexes. This condition will produce more hydrochromate ions in the feed phase and increases the rate formation of the solute-carrier complexes. In that case more chromium ions can be transported through the membrane, thus enhancing the permeation rate. Furthermore, the higher proton concentration also can act as a driving force to encourage the permeation of the chromium ions through the membrane. This is strongly supported by Raut et al. [15] who reported that the acidic feed solution give the high permeability values for strontium transport due to the tendency of ionic complexes formation. Under neutral condition (pH 7), the removal percentage was also high which is 87% with permeability value of 5.83 x $10^{-2}$ $cms^{-1}$. At this stage, chromium predominantly exist as chromate ions ($CrO_4^{2-}$). This anion species requires two carrier for the complexation [16]. So this condition greatly enhances the permeation of chromium ions through the membrane.

At the recovery stage as shown in Figure 4 (b), the percentage of chromium recovery gradually decreased from 98 to 56% upon increasing the pH value from 2 to 7. At acidic range, the difference in the proton concentration gradient between the feed and receiving phases is the driving force for the transportation of chromium ion into the stripping phase. In contrast, at the neutral condition, the presence of ($CrO_4^{2-}$) ions react slowly with TOMAC in the membrane phase with 1:2 mole ratio of Cr: TOMAC as shown through equation (9) below, thus causing the recovery rate to be reduced. Hence, the optimum pH for removal and recovery of chromium achieved at pH 2.

$$CrO_4^{2-} + [R_4N^+Cl^-]_{org} \quad [R_4N\text{-}CrO_4\text{-}NR_4]_{org} + [Cl^-]_{aq} \quad (9)$$

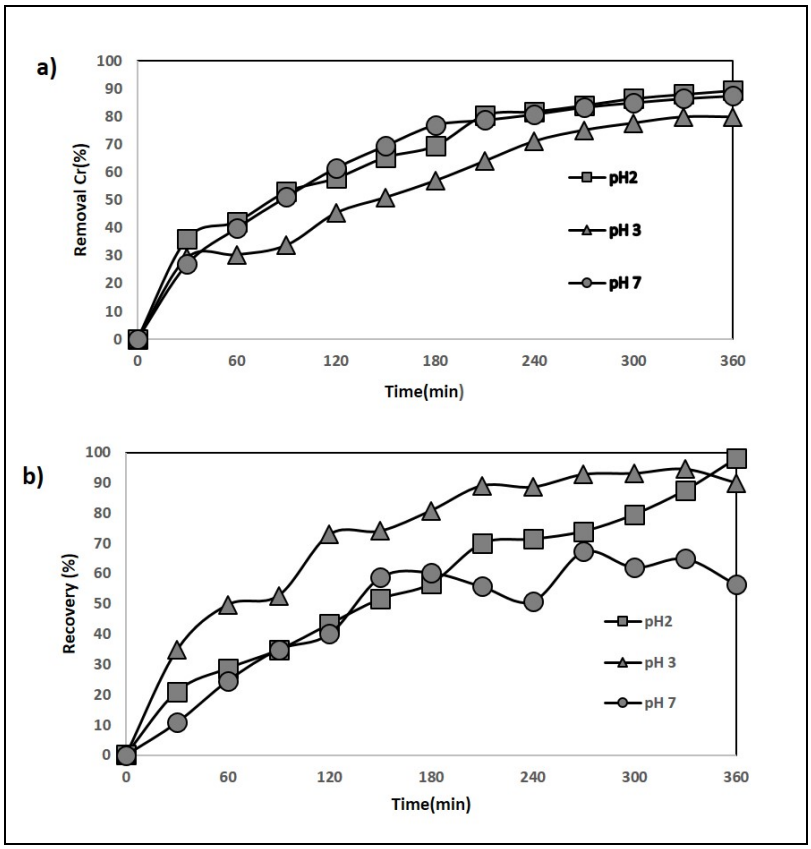

Figure 4. (a) Effect pH of feed phase on the removal of chromium ion (Experimental condition: Feed phase= 150 ppm, TOMAC = 1.0M; NaOH =1.0M, flow rate = 100 ml/min) and (b) Effect pH of feed phase on the recovery of chromium ion (Experimental condition: Feed phase = 150 ppm, TOMAC =1.0M, NaOH = 1.0M, flow rate = 100 ml/min)

Table 1. Permeability coefficient value as a function of pH of feed phase

| Effect pH of Feed Phase | Permeability Value ($P \times 10^{-2}$ , $cms^{-1}$) |
|---|---|
| 2 | 5.91 |
| 3 | 4.32 |
| 7 | 5.83 |

**Effect of carrier concentration**

Figure 5(a) presents the effect of carrier concentration on the removal of chromium ion by varying the TOMAC concentration from 0.5 to 1.5 M. The permeability value as a function of carrier concentration is also shown in Table 2. Basically, the carrier in the liquid membrane phase plays a significant role through complexation with the chromium ions in the feed-membrane interface which reversibly transport them to the internal phase. The results show that the removal percentage of chromium ions increased from 13 to 89% and reached a plateau within 360 min of extraction upon increasing TOMAC concentration from 0.5 to 1.5 M, respectively. Besides, the permeability value also increased from $0.53 \times 10^{-2}$ $cms^{-1}$ to $5.91 \times 10^{-2}$ $cms^{-1}$ with increasing carrier concentration from 0.5 to

1.0 M, respectively. At 0.5 M, the carrier concentration is inadequate to aid the mass transfer of chromium ion through SLM process. Therefore more chromium anion accumulate in the feed-membrane interface without being transported. So this condition increased the mass transport resistance and leads to the low permeation of chromium ions through the membrane phase. In contrast, at higher carrier concentration, there are more available carriers for the formation of solute-carrier complexes, hence enhancing the removal efficiency.

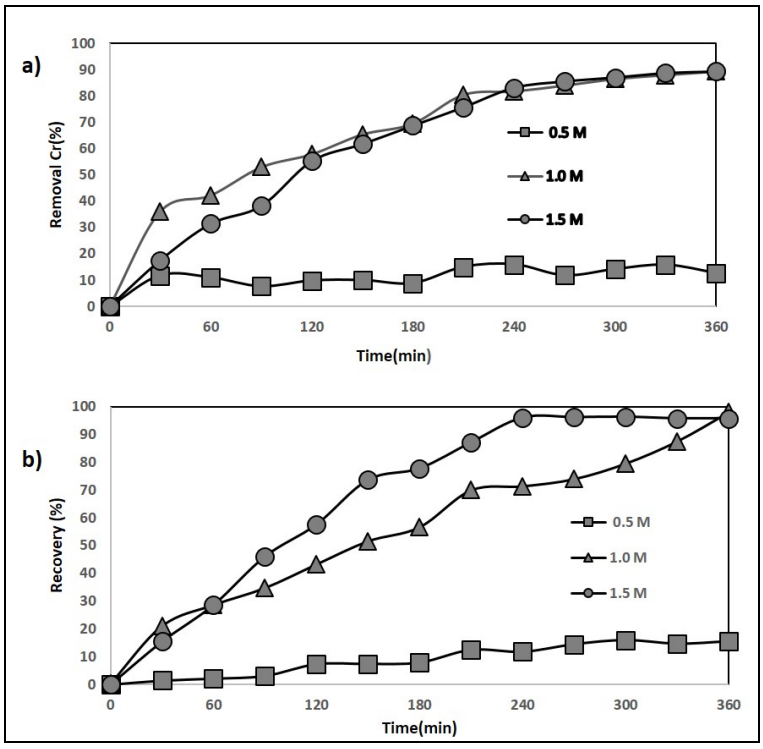

Figure 5. (a) Effect of TOMAC concentration on the removal of chromium ion (Experimental condition: Feed phase = 150 ppm (pH: 2), NaOH = 1.0M, flow rate = 100ml/min) and (b) Effect of TOMAC concentration on the recovery of chromium (Experimental condition: Feed phase = 150 ppm (pH: 2), NaOH = 1.0M, flow rate = 100 ml/min)

Based on the result obtained, 1.0 M TOMAC is adequate for the chromium ion transportation in SLM process with the highest permeability value of 5.91 x $10^{-2}$ $cms^{-1}$. This is strongly supported by Nayl and Aly [17] who reported that 1.0 mol TOMAC required 1.0 mol Cr during the reaction of extraction occur in the membrane phase. Further increase of carrier concentration only cause the excess carrier in the membrane phase which thereby affecting the removal efficiency. This is also in agreement with Kumar et al. [18] who claimed that above the optimal value, the solute transportation decreased because of the extra resistance offered by the excess carrier molecules in the membrane phase. As can be seen, beyond 1.0 M, the permeability value also decreased to 5.74 x $10^{-2}$ $cms^{-1}$. This is due to the viscosity effect caused by the excess carrier concentration which resists the transportation of the chromium ions through the membrane phase. This result is in line with Bey et al. [19] who reported that at certain values of carrier concentrations, the viscosity of the organic phase increases, thus slowing the organic complex diffusion through the pores.

On the other hand, Figure 5(b) displays the recovery result of the Cr(VI) extraction for various carrier concentration from 0.5 to 1.5 M. The maximum recovery was achieved at 1.0 M TOMAC (98%) followed by 1.5 M (96%) and 0.5 M (16%). It indicates that simultaneous extraction and stripping occurred completely during the process. This

means the carrier concentration increased proportionally with the recovery percentage of chromium ion in the stripping phase. The higher carrier concentration means higher opportunity of chromium-carrier complexes to be stripped by stripping agent at the membrane-internal interface, hence leading to the higher recovery percentage. According to Equation (6) and (7), 1 mol of Cr ion needs 1 mol of TOMAC for the complexation, thus 1.0 M TOMAC was enough for the next experiment.

Table 2. Permeability coefficient value as a function of carrier concentration

| Effect of TOMAC Concentration (M) | Permeability Value ($P \times 10^{-2}$, $cms^{-1}$) |
|---|---|
| 0.5 | 0.53 |
| 1.0 | 5.91 |
| 1.5 | 5.74 |

**Effect of stripping agent concentration**

A stripping agent in the receiving phase plays an important role in order to completely strip the solute ion at the membrane-internal interface. Therefore an appropriate stripping agent which can chemically complex with the desired solute ion is necessary to successfully recover the targeted solute. Figure 6(a) depicts the relationship between NaOH concentration and the removal percentage of chromium ions. The permeability result is also presented in Table 3. Based on the result obtained, as increasing NaOH concentration from 0.5 to 1.5 M, the removal efficiency of chromium linearly increased from 80 to 89% and reached plateau. The permeability value also increased proportionally with stripping agent concentration from $4.06 \times 10^{-2}$ $cms^{-1}$ to $5.91 \times 10^{-2}$ $cms^{-1}$ at 0.5 M and 1.0 M, respectively. This can be attributed to the insufficient stripping agent at 0.5 M to strip the chromium ions into the stripping phase. Therefore, more available of chromium-TOMAC complexes are trapped and accumulated in the membrane-strip interface without being stripped which tends to block the transportation of the other complexes through the membrane.

As can be observed, the permeability value at this time is the lowest, which indicates that very low permeation occurred because the membrane phase is clogged with these complexes. Further increase up to 1.0 M NaOH, the highest permeability reached up to $5.91 \times 10^{-2}$ $cms^{-1}$. At this state, more available NaOH appeared in the membrane-strip interface, thereby enhancing the transportation of more chromium ions through the membrane phase. This is in line with Alguacil et al. [20] who reported that the overall permeation coefficient of Cr(VI) increases with the concentration of stripping agent. However, beyond 1.0 M, the permeability value slightly decreased to $5.11 \times 10^{-2}$ $cms^{-1}$. Based on the transport mechanism shown in Figure 3, the counter transport also occurred where the $OH^-$ ion from stripping phase also acts as a driving force by complexation with the carrier in the membrane- strip interface to aid the permeation of chromium ions through SLM process. Therefore at excess NaOH concentration, the driving force from the stripping phase only become saturated. At this condition, the number of chromium ion which permeate through the membrane phase seems to reduce as about 100% of chromium ions were already transported to the stripping phase at 1.0 M NaOH. Besides, a higher concentration of NaOH will lead to the higher ionic strength which thereby causing the inefficiency of the recovery process.

Venkatesan and Palanivelu [21] also reported that the degree of extraction remains constant afterwards as the stripping agent concentration achieved the maximum rate. This is due to the saturation of the driving force for diffusion through the SLM owing to an increase of metal complexes concentration at the membrane-internal interface. So, 0.5 M NaOH concentration is adequate for the chromium extraction. Besides, Figure 6(b) shows the recovery result at 0.5 M NaOH concentration is higher than 1.0 M. This means that the stripping reaction occurs very fast at the membrane-internal interface. Thus 0.5 M of NaOH concentration is adequate in achieve a high recovery rate of chromium.

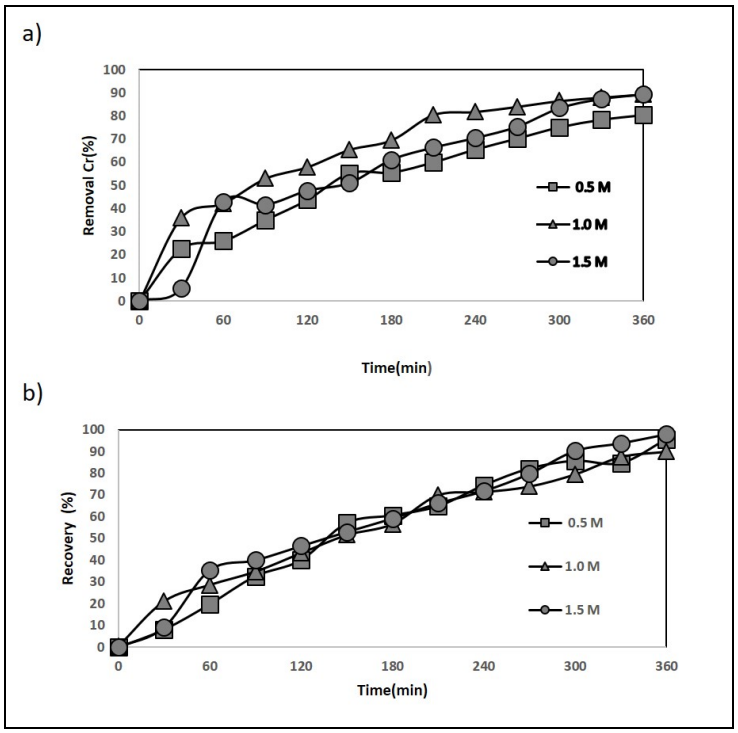

Figure 6. (a) Effect of NaOH concentration on the removal of chromium ion (Experimental condition: Feed phase = 150 ppm (pH: 2), TOMAC = 1.0M, flow rate = 100 ml/min) and (b) Effect of NaOH concentration on the recovery of chromium ion (Experimental condition: Feed phase = 150 ppm (pH: 2), TOMAC = 1.0M, flow rate = 100)

Table 3. Permeability coefficient value as a function of stripping agent concentration

| **Effect of NaOH Concentration (M)** | **Permeability Value ($P \times 10^{-2}$ , $cms^{-1}$)** |
|---|---|
| 0.5 | 4.06 |
| 1.0 | 5.91 |
| 1.5 | 5.11 |

## Conclusion

In conclusion, the extraction of Cr(VI) was successfully performed in SLM process using TOMAC as a carrier and NaOH as a stripping agent. TOMAC and NaOH can act as an excellent carrier and stripping agent for the removal and recovery of chromium ion. At pH 2 of feed phase with 1.0 M TOMAC and 0.5 M NaOH, about 90 and 98% of chromium can be successfully removed and recovered, respectively using a supported liquid membrane process.

**Abstract**

Various Endocrine Disrupting Compounds (EDCs) either natural or synthetics have been identified including bisphenol A (BPA), dioxin, polychlorinated biphenyls, and dichlorodiphenyltrichloroethane (DDT). These compounds which present widely in the product of solvent industry, agricultural, pharmaceuticals and household convenience may directly or indirectly interrupt the normal function of endocrine system. Recently, the EDCs threats to human health have led to the increasing demand of clean water sources which excites a challenge for the contaminants removal processes. Conventional treatment methods may not completely remove the contaminants, meanwhile advanced oxidation process (AOPs) especially photocatalysis have been proven efficient in removing the contaminants. Even though photocatalysis is efficient in suspension of either nano- or microscale, the immobilizing $TiO_2$ in the membrane matrix for catalyst separation purposes have decreased the adsorption of organic substances on the $TiO_2$ surface with potential loss of $TiO_2$ during long-time usage. This lead to the emerging in the exploration and fabrication of dual layer hollow fiber (DLHF) membrane for better performance of immobilized $TiO_2$. Therefore, we exploit this fact to investigate the incorporation of photocatalysis into dual-layer hollow fiber membrane which are believed may improve the photocatalytic degradation and separation efficiency. The FESEM results showed that both layers are compatible with each other and there are no delamination found between layers. The presence of outer layer does not influence the surface roughness; however improve the hydrophilicity and membrane strength. Altogether, photocatalytic dual layer hollow fiber (DLHF) membrane was successfully fabricated using co-extrusion technique.

**Keywords:** dual layer, hollow fiber, $TiO_2$, photocatalytic

**Abstrak**

Pelbagai sebatian pengganggu endokrin sama ada semula jadi atau buatan telah dikenalpasti termasuk bisphenol A (BPA), dioxin, polychlorinated biphenyls, dan dichlorodiphenyltrichloroethane (DDT). Sebatian ini yang wujud secara meluas di dalam produk industri pelarut, pertanian, farmaseutikal, dan keperluan rumah mampu menggangu secara lansung atau tidak langsung fungsi normal sistem endokrin. Baru-baru ini, ancaman sebatian pengganggu endokrin kepada kesihatan manusia telah membawa kepada peningkatan permintaan sumber air bersih yang merangsang satu cabaran bagi proses penyingkiran bahan pencemaran.. Kaedah rawatan konvensional mungkin tidak membuang bahan pencemaran dengan sepenuhnya, tetapi proses pengoksidaan maju (AOP) terutama fotopemangkinan telah terbukti berkesan dalam menyingkirkan bahan pencemaran. Walaupun fotopemangkinan cekap dalam skala nano atau skala hablur pemangkin, immobilisasi $TiO_2$ ke dalam matriks membran untuk

tujuan pemisahan pemangkin telah mengurangkan penyerapan bahan pencemar di permukaan $TiO_2$ dengan potensi kerugian $TiO_2$ untuk penggunaan yang lama. Ini membawa kepada penerokaan dan fabrikasi dwi lapisan gentian berongga (DLHF) membran untuk prestasi immobilisasi $TiO_2$ yang lebih baik. Oleh itu, kami mengeksploitasi fakta ini untuk menyiasat penubuhan fotopemangkinan ke dalam dwi-lapisan membran gentian berongga yang dipercayai boleh meningkatkan kecekapan fotopemangkin dalam proses degradasi dan pemisahan bahan pencemar. Keputusan FESEM menunjukkan bahawa kedua-dua lapisan serasi dengan satu sama lain dan tidak ada delaminasi di antara dua lapisan. Kehadiran lapisan luar tidak mempengaruhi kekasaran permukaan; bagaimanapun meningkatkan sifat hidrofilik dan membran kekuatan. Secara keseluruhan, dwi lapisan membran gentian berongga telah berjaya direka menggunakan teknik penyemperitan bersama.

**Kata kunci:** dwi lapisan, gentian berongga, $TiO_2$, fotopemangkin

## Introduction

Endocrine system plays a vital role in the in the regulation of hormone and body homeostasis, hence slight interruption in their normal behavior by exogenous chemicals may ruin the entire system [1]. Therefore, endocrine disrupting compounds (EDCs) can be defined as exogenous chemicals that may directly or indirectly interrupt the normal function of endocrine system functions [2]. These contaminants either natural or synthetics [3] are detectable in the product of industry, agricultural, pharmaceuticals and household convenience [4]. Various EDCs have been identified including bisphenol A (BPA) [5], dioxin, polychlorinated biphenyls, dichlorodiphenyltrichloroethane (DDT) [6] and many more. Since decades ago, the presence of EDCs in household water has become major concerns among public. In addition, some EDCs including BPA have long half-lives as they are designed to improve the product usage however, they are not easily biodegradables, thus turn out to pose a threat to wildlife and humans [7]. These threats have led to the increasing demand of clean water sources which excites a challenge for the contaminants removal processes. Conventional treatment methods such as membrane filtration, adsorption and bioreactor based membrane and bioreactors may not completely remove the contaminants, meanwhile advance treatment options, including ultraviolet (UV) irradiation, hybrid system and advanced oxidation process (AOPs) have been proven efficient in removing the contaminants. Advanced oxidation processes, photocatalysis can be widely defined as photochemical reaction accelerated by the presence of a catalyst [8]. In particular, photocatalysis have been used for such significant applications such as production of renewable fuels, disinfection of water and air, mineralization of organic contaminants, and synthesis of organic compounds [2]. Heterogeneous photocatalysis accelerated by semi-conductor metal oxides is a fast-growing field and identified as a promising tool for water treatment [9] where organic contaminants are shown to be degraded up to 90% under suspension of semi-conductor photocatalytic operation [10].

Several semiconductors such as Titanium Oxide ($TiO_2$), Zinc Oxide (ZnO), Ferric Oxide ($Fe_2O_3$), Cadmium Sulfide (CdS), and Zinc Sulfide (ZnS) can act as photocatalysts [11], however among many candidates; $TiO_2$ is the most suitable material use at present due to its impressive photoactivity [12]. More significantly, $TiO_2$ exhibit strong oxidizing ability and high stability properties in addition to the lowest cost of operation [13]. Even though photocatalysis is efficient in suspension of either nano- or microscale $TiO_2$ catalyst particles in a photocatalytic reaction, the separation of the $TiO_2$ particles is a major problem that always limits the application of these photocatalytic processes for treating the contaminants. Immobilizing $TiO_2$ in the membrane matrix is thought to solve the separation problem; however this method decreased the adsorption of organic substances on the $TiO_2$ surface with potential loss of $TiO_2$ during long-time usage [14]. This lead to the emerging in the exploration and fabrication of dual layer hollow fiber (DLHF) membrane for better performance of immobilized $TiO_2$.

A series of studies have revealed the use of polymeric dual-layer hollow fiber membranes for various applications, such as gas separation [15], forward osmosis (FO) [16], protein and liquid separation [17] as well as nanofiltration (NF) [18]. Compared to the single layer hollow fiber (SLHF) membrane, dual layer hollow fiber membrane are much more attractive because it significantly saves materials cost, less complex post treatment process and better membrane performance. Recently, polyvinylidene fluoride (PVDF) has been widely used as both outer and inner layer membrane material as they are recognized to have excellent resistance to corrosive chemicals, powerful mechanical strength, good thermal stability and ease of processing ability with common organic solvents [19]. Meanwhile the incorporation of an additive into polymer membrane is shown to increase the membrane pore size and porosity [20]. In this regard, the outer layer of dual layer hollow fiber membrane immobilized with $TiO_2$ will

provide reaction site for the photocatalytic degradation in the presence of UV light, while the inner membrane layer will act as separation layer. Therefore, the photocatalytic degradation process may be performed in a system in which reaction and separation processes occur simultaneous. In addition, high $TiO_2$ is expected to speed up the processes.

To date, no studies have been reported on the degradation of EDCs by photocatalytic dual-layer hollow fibre membrane reactions. Hence, the present study is conducted to investigate the incorporation of $TiO_2$ photocatalysis into dual-layer hollow fiber membrane to improve the photocatalytic degradation efficiency.

## Materials and Methods

The fabrications of dual layer hollow fiber membranes consist of polymer dope preparation and dry-wet spinning method, followed by qualitative and quantitative examination of the membrane morphology and properties.

### Materials

Polyvinylidene fluoride (PVDF, Kynar 760 Series-powder, Solvay Specialty Polymers France) was used as polymer based without purification. A titanium dioxide ($TiO_2$ P25) nanoparticle was supply by Evonik GmbH, Germany. Polyethelene Glycole (PEG) 6000 was purchased from FLUKA. Dimethylacetamide (DMAC, QReC) was used as solvent to dissolve polymer without further purification.

### Preparation of dope solution

PVDF, PEG and $TiO_2$ were dried in a 50 $^{\circ}$C vacuum oven for 24 hours to remove moisture prior to dope preparation. The, PEG/$TiO_2$ and DMAc at desired amount were added in Scott bottle with an overhead stirrer. After the PEG/$TiO_2$ mixture became a homogeneous solution, the desired amounts of PVDF were added to the solution. The detailed compositions of the polymer dope solutions and spinning condition are shown in Table 1. The viscosity of the polymer dope solutions were measured using viscometer.

Table 1. Dope composition and spinning conditions of the hollow fiber membranes.

| | **Dual layer (DL)** | **Single Layer (SL)** |
|---|---|---|
| Outer dope composition (wt.%) | PVDF/$TiO_2$/DMAc (15/3/82) | - |
| Outer dope flow rate (ml/min) | 2 | - |
| Inner dope composition (wt.%) | PVDF/PEG/DMAc (18/5/77) | PVDF/$TiO_2$/DMAc (15/3/82) |
| Inner dope flow rate (ml/min) | 8 | 8 |
| Bore fluid | Distilled water | Distilled water |
| Bore fluid flow rate (ml/min) | 8 | 8 |
| Air gap (cm) | 10 | 10 |
| Take up speed (Hertz) | 1.3 | 1.3 |
| Spinneret dimension (mm) | 0.8/1.2/2.6/3.0/3.5 | 0.8/1.2/2.6 |

Then, the dope solutions were cooled down to room temperature, followed by degassed using ultrasonic bath system at ambient temperature overnight prior to spinning. Both SLHF and DLHF membranes were fabricated using dry/wet phase inversion spinning technique (Figure 1).

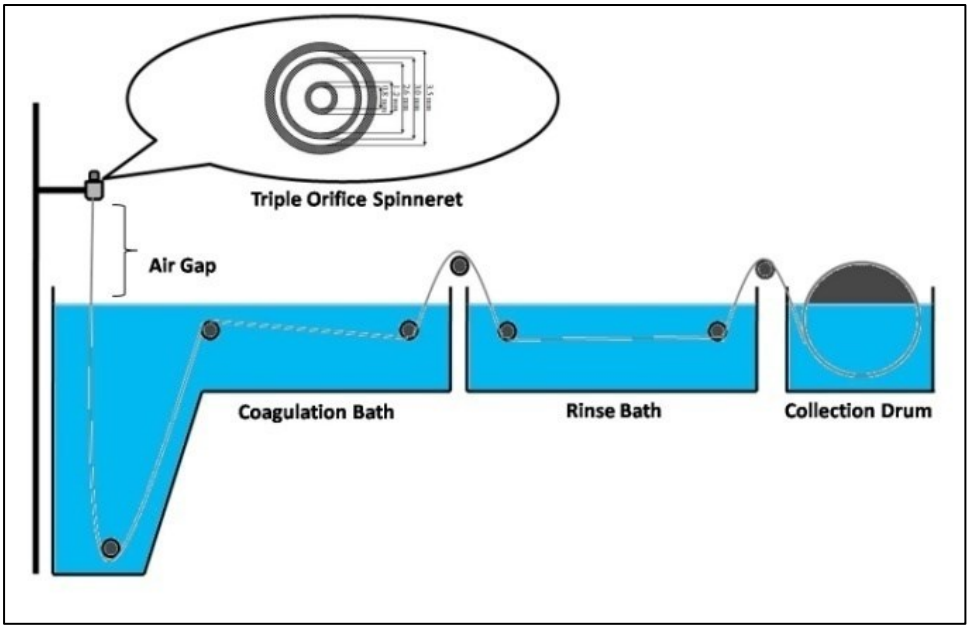

Figure 1. Dual layer hollow fiber spinning method

The dope solution was transferred into dope reservoir syringe pump followed by the dope extrusion using a triple orifice spinneret. Prior to drying, the as-spun membrane fibers were immersed into water bath for 1 day to remove residual solvent. Then, 50 pieces of 30 cm length of as-spun fiber segments were put together to form a bundle. Four to six bundles were sent to post treatment in one batch using ethanol: water, 50:50 wt.% for 1 hour followed by 100% of ethanol for another 1 hour in order to improve the membrane wet ability and pore collapse. Finally, the fibers bundles were dried at room temperature for 3 days.

**Characterization of the dual layer hollow fiber membrane**

The morphological nature of both DLHF and SLHF were explored qualitatively with the help of Field Emission Scanning Electron Microscopy (FESEM; Model: SU2080, Hitachi). The $TiO_2$ nanoparticle distribution on top surface of the tested composite membrane was investigated using the line scan of spectrum of Energy Dispersion of X-ray (EDX; Model: X-MaxN 51-XMX1011, Oxford Instrument). Prior to positioned on a metal holder, both DLHF and SLHF were immersed in liquid nitrogen for 1 min and then fractured into short samples to expose their cross sectional characteristics. The samples then were sputter coated with gold under vacuum approximately for 3 min. The cross section and surface DLHF and SLHF were examined at various magnifications. The distribution of $TiO_2$ nanoparticles on both DLHF and SLHF membrane surface were scan randomly by EDX.

The membrane surface roughness was determined using Atomic Force Microscopy (AFM; Model: SE-100, Park System). DLHF and SLHF samples were cut into pieces of 3 cm by 5 cm and areas of 20 µm x 20 µm of sample were scanned by tapping mode.

Contact angle measurements were conducted using the contact angle goniometer (Model: OCA 15EC, Dataphysic). 2µL of deionized water as contact liquid was dropped on the fiber surface and the measurements were obtained at different points of each sample.

The measurement of tensile strength of the hollow fibers was established by LRX, LLYOD test machine. At least six fibres with 50 mm length were tested with a load cell of 2.5 kN, at a constant elongation velocity of 10 mm/m at room temperature and the average data were taken for each sample. Tensile strength were determined by using the following equation (1) (IPC-TM-650):

$$\text{Tensile strength (Pa)} = \frac{\text{Load at break(N)}}{\text{Cross sectional area (m}^2\text{)}} \quad (1)$$

The membrane porosity, ε was measured using dry-wet weight method. The membrane was soaked in pure water for 3 hours, and then was weighed after absorption of the pure water. The membrane then was dried by filter paper before weighed again to obtain their dry weight. The porosity of membrane was calculated by using the following equation (2):

$$\varepsilon = \frac{w1-w2}{V\rho w} \times 100\% \quad (2)$$

where ε is the porosity of the membrane (%), *w1* is the mass of the wet membrane, *w2* is the mass of the dry membrane, *V* is the volume of the membrane and *ρw* is the density of water (1.0 g/cm$^3$).

## Results and Discussion

Figure 2 shows representative FESEM images of the dual layer and single layer $TiO_2$/PVDF hollow fiber membrane. As shown in the Figure 2 (a2), the finger like structure developed at the outer and inner layer, whereas the sponge like structure developed at the intermediate layer. Porous structure was achieved with the addition of the pore former, PEG 6000 into the DLHF inner layer dope solution. As shown in the Figure 2 (a2), the resultant DLHF have large macrovoids and porous inner layer membrane. This finding is in an agreement with previously reported study where they reported the formation of a macrovoids and a large area of sponge-like structure in their membrane [21]. Both layers are compatible with each other and there are no delamination and interfacial resistance when PVDF was used for both inner and outer layer dopes.

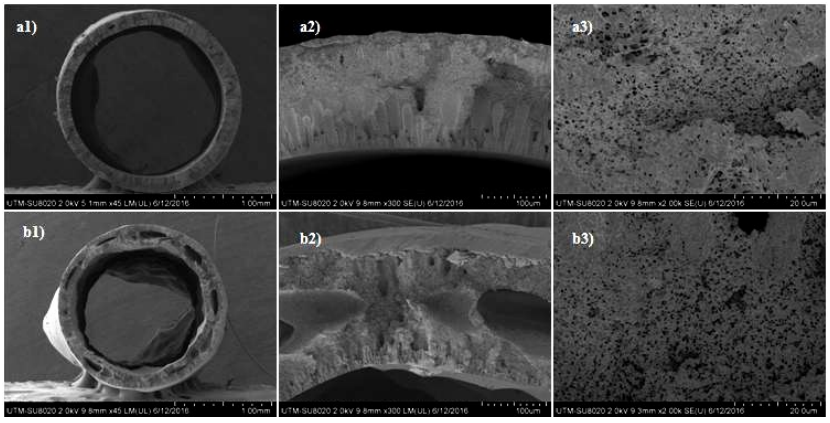

Figure 2. Cross-sectional and partial cross section FE-SEM images of the dual layer and single layer $TiO_2$/PVDF hollow fiber membrane for (a) DLHF and (b) SLHF

It is expected that the mutual diffusion of polymers was established between the inner and outer layers, thus two distinct layers cannot be observed. Hence, the estimation of outer layer thickness of DLHF membranes was performed by the distribution of $TiO_2$ nanoparticles in the outer layer as shown in the Figure 3 (a4). EDX analysis show that there is less diffusion of $TiO_2$ particles into the inner layer of DLHF membrane as compared to SLHF membrane. It is believed that the particles might have distributed evenly over the DLHF outer membrane surface. Even though SLHF showed higher $TiO_2$ loading, the $TiO_2$ nanoparticles are entrapped in the membrane matrix. Therefore, they might not be fully utilized for their photocatalytic properties due to the limit penetration of the light source through thick membrane layer. Hence, higher $TiO_2$ loading in SLHF are wasted as compared to the lower $TiO_2$ loading on the membrane surface of DLHF.

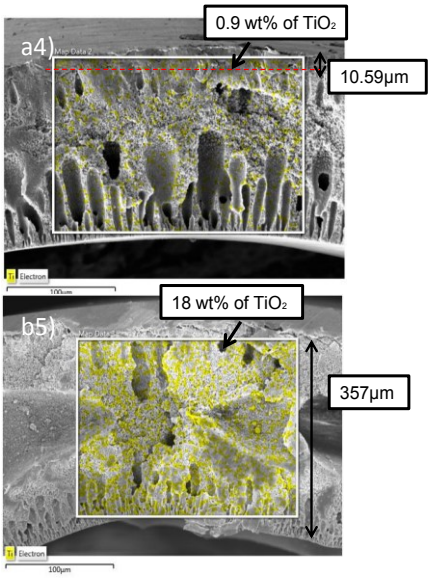

Figure 3. The EDX mapping of TiO2 distribution in DLHF (a4) and SLHF (b5) membrane layer

Figure 4 present the FESEM images of the outer surface of the DLHF and SLHF membranes. As can be seen, the $TiO_2$ nanoparticles were uniformly distributed on both configurations of the membrane surfaces. The surface of both membranes is composed of a microporous structure with relatively large pores as determined by AFM analysis.

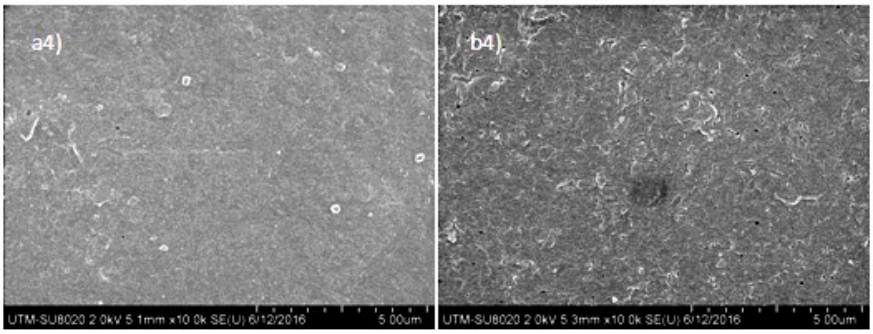

Figure 4. Surface FE-SEM images of the dual layer and single layer TiO2/PVDF hollow fiber membrane for (a) DLHF and (b) SLHF

Figure 5 shows the three dimensional AFM images and surface roughness (Ra) of the DLHF and SLHF $TiO_2$/PVDF membranes. The AFM images clearly show that the membrane surface roughness of both configurations has no significant difference because the $TiO_2$ particles loading in the dope solutions are equal. The surface roughness was strongly dependent on the $TiO_2$ loading and distribution of $TiO_2$ on the membrane surface. The Ra value of DLHF and SLHF membranes were 41.550 and 40.934 nm, respectively.

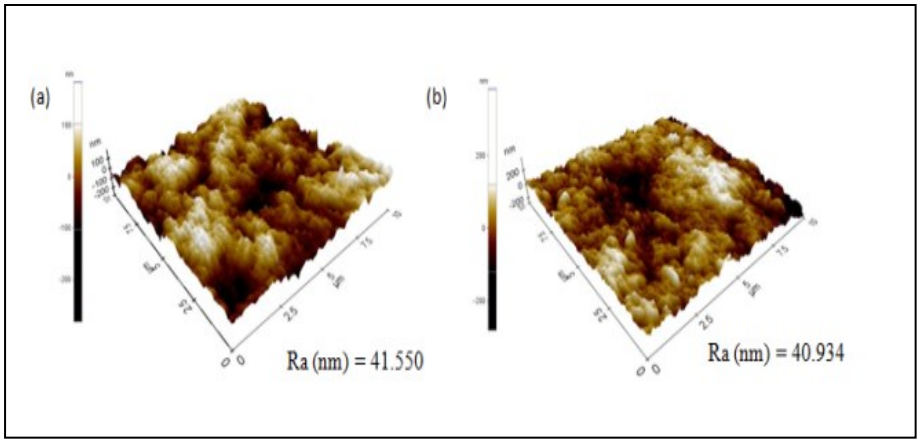

Figure 5. Surface roughness image of outer surface of (a) DLHF and (b) SHLF TiO2 /PVDF hollow fiber membranes

Table 2 summarizes the results of the tensile strength, elongation at break, contact angle, pure water flux, rejection, porosity and pore size of the membranes of both configurations. The tensile strength and elongation at break of the DLHF membranes was higher than SLHF membranes. This is because the presence of the outer layer of DLHF membranes has strengthened its structure. DLHF is more hydrophilic than SLHF. It could be observed from contact angle analysis as listed in Table 2. This finding is accordingly with the findings reported by Dzinun et al. [22]. The presence of hydrophilic nature of $TiO_2$ particle at the outer layer of the DLHF membranes has successfully improved the hydrophilicity of the membrane, which higher affinity towards water is better for water-related separation process. In addition, uniform distribution of $TiO_2$ particles at the outer layer surface will improved photocatalytic reaction site too. Therefore, the degradation and separation of EDCs are promisingly efficient.

Table 2. Performance of hollow fiber membranes with different configuration

| **Configuration** | **Tensile Strength (Mpa)** | **Elongation at Break (%)** | **Contact Angle (°)** | **Porosity** |
|---|---|---|---|---|
| Dual Layer Hallow Fiber (DLHF) | 15.87 ± 0.52 | 90.33 ± 13.81 | 64.60 | 2.081 ± 1.009 |
| Single Layer Hallow Fiber (SLHF) | 11.14 ± 0.35 | 59.95 ± 2.21 | 79.32 | 1.509 ± 0.262 |

## Conclusion

Dual layer hollow fiber membranes have successfully fabricated by single step co-extrusion techniques. The obtained dual layer hollow fiber membranes consists of sandwich-like structure where finger-like voids formed from the inner and the outer surface of membrane and separated by sponge-like structure at the middle of the membranes cross-section. The incorporation of $TiO_2$ nanoparticles into the outer membrane layers has increased their hydrophilicity, thus suggesting that the photocatalytic DLHF membranes also have a good separation potential in water-related processes. It is interesting to note that the co-extrusion technique is capable to produce a DLHF membrane with uniformly distributed high loading of $TiO_2$ particles at the outer layer surface which might highly efficient for photocatalytic degradation of EDCs. However, the investigation of photocatalytic reactions are needed in the future works to justify their degradation capability.

**Abstract**

Graphene oxide sulfonated polyether ether ketone (GO-SPEEK) is a promising proton exchange membrane (PEM) to replace the commercial PEM in Direct Methanol Fuel Cell (DMFC) application. The GO films were prepared from natural graphite flakes by the modified Hummer's Method. The structure and physicochemical characterization techniques were applied to impart insight into the specific structure, element composition as well as the functional groups by using Attenuated Total Reflection infrared spectroscopy (ATR), X-Ray diffraction (XRD), and Raman Spectroscopy. The incorporation of graphene oxide in SPEEK not only improved membrane behaviors of PEM in terms of ion exchange capacity (1.231 mequiv.g$^{-1}$), water uptake (53.45%) and proton conductivity (0.0537), but also positively blocking of methanol molecules passing through membrane, thus making them appealing as proton exchange membranes (PEMs).

**Keywords**: graphene oxide, sulfonated polyether ether ketone, proton exchange membrane, X-ray diffraction

**Abstrak**

Grafin oksida sulfona polieter eter keton (GO-SPEEK) merupakan proton pertukaran membran (PEM) yang menjanjikan pengantian PEM komersial dalam aplikasi sel bahan api metanol langsung (DMFC). Filem GO dihasilkan daripada grafit semulajadi menggunakan kaedah Hummer diubahsuai. Teknik – teknik pencirian struktur fizikal dan kimia telah digunakan untuk mendapatkan maklumat tentang struktur spesifik, komposisi elemen dan juga kumpulan berfungsi dengan menggunakan ATR spektroskopi inframerah, pembelauan sinar-X (XRD), dan spektroskopi Raman. Penambahan grafin oksida kedalam sulfona poli (eter eter keton) bukan sahaja meningkatkan prestasi PEM dari aspek kapasiti pertukaran ion (1.231 mequiv.g$^{-1}$), pengambilan air (53.45%) dan kekonduksian proton (0.0537), tetapi juga mampu untuk menahan molekul metanol dari merentasi membran, sekaligus menjadikannya sangat sesuai sebagai PEM.

**Kata kunci:** grafin oksida, polieter eter keton tersulfon, proton pertukaran membran, pembelauan sinar-X

## Introduction

Fuel cells are electrochemical devices that manage to directly convert chemical energy into electrical energy. Thus, it offers a promising alternative to conventional fossil fuel systems, due to their high efficiency, environmental

friendly and flexible application. Among them, proton exchange membrane fuel cell (PEMFC) has been gaining much attention due to its low system complexity, with high power density.

The proton exchange membrane (PEM), a thin membrane plays a crucial role in the performance of PEMFC as it is the heart of the PEMFC system enables fuel cells to conduct its electron by attracting the protons, and enabling them to diffuse through the layer, while maintaining their proton state. One of the most common and commercially available PEMs is the Dupont's Nafion® due to their high proton conductivity and chemical stability. However, the performance efficiency and application has been greatly hindered by several challenges such as high cost, methanol crossover and loss of conductivity above 80 °C in DMFC [1].

To overcome these issues, many studies have been conducted to develop affordable PEM with low methanol permeability for DMFC applications [2 – 4]. Sulfonated poly (ether ether ketone)(SPEEK), the most influential sulfonated aromatic polymer, is widely considered as a promising polymer electrolyte for proton exchange membrane fuel cells (PEMFC) as it offers adequate proton conductivity with low cost of production [5].

## Materials and Methods

The materials used in the experiments were included of commercial graphite powder (60–85%) supplied by Superior Graphite Co. while hydrochloric acid (HCl, 37%), sodium hydroxide (NaOH), sodium nitrate ($NaNO_3$) and sulfuric acid ($H_2SO_4$, 95 – 97%) were from Merck. Potassium permanganate ($KMnO_4$, 99%) was purchased from Bendosen. Hydrogen peroxide ($H_2O_2$, 35%). All materials were used as received. Distilled water was used throughout this study.

### Preparation of graphene oxide films

In order to prepare graphene oxide (GO), natural graphite powders and $NaNO_3$ are added slowly into the concentrated $H_2SO_4$ in ice bath with constant stirring for 45 min. Then, $KMnO_4$ (6 g) is added slowly to the solution and ensured the mixture temperature not exceeding 5 °C. The mixture then kept stirred for 1 hour before removing the ice bath. At intermediate temperature stage (35 – 37 °C) the mixture was stirred for 1 hour until it became pasty brownish. The reaction was continued with addition of distilled water (115 mL) resulting in sudden increases of temperature which was maintained at 90 °C for 15 min. Finally, the oxidation reaction was terminated by the addition of distilled water (350 mL) and $H_2O_2$ (30%, 10 mL). The mixture then left overnight with agitation to ensure its homogeneity followed by washing with HCl for several times. After that, the yield will be washed with distilled water several times and sonicated for 30 min in order to obtain the GO solution. The dry form of GO was obtained after drying for 24 hours in the oven [6, 7].

### Preparation of SPEEK and GO-SPEEK

For preparation of proton exchange membrane (PEM), 10 wt.% of SPEEK solution was prepared by dissolving SPEEK in DMSO. An amount 0.1 g of GO were added into DMSO and stirred for 3 hours to produce homogeneous solution. This solution then added into SPEEK solution, and the mixture was vigorously stirred for 24 hours at room temperature in order to produce homogeneous solution. The mixture then heated to 100 °C to evaporate the DMSO solvent. This preparation method was known as solution intercalation method. The solution then was cast on a glass plate with casting knife to form a solution film. The resultant film then dried in oven for 24 hours at 70 °C. The membrane was further dried for 6 hours at 100 °C to completely remove residual solvent. Finally, the membrane was treated with 1 M sulfuric acid solution for 24 hours at room temperature and subsequently rinsed with water several times in order to remove the remaining acid [8].

### Characterization of GO and hybrid nanomaterial

In order to characterize GO and PEM, the samples were examined by Perkin Elmer Spectrum One ATR in the mid IR region. The morphology of samples was determined by Field-Emission Scanning Electron Microscope (FESEM) model Hitachi SU8020. All X-ray diffraction (XRD) spectra of GO and PEM were scanned by Bruker Advance D8 Siemens 500 diffractometer, using Cu Kα radiation ($\lambda$ = 0.15418 nm, 40 kV, 40 mA). The scanning rate is 1 s with interval of 0.05°, 2θ range of 20° – 80° in the ambient temperature. Raman spectra were recorded from 200 to 2000 $cm^{-1}$ on a Reninshaw Via-Reflex Concoal Raman Microprobe of England using a 532 nm excitation.

Liquid uptake measurement is a technique to study the swelling behavior of SPEEK and GO-SPEEK membrane. The membranes will be dried in oven at 60 °C for 48 hours. The films will be initially weighted before soaking in deionized water for overnight at room temperature, and then will be blotted dry with adsorbent paper to remove any surface moisture. It then will be reweighted. The water uptake will be calculated as follows (equation 1):

$$\text{Water Uptake} = (W_w - W_d)/ W_d \times 100 \quad (1)$$

where $W_w$ and $W_d$ are the weights of the wet membrane and the dry membrane, respectively.

The proton conductivity was measured by impedance spectroscopy over a frequency range of 1 Hz to 107 Hz with 50 mV to 500 mV oscillating voltage, using solatron 1260 gain phase analyzer. The ion exchange capacity (IEC) of the membranes was measured with the titration technique. GO-SPEEK and Nafion were soaked in a large volume of 0.1 mol $L^{-1}$ HCl solution, washed with distilled water to remove excess HCl and then immersed in 1 M sodium chloride (NaCl) aqueous solution to release protons from the membrane. The released $H^+$ was back titrated with a 0.01 M sodium hydroxide (NaOH) aqueous solution using phenolphthalein as an indicator. The IEC value (in meq.$g^{-1}$), which is defined as milli equivalents (meq.) of sulfonic groups per gram of dried sample is obtained from the following equation 2:

$$IEC = V_{NaOH} \times C_{NaOH}/W_{dry} \quad (2)$$

where $V_{NaOH}$ is the volume of NaOH consumed, $C_{NaOH}$ is the concentration of NaOH and $W_{dry}$ is the weight of the dry membrane (g) [9].

The methanol permeability of membrane was measured using permeation cell composed of two reservoirs, each with a capacity of 50 ml. Before the test, the membranes were prehydrated for at least 24 hours. Each reservoir was separated by membrane. One reservoir was filled with a 1 M methanol solution, and deionized water was placed in the other reservoir. Both compartments were stirred continuously with a magnetic stirrer during the permeability experiment. The methanol permeability was found using this equation 3:

$$C_B(t) = A/V_B \times (DK/L)\, C_A (t - t_o) \quad (3)$$

where $C_A$ and $C_B$ are the concentrations of methanol in the donor and receptor reservoirs. A and L are the diffusion area and thickness of the membrane, respectively. The product of D and K is the methanol permeability ($cm^2s^{-1}$).

## Results and Discussion

### Attenuated total reflection infrared spectrometer

The availability of functional groups in GO and the chemical interactions between the functional groups of GO and SPEEK were examined by ATR spectroscopy. Figure 1 depicted the spectra of GO and GO-SPEEK. The spectrum of GO illustrates a strong and broad absorption in the range of 3700 – 2000 $cm^{-1}$ can be assigned to the stretching vibrations of structural OH groups and physisorbed water molecules. The band at 1716.8 $cm^{-1}$ can be ascribed to the C=O stretching vibration of COOH groups, and the absorptions arising from the O-H bending vibration, epoxide groups and skeletal ring vibrations are observed at 1619.08 $cm^{-1}$. The peaks at 1389.89 $cm^{-1}$ represent the O-H deformation vibration of COOH groups and can be used to evaluate the amount of COOH groups. The appearance of absorption at 1233.6 $cm^{-1}$ is related to phenolic groups. The 1044.72 $cm^{-1}$ is assigned to C-O-C stretching vibrations which confirm the presence of epoxide group in GO layers. For GO-SPEEK spectra, the presence of sulfonic acid group in SPEEK was confirmed by the strong characteristic peaks at 1219.72, 1081.93 and 1024.82 $cm^{-1}$, were assigned to the symmetric and asymmetric O=S=O stretching vibrations, as their intensities with respect to the backbone carbonyl (C=O) band at 1641.32 $cm^{-1}$.The broad peak appearing at 3412 $cm^{-1}$ assigned to O-H vibration double confirmed the presence of sulfonic acid groups in SPEEK samples, which interacting with molecular water [10].

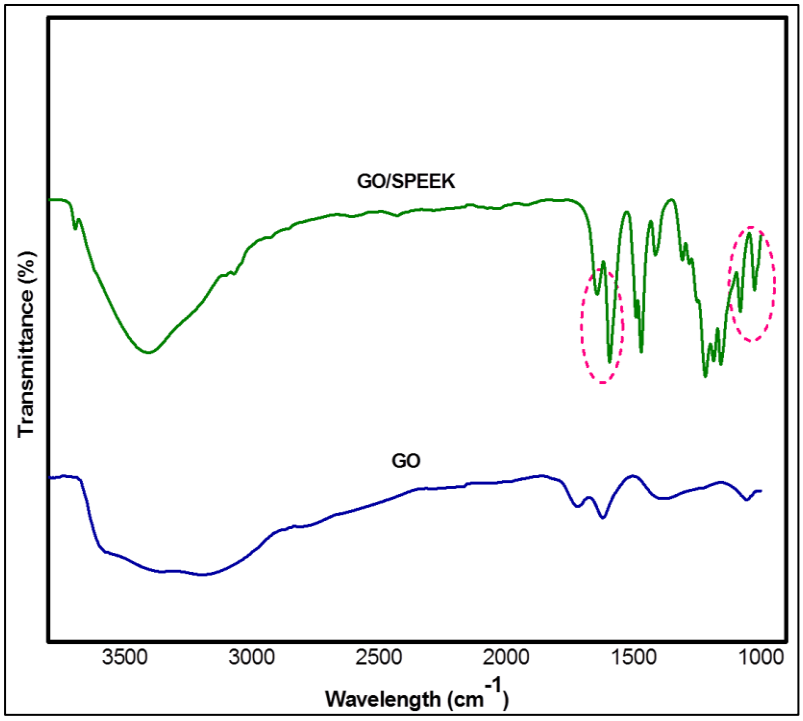

Figure 1. ATR spectra of GO and GO-SPEEK

**Raman spectroscopy**

Typical Raman spectra of pristine graphite, GO and GO-SPEEK obtained at an excitation wavelength of 532 nm are shown in Figure 2. Graphite shows a single sharp peak G band at ~1581 $cm^{-1}$, which corresponds to the vibration of $sp^2$ network, and low intensity of D band indicates defects existed in the graphite edges at 1354 $cm^{-1}$. In Raman spectra, the oxidation of graphite can be manifested by the changes in the relative intensity of two main D and G peaks. In comparison with graphite, GO exhibits a broader and blue-shifted G band at around 1580 $cm^{-1}$ with an intense D band at 1350 $cm^{-1}$ which is consistent with literature reported values [11–14]. During oxidation, the intensity of the D bands increase significantly, suggesting increased disorder and symmetry breaking in the graphitic layers due to attachment of hydroxyl and epoxide groups on the carbon basal plane. After incorporation GO into SPEEK, the D and G band for GO can't be observed as the spectra present at 1152.32 assigned to O=S=O vibration for $SO_3H$ group.

**Field emission scanning electron microscopy (FESEM)**

Field emission scanning electron microscopy (FESEM) images of GO, SPEEK and GO-SPEEK are shown in Figure 3. It can be observed (Figure 3a) that after oxidation, the GO shows an agglomeration of the exfoliated flakes. Moreover, there is some wrinkles and folding on the surfaces and edges indicating that the graphitic domain was decorated with oxygen-containing functional groups. Besides, the morphological features of the membranes show the microscale images of the cross-sectional area of SPEEK and GO-SPEEK (Figure 3b and 3c) with sponge-like structures. The various sizes of GO particles are visible in the GO-SPEEK membrane. These fillers are uniformly distributed throughout the matrix due to the interfacial interaction, which is attributed between the sulfonic group of SPEEK and the oxygenated group of GO through hydrogen bonding.

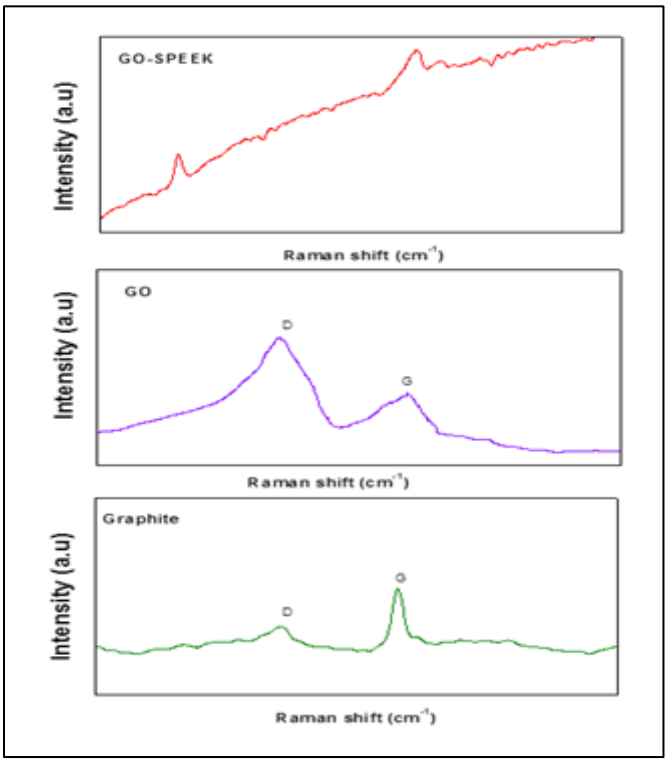

Figure 2. Raman spectra for graphite, GO and GO-SPEEK

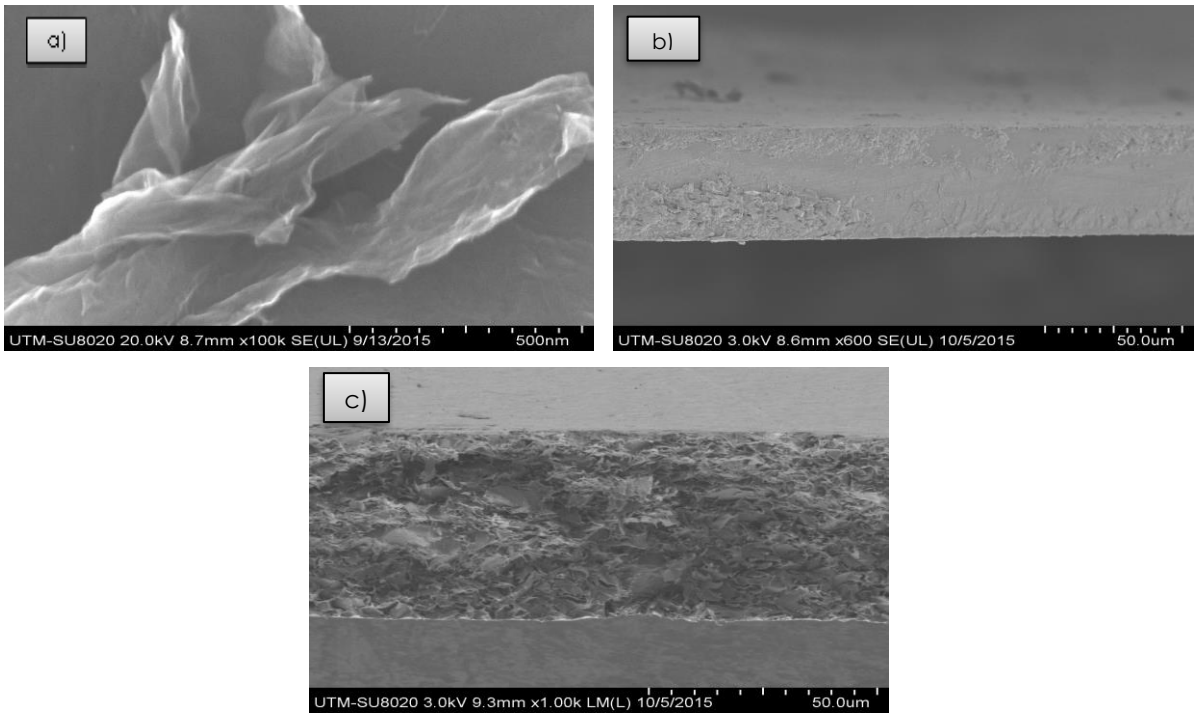

Figure 3. FESEM image of (a) GO, (b) SPEEK, and (c) GO-SPEEK

**X-ray diffraction**

Figure 4 illustrates XRD of graphite, GO, SPEEK and GO-SPEEK. This method can be used to confirm exfoliation process occurred in the pristine graphite during the oxidation process. The pattern of the raw graphite shows a very strong (002) peak at 2θ = 26.35° for a typical graphitic structure with layer spacing of 0.338 nm, indicates highly ordered crystal structure. However, after undergoing oxidation, it is obviously that the characteristic of graphitic peak completely disappears and in the meantime a new diffraction peak of (002) appearing at about 2θ = 11.04° with layer spacing 0.801 nm which indicating the layer distance was higher than the graphite. This happens due to the oxygen functional groups attached to both side of graphene sheets and the increasing atomic scale roughness to the graphene sheets. Therefore, it can be concluded that the expandable graphite was successfully oxidized. In the meanwhile for SPEEK, it was found that it gives a broad signal around the reflections which indicated it exists as fully amorphous structure. Generally, PEEK commonly considered as semi-crystallinity polymer, and that was confirmed by the appearance of a sharp crystalline peak of the range of 20 – 30° [15,16]. However, the crystallinity has been effectively decreased after the process of sulfonation. The XRD pattern of pristine SPEEK shows a broad peak overlay with the range of 13 – 25°, which indicates the lower crystallinity of SPEEK. The incorporated GO sheets are completely covered by the SPEEK polymers; therefore, there are no significant peaks observed for the fillers in the GO-SPEEK composites which indicate crystalline GO nanosized breaks and diffuse inside SPEEK polymer chains thus produce particulate nanocomposites membranes.

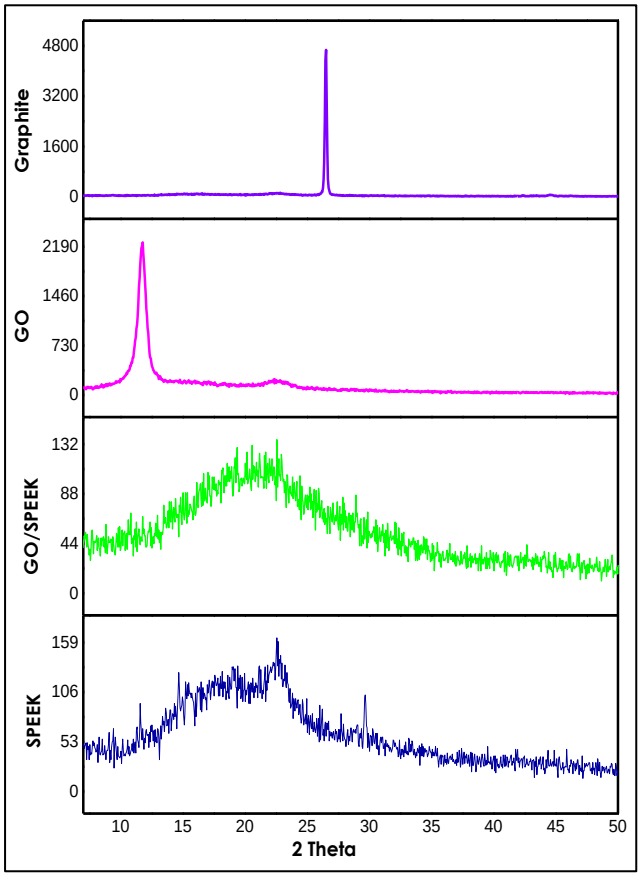

Figure 4. X-ray spectra for graphite, GO, SPEEK and GO-SPEEK

**Water uptake and swelling behaviour**

Water plays a crucial role in proton exchange membranes and influence proton transport across their membranes as proton could transport along with hydrogen-bonded ionic pathway and cationic mixtures such as $H_3O^+$, $H_5O_2^+$ and $H_9O_4^+$ in the water [17]. In order for membranes to have high proton conductivity and low resistance, it is desired for them to have a high water uptake capacity. Low amount of water uptake would reduce proton transport, while too much water uptake leads to excessive swelling hence loss of the dimensional stability. Figure 5 shows the percentage of water uptake for Nafion® 112, SPEEK and GO-SPEEK at varying temperature. The similar trend shows for the all samples which are the water uptake increase with the increasing temperature. Higher of temperature would introduce more movement of polymer chains as a result lead to more free volume for water absorption [9]. Plain SPEEK gives a higher water uptake percentage rather than commercial membrane, Nafion. However the plain SPEEK exhibits higher swelling percentage compared to commercial Nafion as depicted in Figure 6. This shortcoming improved when GO is introduced into the SPEEK. In line to the plain SPEEK, the composite membranes shows an increase in water uptake, even substantially enhanced two times higher than commercial membrane. This may result from the formation of hydrophilic channel within -OH on the GO edge and $–SO_3H$ groups in SPEEK which could lead decreasing of an average inter-chain distance of SPEEK. In contrast to plain SPEEK, GO-SPEEK gives a higher water uptake however surprisingly it gives lower swelling percentage compared to commercial PEM.

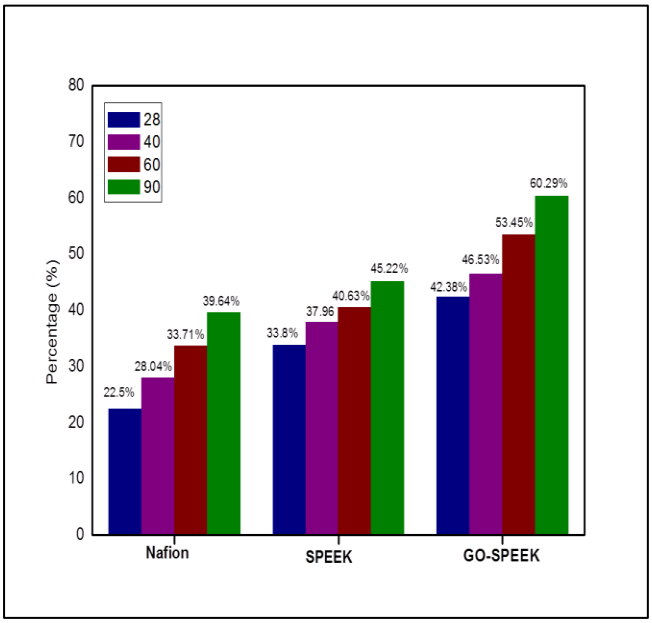

Figure 5. Percentage of water uptake for Nafion, SPEEK and GO-SPEEK at varying temperature

Table 1 depicts the value obtained for IEC and proton conductivity for Nafion, plain SPEEK and GO-SPEEK. Ion-exchange capacity (IEC) is an important property for membranes intended to be used as PEMs. Membranes with high IECs is expected to transport protons effectively through the available conducting ionic sites by proton hopping mechanism[18]. Sulfonic acid based PEMs, with high acidity and high ionization power, are one of the best choices in this area. It is observed that GO-SPEEK was the most acidic membrane as it exhibited the highest IEC compared to other membrane. This is in agreement with water uptake results.

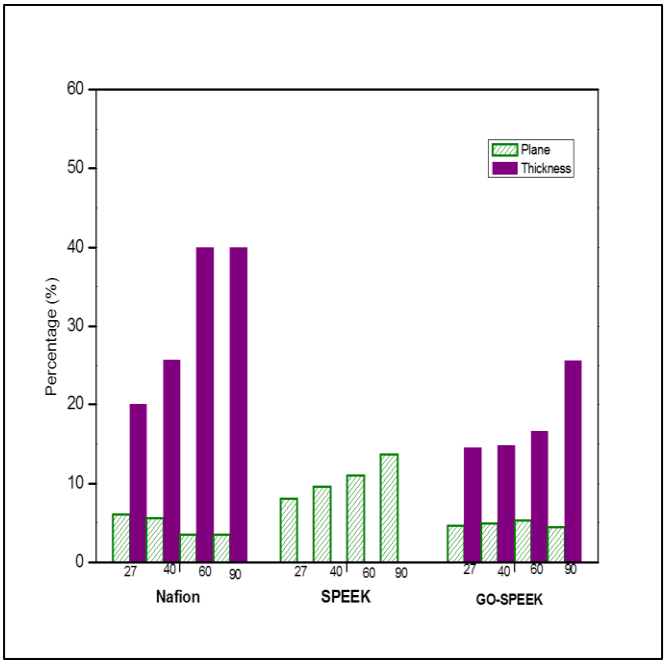

Figure 6. Percentage of swelling for Nafion, SPEEK and GO-SPEEK at varying temperature

Table 1. IEC, methanol permeability and proton conductivity (σ) of the Nafion, plain SPEEK and GO-SPEEK membranes at 85 °C

| **Sample** | **IEC (mequiv.g$^{-1}$)** | **Methanol Permeability (x 10$^{6}$ cm$^{2}$s$^{-1}$)** | **Proton Conductivity (Scm$^{-1}$)** |
|---|---|---|---|
| Nafion® 112 | 0.895 | 1.59 | 0.0612 |
| SPEEK | 0.982 | 0.97 | 0.0382 |
| GO-SPEEK | 1.231 | 0.36 | 0.0537 |

Proton conductivity is a crucial parameter to determine the fuel cell performance l. As shown in Table 1, the proton conductivity of GO-SPEEK membrane a bit lowered rather than the commercial Nafion® 112, however it still higher than 1 x $10^{-2}$ $Scm^{-1}$ which regarded as the lowest value of practical interest for PEM in fuel cells [19, 20] Proton conductivity relies on various factors, such as water uptake, IEC and the microstructure of the membrane [21]. Based on the structure, it could be understandable that by incorporating GO, it introduces inter-connected proton transfers channel [22], which able to facilitate proton transfer through the membrane. Hence this composite membrane exhibits higher proton conductivity compared to blank SPEEK. In addition, the proton transport in membranes requires well-connected channels formed by ion clusters of hydrophilic sulfonic acid groups. Hence, the content and the diameter of the connected channels gives remarkable effect on the proton transport rate in the membrane. The formation of isolated ionic cluster in the continuous hydrophobic phase occurred when the density of sulfonic acid groups low. The ionic clusters might be blocked from the GO with low proton conductivity although the water uptake and IEC increased in GO-SPEEK.

Membranes for practical usage of PEMs in DMFC were required to possess high conductivity and low methanol permeability. The methanol permeability of GO-SPEEK, blank SPEEK, and Nafion® 112 are shown in Table 1. It can be seen that the methanol permeability of SPEEK and GO-SPEEK are much lower than commercial membrane.

These results could be explained by their microstructure. Nafion® 112 membrane creates a simple hydrophobicity-hydrophilicity separation because of high hydrophobicity of the perfluorinated backbone and high hydrophilicity of the attached sulfonic acid groups. These well-connected hydrophilic domains act as substance movement channels, which not restricted to only proton and water, but also smaller polar molecules such as methanol could get through these channels. This circumstance results to high value of methanol permeability. In contrast, the SPEEK has smaller hydrophobicity and hydrophilicity differences compared to commercial membrane. Thus less constructed separation into hydrophobic and hydrophilic domains yields to lower methanol permeability than Nafion [23 – 25]. When the GO incorporated into SPEEK, it functions as barrier to connect the hydrophilic channels. GO block the polar molecules, methanol from easily passing through the membrane. This phenomenon is called "blocking effect". Besides, the interfacial interaction between GO and SPEEK polymer also contributes to the decreasing of it as GO and SPEEK interaction restricts the formation of broad hydrophilic channel requires by methanol transportation [26].

## Conclusion

Composite membrane based on GO-SPEEK had been successfully prepared. Physical and chemical properties were investigated. The performances of the composite membranes such as water uptake, dimensional stability, IEC, methanol permeability and proton conductivity were investigated. Though the capacity of water uptake were greatly improved with the introduction of GO into SPEEK, but it still able to reduce swelling ratio. The proton conductivities of GO-SPEEK slightly decrease compared to commercial membrane, Nafion®112. These results indicate that GO-SPEEK membranes possessed as promising PEM in fuel cell.

**Abstract**

The residence time distribution (RTD) study at power generation plant was successfully carried out using radiotracer technology. In this study, $Tc^{99m}$ was used as the source of radioactive whereas NaI(Tl) detector was the scintillant detector. Previous study only concentrated on getting the flow rate from two successive peaks without producing any mathematical model. Thus, the hydrodynamics behaviour of the liquid inside the plant was weakly described. In this study, axial dispersed plug flow model is the best RTD model due to minimal value of sum of square which is $0.261 \times 10^{-5}$ compare to other RTD models recommended by International Atomic Energy Agency (IAEA).

**Keywords**: residence time distribution, radiotracer technology, RTD models, sum of square

**Abstrak**

Kajian taburan masa mastautin (RTD) telah berjaya dilakukan di loji janakuasa elektrik menggunakan teknologi penyurih. Untuk kajian ini, $Tc^{99m}$ telah digunakan sebagai penyurih radioaktif manakala pengesan NaI digunakan sebagai pengesan sintilasi. Kajian terdahulu hanya memberi maklumat berkaitan pengukuran kadar alir yang terhasil daripada dua puncak turutan yang terhasil tanpa membuat laporan berkaitan permodelan RTD. Oleh itu, kelakuan hidrodinamik bendalir di dalam loji tidak dapat dijelaskan dengan baik. Untuk kajian ini, model aliran palam taburan aksial merupakan model terbaik RTD berbanding model yang dicadangkan oleh IAEA kerana nilai jumlah kuasa dua terhasil yang rendah iaitu $0.261 \times 10^{-5}$.

**Kata kunci:** taburan masa mastautin, teknologi penyurih, permodelan RTD, jumlah kuasa dua

## Introduction

Radiotracers are widely used for the measurement of the flow rate of liquids, gases and solids in many industrial systems. An investigation of many major industrial applications including fluidized beds, sugar crystallizers, trickle bed reactors, cement rotary kiln, wastewater treatment unit and also inter-well communications in oil fields can be performed by the injection of a radiotracer at the inlet of the system and monitoring the radiotracer at the outlet. The output data can be treated and analyzed to investigate the behavior of the system or hydrodynamics of the fluid inside the plant. Moreover, radioisotope-based technology continues to play a rapidly growing role in assisting industry to enhance their production efficiency and also for optimization [1]. Radiotracer technology has proved itself as a sensitive tool for investigating and solving plant process problems namely process malfunctions and anomalies as well as mechanical damages. Radiotracer techniques have many advantages such as high detection

sensitivity, in-situ detection, and availability of a wide range of compatible radiotracers for different phases, rapid response, reliability and accuracy of results [2].

The residence time distribution (RTD) of a reactor is a characteristic of the flow pattern that occurs in the chemical reactor, being one of the most informative characterizations of the reactor [3]. The principle of a tracer experiment consists of a common impulse-response method: injection of a tracer at the inlet of a system and recording the concentration–time curve at the outlet of the system. RTD is obtained after the preliminary treatment of radiotracer data, including background correction, correction, radioactive decay correction, starting point correction, filtering, and data extrapolation and area-normalization as described by Kasban et al. [4]. RTD, which was first developed by Danckwerts [5] has been utilized by many researchers to diagnose the possible system malfunctions such as bypassing, leakage, blockage, channelling, fouling and backmixing as well as helping in estimating the quality of mixing. It also depends on the flow hydrodynamics and the reactor geometry and has influence on the reactor for chemical performances such as conversion and yield. The method gives information on the measured system by evaluating concentration of a tracer compound, which is added as a stimulus at the system inlet.

Moreover, mathematical model should be obtained for hydrodynamics study so that the behaviour of the fluid in the plant or reactor can be understood well. Extensive radiotracer experiments have been carried out successfully in various industries, which indicate the survival and reliability of radiotracers in hostile environments. The next case studies will be describing the successful application of radiotracer technology in industries worldwide. Sugiharto et al. [6] determined the RTD and the system flow rate in a 24 in. multiphase flow hydrocarbon transmission pipeline containing approximately 95% water, 3% crude oil, 2% gas and negligible solid material. Nevertheless, the types of radiotracer sources used in this experiment were different; I-13 and Na-24 were used independently for the measurement of the RTD in hydrocarbons and water, respectively. In this instance, the tanks in series model best described the RTD of the system. The authors also discovered that the water moved faster than the hydrocarbon even though the density of the water is higher. This might be because water is more dominant in the transmission line and because the movement of the crude oil is slowed by friction with gas at the top layer and friction at the water–crude oil interface. Behin and Aghajari [7] studied the RTD measurement in a pilot-scale oil–water separator operated by Drood oil of the Iranian Offshore Oil Company (IOOC) located in Kharg Island using 5mCi I-131 as sodium iodide and 4mCi of I-131 as iodobenzene for the aqueous and organic phase, respectively. The separation of the crude oil and water mixtures is an important process in the oil and chemical industries. The researchers reported that the experimental results were in a good agreement using the model of perfect mixing tanks in series (with a dead zone) to describe the liquid behavior. The models obtained in these two case studies were both tanks in series models. It can therefore be concluded that tanks in series models suited the multiphase flow profile.

In addition, each case study developed a mathematical model that fitted the experimental results satisfactorily although the chosen models varied between applications. Pant et al. [8] conducted an RTD study in a pilot and an industrialized fluid catalytic cracking unit (FCCU) using an intrinsic tracer. The identified tracers were lanthanum-140 and sodium-24 and were obtained from the catalyst sample. The tracers were characterized using neutron activation analysis to investigate the degree of axial mixing and radial distribution in the riser section of the FCCUs and to determine the residence time distribution of the catalyst. The axial dispersion model (ADM) was used to represent the actual RTD obtained from the radiotracer experiments. According to Pant et al. [8], the ADM is the best model to describe material flow in a tabular reactor, such as FCCU, because this model can describe one-dimensional convection and dispersion in a pipe. Radiotracer techniques are extensively used for measurement of process parameters such as mean residence time (MRT), residence time distribution (RTD), flow rate, material inventory in full-scale industrial reactors, high detection sensitivity, physico-chemical compatibility, in-situ detection, limited memory effect and use in hostile industrial environment [1, 2]. In this study, RTD was fruitfully conducted using radiotracer approach in one of the biggest Power Station in Malaysia.

## Materials and Methods

About 10ml of eluted Tc-99m from $^{99}Mo/^{99m}Tc$ generator was engaged as radiotracer in this study. According to IAEA 2008 [1], the injected activity of $Tc^{99m}$ is ≈ 37 GBq is used for water tracing in surface bodies (rivers, sea) for dispersion of effluent studies (outfalls) and dispersion coefficient measurements. Nevertheless, in this study about 10.6Bq was employed. The experiment was carried out by injection of $Tc^{99m}$ into 2.1m diameter underground

Calvert pipeline. The temperature of operating liquid is about 39-40$^{o}$C along the 580m pipeline. The injection point was chosen at the outlet of the condenser and the detection point was at the effluent of pipe which was about 580m away from the injection point. This location showed that the tracer was mixing homogenously with the liquid since according to IAEA practice, the shortest perfect mixing is about 100 inner diameter length [1, 2]. The scintillation detector, NaI was used to detect the presence of the emitted radiotracer for RTD study. Fig. 1 shows the schematic diagram of the buried pipelines. The influent and the effluents are coming from and to the sea respectively.

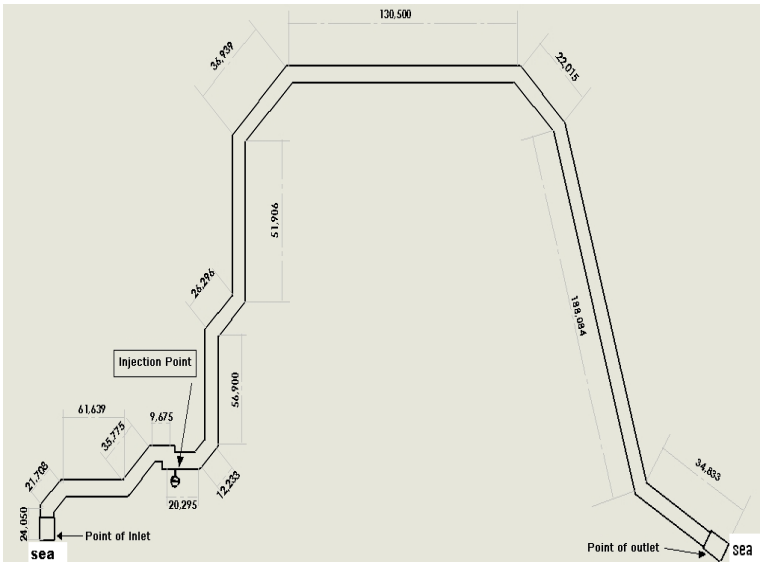

Figure 1. Schematic diagram of buried pipeline

**Results and Discussion**

Figure 2 shows the results of radioactive monitoring in which the gamma rays are detected in count per seconds (cps) from $Tc^{99m}$ and received by scintillation detector. The sampling time was set until the reading from data acquisition system (DAS) showed the background level. The experimental data obtained has statistical fluctuations which need to be treated prior RTD determination. The data has to undergo background correction, radioactive decay correction, starting point correction, filtration and data extrapolation prior RTD modelling.

Residence Time Distribution (RTD) is a fundamental parameter in reactor design which can give information on how long the substrate has been in the reactor and the RTD analysis can help characterizing the extent of their deviation from ideal behavior. The E(t) function is the RTD where E(t) dt is the fraction of the flow, measured at the exit, that is in the system between times t and (t +dt):

$$E(t) = \frac{C(t)}{\int_0^\infty C\,(t)dt} \quad (1)$$

where C(t) is the concentration of radiotracer monitored by NaI scintillation detectors in counts per second (cps) as numerator and denominator is the area under the curve of plotted C(t).

Figure 3 displays the RTD response after application of Equation (1). It shows the tall, sharp and narrow peak of RTD curve or well-defined Gaussian curve which indicates homogenous mixing of radiotracer in the system. The data is continuous RTD curves which represent the relation between radiation intensity versus time. In this study, RTD modelling was performed using International Atomic Energy Agency (IAEA) RTD software. The six recommended RTD models by IAEA are the axial dispersed plug flow model, the axial dispersed plug flow with exchange model, the perfect mixers in series model, the perfect mixers in series with exchange model, the perfect mixers in parallel model and the perfect mixers with recycle model. Details of each model can be obtained from the

IAEA [1, 2]. Mathematical RTD models can provide theoretical information as well as the hydrodynamic behaviour of the reactor.

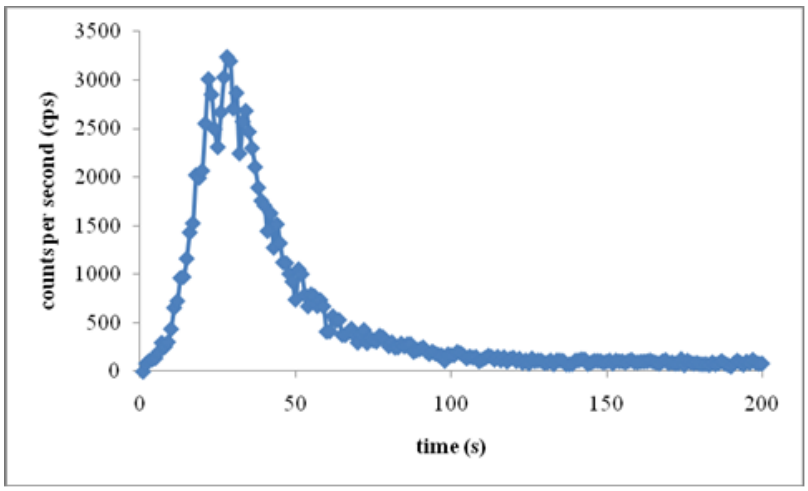

Figure 2. Detection of emitted gamma rays from $Tc^{99m}$

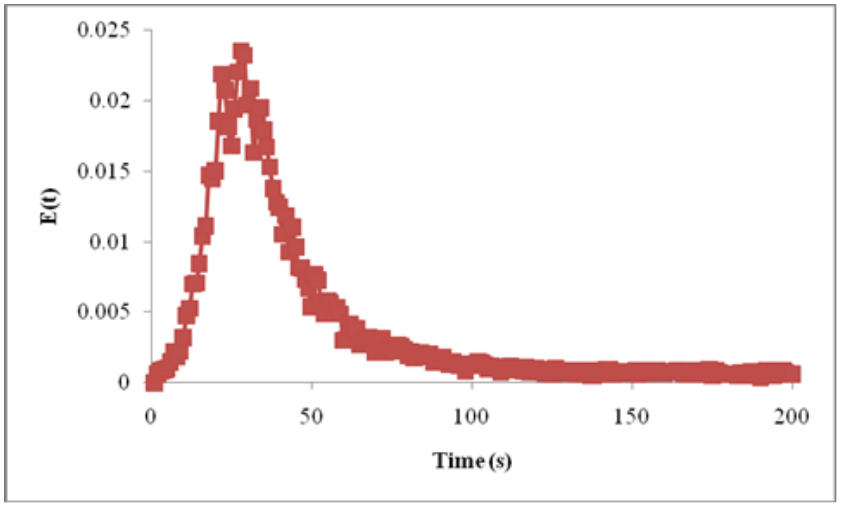

Figure 3. RTD profile of monitored tracer

The radiotracer experiments showed that only three models successfully fitted the experimental data. These RTD models are the axial dispersed plug flow model, the axial dispersed plug flow with exchange model and the perfect mixers in series model as shown in Figures 4, 5 and 6, respectively. The success of the models are due to the fact that the flow that passing through in the pipeline is behaving as plug flow which represents axial dispersion plug flow model. The unsuccessful fitted RTD model was the perfect mixers with recycle model, the perfect mixers in parallel model and the perfect mixers in series with exchange model. The failure of curve fitting from these models due to the absence of perfect mixer in the actual plant. The best fit is chosen based upon the minimum value of sum of square, which is the difference between the experimental data and the model [1, 6].

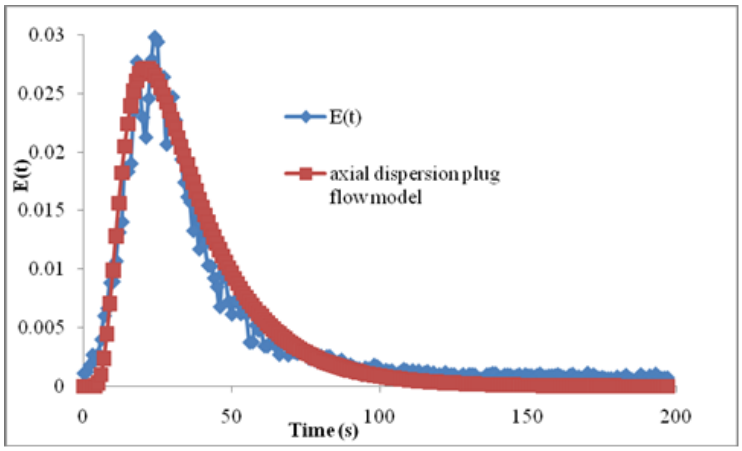

Figure 4. Axial dispersion plug flow model

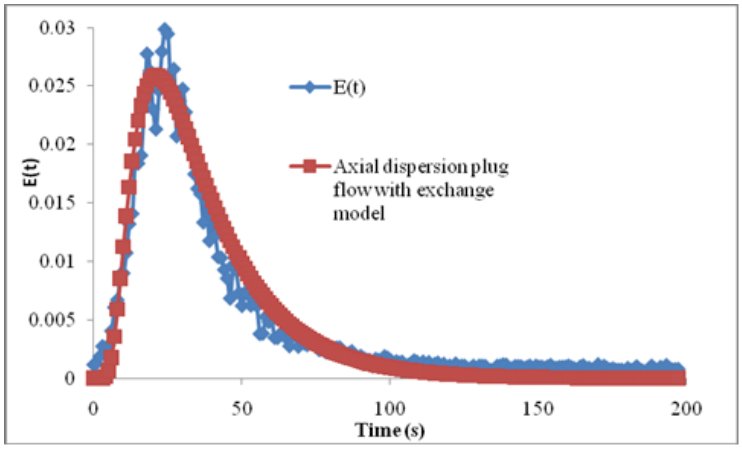

Figure 5. Axial dispersion plug flow with exchange model

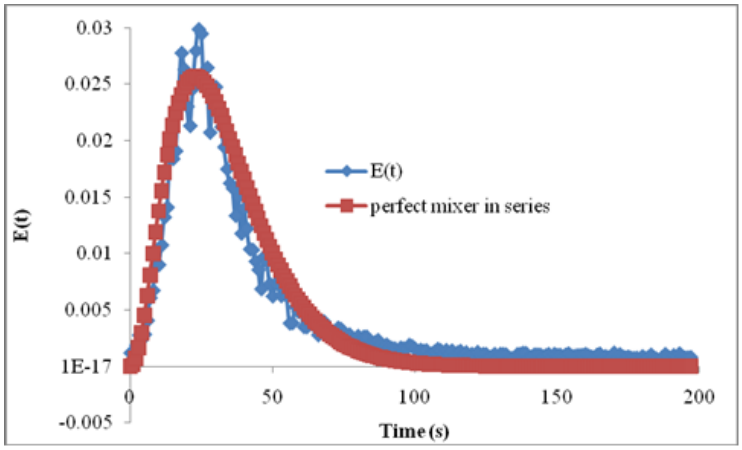

Figure 6. Perfect mixer in series model

The axially dispersed plug flow model is widely used in practice. This flow is the superimposition of convection which is the bulk movement of the fluid as a plug and some amount of dispersion. This model is a proper approximation also for quite a variety of quasi one-dimensional situations such as river flow, underground water flow as well as packed columns and has two parameters which are non-dimensional Péclet number, Pe and τ. The curves get sharper and sharper when Pe is increased. They always have one single peak and the peak height and tail length are correlated (tail is short when peak is sharp and vice versa). It is often necessary to characterize convection as related to velocities and flow rates which is the behavior of plug flow [1, 2].

Furthermore, the sum of the squares of the differences between the model and the data are minimized and fulfilled using the following equation [6]:

$$Sum\ of\ Square\ (SSE) = [\frac{1}{N_T}\int_0^\infty [E_{exp}(\theta) - E_m\ (\theta, N)]^2\ d\theta]^{1/2} = Minimum \quad (2)$$

where $N_T$ is the number of data points, $E_{exp}(\theta)$ is the experimentally measured curve, and $E_m(\theta, N)$ is the simulated model. Table 1 shows the results of optimized parameters for successful RTD model. Only three RTD models have successfully fitted the experimental curve. These model are axial dispersed plug flow model, axial dispersed plug flow with exchange model followed by the perfect mixers in series model.

Table 1. Optimized parameters for each model

| **Models** | **τ** | **Pe** | **N** | **J** | **Sum of square (SSE)** | **Rank** |
|---|---|---|---|---|---|---|
| Axial dispersion plug flow model | 0.36 | 0.53 | 1.0 | *na* | 0.261 x $10^{-5}$ | 1 |
| Axial dispersion plug flow with exchange model | 0.30 | 0.47 | 1.0 | 1.0 | 0.305 x $10^{-5}$ | 2 |
| Perfect mixer in series model | 0.33 | *na* | *na* | 0.33 | 0.348 x $10^{-5}$ | 3 |

Where τ is the mean residence time or the total volume of the system divided by the flow rate,
Pe is Péclet number,
J is number of tank,
N is a mass transfer coefficient;
*na* – not applicable.

According to Table 1, both the axial dispersed plug flow model and the axial dispersed plug flow with exchange model can be considered as the best fit followed by the perfect mixers in series model. The axial dispersed plug flow model is best described the experimental RTD curve because the sum of square (SSE) is minimum which is 0.261 x $10^{-5}$ compare to perfect mixer in series, which is 0.348 x $10^{-5}$. Additionally, the axial dispersed plug flow model is more applicable to flows in long pipes and the axial dispersed plug flow with exchange model indicates that there is effective mixing because the value of N is equal to 1 [1, 2]. Besides, the lowest value of Pe shows that dispersion operation is more dominant than convection, and thus, there is plug flow.

## Conclusion

The present work describes the radioactive experiments using radiotracer technology to study the (RTD). A field study was carried out as a case study and the best RTD models were precisely identified. The axial dispersed plug flow model, the axial dispersed plug flow with exchange model and the perfect mixers in series model are the RTD models which inflexibly fitted the experimental RTD well whereas axial dispersed plug flow model described best RTD model due to minimal value of sum of square.

# RESPONSE SURFACE METHODOLOGY ON WAX DEPOSIT OPTIMIZATION

## (Pengoptimuman Lilin Mendap Menggunakan Kaedah Gerak Balas Permukaan)

**Abstract**

In this study, the application of response surface method design based on rotatable central composite design (CCD) was used to optimize wax deposit using Design Expert 7.1.6 software. The process consisted of 13 experiments involving eight factorial points and five replications at the center point. The influence of operating parameters on the weight of wax deposit was investigated using cold finger apparatus. The experimental result indicated that the amount of wax deposit was significant due to factors of cold finger temperature and experimental duration. The wax deposit amount decreased significantly with the decrease of experimental duration when the cold finger temperature increased to 25 °C. The minimum value of 0.0042 g of wax deposit was obtained at the optimized conditions of 1.5 hours and 25 °C, respectively.

**Keywords**: cold finger method, crude oil, optimization

**Abstrak**

Dalam kajian ini, penggunaan kaedah gerak balas permukaan berdasarkan reka bentuk komposit berpusat berputar (CCD) digunakan bagi mengoptimumkan lilin mendap menggunakan perisian Design Expert 7.1.6. Proses ini terdiri daripada 13 eksperimen yang melibatkan lapan titik faktorial dan lima ulangan di titik pusat. Pengaruh parameter operasi terhadap berat lilin mendap telah dikaji dengan menggunakan radas jejari sejuk. Hasil eksperimen menunjukkan bahawa jumlah lilin mendap dipengaruhi oleh faktor suhu jejari sejuk serta tempoh eksperimen. Jumlah lilin mendap akan berkurang sekiranya tempoh eksperimen dikurangkan berserta peningkatan suhu jejari sejuk kepada 25 °C. Nilai minimum 0.0042g lilin mendap telah diperolehi pada keadaan yang optimum iaitu pada 1.5 jam dan 25 °C .

## Introduction

The major problem faced by the petroleum industry especially in flow assurance is the deposition of wax from crude oil at the tubing, pipeline, and surface flow line [1–3]. The formation of solid wax may lead to increased pumping power, decreased flow rate or even total blockage of line, with loss of production and capital investment [4]. Waxes are solids essentially made of mixtures of long chains, either normal or branched alkane compound formed when the temperature of crude oil falls below the wax appearance temperature (WAT) [5].

Normal conditions for reservoir temperature and pressures are within the range of 70 to 150 °C and 8,000 –15,000 psi, respectively [3, 6], while ocean floor temperature is around 4 °C [3]. When crude oil is transported from reservoir to pipeline, the crude oil temperature decreases below its wax appearance temperature (WAT) due to heat

lost to surroundings [3, 7]. At ambient condition, for carbon atom chains less than four atoms (C1 to C4), it will show a gaseous state. Meanwhile, in the range of carbon atoms from C5 to C16, it turns to liquid and for carbon atoms more that C17, it forms solid [8]. Flow assurance is expected to lead to losses of billions of dollars yearly worldwide [9]. Many remediation techniques to encounter deposition problem have been employed, including removal and prevention approaches such as chemical, mechanical and thermal methods [5, 10 – 12]. To avoid wax deposition problems, the understanding of physicochemical characteristics of wax phase is needed [13].

The deposition of wax from crude oil is influenced by several factors, such as wax content and composition, flow rate, temperature difference between oil and pipe surface, and cooling rate along the pipeline [9]. Kelechukwu et al. [14, 15] claimed that the most common factor for wax deposition is the decrease of crude oil temperature. Many researchers have investigated the factor that gives the best influence on wax deposition. Shear and temperature effects have been observed by Jennings and Weispfennig toward wax deposition [16, 17]. They found an increase in shear increased wax inhibition; however, for the temperature effect, the inhibition result contradicted with the shear effect.

Previously, the optimum combination of operating conditions for minimum wax deposition has been studied by implementing one-factor-at-a-time technique (OFAT). However, this technique cannot examine the interactions of the factors considered. Therefore, to determine the impact of two or more factors on a response, Design Expert (DO) software was introduced. DO is a statistical software package that is specifically designed to perform the design of experiment (DOE). An experiment is a series of tests, called runs, in which changes are made in the input variables in order to identify the reasons for changes in the output response [18 – 20]. This software is able to offer comparative tests, screening, characterization, optimization, robust parameter design, mixture designs and combined designs. It also manages to come up with a systematic plan for the minimum number experiments to avoid time consumption [18, 19].

To optimize a response (output variable) that is influenced by several independent variables (input variables), response surface methodology (RSM) was introduced. RSM is a collection of mathematical and statistical techniques for building an empirical model. A group of researcher has investigated the factor that gives the best influence on wax deposition. For example, Valenijad et al. [21] have studied the experimental factors that affect crude oil wax deposition problem using Taguchi method. These factors include inlet crude oil temperature, temperature difference between the oil and pipe wall, flow rate of crude oil, wax content and time. However, there are limited studies on optimization that have been performed to optimize the process parameters for wax deposition by using response surface methodology and central composite design.

The present study focused on the development of a mathematical model for wax deposit prediction to describe the effects and the relationships between the process variables to obtain minimum yield of wax deposit formation using CCD**.**

## Materials and Methods

### Materials

Poly(ethylene-co-vinyl acetate) (EVA), n-heptane (purity 99.5%), and petroleum ether were obtained from Sigma-Aldrich. The raw crude oil sample was kindly supplied by PETRONAS Refinery from Kerteh, Terengganu, Malaysia. The characteristics of the crude oil sample are listed in Table 1.

### Cold finger experimental set up

The rate of wax deposition of crude oil was evaluated using cold finger apparatus as shown in Figure 1. This apparatus is suitable for understanding the temperature correlation between bulk crude oil and the wall that is exposed to the temperature below WAT [17, 22, 23]. To run the experiment, a stainless steel jar was filled with 300 mL of crude oil sample. The crude oil needs to be conditioned above WAT for the purpose of thermal treatment for 1 hour in order to solubilize any precipitated wax. The experiments were carried out for 2 hours and the temperature of the crude oil sample needed to be maintained at 50 °C. The total amount of inhibitor used for each experiment was about 10 mL. The experiments were repeated three times to obtain precise data. The deposit was then scrapped

off from the finger, weighed, and saved for potential analysis. Visual observation of the wax was made for determining the physical characteristics.

Table 1. Summary of the list of equipment used for physical analysis

| Equipment | Usage |
|---|---|
| Differential scanning calorimeter (DSC) | To determine the wax appearance temperature (WAT) of the crude oil sample. |
| Cloud point and pour point apparatus, model Koehler | To determine the pour point of the crude sample. |
| Brookfield rotational digital, model DV-III (spindle No. 31) | To determine the rheology behavior of the crude oil sample. |
| Gas pycnometer, model Micromeritics AccuPyc II 1340 | To measure the density of the crude oil sample. |
| Acetone precipitation technique (Modified UOP method 46-64) | Extraction of wax crystal from the crude oil sample. |

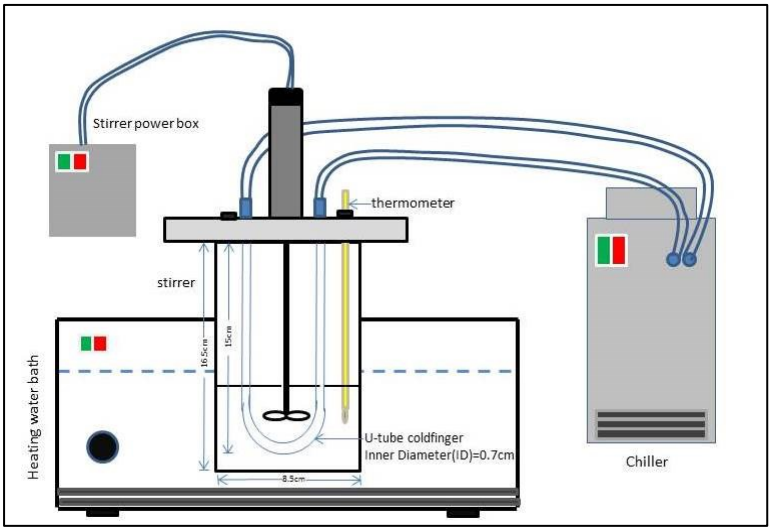

Figure 1. Cold finger apparatus set up

**Experimental design**

A standard RSM design called central composite design (CCD) was applied to study the wax deposit variables. The two independent variables studied were the cold finger temperature (A) and experimental duration (B) that were coded at five levels. Details of the lower limit and upper limit are shown in Table 2. The CCD includes eight factorial points and five replications at the center point, in which a total of 13 experimental runs were employed to fit a second-order polynomial model using Design Expert (State-Ease, USA) version 7.1.6. The inhibitor concentration and speed of rotation were set for 5000ppm and 0 rpm respectively for each run.

Table 2. Five-level two-factor central composite design condition variables

| Independent Variables | Code Symbol | Coded Level | | | | |
|---|---|---|---|---|---|---|
| | | -α | -1 | 0 | 1 | + α |
| Cold finger temperature (°C) | A | 5 | 10 | 15 | 20 | 25 |
| Experimental duration (h) | B | 1 | 1.5 | 2 | 2.5 | 3 |

## Results and Discussion

CCD was employed in this study to optimize wax formation. The experimental work was done using cold finger test. The influence of cold finger temperature (A) and experimental duration (B) on the amount of wax deposit was investigated. An actual experimental model as shown in Table 3 was developed to predict the optimum condition for wax formation in order to minimize the expression of wax deposit. Figure 2 displays the experimental and predicted data from the polynomial relationship for each response. This model indicates a good model and shows a satisfactory correlation between the experimental and predicted values because the clusters of experimental and predicted values for the amount of wax deposit amount are close to the diagonal line in the parity plot (Figure 2). ANOVA test was carried out to prove the significance of each variable in the model. Table 4 shows ANOVA results. The final equation in terms of coded factors for the second-order polynomial is presented by Equation (1).

$$\text{Ln (wax deposit+0.02), g} = -0.19 + 0.15\,B - 1.03\,A - (7.338E-03)\,AB + 0.033\,B^2 - 0.35\,A^2 \quad (1)$$

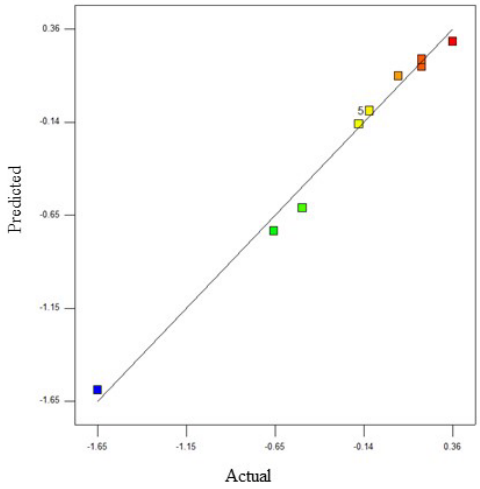

Figure 2. The comparison of predicted and experimental values for wax deposit amount using CCD

The fitness of the model is expressed by the $R^2$ value, which is 0.9886, indicating that 98.86% of the variability in the response can be explained by the model. Meanwhile, the coefficient of determination (adjusted $R^2$) was calculated and determined as 0.9805, indicating that only 1.95% of the total variation were not included in the model. This value indicates a good agreement between the observed and the predicted values of wax deposit formation. Therefore, the regression model was applied to calculate the predicted values and the usefulness of the model as shown in Table 3, where the predicted values are closely matched with the experimental values after the transformation. In other words, the model obtained is applicable to predict the optimum conditions that will minimize the expression of wax deposit.

Table 4 shows the results for ANOVA. The significant terms are corresponded to A, B and $B^2$. This result reveals that cold finger temperature (B) gave the most significant effect to the expression of wax deposit ($P < 0.0001$) compare to experimental duration (A) factor. However, this significant effect could also be easily observed from Figure 3, where the highest cold finger temperature reduced the expression of wax deposit amount, and in contrast, lower temperature enhanced the formation of wax deposit.

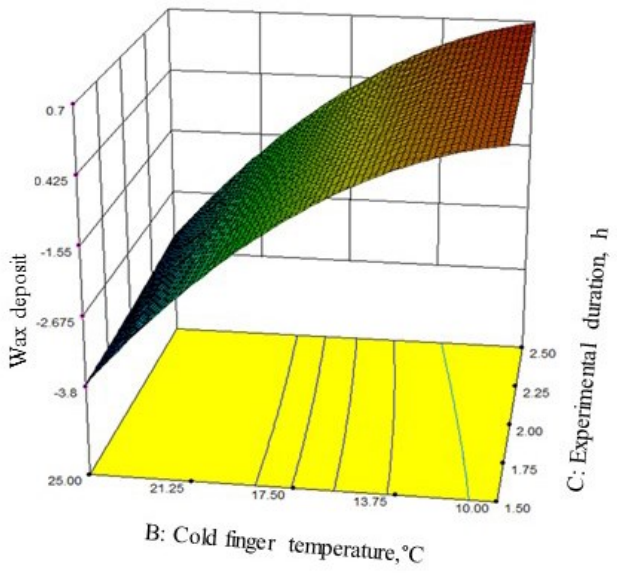

Figure 3. The comparison of predicted and experimental values of wax deposit amount using CCD

For model validation, 10 additional experiments were conducted by varying the experimental duration and cold finger temperature within the factor limit. The model validation of experimental and predicted data is shown in Table 5. The percentage between experimental and predicted values based on the model was found less than 10%. It can be seen that the validation correlation between the experimental and predicted values of wax deposit is in the form of a satisfactory correlation. For example, the actual experimental validation of 0.73 g of wax deposit was obtained at 1.5 hours and 15 °C. Meanwhile, the predicted values of wax deposit at the same condition was 0.72 g. Hence, the model for wax study can be considered to be valid.

**Optimization studies**

The optimization was performed to minimize the amount of wax deposited on the cold finger by using the selected range of variables after investigating the effect of experimental duration (A) and cold finger temperature (B), in which contour plots and response surface plot were produced according to the model (Equation (1)) as shown in Figure 3.

The response surface plot shows the optimum predicted wax amount for minimum wax formation. By applying the desirability function method in RSM, 9 solutions were obtained for the optimum covering criteria with the desirability value close to 1. In this case, the first solution was selected as a good desirability for a minimum amount of wax deposit with the desirability equal to 0.992. At this point, weight deposit is 0.0042 g at 1.5 hours experimental duration and 25 °C cold finger temperature, respectively. Table 6 shows the summary of the optimized wax deposit condition compared to the original value. It was found that after the optimization, the minimum value of 0.0042 g was achieved. It shows that 150-fold decrement of wax formation expression was achieved compared to prior the optimization.

Table 6. Summary of the optimized wax deposit condition

| Factor | Optimum Condition | Original Condition | Experimental Optimum Value[a], G | Experimental Original Value[b], G [24] |
|---|---|---|---|---|
| A - Experimental duration (h) | 0 | 0 | 0.0042 | 0.7500 |
| B - Cold finger temperature (°C) | 25 | 15 | | |
| C - Speed of rotation (rpm) | 1.5 | 2 | | |
| D - Inhibitor concentration (ppm) | 5000 | 5000 | | |

[a]Optimum condition and optimum values obtained from RSM result
[b]Original condition and the best experimental values obtained from FFD result [24]

## Conclusion

The optimization for the condition of wax deposit formation was achieved using response surface methodology. The optimized conditions were obtained at 1.5 hours and 25 °C. The minimum value achieved after the optimization was 0.0042 g, which is 150-fold decrement of wax formation expression compared to prior the optimization.

**Abstract**

Carbon capture and storage (CCS) through biological approach has attracted much attention as global warming and climate change issue becomes a worldwide agenda. Energy production industry from coal in Malaysia produced 50.661 million metric tons of carbon dioxide in 2012, and the trend showed it will keep increasing year by year. CCS through biological approach can be done by microalgae which are versatile microorganism which perform photosynthesis process that can store $CO_2$ in the biomass form. In this study, microalgae strains were isolated from the native environment nearby a coal-fired power plant, where samples were collected in different canal in which pre-treated flue gases are discharged. The microalgae strains were identified by both morphological and molecular approaches. Result from 18s rRNA gene sequencing showed that the isolated strains is *Chlorella* sp. with similarity 99% with *Chlorella* sp. SAG 211-18. The identified strains of microalgae then cultivated with three concentration of $CO_2$ (ambient air, 1% and 5%) and the growth rate showed 0.4017 $day^{-1}$, 0.5752 $day^{-1}$ and 0.4427 $day^{-1}$ respectively. Different concentration of $CO_2$ (ambient air, 1% and 5%) showed that the isolated strains yielded 1.005$gL^{-1}$, 1.101$gL^{-1}$ and 1.035$gL^{-1}$ respectively. This study also showed that with different concentration of $CO_2$, the sequestration rate is ranging from 1% to 4.3%.

**Keywords**: microalgae, isolation, purification, DNA sequencing

**Abstrak**

Pemerangkapan dan penyimpanan karbon (CCS) melalui pendekatan biologi telah menarik minat pengkaji disebabkan masalah pemanasan dan perubahan iklim global. Pada tahun 2012 sahaja, Malaysia telah menghasilkan 50.661 juta ton metrik karbon dioksida hasil daripada penghasilan tenaga yang bersumberkan arang batu, dan tahun demi tahun penghasilan karbon dioksida dijangkakan akan terus meningkat. Pemerangkapan dan penyimpanan karbon melalui pendekatan biologi boleh dilakukan oleh mikroalga yang merupakan mikroorganisma unggul di mana ianya berupaya menjalankan proses fotosintesis dalam menukarkan karbon dioksida ke dalam bentuk biojisim. Dalam kajian ini, mikroalga dipencilkan daripada habitat asal yang merupakan terusan bagi air penyejuk untuk stesen janakuasa arang batu. Mikroalga yang diperoleh, dikenalpasti menggunakan kaedah pengecaman secara morfologi dan molekul. Hasil keputusan pengenal pastian molekul menggunakan kaedah penjujukan genom 18s rRNA mendapati, mikroalga yang berjaya dipencilkan adalah *Chlorella* sp. yang mempunyai persamaan sehingga 99% dengan *Chlorella* sp. SAG 211-18. Mikroalga yang telah menjalani proses identifikasi kemudiannya dikultur menggunakan 3 kepekatan karbon dioksida yang berbeza ($CO_2$ pada udara persekitaran, $CO_2$ 1% dan $CO_2$ 5%) dan hasil menunjukkan kadar pertumbuhan masing-masing adalah 0.4017 $hari^{-1}$, 0.5752 $hari^{-1}$, dan 0.4427 $hari^{-1}$. Pada kepekatan $CO_2$ yang berbeza ($CO_2$ pada udara persekitaran, $CO_2$ 1% dan $CO_2$ 5%), hasil biojisim yang terkumpul daripada pengkulturan mikroalga masing-masing

adalah 1.005gL$^{-1}$, 1.101gL$^{-1}$ dan 1.035gL$^{-1}$. Kajian juga menunjukkan pada kepekatan $CO_2$ yang berbeza, kadar pemerangkapan karbon dioksida adalah pada kadar 1% sehingga 4.3%.

## Introduction

Studies on microalgae mostly ranging around the ability of biomass accumulation for food additive, colouring and high value product such as anti-oxidant. This research field has been widely explore in the previous decade and the exploration on other branches of microalgae utilization has taken place recently due to environmental concern especially regarding to global warming due to the rising of carbon dioxide produce by human activities [1 – 4]. Microalgae are a robust microorganism which can survive and thrive in different mode; photo-autotrophic, mixotrophic, heterotrophic and some mixture of complex metabolism to survive in harsh culture condition [5 – 8]. The ability of microalgae to conduct photo-autotrophic showed that microalgae has the potential to be applied in the process of carbon capture and storage (CCS) [9].

As the world progress and develop in becoming more advanced society, the energy demands around the world keep increasing year by year. Energy is a vital factor for progress to the advanced society since large scale activities such as urbanization, industrial activities; plantation, mining and livestock farming are becoming into commercial scale and subsequently demand higher energy input. Most of the world energy demand is supplied by fossil fuels burning power plants, which are using different sources of fossil fuel such as coal, natural gases, and petroleum based product [10, 11]. According to a report from Suruhanjaya Tenaga Malaysia, there are 4 main sources of fossil fuels are used as primary energy supply in Malaysia. The sources are crude oil, petroleum product, natural gas and, coal and coke [12]. All this generates $CO_2$, carbon monoxide and methane which is the main contributor to the global warming effect since these gases trap the heat and has increased the world temperature in the range of 1° to 2° C over the past decade. The only renewable source of energy used by Malaysia from 1978 until 2010 was hydropower energy. However since the year 2011, biodiesel, biomass, biogas and solar has contribute small portion of energy supply which around 115, 183, 4, 11 ktoe respectively for year 2012 [12].

Before the pre-industrial era, the $CO_2$ concentration in the air was recorded below 300 ppm. Since then, the concentration of $CO_2$ has steeply increased and has causing the rise of global temperature. According to the report from Mauna Loa Observatory (NOAA-ESRL), the atmospheric $CO_2$ concentration on June 2015 was recorded around 402.8 ppm [13]. Compare to the previous years of June 2014 and 2013, the concentration of $CO_2$ was recorded at 401.15 ppm 398.58 ppm. The effect of higher $CO_2$ concentration has been affecting the human life since breaking hot temperature during the summer season has been recorded around the world [14]. The effect of global warming has also affecting Malaysia; where for the past two years Malaysia had experienced hot temperature well above the normal average temperature.

Tenaga Nasional Berhad (TNB) is the largest utilities company in Malaysia and supplies most of the electricity to Malaysian Peninsular and State of Sabah through the Malaysian National Grid. The main energy source for electricity power generation for TNB is coal and coke which is relatively cost effective, coupling with state of the art technology in reducing $CO_2$ emission with collaboration with Alstom S. A. from France [15]. However, the emission of $CO_2$ is still an '*Achilles Heels*' for this system and thus, new approach has been embarked to counter and reduce more on $CO_2$ emission. The available solution is though CCS using microalgae [16, 17]. Thus, this paper reports on the works and progress of isolation of microalgae in the native environment near to the coal-fired power plant [18]. This works covers the isolation, morphological and molecular identification of isolated microalgae.

## Materials and Methods

### Isolation of microalgae

Samples were collected from the canal of cooling water from Stesen Janakuasa Sultan Azlan Shah, Manjung Perak, west coast of Malaysian Peninsular, 4° 9' 31.158" S latitude and 100° 38' 30.3396" E longitude. The power plant uses coal as the fuel and is among the major power generation plant in Malaysia, having installed capacity of 3 units of 700 MW. The canals form a discharge point of sea water used in the steam cooling process in the upstream. Besides steam cooling, the sea water also was used as jet water spray as to discard debris, being injected with hypochlorite as

disinfectant and also sprayed as part flue gas desulphurisation process before finally aerated (air bubbled) in the canals before being discharged to the open sea. Thus, any microalgae species that are available from the sea water intake shall experience varying degrees of hydrodynamic stresses, disinfection and temperature difference based on the process described above, and thus any ones which found dominant in the canals shall be the ones who are robust enough to survive further in bioreactors performing carbon biofixation exposed to actual power plant's flue gas. Collections of samples were conducted during the noon time where the suspected source areas of microalgae were exposed to sunlight at the maximum light density. The light intensity during the afternoon period can reach as high as 60,000 Lux during the sunny day. Microalgae which survived in photo-autotrophic mode tend to float on the surface area to capture energy from the sun for photosynthesis process.

The samples from the source were added with F/2 Medium, TNBR medium and Bold Basal's Medium (BBM) respectively with ratio of 1:1 (volume/volume) to promote growth of microalgae available in the targeted samples. The samples were maintained in 50 mL centrifuge tube, at room temperature at 28 °C and kept with continuous light exposure at 12,000 lux by 50 W fluorescent daylight type lamps. The samples were monitored daily to determined suitable medium for isolation as well as the growth curves of microalgae.

The samples were maintained and observed under microscope (Cole-Parmer, USA) for isolation and morphological screening purpose. Microscope used is equipped with light chamber, measuring grid embedded with the software provided by Motic Image Plus 2.0 and image capturing camera. Observation of microalgae growth in the liquid medium was continued with plating method by using the respective medium with 1.25% agar plate. In the parallel of liquid medium and 1.25% agar cultivation, the growth of microalgae were measured by biomass accumulation, cell density and amounts of colonies on the plate respectively.

**Cultivation**

Samples of microalgae which has been promoted by F/2 medium, TNBR medium and BBM medium were observed and screened morphologically and has been done by comparing to the online catalogue provided by University of Texas, The Culture Collection of Algae at Goettingen University (international acronym SAG). Morphological identification was done by determining the characteristic of isolated microalgae; size, availability of membrane wall and flagella, and the shape of chloroplast.

After growth of microalgae were observed, cultures of microalgae were transferred into 250 mL Duran Schott Bottle with F/2 medium, TNBR medium and BBM medium respectively with 10 percent of inoculums from the source of microalgae. To promote more growth, cultured microalgae were sparged with air to avoid settling as well as providing the $CO_2$ from ambient air. Cultivation of microalgae was then continued until single/pure strain achieved in the culture system. Single/Pure strains of microalgae was achieved by continuous plating using F/2, TNBR, and BBM Medium agar. The pure strains were then re-cultivated into F/2 medium and TNBR medium liquid solution for inoculum preparation as well as for the molecular identification purpose. Microalgae biomass were collected daily to plot the growth curve of microalgae and calculate the specific growth rate ($\mu_{max}$). The $\mu_{max}$ value was determined by using the MathLab 9.0 version software with application of Logistic Modelling. Generally the growth curve of microalgae is in the sigmoid shape and previous studies has successfully fit the original data with the Logistic Model [19, 20, 21]. Thus, in this study, Logistic Model was used to fit the data and determined the value of $\mu_{max}$. The $\mu_{max}$ values were calculated using Equation 1 below:

$$X = \frac{XoXmax \cdot e^{\mu_{max}t}}{Xmax - Xo + Xoe^{\mu_{max}t}} \quad (1)$$

where X is the value of predicted biomass achieved by the Logistic Model, $X_0$ is the initial biomass achieved during the experimental set up, and $X_{max}$ is the maximum biomass achieved while t is the time take during the experiment.

**Molecular identification**

Single/Pure strain of microalgae achieved in isolation process was used in molecular identification. Wet biomass of microalgae were collected and genomic DNA was extracted from it by using liquid nitrogen. Liquid nitrogen is a good agent for extraction due to the low temperature properties which it has boiling point at -196 °C and this will freeze and

crystalize the microalgae cells in the biomass instantly. Wet biomasses from cultivated microalgae were soaked into liquid nitrogen and homogenized with mortar and pestle for initial steps in breaking the cell wall of microalgae in order to extract the genomic DNA (gDNA). Next steps in achieving gDNA, extraction kit from Promega containing nuclei lysis solution, protein precipitation solution, isopropanol, ethanol and RNase solution was used according to manual from the manufacturer. Biomass achieved was then extracted using plant extraction kit by Promega Wizard Genomic DNA Purification Kit [22]. 18s rRNA genes Polymeric Chain Reaction (PCR) amplified using forward (50 TACTGTGAAACTGCGAATGGCTC 30) and reverse (50 TGATCCTTCCGCAGGTTCACCTA 30) primer was used in this process [23, 24]. The primer was design by FirstBase Sdn Bhd. Purified and single cultured microalgae from the coal-fired power plant were further identified using molecular identification.

PCR products were sequenced by Life Technologies (China). The sequenced products were compared with NCBI data bank using the BLAST Program. (NCBI BLAST, USA). Top ten similar results were achieved and compared for the similarity in the percentage value.

**Carbon dioxide sequestration**

Single/Pure strain of microalgae were then cultivated in 2L Schott Duran Bottle with 3 outlets on the top of the cap; 1) used for $CO_2$ sparging inlet point, 2) used for $CO_2$ sampling outlet, 3) used for secondary outlet as shown in Figure 1. Different $CO_2$ concentration at ambient air condition, 1% $CO_2$ and 5% $CO_2$ were tested to determine the preliminary result for $CO_2$ sequestration rate. $CO_2$ analyzer (Quantek, Model902D) was used in this run where infra-red sensor read the $CO_2$ concentration continuously. Continuous data were collected using data logger.

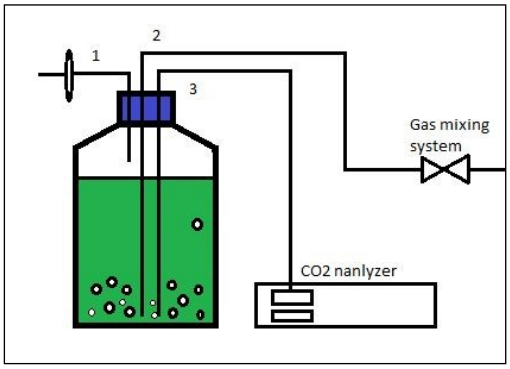

Figure 1. Schematic of cultivation in 2L Schott Duran for $CO_2$ sequestration experiments; 1) air outlet, 2) gas mixing system inlet and 3) $CO_2$ analyzer outlet

## Results and Discussion

**Isolation of microalgae**

The samples that were collected have a pH ranging around 7.0 to 8.5. This alkalinity can be explained due to the sample of the water; usage water containing isolated microalgae source was used as a cooling water for the coal-fired power plant which ash from the burning coal contribute to this phenomena [25, 26].

Isolation process of microalgae with both liquid medium and 1.25% agar plate showed that microalgae only survived in the F/2 Medium and TNBR medium. Isolation using BBM in liquid medium and agar plate showed lower growth in liquid medium cultivation, while in agar plate there was no colony detected. This can be explained due to higher salinity of F/2 medium and TNBR medium which both used artificial seawater as a component of the medium, while BBM has much lower salinity [27]. Microalgae which has been collected from the source has been exposed and acclimatized to the higher salinity environment for long period of time. From this finding, it can be determined that F/2 medium and TNBR medium is the most suitable medium compare to BBM. Thus, only F/2 medium and TNBR medium was chosen for the next experiment on purification and identification process. Besides sea water as the main

factor for higher salinity, higher alkalinity of the water at the source of isolation place was effected by the ash produced by the coal-fired power plant. Result also showed that at pH more than 7, isolated microalgae start to pick up the higher phase of growth.

**Cultivation and morphological identification of microalgae**

Isolated and purified microalgae were cultivated in F/2 medium and TNBR medium. Growth profiles of the microalgae were determined by biomass accumulation in both F/2 and TNBR medium. Figure 2 showed the growth curve of isolated microalgae in TNBR medium (ambient air, 1% and 5% $CO_2$) and Figure 3 showed the growth curve of isolated in F/2 medium (ambient air and 5% $CO_2$). From the growth profile, the specific maximum growth rate ($\mu_{max}$) of each cultivation was determined by using MathLab 9.0 version software. Logistic model was used for the curve fitting in for the microalgae growth curve. Population and productivity of microalgae has been widely using Logistic Model for curve fitting since the Logistic equation often represent growth data better than the exponential one [21]. The value of $\mu_{max}$ was calculated according to the Equation 1.

Result of $\mu_{max}$ showed that TNBR medium promote better growth by producing higher $\mu_{max}$ value compare to F/2 medium. By using TNBR medium the value of $\mu_{max}$ achieved were 0.4046 $day^{-1}$, 0.4288 $day^{-1}$ and 0.4908 $day^{-1}$ for ambient air, 1 % $CO_2$ and 5% $CO_2$ respectively. Result of $\mu_{max}$ from F/2 medium achieved were 0.2784 $day^{-1}$ and 0.3937$day^{-1}$ for ambient air and 5% $CO_2$ respectively. Higher value of $\mu_{max}$ achieved by TNBR medium cultivated microalgae was due to high nutrients content compare to the F/2 medium. TNBR medium used in this experiment is an optimized medium from F/2 medium.

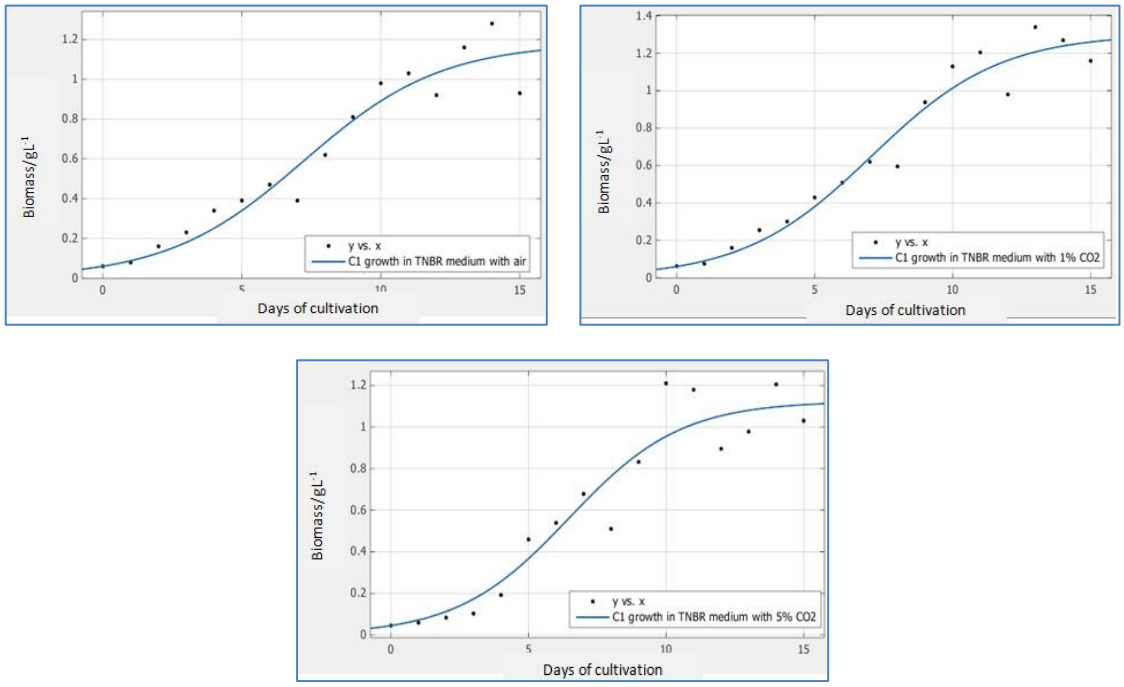

Figure 2. Growth curve of isolated *Chlorella* sp. with TNBR medium at ambient air, 1%and 5% $CO_2$

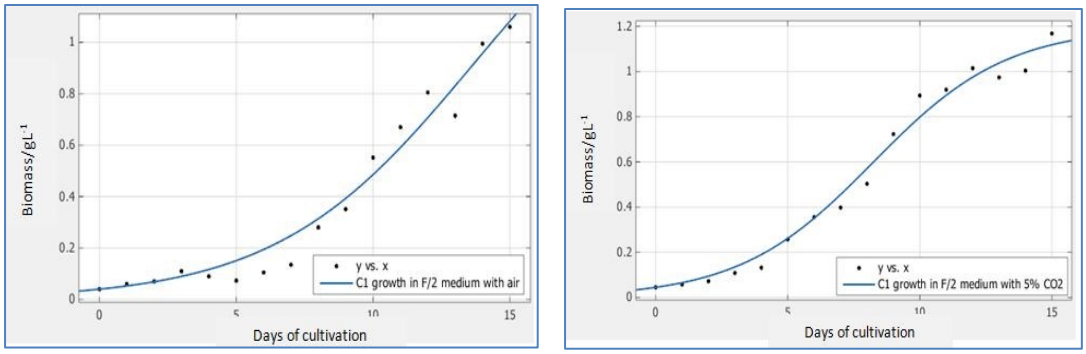

Figure 3. Growth curve of Chlorella sp. with F/2 medium at ambient air, and 5% $CO_2$

Morphological identification was conducted by characterization of microalgae. Under microscopic observation, the size of the purified microalgae is ranging around 4.24 ~10 µm with the area around 56.48 $\mu m^2$. The visible characteristic that can be observed was round shape with transparent outer membrane. All the purified microalgae showed round or ellipsoidal shape with a thin layer of membrane without any extension of flagella. The purified microalgae also have gridle shape of chloroplast. The chloroplast occupies most of periphery except for the cell ends. It also has the tendency to clump together into big colonies with a slow movement [28]. By assessment of all the morphological characteristic of the isolated microalgae, the suspected species was *Chlorella* sp. Figure 4 shows the morphological view under 400x magnifications with comparison from *Chlorella* sp. from UTEX (1000x magnification). Microalgae *Chlorella* species is blue-green algae which is belongs to phylum chlorophyta division. Most of Chlorella species survived and cultivated in freshwater conditions. However, several reports and studies on isolation showed the versatility and the availability of *Chlorella* species to adapt and survive in marine environment [29, 30]. Other result from NCBI also showed that several microalgae which were isolated from South China Sea were confirmed to be *Chlorella* species. Thus, it make the morphological identification of this experiment valid to be *Chlorella* sp. Further identification was confirmed with molecular identification with genes sequencing.

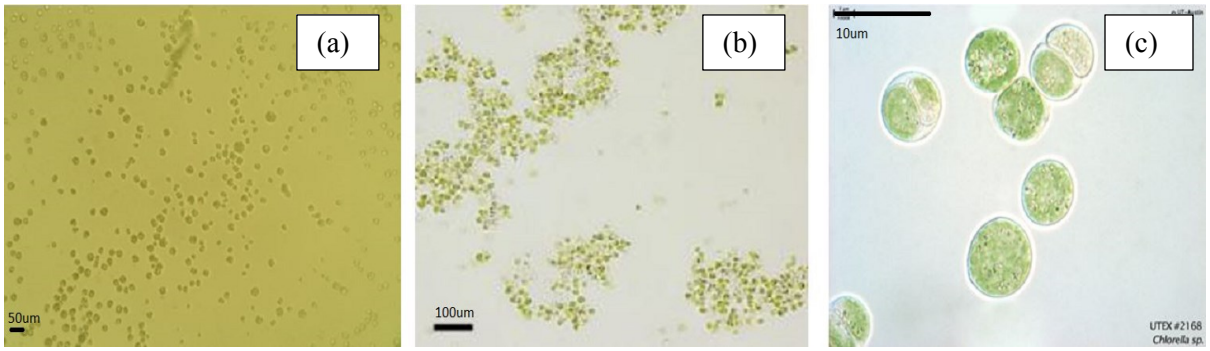

Figure 4. Morphological observation of (1)isolated microalgae (40x magnification) with comparison from (2) Imase et al. and (3) *Chlorella* sp. of UTEX (1000x magnification) [31]

**Molecular identification of microalgae**

Extraction and Purification of gDNA was conducted with a procedure suggested by the manual form the manufacturer (Promega) as mention in methodology section. Extracted gDNA then amplified using PCR with 18s rRNA primer before it is sequenced. Figure 5 showed that PCR product were run into gel for confirmations before the PCR product undergoes sequencing process.

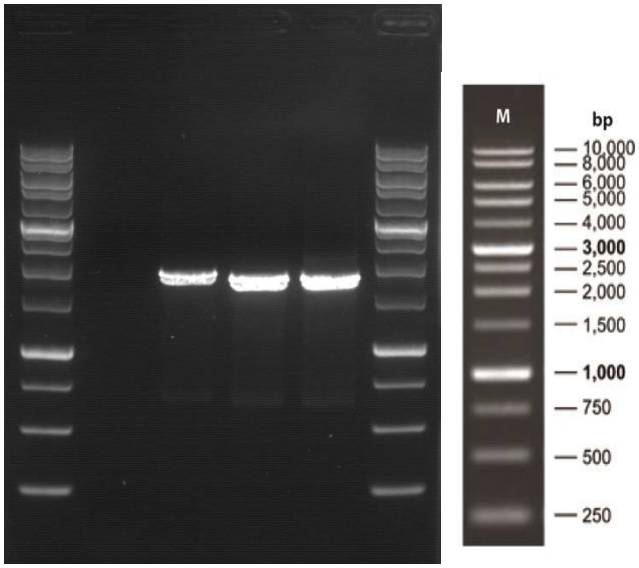

Figure 5. Result of PCR gel run on the ladder. Negative (-) was the PCR non-template control (water only), and positive (+) is positive control using DNA extracted from human blood sample as a template

PCR product which has been successfully sequenced has the size of 1792bp. Full sequenced by 18s rRNA gave full sequenced of the isolated microalgae. Full sequenced obtained from sequencing process was blast into the NCBI BLAST software to compare the obtained result with the gene bank for the identification purpose. Top ten hits blast result were observed and showed in the Figure 6 in the form of phylogenetic tree where most of the result showed the similarity to the isolated microalgae from the coal-fired power plant. Result from the list of showed seven out of ten confirm up to 99% that an isolated, purified and sequenced microalgae is *Chlorella* sp. Thus, from molecular result plus with similar characteristic by morphological identification, it was confirm that isolated microalgae were *Chlorella* sp.

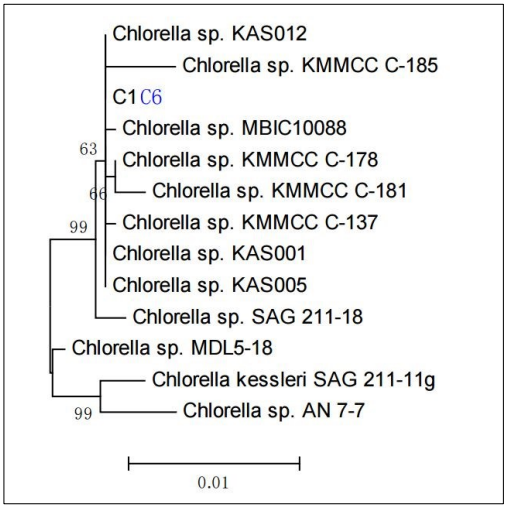

Figure 6. Top ten of phylogenetic tree of isolated microalgae; *Chlorella* sp. from NCBI genes bank database

Among the similar result from the phylogenetic tree, *Chlorella* sp. SAG 211-18 showed similarity almost to 99%. According to the data base from the Experimental Phycology and Culture Collection of Algae at the University of Goettingen (EPSAG), this microalgae which was formally called as *Chlorella sorokiniana* was isolated from Sweden. The source of the microalgae was from freshwater habitat which is surrounded by the Baltic Sea. Similar to the isolated microalgae in this study, the species was exposed to harsh environment surrounding of coal-fired power plant and closed proximity to the marine environment.

**$CO_2$ sequestration**

Isolated native microalgae were tested for its capability in performing carbon capture and storage (CCS) by sequestration of $CO_2$. Result from the $\mu_{max}$ value, showed that TNBR medium gave better result in the growth profile of microalgae. Thus in the $CO_2$ sequestration test, TNBR medium was used as the main medium for microalgae cultivation. $CO_2$ was supplied by mixing the 95% purity of $CO_2$ with compress air. At 1% and 5 % concentration, $CO_2$ were fixed for the run and the percentage was set using volume/volume ratio (v/v).Results of $CO_2$ sequestration by isolated *Chlorella* sp. are shown in Figure 7a and 7b. Result from 1% and 5% of $CO_2$ input showed that isolated *Chlorella* sp. manage to sequester $CO_2$ up to 4.3% and 4.5% respectively. Comparison with previous result showed that marine *Chlorella* sp. showed lower $CO_2$ sequestration uptake compare to the *Chlorella* sp. which has been reported previously which is ranging from the 15% to 30% ability to absorb the CO2 into the biomass form [18, 32]. Higher uptake $CO_2$ can be achieved in optimization of higher $CO_2$ input and aeration rate.

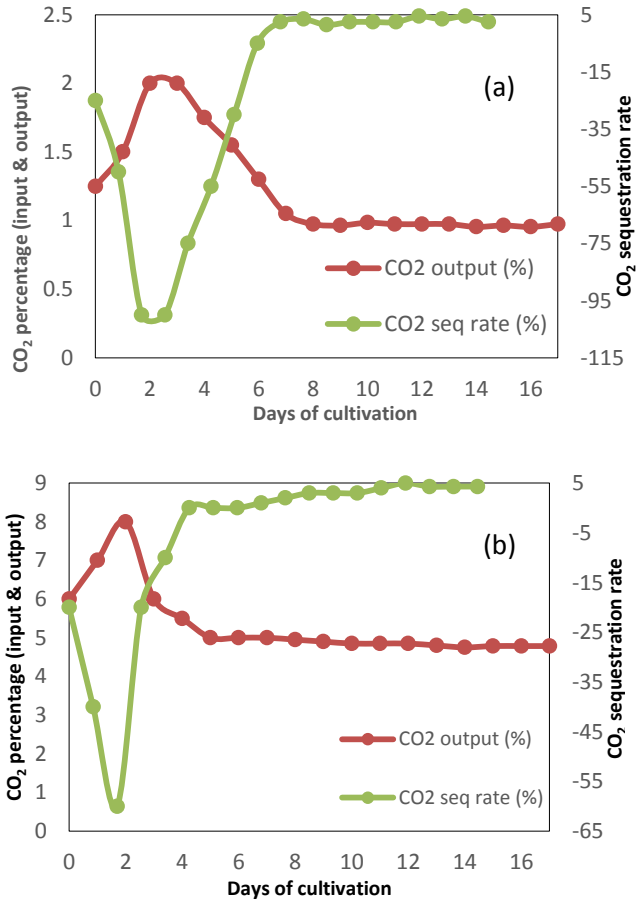

Figure 7. Result of *Chlorella* sp. in performing $CO_2$ sequestration at a) 1% $CO_2$ concentration and b) 5% $CO_2$ concentrations, repectively

However, higher accumulation of $CO_2$ in the first phase of algae culturing has produce a spike in the beginning of 5 to 7 days of cultivation periods. These phenomena can be explained by the lag phase of microalgae which has lower growth at the initial stage. Higher accumulation at the initial stage can be reduced with better inoculation process which is inoculums at the exponential phase are used for every single run. Acclimatization of microalgae to higher $CO_2$ concentration will also contribute to higher sequestration rate and reduce the accumulation of $CO_2$ in the initial phase.

The spike reduction with time of cultivation has shown that microalgae has the potential that can be tapped to produced biomass even with higher $CO_2$ concentration compare to the ambient air and this biomass later can be utilized in other product that can contribute to more capital as the world moving forward for the generating waste from the wealth. Thus, the isolated *Chlorella* sp. showed significant result in CCS by converting the $CO_2$ supplied into the biomass form.

## Conclusion

Chlorella sp. has been isolated from the native environment of Stesen Janakuasa Sultan Azlan Shah. Through morphological and molecular identification it has been confirmed that isolated strain is Chlorella sp. which has similar sequenced to *Chlorella sorokinia* from SAG 211-18. Isolated *Chlorella* sp. also showed that for higher growth it more favor the TNBR medium by achieving higher μmax value compare to the F/2 medium. At higher $CO_2$ percentage, isolated Chlorella sp. showed that it has potential in reducing the $CO_2$ while still survive and accumulate the biomass. Therefore, isolated Chlorella sp. can be used and explored more on its $CO_2$ tolerance at higher $CO_2$ concentration and can be utilized to biofixation of $CO_2$ from coal-fired power plant, which contributes to a reduction in global warming.

## Acknowledgement

The authors would like to acknowledge and thank TNB Research Technical Board Committee for approving a seed fund no. TNBR/SF0157/2014 and UKM in supporting the research financially and educationally between 2014 and 2015. Also appreciating the Management of TNB Janamanjung Sdn. Bhd. for their co-operation and support.

**Abstract**

Approximately, about 50 million tons of Palm Oil Mill Effluent (POME) is produced every year, however, discharge of POME to open water source will cause negative impact to environment. High production of POME makes it impossible to dispose at the disposal company, therefore, *in-situ* treatment has been developed. Current disposal method implemented by palm oil industries is through biodegradable pond. This method is applied due to high water content in POME about 90% of water. Microwave assisted pyrolysis would be an alternative method to deal with the POME since not only can disposed but also can convert to valuable material such as solid char and pyrolytic oil. In this paper, effect of mass loading of POME at a range of 100 to 500 grams with additional activated carbon (AC) was studied. Microwave power level, radiation time and mixing ratio of AC were set constant at 1000 W, 30 minutes and 5%, respectively. Product yields of solid and liquid were analyzed for the best process performance. Solid char obtained has a potential to be utilized as solid fuel since its energy content was >20 MJ/kg and has high carbon content at >80%. Meanwhile, about 20% of chemical content in the pyrolytic oil has the carbon number in the range of $C_1$ to $C_{10}$.

**Keywords**: mass loading, microwave absorber, microwave-assisted pyrolysis, palm oil mill effluent

**Abstrak**

Dianggarkan lebih kurang 50 juta ton Sisa Buangan Kilang Kelapa Sawit (POME) dihasilkan setiap tahun. Pembuangan POME ke sumber air semulajadi seperti sungai akan menyebabkan impak negatif kepada alam sekitar. Penghasilan POME yang tinggi menyebabkan ianya mustahil untuk dilupuskan oleh syarikat pelupusan, oleh yang demikian, rawatan *in-situ* dibangunkan. Cara pelupusan terkini oleh industri kelapa sawit adalah melalui kaedah kolam bio-degradasi. Kaedah ini diaplikasikan berikutan kandungan air yang tinggi di dalam POME iaitu lebih kurang 90% daripada isi kandungannya. Oleh yang demikian, kaedah menambahbaik pirolisis bantuan gelombang mikro (MAP) digunakan dan sekaligus POME dapat dilupuskan dan menukar hasil yang bermanfaat seperti arang pepejal and minyak pirolisis. Di dalam kajian ini, kesan berat kandungan POME di dalam anggaran 100 g ke 500 g dengan penambahan karbon aktif diberi tumpuan. Kadar kekuatan gelombang mikro, masa radiasi dan nisbah pencampuran karbon aktif masing – masing dimalarkan pada kadar 1000 W, 30 minit dan 5%. Penghasilan produk arang pepejal dan minyak pirolitik dianalisis untuk menentukan kadar terbaik penghasilannya. Arang pepejal yang terhasil mempunyai potensi sebagai sumber tenaga dan mempunyai kapasiti tenaga sekurang-kurangnya >20 MJ/kg dan mengandungi kandungan

karbon >8%. Sementara itu, lebih kurang 20% kandungan bahan kimia di dalam minyak pirolitik terdiri daripada karbon nombor pada kadar $C_1$ to $C_{10}$.

**Kata kunci:** beban jisim, penyerap ketuhar gelombang mikro, pirolisis bantuan gelombang mikro, air sisa kilang saw

## Introduction

In general, agriculture is one of the industries that generates large amount of harmful wastes or effluents. Example of effluent produced from agriculture industry is palm oil mill effluent (POME). According to Aziz and Mun, the palm oil industry has generated the highest percentage of effluent as compared to the other agriculture industries [1]. Due to this problem, most of the palm oil mills applied the cheapest alternatives by discharging POME on the land or releasing it into the river. Consequently, this action will cause negative impacts to human health, aquatic life, environment and ecological system such as clogging and water logging of the soil, kills the vegetation on contact, water depletion and aquatic pollution if not treated properly [2]. There are several methods that have been applied in palm oil industry to treat POME such as aerobic, anaerobic, digestion, biodegradation, gasification and ponding treatment [3]. However, there are drawbacks from these methods, which can reduce the efficiency of POME treatment. Lorestani et al., stated that ponding treatment provides longer retention time for the POME to be degraded, low treatment efficiency, large requirement of land, large amount of methane being released and large amount of sludge production [4]. Therefore, there is a potential method as an alternative treatment of POME through microwave pyrolysis. According to Khalid et al. and Salema et al., various studies about microwave heating on POME have been performed by researchers nowadays [5, 6]. Microwave pyrolysis can convert POME into three different useful products which are solid-char, liquid and gas. Moreover, microwave pyrolysis provides more advantages compared to the other methods such as shorter exposure time for POME to be degraded and can break down polycyclic aromatic hydrocarbon into low hydrocarbon chain. In addition, microwave pyrolysis is more economical and convenient since it can be operated *in-situ* [7]. Therefore, the aim for this study is to investigate the feasibility of converting POME into valuable materials such as solid char and pyrolytic oil through microwave assisted pyrolysis process.

About 2.5 tons of palm oil mill effluent (POME) was generated for every ton of palm oil produced. According to Lorestani et al., it was stated that the huge contribution of POME was generated from the combination of wastewater from three main sources which are sterilization, clarification and hydrocyclone processes [4]. POME can be considered as the most harmful waste to human health and environment. POME has high organic load and concentrated colloidal slurry of 95 - 96% of water, 0.6 - 0.7% of oil and 4 - 5% of fine cellulose material [8]. According to Lorestani et al., it was stated that POME contains various suspended materials including short fibers, cell wall, organelles, nitrogenous materials ranging from proteins to amino acids, carbohydrates that ranging from hemicelluloses to a simple sugar, free organic acids and some mineral constituents [4]. Moreover, liquid effluent from palm oil mill includes dissolved constituents such as high concentration of carbohydrates, protein, minerals, nitrogenous compounds and lipids which can be converted into useful materials using specific process. Other than that, POME has a bad odor and thick brownish liquid that contains high solids, oil and grease, high content of chemical oxygen demand (COD) and biochemical oxygen demand (BOD) [2]. It is proven that POME is harmful to human health, aquatic life and environment not only because it contains so much pollutants but the dark brown color itself can impart some negative effect. Therefore, it is necessary to treat the POME before being discharged to the environment.

There are numerous treatments of POME that proposed by several researchers. POME can be treated by conventional method or biological method. However, limited studies on microwave pyrolysis are available particularly relating to treatment of POME. The list of methods and its details are presented in Table 1. As can be seen, the existing methods available had not focused on upgrading the wastes to valuable materials. Thus, microwave assisted pyrolysis technique deems feasible for the recovery of POME to produce valuable materials such as bio-char and pyrolytic oil.

Table 1. List of palm oil mill effluent treatment methods

| Treatment | Details | References |
|---|---|---|
| Anaerobic digestion | • Breakdown the biodegradable material without the presence of oxygen<br>• Produce methane, carbon dioxide and fertilizers | [4, 8, 9] |
| Adsorption by Fungi | • To remove the impurities and colour from the POME.<br>• This treatment takes time as it needs to nurture the fungi. | [10] |
| Aerobic biological | • Degradation of organic material with the presence of oxygen.<br>• Decrease carbon content and inorganic nitrogen.<br>• Can change the pH from acidic to alkali. | [11, 12] |
| Facultative pond | • The effluent is discharged to the pond and let it degrades by itself.<br>• It takes longer retention time. | [13, 16] |
| Membrane | • Separate organic material effectively | [14, 17] |

Pyrolysis is a heating process of materials without the presence of oxygen. Generally, conventional pyrolysis transfers the heat from outer surface to the center of the material by external heating which includes conduction, convection and radiation [18]. In conventional heating, material is heated volumetrically by heating energy is dissipated through the material from the surface by means of convection, conduction and radiation [19]. In comparison to conventional pyrolysis, microwave pyrolysis technique uses microwave radiation in order to generate heat. As the microwave radiation is penetrated into the material, it causes the electromagnetic energy to be converted into thermal energy. Microwave consists of electric and magnetic field which perpendicular to each other and will cause rotation or collision of the molecules. By referring to the microwave frequency, the molecular dipole inside the material will rapidly rotate about 2450 million times per second and causing frictions that convert the electromagnetic energy into heat [20]. In addition, microwave radiation will penetrate into the material and heat the absorber first [21]. Material that can absorb microwave radiation is called as dielectric [22]. The examples of materials that influence the dielectric properties are water and salt. Therefore, microwave heating is most efficient on the material that contain high amount of dielectric molecules. Since, POME has high moisture content, microwave-assisted pyrolysis is very suitable for treating POME. Additional of microwave absorber material such as activated carbon can enhance microwave assisted pyrolysis process. There are several methods of application of microwave absorber in the microwave assisted pyrolysis process. Microwave absorber could be mixed homogeneously with sample [23] or it can be in separate crucible [21]. Both of these methods could give different effects on the product yields. In this study, both methods were applied in order to study the effect of mass loading toward the method of application of microwave absorber.

## Materials and Methods

### Experimental setup

In this study, the untreated POME was used as a sample for microwave pyrolysis process. The untreated POME sample was collected from the final discharge point in FELDA Serting, Negeri Sembilan before it was channeled to the treatment pond. The samples were prepared in three conditions namely a sample without the presence of activated carbon, a sample mixed homogeneously with activated carbon and a sample with the presence of activated carbon in crucible as stated in Figure 1. Each condition has 5 different mass loading which are 100, 200, 300, 400 and 500g of POME. Activated carbon used in this study was obtained from Sigma-Aldrich. About constant 5% wt/wt of activated carbon was used in this study. Therefore, the mass loadings used in this experiment and the weight percentage of activated carbon used in this study are stated in Table 2. Wet POME sample that had been prepared was placed in a quartz reactor.

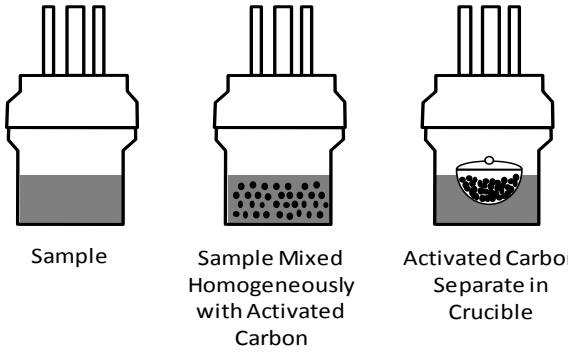

Figure 1. Method application of activated carbon in reactor

Table 2. Mass loading and activated carbon ratio

| Mass of POME Sample (g) | Weight of Activated Carbon (g) |
|---|---|
| 100 | 5 |
| 200 | 10 |
| 300 | 15 |
| 400 | 20 |
| 500 | 25 |

Then, the reactor was placed into the microwave chamber with a lid having three openings, each for inert gas input, thermocouple and gas exit, respectively. The quartz reactor was purged for duration of 20 minutes with nitrogen gas (99.9%) at a flow rate of 250 mL/min in order to remove any remaining oxygen. However, the flow rate of nitrogen gas was kept constant at 150 mL/min during the process[26]. POME sample was run with the different conditions and mass loadings in order to obtain an optimum mass that can produce highest yields of solid and liquid product. The microwave power input and radiation time were kept constant at 1000 W and 30 minutes, respectively.

**Analytical methods**

The liquid product was condensed in the condenser and collected in the liquid sample holder. After that, the liquid product was washed with hexane and then analyzed with the analytical method. For solid product (char), it is collected once the experiment was completed and analyzed after being cooled down at room temperature. Figure 2 shows the schematic diagram for the microwave pyrolysis system. Solid product which is the solid char obtained was analyzed for its physical properties through proximate, ultimate and calorific analyses was conducted by using thermogravimetric analysis (TGA/ SDTA851) manufactured by Mettler, elemental analyzer (Thermo Finnigan Flashed 1112) and bomb calorimeter (Ika-works C5000 Control Germany D79019), respectively. Meanwhile, pyrolytic oil extracted from the liquid product was analyzed using gas chromatography mass spectrometer (GCMS) model GC Varian 450-GC. Helium was used as a carrier gas at a flow rate of 1 mL/min. Non-polar capillary column was selected for detection of C and H atoms or C-C bonds. Oven temperature initially was set at 100 °C and then it is kept constant for 2 minutes at a heating rate of 5 °C/min. After that, it was increased to 200 °C at a heating rate of 10 °C/min. Then, it was followed by heating to 260 °C at a heating rate of 4 °C/min. Temperature was maintained at 260 °C for 15 minutes. For chromatography, injection temperature was set at 270 °C. Chemical compound in the liquid oil was traced and identified at the setting of mass per ion, M/Z = 30 – 500. Split ratio was set at 1:10.

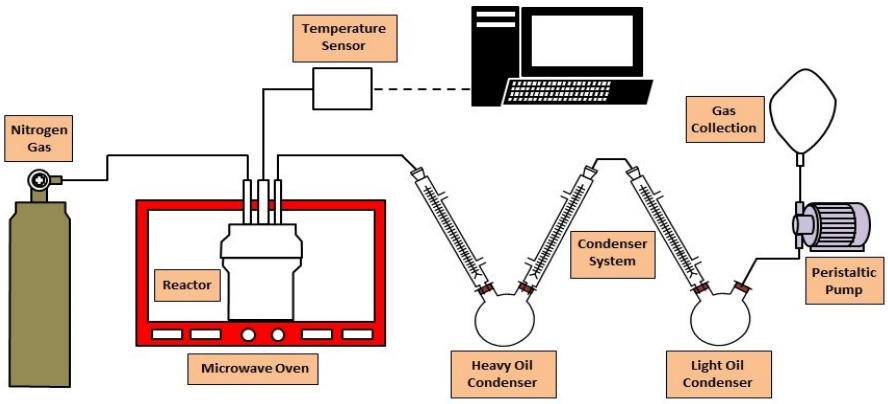

Figure 2. Schematic diagram for microwave pyrolysis system [26]

## Results and Discussion

### Raw material characterization

In general, the characteristic of raw material can be classified into two types which are physical and chemical properties. Physical properties of POME obtained from proximate analysis using Thermogravimetric Analyzer (TGA) Mettler Toledo TGA/SDTA 851 and followed the standard of ASTM D7582-12. Figure 3 shows that water content in dried POME start to vaporize at temperature 40 °C to 136 °C.

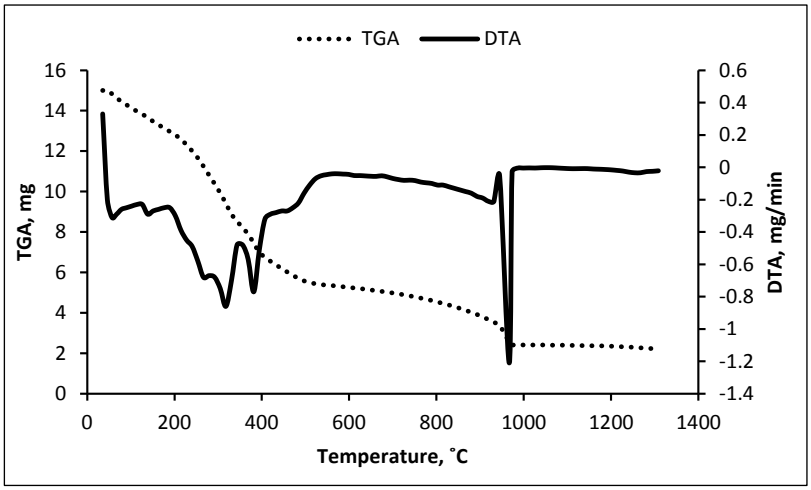

Figure 3. Thermal degradation of proximate analysis of raw material

All volatile matter inside POME starts to degrade at temperature 139 °C to 939 °C before it is released to surrounding. The optimum temperature for degradation of POME is known to be at the temperature of 320.13 °C where all longer hydrocarbons are converted into lower hydrocarbons. Other than that, thermal degradation of proximate analysis of raw material also provides value for moisture content, volatile combustible matter, fixed carbon and ash. Fixed carbon is a combustible residue after volatile matter was removed and ash is a weight of residue after combustion in an open crucible. All the values obtained from proximate analysis are important for raw material characterization. Therefore, the characterization of POME is stated in the Table 3. Chemical properties of palm oil mill effluent (POME) can be obtained from ultimate analysis, energy content and fusing point of ash. Since

POME is in the form of liquid, the physical properties of this raw material can only be analyzed by observation of specific weight such as volume.

Table 3. Characterization of raw palm oil mill effluent (POME)

| Characteristic | % |
|---|---|
| Moisture content | 14.4 |
| Volatile combustible matter | 13.7 |
| Fixed carbon | 71 |
| Fixed ash content | 0.9 |

Ultimate analysis is used to determine the percent of C, H, N, S, O and ash. The percent of C, H, N, S, O and ash obtained is important in order to identify chemical formula which then can be used in various chemical and biological reactions. However, for this analysis, the chemical composition of POME is obtained from literature. According to Khairuddin et al., the chemical formula for POME is $C_{25}H_5N_5SO_{59}$ [24]. Table 4 shows the percent C, H, N, S and O of POME obtained from the literature. Energy content is a potentially critical element in combustion. For this study, the energy content of POME is obtained from the literature. In a study by Januri et al., energy content in POME can be considered as high which is 16.16 MJ/kg [25]. Since the energy content inside POME is high, it has a potential to be used in future as fuel and the source of energy.

Table 4. Ultimate analysis for raw palm oil mill effluent (POME)

| Element | C (%) | H (%) | N (%) | S (%) | O (%) |
|---|---|---|---|---|---|
| As Received | 26.57 | 4.97 | 5.66 | 1.05 | 61.78 |
| Dry basis | 31.04 | 3.92 | 6.61 | 1.23 | 56.15 |
| Dry Ash free basis | 31.37 | 5.87 | 6.68 | 1.24 | 54.84 |

**Product yield**

Generally, the pattern of product yield formed from microwave pyrolysis of POME for solid are showed an increment with the increased of mass loadings as shown in Figure 4. However, the conversion of POME into solid char show a divergent pattern as shown in Table 5 as the mass loading increased, the conversion dropped from ~98 to ~61%. This is due to the condition where water is the dominant inside the POME was activated, self-propagated and vaporized during the pyrolysis but it limited the pyrolysis process condition, which reduced the conversion of solid char. Process of releasing the water content from the POME took place and decreased the pyrolysis reaction. No conversion of solid char was observed for all samples with non-microwave absorber indicating the sample was not fully pyrolyzed even though high conversion was achieved. Meanwhile, sample with microwave absorber regardless it is mixed homogeneously or in separate crucible, solid char was formed at low mass loading below 200 g with yield and conversion for both mixed homogeneously and in separate crucible were ~1.5% yields; ~98.5% conversion and ~3.3% yields; 96.7% conversion, respectively. Addition of microwave absorber has increased the reaction temperature and consequently increased the product yields [27]. Solid char was formed with aid of microwave absorber during microwave assisted pyrolysis process. Indeed the introduction of microwave absorber via separate crucible has increased yields of solid char formed. Microwave absorber bed in separate crucible improved the microwave irradiation towards the absorbance properties of POME [21]. Low conversion of solid char was observed at high mass loading at range 300 to 500 g. This was due to the depth of penetration of microwave radiation through the sample. The depth of penetration of microwave energy into the sample is measurement to determine how much the completion of pyrolysis.

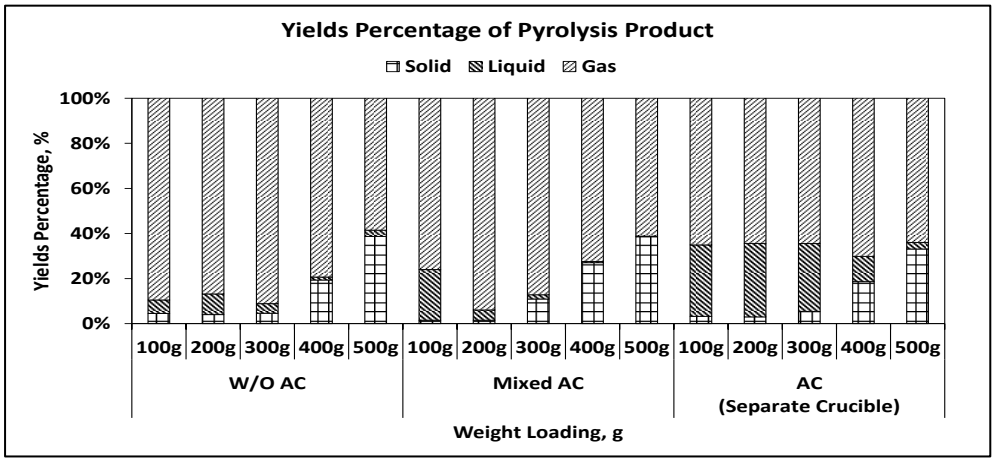

Figure 4. Yield percentage of product distribution

Table 5. Conversion of POME into solid char

| Conditions | Mass Loading (G) | Solid Yields (%) | Conversion (%) | Visual Result |
|---|---|---|---|---|
| No activated carbon | 100 | 4.50 | 96.00 | Semi coke |
| | 200 | 4.05 | 95.95 | Dried sample |
| | 300 | 4.67 | 95.33 | Dried sample |
| | 400 | 19.40 | 80.60 | Undried sample |
| | 500 | 38.70 | 61.30 | Undried sample |
| With activated carbon (mix homogeneously) | 100 | 1.50 | 98.50 | Char |
| | 200 | 1.50 | 98.50 | Char |
| | 300 | 10.97 | 89.03 | Semi coke |
| | 400 | 27.03 | 72.98 | Undried sample |
| | 500 | 38.54 | 61.46 | Undried sample |
| With activated carbon (separate crucible) | 100 | 3.30 | 96.70 | Char |
| | 200 | 3.05 | 96.95 | Char |
| | 300 | 5.47 | 94.53 | Semi coke |
| | 400 | 18.60 | 81.40 | Dried sample |
| | 500 | 33.08 | 66.92 | Dried sample |

The practical reason for determining the depth of penetration is to ensure efficient heating of the materials throughout its interior. If the frequencies are higher, the microwave radiation might get absorbed on the surface of the materials, and will penetrate only a short distance [28]. High volume of sample might affect the depth of penetration of microwave radiation. Thus, the presence of activated carbon with high dielectric properties enhanced the depth of penetration of microwave radiation and heated the materials uniformly. It has been stated by R. Meredith (1998), dielectric constant plays an important role in the power penetration [29].

In comparison, yield of liquid product decreased when the mass loading increased as shown in Figure 4. Liquid product yield consists of two components, which are pyrolytic oil and water in the form of aqueous that had been vaporized during the microwave assisted pyrolysis process. This is due to the effectiveness of pyrolysis condition of POME, which is the mass loading to the microwave irradiation. Through observation of Figure 5, yields of liquid product increased with two different methods application of activated carbon as microwave absorber applied. Thus, pyrolytic thermal cracking could be achieved with the application of microwave absorber during microwave assisted pyrolysis process [30]. Consequently it would increase yields of liquid product with the addition of microwave absorber into raw material [27, 31]. Activated carbon in separate crucible produced more yields of liquid product and furthermore, the percentage of pyrolytic oil separated from yields of liquid product was also higher compared to pyrolytic oil gain from the process which sample has been mixed homogeneously with activated carbon. It could be said that, microwave assisted pyrolysis process achieved highest reaction temperature from the heating of activated in separate crucible which promoted high hydrocarbon breakdown of POME and produced more pyrolytic oil. Similar trend was observed from other researcher by formed the microwave absorbent bed in the microwave assisted pyrolysis reactor that increased the pyrolytic oil yield [32]. Increase in the mass loading has reduced the pyrolytic oil yields in the yields of liquid product due to the incomplete pyrolysis reached. Hence, sample that has mass loading more than 300 g in average cannot obtain fully pyrolyzed condition successfully, indicating by the low conversion percentage of solid char, low solid char yields and low pyrolytic oil yields. This can be concluded that 300 g sample with the presence of microwave absorber can be the maximum mass loading to pyrolyze POME and separated microwave absorbent during microwave assisted pyrolysis process will be the best applicable method for microwave absorbent application in the process.

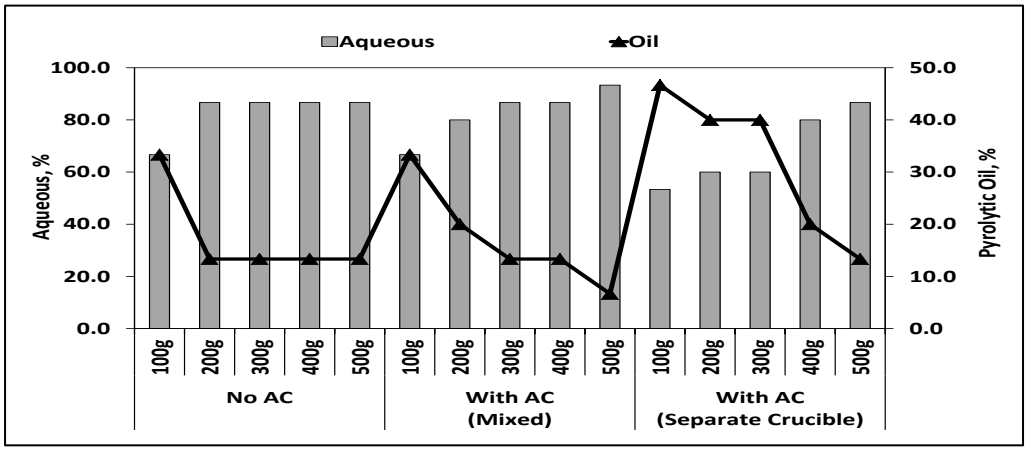

Figure 5. Aqueous –pyrolytic oil percentage extracted from liquid yields

**Solid product analysis**

Solid char was analyzed for it physical properties by proximate and ultimate analysis. From the proximate analysis data obtained from Table 6, microwave assisted pyrolysis released the volatile matter out from the raw POME thus it promoted the formation of solid at low mass loading at 100 g. Indeed almost complete pyrolysis was achieved by POME using this method. Lack of dielectric constant properties in raw POME has reduced the potential of microwave assisted pyrolysis.

With the improvised microwave assisted pyrolysis method by the addition of the microwave absorber such as activated carbon, has increased the total dielectric constant of the sample thus enhanced the pyrolysis process through higher temperature [33-35]. It was observed that the addition of microwave absorber (AC), for both mixed homogeneously and in separate crucible has increased the efficiency of pyrolysis through the effectiveness of microwave radiation absorbed and activated more molecule to generate more heat energy at high mass loading such as 200 g and 300 g for the method of mixed AC homogeneously and in separate crucible respectively. By releasing

the higher amount of volatile matter from raw POME during pyrolysis process, it elevated the fixed carbon content in the solid char derived and it is consistent with the findings reported by other researchers on char derived from microwave assisted pyrolysis process [28, 36, 37]. Meanwhile, other research was found on pyrolysis of POME for bio-char, it resulted moisture content and ash content that were consistent with the char obtained [38]. On the other hand, high fixed carbon content in the solid char indicated high percentage of carbon element in the solid char, as can be seen in the ultimate analysis result in Table 6.

Table 6. Proximate and ultimate analysis of solid product of microwave assisted pyrolysis of POME

*Dry ash free basis
** Calculated by difference

Elemental content obtained from this analysis is then compared to the coal since coal is used as a solid fuel. According to Jing-biao et al., the percentage of C, H, N, S and O of *Baotou* bituminous coal are 70.18, 4.64, 1.5, 0.44 and 11.36%, respectively [39]. It was observed that carbon content in the microwave assisted pyrolysis process with the microwave absorber in separate crucible has high carbon content as compared to the one the mixed homogeneously. In comparison to the percentage of C, H, N S, O of coal, the solid char obtained from microwave assisted pyrolysis process with microwave absorber in separate crucible had almost identical elemental properties. The O/C ratio of the char obtained from microwave assisted pyrolysis process in separate crucible has low value as compared to other process. Solid char obtained has low H/C and O/C atomic ratio which indicates high carbon content and low hydrogen and oxygen content indicating the presence of low hydrocarbon compound in the solid char. The energy content is determined in order to identify the feasibility of utilizing solid product from pyrolysis of POME as alternative fuel in future. Figure 6 shows the gross calorific value of solid product from microwave pyrolysis of POME. It was observed that gross calorific value for both the chars obtained in the absence and the presence of microwave absorber in the condition of mixed homogeneously were kept increasing at range 100 g to 300 g except for the solid char obtained from process that microwave absorber in separate crucible. Its energy content decreased when mass loading increased to 300 g. In addition, sample having mass loading of 400 and 500 g for all methods/arrangements are known to be zero since the samples were in un-dried condition. Incomplete pyrolysis condition was found in this mass loading.

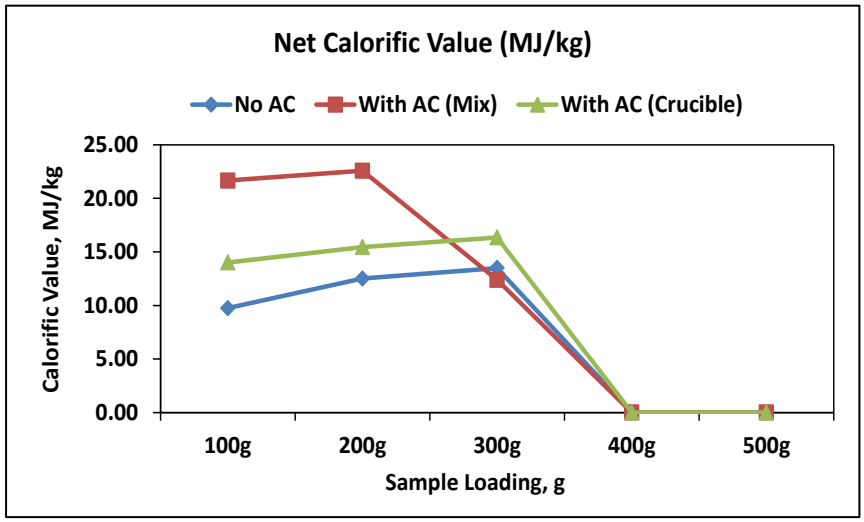

Figure 6. Net calorific value of solid product of POME

It is proven that solid product of microwave pyrolysis of POME that has high energy content which is more than 15000 J/g can be used as an alternative fuels in future. According to Thangalazhy-Gopakumar, solid char obtained from pyrolysis of POME was around 12.8 ± 0.2 MJ/kg [38]. It is consisted with the energy content obtained from microwave assisted pyrolysis of POME without the presence of microwave absorber. Energy content slightly increased from when it was pyrolysis with the aid of microwave absorber during the microwave pyrolysis process in separate crucible. The presence of microwave absorber increased the reaction temperature and consequently increased the fixed carbon content and elevated the energy content. However, solid char obtained from microwave assisted pyrolysis with the mixed homogeneously with activated carbon has higher energy content from the rest. Activated carbon itself has a quite high of energy content thus it increased the energy content of solid char obtained. Table 7 shows the gross and net calorific value of microwave pyrolysis of POME. The equation used to calculate net calorific value is shown in Equation 1.

$$\text{Net calorific value, kJ/kg} = \text{Gross calorific value} - 24.44(9\%\ \text{H} + \%\text{M}) \quad (1)$$

**Pyrolytic oil analysis**

Pyrolytic oil extracted from liquid product was analyzed for its chemical content by using gas chromatography mass spectrometer (GCMS). Pyrolysis oil extracted from the liquid product contain valuable hydrocarbon that can be potential to recover either in single component or as the oil. Through the observation in Figure 7, it was found that low chain ester such as 1,2-benzenedicarboxylic acid diisooctyl ester, 2-propenoic acid, 2-methyl dodecyl ester, and 9,12-octadecadienoic acid (Z,Z)- phenylmethyl ester was recovered in the pyrolytic oil at low mass loading. It was consistent with research on the pyrolytic oil from sewage sludge by other researchers [40, 41]. Meanwhile the nitrogenated compound was highly observed in the pyrolytic oil from microwave assisted pyrolysis of POME without microwave absorber. Nitrogenated compounds were not favorable for fuels; however, their presence can be reduced by changing the operating parameters [38].

Table 7. Gross and net calorific value of solid product of POME

| Conditions | Sample (g) | Gross Calorific Value (MJ/kg) | Net Calorific Value (MJ/kg) |
|---|---|---|---|

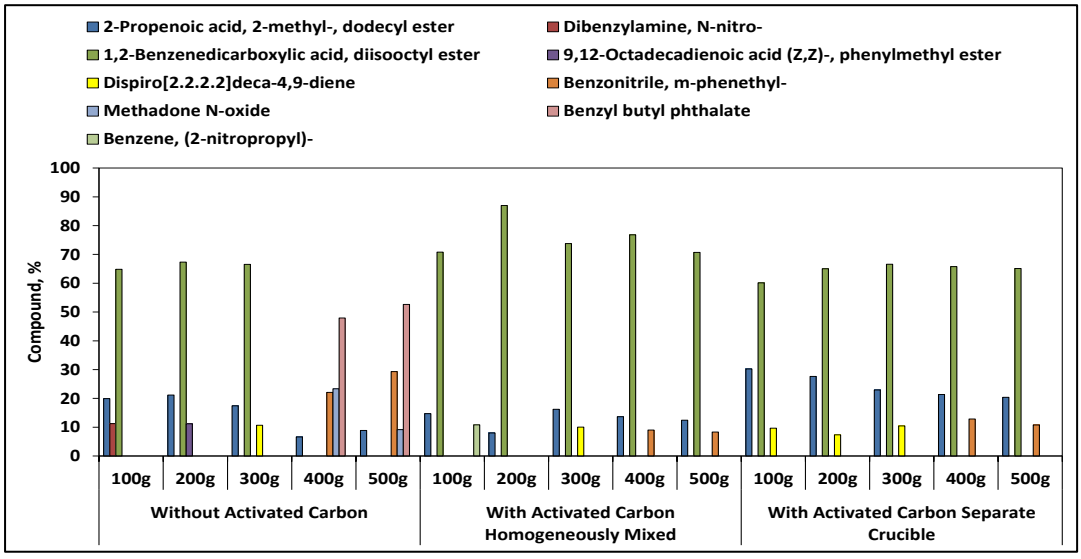

Figure 7. Chemical compound percentage from total ion chromatogram of pyrolytic oil

Thus, pyrolytic oil for both process mixed microwave absorber homogeneously and in separate crucible, eliminated and breakdown the nitrogenated compound into other low hydrocarbon compound. Moreover, low hydrocarbon chain compound production was elevated in the process with microwave absorber in separate crucible as shown in

Figure 8. Radiation temperature increased rapidly during the course of pyrolysis when microwave absorber in separate crucible was used. The introduction of microwave absorber added further reaction by increasing the radiation temperature and enhancing the hydrocarbon cracking with the dehydrogenation process through the Diels-Alder reaction [42]. With the increased of low hydrocarbon chain in the pyrolytic oil, it would increase the potential of pyrolytic oil to become fuel.

## Conclusion

In conclusions, this research has been carried out in order to study the effect of different sample mass loading and method application of activated carbon as microwave absorbent to the product yield of microwave-assisted pyrolysis of palm oil mill effluent (POME). POME cannot be fully pyrolyzed using domestic modified microwave oven with the highest microwave power level and longest radiation time. With the presence of activated carbon either by mixed it homogeneously or in the separate crucible, pyrolysis of POME can be improved. Solid product obtained from this study has high energy and oil extracted from liquid product condensed contain some chemical that has tendency to be an alternative fuel in future. Therefore, microwave-assisted pyrolysis treatment of POME is an alternative way to reduce the waste, hence preventing negative impacts to human and environment such as disease and pollution. These advantages have proven that microwave-assisted pyrolysis technique is able to transform waste into wealth in future.

# MOLECULAR WEIGHT CUT-OFF DETERMINATION OF PRESSURE FILTRATION MEMBRANES VIA COLORIMETRIC DETECTION METHOD

## (Penentuan Berat Sekatan Molekul Bagi Membran Penurasan TekananMelalui Kaedah Pengesanan Kolorimetri)

**Abstract**

Molecular weight cut-off (MWCO) of commercial and in-house fabricated membranes is obtained at 90% rejection of various types of solutes with different molecular weights (MWs). PEG quantification methods have been favorably employed to determine membranes' MWCO. Most of the quantification methods utilizing high-end equipment using high performance liquid chromatography (HPLC) and low-end colorimetric method. HPLC method requires an established chromatographic technique using specific diluents, columns and detectors while the most referred colorimetric method requires a few processing steps with concentration up to 7.5 ppm by using UV spectrophotometer. In this work, a newly modified colorimetric method was established to conduct a simple measurement for a membrane's MWCO. The newly modified method has an excellent linearity for the calibration curves which $R^2$ values are closed to 1 with concentration of up to 150 ppm. A MWCO determination test conducted using different commercial membranes for confirming this newly modified method found that similar MWCO values were obtained as given by the membrane' manufacturers. In conclusion, this newly modified method is simpler than the formerly used colorimetric method, reliable and applicable for determining the MWCO of membranes ranging from UF to NF at a higher range of PEG concentrations (>150 ppm).

**Keywords:** molecular weight cut-off, polyethylene glycol, spectrophotometric, colorimetric, membrane

**Abstrak**

Berat sekatan molekul (MWCO) bagi membran komersial dan yang dihasilkan sendiri diperolehi pada 90% penolakan pelbagai jenis bahan larut dengan berat molekul yang berbeza (MWs). Kaedah kuantifikasi menggunakan PEG adalah yang paling digemari digunakan bagi menentukan MWCO daripada membran yang di sintesis. Kebanyakan kaedah menggunakan peralatan atasan seperti kromatografi cecair berprestasi tinggi (HPLC) dan kaedah bawahan seperti kaedah kolorimetri. Kaedah HPLC memerlukan teknik kromatografi yang tertubuh menggunakan bahan pencair, tiang dan pengesan tertentu manakala kaedah kolorimetri memerlukan beberapa langkah pemprosesan dengan kepekatan hanya dalam julat sehingga 7.5 ppm menggunakan spektrofotometer UV. Oleh yang demikian dalam kajian ini, satu kaedah kolorimetri baru yang diubahsuai telah ditubuhkan untuk mengukur MWCO membran. Kaedah ini mempunyai kelinearan yang sangat baik, di mana nilai $R^2$ menghampiri 1 dengan kepekatan sehingga 150 ppm. Ujian penentuan MWCO dijalankan menggunakan beberapa membran komersial yang berbeza untuk mengesahkan kaedah baru diubahsuai ini didapati bahawa nilai MWCO yang sama telah diperolehi bagi membran, seperti yang diberikan oleh pengeluar membran. Kesimpulannya, kaedah yang baru diubahsuai ini adalah lebih mudah daripada kaedah kalorimetri yang dahulunya digunakan, boleh dipercayai dan diguna pakai bagi menentukan MWCO daripada membran NF sehingga membran UF malah pada julat kepekatan PEG yang lebih tinggi.

**Kata kunci:** berat sekatan molekul, polietilena glikol, spektrofotometer, kolorimetri, membran

## Introduction

Membrane-based technologies are the leading technology for all kinds of separation techniques due to its intrinsic characteristics such as operational simplicity, environmental impact, high selectivity and permeability in transport of specific components [1]. A membrane is an interphase between two adjacent phases acting as a selective barrier, regulating the transport of substances between the two compartments for separating feed species such as mixture of liquid, gas and colloidal particle [2, 3]. Membranes with good resistant and selectivity are necessary to ensure efficient separation process and very important for the industrial sector to obtain high purity products. Selectivity is dependent on the pore size of the membranes [4]. Furthermore, one of the major factor in obtaining an effective separation is by determining relative size of solute molecule to pass through the membrane pores [5]. Thus, the pore sizes of the membrane and its distribution play a crucial role in determining the efficiency of filtration [6, 7].

Membrane pore sizes could be determined by several analytical methods. Solute rejection method, bubble point method, soluble probe method, liquid replacement and visual observation techniques (e.g., atomic force microscopy and scanning electron microscopy) are the methods commonly employed to measure the pore sizes of membranes [8 - 10]. Each of these methods has its own advantages and limitations. Some of the techniques outlined might not be useful in the determination of pore size of membranes in term of their molecular weight cut-off (MWCO) since they cannot predict the membranes' sieving effects based on the removal of particles and solutes through the membranes under actual operating conditions and transport mechanism [10, 11].

Among the outlined methods, the solute rejection method is an effective technique to investigate the separation characteristics of various solutes by membranes because it measures solute rejection using actual filtration experiments with non-ionic solutes of a known molecular weight (MW) such as polyethylene glycol (PEG), oligostyrenes, alkanes and dextrans[10]. A membrane's MWCO is a representation of membrane selectivity for solute molecules of different MW, where the MW value is obtained from the solute molecule that gives a 90% rejection when a range of different MW solutes are filtered in the targeted solvent [12, 13]. PEGs have been widely used for the determination of the nominal MWCO because of their colloidal properties, which gives low-fouling levels [11]. There are various detection methods for PEG but most of the methods utilizing high-end equipment such as high performance liquid chromatography (HPLC) and low-end colorimetric method. HPLC method requires an established chromatographic technique using specific diluents, columns and detectors while colorimetric method requires a number of processing steps to dilute PEG based on the formation of a complex with barium chloride and iodine solution until a very low concentration of up to 7.5 ppm using UV spectrophotometer [14]. Since most reliable PEG detection techniques require the use of sophisticated instruments (which some instrument may not be available in many laboratories) and apply complex protocols, the colorimetric detection method have attracted considerable attentions in PEG detection applications with regard to their simplicity and versatility [15].

MWCO determination by colorimetric method was first used by [16] and has been extensively used thereafter by many research groups worldwide for quantifying the MWCO of their fabricated membranes [3, 5, 17-19]. However, there is no work ever reported to date, on the verification of the method with any types of commercial membranes of known MWCO to confirm its accuracy. Furthermore, the MWCO of the reported synthesized membranes were only in the ultrafiltration (UF) ranges. For instance, [16] reported the MWCO of the synthesized membrane from cellulose acetate butyrate was around 15,000 g/mol upon using PEGs in range of 1,000 to 20,000 g/mol to determine the MWCO value. In different occasions, [3] and [17] have used PEGs with MW of up to 35,000 and 65,000 g/mol, respectively, for the MWCO determination and the reported MWCO was also in UF ranges. So far, the method has never been reported for determining the MWCO of nanofiltration (NF) range membranes other than UF only. NF membrane is one type of pressure filtration membrane, situated between reverse osmosis (RO) and UF. NF typically represents filtration and rejection of solutes with sizes in the region of 200 – 2,000 g/mol [20] while UF represents solutes greater than 2,000 g/mol. Thus, this colorimetric method for PEG detection in the NF to UF membrane MWCO application has become the basis to be focused in this study.

Next, one of the identified drawback of this colorimetric method for MWCO determination is that it uses very low solute concentrations [16]. This is because at high concentration of PEG, the solute solution tends to precipitate. Thus, the reaction for this method is dependent on the concentration of the solution used [21]. However, low concentration of solute rejection may affect the membrane solute retention, in which consequently caused inaccurate MWCO reading. The concentration influenced the dipole moment interaction, which in turn affected the solute rejection [20]. Therefore, high concentration of feed solution is required to be used when performing the pressured membrane filtration in order to obtain a more accurate permeate concentration prediction [22]. Therefore in this study, a simple yet sensitive and detectable PEG of various MW ranges (600 – 20,000 g/mol) at different concentration ranges from low (0 ppm) and high (150 ppm) was established for a simple and reliable MWCO determination method in comparison to the previous method reported by [16]. This newly modified method is further tested using various commercial membranes of NF and UF for method verification to confirm the feasibility of the modified colorimetric method for determining MWCO of the membranes.

## Materials and Methods

### Materials

Barium chloride, hydrochloric acid, potassium iodide and iodine were supplied by Friendemann Schmidt from Chemolab Supplies. PEG with nominal MW (g/mol) of 600 (PEG600), 1,000 (PEG1000), 3,000 (PEG3000), 6,000 (PEG6000), 10,000 (PEG10000) and 20,000 (PEG20000) were from Sigma Aldrich supplied by Chemolab Supplies. Table 1 showed the properties of the PEGs involved. All chemicals were used as received.

Table 1. Various PEG properties differentiated by their MW

| PEG MW | Appearance | $M_n$ (g/mol) | Hydroxyl Value |
|---|---|---|---|
| PEG600 | Clear viscous colourless liquid | 590 – 610 | 176 – 200 |
| PEG1000 | White waxy solid | 950 – 1,050 | 105 – 120 |
| PEG3000 | White flakes | 2,700 – 3,300 | 34 – 42 |
| PEG6000 | White flakes | 5,500 – 6,500 | 16 – 20 |
| PEG10000 | White flakes | 9,000 – 12,500 | 9 – 12 |
| PEG20000 | White flakes | 16,000 – 28,000 | 4 – 7 |

A range of commercial membranes with different nominal MWCO from 200 to 20,000 g/mol (produced by different manufacturers) that were used in this work are tabulated in Table 2 below.

Table 2. List of commercial membranes with their nominal MWCO and manufacturer

| Membranes | Nominal MWCO Given by Manufacturer (g/mol) | Manufacturer |
|---|---|---|
| NF™ | 200 – 300 | Dow Filmtec™ |
| NF2 | 200 – 400 | Amfor Inc. |
| NF270 | 400 | Dow Filmtec™ |
| PES3 | 3,000 | Amfor Inc. |
| TF(GM) | 4,000 | GE Osmonics |
| PES10 | 10,000 | Amfor Inc. |
| PS20 | 20,000 | Amfor Inc. |

**Reagents and PEG preparation**

There were two types of reagents used for the determination of PEG, namely iodine solution (Reagent 1) and barium chloride solution (Reagent 2). Reagent 1 was prepared by dissolving 1.27 g iodine crystal in 100 mL of 2% (w/v) solution. It was further diluted for 10 times prior to use. Reagent 2 was prepared by dissolving 5 g of barium chloride in 100 mL of 1 M hydrochloride acid to form a 5% (w/v) solution [16]. 150 ppm PEG solutions (PEG600, PEG1000, PEG3000, PEG6000, PEG10000 and PEG20000) were prepared by dissolving 0.15 g of PEG in 1 L ultrapure water (Arium® Pro, Sartorius Malaysia Sdn Bhd, Malaysia). The solution was then being sonicated by using Analog Ultrasonic Cleaner (WUC-A03H, Daihan Scientific).

To plot PEGs standard curve, a series of concentration were prepared in range 2.5 - 7.5 ppm for Sabde et al. method while 10 – 150 ppm for the newly modified method (proposed in this work). Blank for both methods were prepared by using ultrapure water and were also added with reagent 1 and 2 as samples while blank used for spectrophotometer (Genesys 10UV, Thermo Electron Corporation, USA) was ultrapure water without addition of any reagents.

**Newly modified PEG method**

In initial MWCO determination method using PEG, the basis of the work was based on the method reported by [16], which applies the reaction of barium and iodide with PEG to form two complexes. Whereas this newly modified method is based on the formation of a single complex between PEG and iodine only. The comparison of both methods is presented in Table 3. In the newly modified method, the concentration range is increased to 150 ppm from 7.5 ppm in Sabde et al. method. The PEG sample volume used for the test was only 0.3 mL instead of 4 mL as compared to the previous method. Furthermore, only 1 reagent was used in the newly modified method than the other method, which used 2 reagents. However, the reaction time to dissolve the PEG in the reagent was double to stabilize the reaction.

Table 3. Comparison between the newly modified method and the method used by Sabde et al.

| Conditions | Sabde et al. Method | Newly Modified Method |
|---|---|---|
| Reagent 1 (mL) | 1 | 3 |
| Reagent 2 (mL) | 1 | None |
| Samples volume (mL) | 4 | 0.3 |
| Concentration range (ppm) | 0 - 7.5 | 0 - 150 |
| Reaction Time (min) | 15 | 30 |
| Spectrophotometer wavelength (nm) | 535 | 535 |
| PEG MW range (g/mol) | 600 – 20,000 | 600 – 20,000 |

In preparation to plot PEGs standard curve according to [16], 4 mL of PEG solution with different concentration were prepared in range 0 – 7.5 ppm. Then, 1 mL of each Reagent 1 and 2 were added. After 15 minutes, absorbance values were taken by using a spectrophotometer 535 nm against the blank reagent.

Meanwhile the standard curve plots for the newly modified method required the use of 0.3 mL of PEG solution in water with different concentration in the range of 0 – 150 ppm. Then, 3 mL of Reagent 1 was added. After 30 min, absorbance values were taken by using a spectrophotometer at the same wavelength with the previous method.

**Methods accuracy test**

In order to test the accuracy for both methods presented and reported by Sabde et al. [16] and the newly modified method (refer Table 4), three PEG sample solutions were used to calculate their concentration by using dilution equation ($M_1V_1 = M_2V_2$) from the initial PEG concentration of 150 ppm. These solutions were prepared for every MW of PEGs used (from PEG600 to PEG20000). The solutions were then being tested using both methods. Table 4

show the three solutions that were used in this test. The accuracy test is considered as successful when the final concentration values of the PEG solution calculated from dilution equation is the same or very near with the concentration values obtained from the standard curve plotted.

Table 4. Sample solutions used for methods accuracy test

| Volume of initial PEG solution (mL) | Volume of ultrapure water added into the solution (mL) | Final concentration of PEG solution calculated (ppm) |
|---|---|---|
| 0.2 | 14.8 | 5.3 |
| 0.6 | 14.4 | 16.0 |
| 1.0 | 14.0 | 26.7 |

Note: The PEG sample tested was from PEG600 to PEG20000

**Membrane filtration**

MWCO values of various commercial NF and UF membranes were given by the manufacturers (refer Table 2) are to be confirmed by using the newly modified method in comparison to Sabde et al. method. To determine this, solute rejections (SR) of the membranes were evaluated with various MW PEG solutions from 600 to 20,000 g/mol with concentration of 150 ppm at 30 bar by using a dead-end filtration cell (HP4750, Sterlitech Corporation, USA) [12]. The typical representation of the feed, permeate and retentate of the filtration solution through the membrane is shown in Figure 1. The membrane SR is defined by using Eq. (1) where, $C_f$ and $C_p$ are the PEG concentrations in the feed and permeate solution, respectively. The concentration of PEG was determined based on its absorbance mode in UV-spectrophotometer at wavelength 535 nm.

$$SR = \left(1 - \frac{C_p}{C_f}\right) \times 100 \quad (1)$$

Water flux of membrane with an active surface area of 14.6 $cm^2$ (which was compacted at 30 bar for 30 min) was determined by using Eq. (2) where J is the permeate flux (L./$m^2$.h), V is volume of permeate (L), A is effective membrane area ($m^2$) and t is operating time (h).

$$J = \frac{V}{A \times t} \quad (2)$$

## Results and Discussion

### Newly modified PEG methods for MWCO determination

The standard calibration curves plot for the newly modified method in comparison to the method used by Sabde et al. [16] are shown in Figure 2 and the summary of the linear equations from the plot is presented in Table 5. Note that Sabde et al. [16] did not present their calibration curve plot in their report, thus re-plotting is required for a fair comparison for both methods.

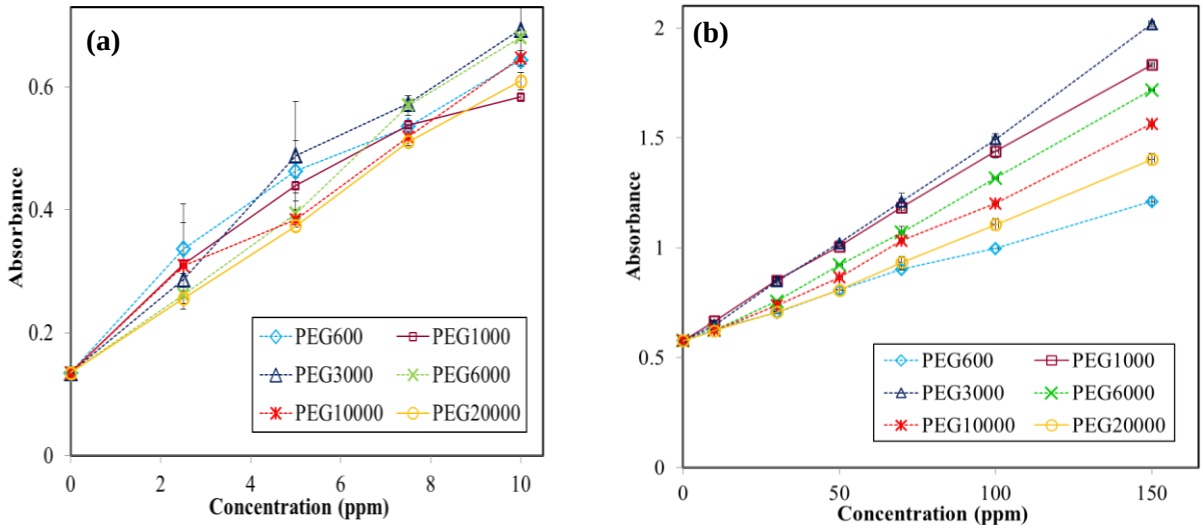

Figure 2. Standard curve of PEG for both methods with uses of PEG from MW 600 to 20,000 g/mol, a) Sabde et al. method and b) newly modified method

As shown in Figure 2 (a) and 2 (b), both methods gave a linear response to PEG at certain concentration for certain MW PEG. However, the curves for Sabde et al. method for different MW PEGs were only slightly differ to each other causes overlapping between the curves probably due to the low concentration of each of the PEGs solution used. On the other hand, the standard curves of the newly modified method showed linear curves without overlapping with one another probably because higher concentrations of solutions were used. These distinguished each curve of different PEGs MW. The curves are expected to be separated from one another for different PEGs MW since they have a different value of hydroxyl value for each of the PEGs (refer Table 1). PEG600 have the highest hydroxyl value as compared to other PEGs while PEG20000 has the lowest value. This hydroxyl value of PEG influences the absorbance reading in UV-spectrophotometer, where high MW of PEG will give low absorbance reading since their hydroxyl values are low and vice versa. The method used by Sabde et al. [16] did not show that they have this characteristic since all the standard curves plotted have overlapped to each other. This happened probably because of the reactivity of halogen group ($Cl^-$ from barium chloride) in Sabde et al. method was lower than the iodide ion ($I^-$) used in newly modified method. The reactivity in halogen group is in the following order (I > Br > Cl > F) [23, 24], where $Cl^-$ is confirmed to have a low reactivity than $I^-$ in their group. Thus, it is difficult for the $Cl^-$ to completely substitute the hydroxyl group in PEG. As a result, almost the same absorbance values for PEGs were obtained even at different MW and were used to plot the standard curve at the y-axis (refer Figure 2).

Moreover, the method used by Sabde et al. [16] obtained in this work possessed linear plots for concentration from 0 to 10 ppm only for PEG600 to PEG20000. At higher concentration (above 10 ppm), the complex tends to precipitate causing non-linear plots if the data is included. Although we found that 10 ppm is the highest

concentration to get a plot with $R^2$ of above 0.9 than 7.5 ppm as reported, this concentration is way too low compared to the newly modified method that can reach 150 ppm or may be more. Initially, this colorimetric method has been successfully used by few researchers in biological fields for many years [25]. For example, it was used for detecting PEG and PEGylated molecules in biological samples like protein [26], enzyme [13] and genes [21]. Shaffer and Critchfield on year 1947 was the first to develop this most commonly cited method for quantification of PEG molecules based on the formation of insoluble complexes between PEG and heteropoly inorganic acids (phosphomolybdic and silicotungstic acid) in the presence of barium chloride. The precipitate was then collected and washed for several times prior to testing it with iodine in order to detect the PEG [25]. Perhaps, this was the main reason for the employment of barium chloride for the quantification of PEG/PEGylated molecules in biological samples and this has answered the importance of the precipitation to occur in the method reported by Shaffer and Critchfield [25]. However, in the application of membrane technology especially for MWCO determination, it was found that precipitation of PEG is an undesirable step and must be avoided since it could interfere during the reading of absorbance values by using UV spectrophotometer. The presence of precipitate causes spectral interferences due to the colloidal particles spread in the solution [27, 28]. Therefore, in order to have an accurate absorbance reading, appropriate dilutions of the samples are necessarily required to make sure their concentrations are below 7.5 ppm before the addition of the two reagents (barium chloride and iodine) into the samples to avoid precipitation from occurs.

Table 5. Equation of standard curve and $R^2$ values for Sabde et al. method and newly modified method

| PEG MW (g/mol) | Sabde et al. Method | | Newly Modified Method | |
|---|---|---|---|---|
| | **Linear Equation** | **$R^2$ Value** | **Linear Equation** | **$R^2$ value** |
| PEG600 | y = 0.0546x + 0.135 | 0.9431 | y = 0.0043x + 0.578 | 0.9959 |
| PEG1000 | y = 0.0506x + 0.135 | 0.9319 | y = 0.0085x + 0.578 | 0.9991 |
| PEG3000 | y = 0.0588x + 0.135 | 0.9779 | y = 0.0094x + 0.578 | 0.9977 |
| PEG6000 | y = 0.0551x + 0.135 | 0.9955 | y = 0.0074x + 0.578 | 0.9952 |
| PEG10000 | y = 0.0517x + 0.135 | 0.9863 | y = 0.0064x + 0.578 | 0.9954 |
| PEG20000 | y = 0.0484x + 0.135 | 0.9982 | y = 0.0053x + 0.578 | 0.9937 |

Based on the results shown in Figure 2(b) and Table 5, the newly modified method gave linear relationship from 0 to 150 ppm for PEG600 to PEG20000 with $R^2$ values nearly 1. Please note that this newly modified method is solely depended on complex formation between PEG and iodine only. The reaction is called halogenation where hydroxyl group in PEG will be substituted by iodide ion [24]. In this reaction, there is no precipitation produced and observed since there is no involvement of metal ions like barium ion that can form precipitate. The main advantage of this method is that there is no precipitate formed even at concentration up to 400 ppm. Furthermore, this newly modified method only used 0.3 mL of the collected samples, is tenth times much lower than Sabde et al. method which required as much as 4 mL samples during PEGs detection. There are membranes which requires 1 hour only to collect 1 mL permeate, thus this newly modified method could reduce the time required for permeate collection.

Since there was no reaction mechanism so far reported for both methods, the mechanisms are proposed in Figure 3 based on the findings obtained in this work. Both methods use Lewis acid-Lewis base reaction as basis, where halogen (Cl or/and I) acts as the electrophilic species (Lewis acid) while electron-rich organic compound (PEG) as the nucleophilic species (Lewis base) [24]. As for the former method by Sabde et al. [16], the mechanism is as shown in Figure 3 (Reaction 1). Firstly, hydroxyl group (OH) at both end of PEG is substituted with chloride ion ($Cl^-$) (upon addition of barium chloride solution into PEG solution), left barium ion ($Ba^{2+}$) on its own. $Ba^{2+}$ thereafter forms ionic bonding with iodide ion ($I^-$) after the addition of iodine solution into the mixture. This bonding tends to precipitate at concentration 10 ppm. In contrast, hydroxyl group of PEG is substituted directly by $I^-$ upon the addition of iodine solution into PEG solution as illustrated in Figure 3 (Reaction 2) for the newly modified method. No precipitation is produced in Reaction 2 as found in Reaction 1.

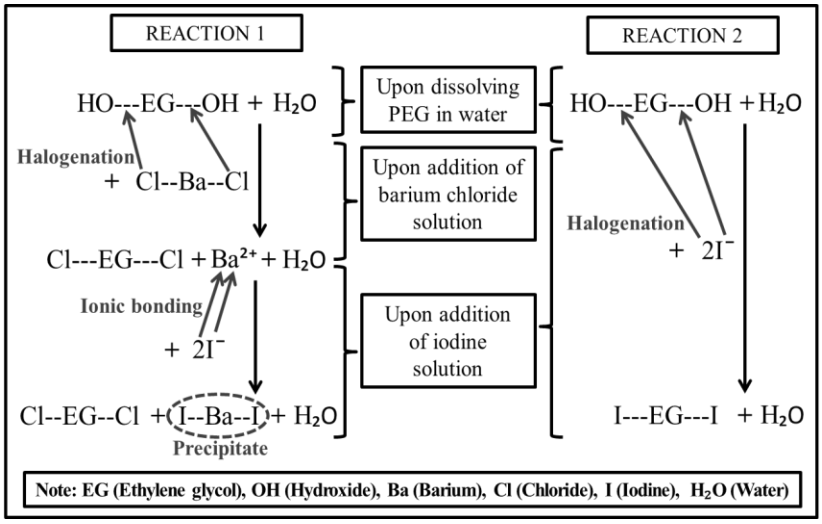

Figure 3. Proposed reaction mechanism for MWCO determination methods

**Methods accuracy test**

Three types of PEG with different MW were used for this accuracy test which is PEG with lowest (PEG600), middle (PEG6000) and highest (PEG20000) MW. A set of samples solution were prepared from these three PEGs to examine the accuracy of both compared methods. The test was repeated for three times to determine the standard deviation and further minimizing the error.

From the results showed in Table 6, both methods gave accurate values (calculated and actual) for the concentration of the samples solution. There was no dilution needed during the accuracy test for the newly modified method. However, the former method required some dilutions to be done especially for PEG6000 and PEG20000 (refer Table 6). The concentrations of the solutions were 16.0 and 26.7 ppm, respectively. At this concentration, precipitation tends to occur since their concentrations are above 10 ppm. Therefore, dilution must be conducted during using the former method to determine the concentration of the solutions. Luckily, the dilution work that has been conducted to eliminate precipitation is easily done since their final concentration is known. However, if this former method is applied for quantifying the MWCO of a membrane from pressure filtration, it will be very difficult to identify the dilution factor to bring the solution's concentration at below 10 ppm since the permeate concentration is unknown. Thus, this test can be showed as a proof that the newly modified method is easier, more reliable and accurate to be used in determining MWCO of various filtration membranes specifically for NF and UF than the former method reported by Sabde et al. [16].

**Commercial membranes solute filtration test**

Commercial NF and UF membranes were used in solute filtration test for the MWCO study. NF and NF270 membranes were kindly donated by Dow Chemical Company. TF(GM) membranes and NF2, PES3, PES10, and PS20 were purchased from GE Osmonics and Amfor Inc. respectively (refer Table 2 for details). MWCO of all membranes were determined by using PEG with MW ranges from 600 to 20,000 g/mol. The solute MW ranges was divided into two categories: (i) NF range for MWCO below 2,000 g/mol, and (ii) UF range for MWCO above 2,000 g/mol. Table 7 and Figure 4 show the results of the fluxes and MWCO for all the NF and UF membranes tested by both methods. It was found that the fluxes for the membranes in water were higher than in the PEG solutions, as expected. This is because the solutes in the solution hinder the permeation of water thus reducing the flux. The PEGs used for the flux in PEGs are from PEG600 to PEG20000. This flux value was averaged out from the flux obtained at each PEG solutions used. The higher the MW of PEG used, the lower the flux recorded.

Table 6. Comparison between calculated and actual concentration of unknown samples

| **PEG MW (g/mol)** | **Sabde et al. Method** | | | **Newly Modified Method** | | |
|---|---|---|---|---|---|---|
| | **600** | **6000** | **20000** | **600** | **6000** | **20000** |
| Dilution factor | No | 0.25 | 0.25 | No | No | No |
| Absorbance value | | | | | | |
| Run 1 | 0.427 | 0.362 | 0.469 | 0.601 | 0.697 | 0.721 |
| Run 2 | 0.427 | 0.361 | 0.466 | 0.601 | 0.697 | 0.721 |
| Run 3 | 0.426 | 0.362 | 0.464 | 0.601 | 0.696 | 0.721 |
| Values by standard curve (ppm) | | | | | | |
| Run 1 | 5.3 | 16.5 | 27.6 | 5.3 | 16.0 | 26.7 |
| Run 2 | 5.3 | 16.4 | 27.4 | 5.3 | 16.0 | 26.7 |

Table 7. Membrane separation properties (flux and MWCO) of the different commercial membranes obtained from dead-end filtration test

| **Membrane** | **Pure Water Flux ($L/m^2.h$)** | **PEGs Flux ($L/m^2.h$)** | **Sabde et al. Method** | | **Newly Modified Method** | | **Nominal MWCO by Manufacturer (g/mol)** |
|---|---|---|---|---|---|---|---|
| | | | **MWCO** | **% Error** | **MWCO** | **% Error** | |
| NF$^{TM}$ | 175.2 | 163.7±2.95 | 550 | +83.3 | 550 | +83.3 | 200 – 300 |
| NF2 | 174.8 | 109.6±1.16 | 500 | +25.0 | 500 | +25.0 | 200 – 400 |
| NF270 | 389.2 | 194.3±4.92 | 530 | +32.5 | 530 | +32.5 | 400 |
| PES3 | 175 | 164.4±2.45 | 3250 | +8.3 | 2980 | -0.7 | 3000 |
| TF(GM) | 258 | 244.9±1.01 | 4600 | +15.0 | 3990 | -0.3 | 4000 |
| PES10 | 150 | 129.3±0.65 | 2600 | -74.0 | 10000 | 0 | 10000 |
| PS20 | 280 | 205.5±0.78 | 8600 | -57.0 | 19850 | -0.8 | 20000 |

In terms of the MWCO values, the newly modified method gave the most accurate values for the UF membranes as given by the manufacturers. For example, PES10 has the same value as given while PES3, TG(GM) and PS20 values were found to be <1% difference than the given values indicating the accuracy of the newly modified method. However, the MWCO values of the UF membranes determined by Sabde et al. method was different from the nominal MWCO given by the manufacturer. There are up to 74% difference in the calculated values. Of all the tested UF membranes, PES10 and PS20 have the farthest difference compared to others. This difference might be due to the dilution factor, which is required during the determination. The bigger the concentration of the PEG, the tendency for precipitation to occur is higher. Therefore, the detection of the absorbance values in spectrophotometer became imprecise.

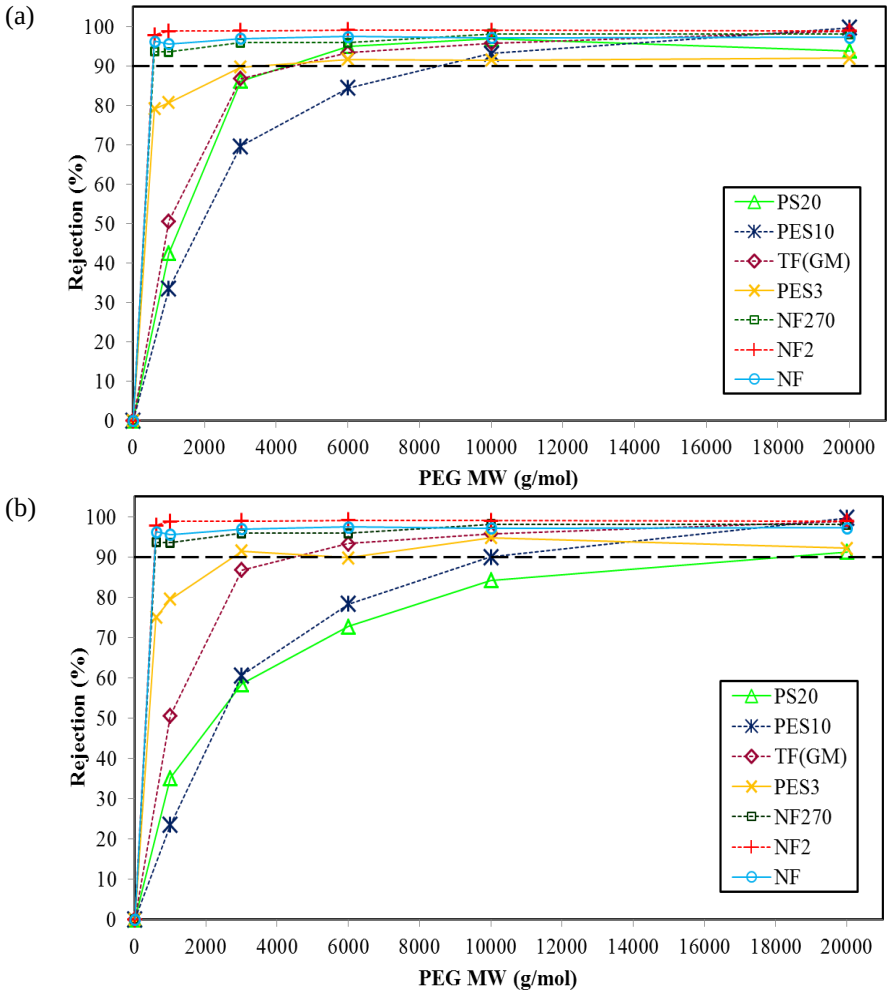

Figure 4. MWCO curve for commercial membranes using the PEG as solute filtration following both methods, (a) Sabde et al. and (b) newly modified method

Meanwhile the difference in MWCO values for NF membranes (for both method) were unavoided due to the lowest MW of PEG is 600 g/mol only while the membranes' MWCO were given in the range of 200 to 400 g/mol. NF270 and NF2 have the closest MWCO values while NF™ has the farthest values. Since the current method could not apply PEG 200 and 400 yet, optimization of the method is still on going to include this PEG in the range. NF membrane's MWCO at 500<MWCO<2000 g/mol is expected to give accurate values as found in UF ranges. Similar research work was reported to confirm the developed MWCO method [12, 29, 30]. The difference in the MWCO of the membrane in comparison to the values provided by the manufacturers was discussed in details. For example, [12] have found a single run of pressure filtration with a mixture of PEGs in aqueous solution to determine MWCO of membranes. However, the method used to determine the MWCO have utilized a high-end equipment of HPLC coupled with ELSD detector though using PEGs as the solutes. Other work has also used gas chromatography (GC) with specific column to determine the styrene derivatives [10], alkanes detected in HPLC [30]. Based on this comparison study, the newly modified method is confirmed can accurately determine the MWCO in the range of 500 to 20,000 g/mol, which indicates the reliability of this method to substitute the method currently referred to [16].

## Conclusion

A simple yet sensitive MWCO detection method was modified and developed from the commonly referred method in order to accurately determine PEG concentration in solute retention. The accuracy of this method is confirmed based on the filtration test using a range of commercial membranes. The MWCO values were found to be closed to the values given by the manufacturer. Since the accuracy of this method was verified and confirmed, this newly modified method could be used for determining membranes MWCO of either commercial or synthesized ones. High concentration of PEGs solution could be detected without the need for dilution since appropriate single reagent was used, thus no precipitation is presence as supported by the proposed reaction mechanism. This method can accurately determine the membrane MWCO (g/mol) in the range of 500<MWCO<20,000 as confirmed in this work.

**Abstract**

The use of precursors from natural based polymers offer a more biocompatible and biodegradable properties in producing polymer drug vehicle compared to drug vehicles made from synthetic polymer precursors, which normally found in high molecular weight (MW). High MW polymer will lead to immunologic inflammatory responses due to their lower biodegradability and higher cytotoxicity compared to low MW that could give smaller particle size, higher solubility, higher release efficiency, non-immunogenic, better biodegradability and lower cytotoxicity. Therefore, this study is aimed to produce valuable precursors, particularly to produce epoxidized palm olein (EPOo) and diol, to be used in the development of a new polymeric drug vehicle with low MW. An EPOo was synthesized via *in-situ* epoxidizing of palm olein (POo) with peracid and sulfuric acid ($H_2SO_4$) catalyst. Meanwhile the diol was synthesized using hydroxylation of palm oil-based oleic acid via esterification of oleic acid (OA) with glycerol and 4-dodecylbenzyl sulfonic acid catalyst (DBSA). It was found that both palm oil-based precursors have been successfully synthesized from natural resources of palm oil. Physico-chemical properties of the synthesized precursors showed that the EPOo and the diol possess average molecular weight (MW) between 900-1500 g/mol and hydroxyl functionality between 2 and 3, based on the presence of hydroxyl (O-H) group functionality, showed in the Infra-red (IR) spectra in the range of 3200-3600 $cm^{-1}$. These low MW palm oil based-precursors have potential uses for the design and development of new properties of polymeric drug vehicle such as acrylated palm olein (APOo) and polyol polyester, which will produce particle size in the range of 100 - 200 nm or smaller with high efficiency drug loading and controlled release profiles.

**Keywords**: drug delivery system, palm oil, polymeric nanoparticle

**Abstrak**

Penggunaan pelopor dari polimer semulajadi bagi menghasilkan penyampai ubat polimer mempunyai kelebihan tertentu iaitu ianya bersifat bioserasi dan biodegradasi berbanding sistem penyampai ubat yang dibuat daripada pelopor polimer sintetik, kebiasaannya mempunyai berat molekul (MW) yang tinggi. Polimer dengan MW yang tinggi boleh menyebabkan gerak balas keradangan keimunan akibat kurang keterbiodegradasikan dan kesitotoksikan yang tinggi dibandingkan MW yang rendah yang boleh menghasilkan partikel bersaiz lebih kecil, keterlarutan dan kecekapan perlepasan yang tinggi, tidak imunogen, terbiodegradasi dengan lebih baik dan sitotoksiti yang rendah. Oleh itu, kajian ini bertujuan menghasilkan pelopor yang bersifat istimewa, terutamanya minyak sawit olein terepoksida (EPOo) dan diol yang digunakan dalam membangunkan sistem penyampaian ubat dengan MW yang rendah. EPOo telah disintesis menggunakan pengepoksidaan *in-situ* minyak sawit olein (POo) dengan perasid dan pemangkin asid sulfurik ($H_2SO_4$). Sementara itu, diol disintesis menggunakan penghidroksilan minyak sawit oleik menggunakan pengesteran asid oleik (OA) dengan gliserol dan pemangkin asid sulfonik 4-dodesilbenzil (DBSA). Hasil penemuan mendapati kedua-dua pelopor yang berasaskan minyak sawit ini telah berjaya disintesis daripada sumber semulajadi minyak sawit. Sifat fisiko-kimia pelopor yang telah disintesis menunjukkan EPOo dan diol mempunyai berat

molekul (MW) antara 900-1500 g/mol dan bilangan hidroksil antara 2 dan 3, berdasarkan kehadiran kumpulan berfungsi hidroksil (O-H), yang ditunjukkan dalam spektra Infra-merah (IR) dalam julat 3200-3600 $cm^{-1}$. Pelopor berasaskan minyak sawit yang mempunyai berat molekul yang rendah berpotensi untuk direkabentuk bagi membangunkan sistem penyampai ubat polimer yang bersifat baru seperti minyak sawit olein terakrilat (APOo) dan poliol poliester, yang menghasilkan partikel bersaiz 100-200 nm atau lebih kecil dengan kecekapan pemuatan ubat dan profil perlepasan terkawal yang tinggi.

**Kata kunci:** sistem penyampai ubat, minyak sawit, nanopartikel polimer

## Introduction

Polymers are amongst the most extensively explored and widely use materials as drug vehicles for localized and sustained delivery of drug (medication) to a patient [1, 2]. There are different types of drug vehicles such as macromolecular carriers (macromolecular prodrugs, protein-macromolecule conjugates and gene medicines complexed with macromolecular carriers), particulate carriers (micro/nanoparticles, liposomes, dendrimers, lipoproteins, nanotubes, micro/nanospheres and micro/nanoemulsions) and cellular carriers (leucocytes, platelets, erythrocytes, nanoerythrocytes, hepatocytes, and fibroblast) [3-5].

Natural polymers are currently gaining a lot of research interest due to their advantages such as utilizing environmental friendly materials and involving low energy process which is way better than the synthetic polymers produced via chemical synthesis. The trend of using palm oil based materials for the development of polymeric drug vehicles is growing due to the natural polymer's biocompatibility compared to the petrochemical-based polymers [6-11]. In addition, the synthetic polymers commonly use chemicals that emits greenhouse gases (GHGs), utilizes high energy during the products preparation and processing and most importantly generates toxic by-products [12]. Thus, the use of renewable feed stock resources such as from palm oil products is receiving numerous interest compared to petrochemical-based products.

In this study, new precursors namely epoxidized palm olein (EPOo) and diol were developed from the palm oil product of palm olein (POo) and oleic acid (OA) for the EPOo and diol, respectively. The chemical reaction of epoxidation and esterification processes were applied in developing a non-toxic and cleaner reaction of the palm oil based-precursors. Epoxidation process is performed using *in-situ* generated peroxyacetic acid due to several advantages, such as minimum amounts of reactants are needed to prepare the epoxidising reagent and safer preparation and handling, compare using the preformed peroxyacid that had handling problems since the concentrated peroxyacid is unstable and explosive [13]. Besides, the peroxyacetic was selected due to its easy availability, low production cost and stability at high temperatures, compare to the peroxybenzoic acid, peroxyformic acid, peroxyfluoroacetic acid, *m*–chloroperoxybenzoic acid and *m*–nitroperoxybenzoic acid [13-14].

Esterification process is performed with an oleic acid and a 4-dodecylbenzyl sulfonic acid (DBSA) for the diol production, in the absence of solvent. The DBSA was selected because is more efficient catalyst in water where it can act as emulsifier and catalyst compared to other catalysts such as hydrochloric acid, sulphuric acid, phosphoric acid ($H_3PO_4$ and *p*-toluenesulfonic acid [15-17]. Besides, the esterification process with the DBSA catalyst is considerable as green process, cheap and high product yields [17].

In this work, the study included synthesizing and characterizing of the synthesized precursors. The EPOo and diol produced from the palm oil product are expected to exhibit promising physicochemical properties and have great potential for application in development of new polymeric drug vehicles.

## Materials and Methods

In both preparations of the EPOo and diol, the experimental set-up used in this work was reported and referred in our previous work [18, 19]. The set-up consists of reaction flask, mechanical stirrer, thermometer, reflux condenser and oil batch.

### Preparation of epoxidized palm olein based precursors

A food grade palm olein (POo) (FFM Marketing Sdn. Bhd) was used as a feedstock to produce the EPOo while other chemicals in this preparation were purchased from Systerm Chem Ar. Initially the POo was vacuum distilled

prior to use. Then the POo (1.62 mol) underwent in-situ epoxidizing in the per-acid solution to form the EPOo at the temperature between 60 – 65 $^{o}$C for 2.5 hours [14, 20]. The per-acid solution consisted of a glacial acetic acid (4 mol), a hydrogen peroxide (8.24 mol) and a sulphuric acid (1%). The chemicals were purchased from Systerm Chem Ar., Merck and HmBG Chemical, respectively. After the epoxidation reaction was completed, the EPOo was immediately transferred from the reaction flask to 2 L glass beaker. Next, the EPOo was washed with distilled water and vacuum distilled. The summary of the overall EPOo synthesis process is presented in Figure 1 below.

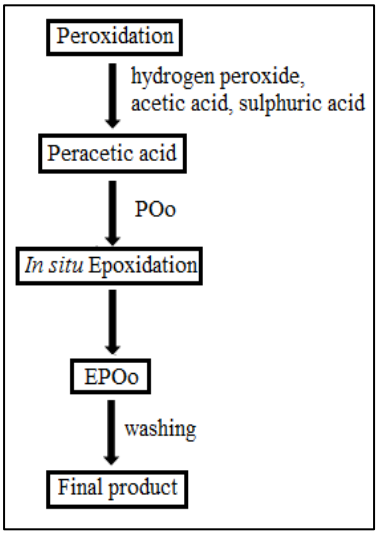

Figure 1. The synthesis routes of the EPOo

**Preparation of diol as palm oil based precursors**
On another occasion, oleic acid (OA) (R&M Chemicals) was vacuum distilled for 3 hours before vacuum recrystallized in acetonitrile. After recrystallization, the OA (1.2 mol) was esterified with glycerol (2.4 mol) and 4-dodecylbenzyl sulfonic acid (DBSA) (0.15 mol) to produce diol at the temperature below 120 $^{o}$C for three hours [15]. The chemicals were purchased from R&M, Systerm Chem Ar. and Fluka, respectively. Next, the synthesized diol was immersed in a mixture solution consist of ethanol (5%) and natrium chloride (5%) for 24 hours before vacuum distilled and collected for characterization.

The yield of the reaction for the EPOo and the diol was calculated using Equation (1).

$$\% \text{ Reaction yield} = \left[\frac{\text{Final yield (g)}}{\text{reactant(g)}}\right] \times 100 \quad (1)$$

**Characterization of the precursor's physicochemical properties: Oxirane oxygen content (OOC)**
The OOC test was performed following the standard method of AOCS method Cd 9-57, 1963 [21].

$$\% \text{ OOC} = \frac{(1.6 \times \text{N} \times \text{v})}{\text{w}} \quad (2)$$

where N is normality of hydrogen bromide (HBr), while v is volume of HBr in mL and w is weight of resin in gram.

**Acid value**
The acid value (AV) was calculated according to the test method is technically equivalent to ASTM D974 [22]:

$$AV=\frac{(5.61 \times v)}{w} \quad (3)$$

where 5.61 is a concentration conversion coefficient (a number of mg KOH corresponding to 1 mL of 0.1 N KOH), v is volume of 0.1 N KOH and w is weight of resin in gram.

**Saponification value**
The saponification value (SV) was calculated according to the test method ASTM D 1962-67 [23].

$$SV=\frac{[56.1\ (B-S) \times N]}{w} \quad (4)$$

where B is volume of 0.5 N HCl required by Blank, S is volume of 0.5 N HCl required by Sample, N is concentration value of HCl = 0.5 N and w is weight of resin in gram.

**Iodine value**
The iodine value (IV) was calculated according to the Hanus method as described in the AOCS (Cd 1-25) [24].

$$IV=\frac{[(B-S)\times N \times 0.127\ X\ 100]}{w} \quad (5)$$

where B is volume of 0.1 N sodium thiosulfate required by Blank, S is volume of 0.1 N sodium thiosulfate required by Sample, N is concentration value of sodium thiosulfate = 0.1 N and w is weight of resin in gram.

**Ester value**
Ester Value (EV) is defined as the mg of KOH required to react with ester content (glycerin or glycerol) after saponification one gram of fat. EV was determined by the equation described in literatures [25-27], where the EV is defined as the difference between the saponification value and acid value:

$$EV = SV - AV \quad (6)$$

where SV is saponification value and AV is acid value of sample.

**Percentage of ester**
Percentage of ester was calculated from ester value and molecular weight by the Equation (7) described by Lubrizol [27]:

$$\%\ Ester = \frac{[(EV)(MW\ ester)]}{10 \times 56.1} \quad (7)$$

where EV is ester value of sample and the value calculated following Equation (6) and MW is molecular weight of ester = 126.11 g/mol.

**Hydroxyl value**
The OHV was calculated according to the test method ASTM D4274-99 Method C [28].

$$OHV=\frac{(B-S)\times 28.05}{w} + AV \quad (8)$$

where B is volume of 0.5 N ethanolic potassium hydroxide required by Blank, S is volume of 0.5 N ethanolic potassium hydroxide required by sample, w is weight of resin in gram and AV is acid value of sample.

**Hydroxyl number functionality**
The hydroxyl number functionality (OHf) was determined by the equation described by Ionescu [29] and used known hydroxyl value and molecular weight of sample:

$$\mathrm{OHf} = \frac{\mathrm{OHV} \times \mathrm{MW}}{56100} \tag{9}$$

where OHV is hydroxyl value of sample and MW is average molecular weight of sample.

**Dynamic viscosity**
The dynamic viscosities of the products in liquid form were measured using Brookfield viscometer (Model RV: DVII + Pro) at 25 °C [30]. The spindle plate with grade 40 and CPE-44PY cup were selected for measuring viscosity.

**Average molecular weight**
The average molecular weight of sample was determined by the equation described by Xu et al. [31] by using known saponification value (SV) and acid value (AV) of sample.

$$\text{Average Molecular Weight} = \frac{168300}{\mathrm{SV\text{-}AV}} \tag{10}$$

where SV is saponification value and the value was obtained using method (iii) and calculated following Equation (4) and AV is acid value and the value was obtained using method (ii) and calculated using Equation (3).

**Fourier transform infrared spectroscopy**
The infrared (IR) spectroscopy of the samples was performed using diamond attenuated total reflectance (DATR) technique. The infrared spectrums of the samples were recorded in the range of 4000 $cm^{-1}$ to 650 $cm^{-1}$ by spectrum 400, FT-IR/FTNIR spectrometer (Perkin Elmer, UK).

**Thermogravimetric analysis**
Thermogravimetric analysis (TGA) was performed using the TGA-SDTA 851e Mettler Toledo instrument (USA). Samples were analyzed in temperature range from 27 °C to 800 °C, heating rate of 10 °C/min.

**Differential scanning calorimetry**
Differential scanning calorimetry (DSC) was carried out using the DSC 822, Mettler Toledo instrument (USA). Samples were scanned at 5 °C/min at first heating cycle from -100 °C to 200 °C and followed by the cooling cycle from 200 °C to -100 °C.

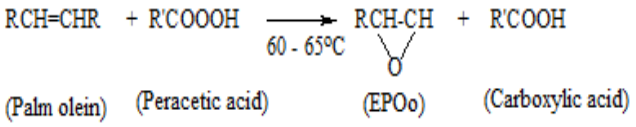
## Results and Discussion

**Physico-chemical properties of the palm oil based precursors**
Table 1 showed the physico-chemical properties of the palm oil-based precursors. The values in Table 1 were obtained using Equation (2) to (8). The acid value of POo and OA was 0.56% and increased to 8.09% and 67.32% after conversion to EPOo and diol, respectively. The iodine value of POo and OA were 61.47 mg KOH/g oil and 83.91 mg KOH/g oil which is almost similar to the work reported by Ramli et al. [32] at 61.67 mg KOH/g oil and Derawi et al. [8, 14] at 62 mg KOH/ g oil, but slightly higher to the work reported by Ramli et al. [33] at 78.2 mg KOH/g oil for the IV value of high-oleic acid palm oil. The POo was found to have a complete epoxidization to EPOo based on the reduction of the iodine value of POo from 61.47 to 0 mg KOH/g oil (Table 1), which corresponds to the complete conversion of the POo carbon double bond (C=C) to the epoxide (oxirane) ring of EPOo and similar to the reported previous study by Derawi et al. at IV 61.67 drops to 3.30 to 0.51 [14]. Due to this reason, the oxirane oxygen content (OOC) of the EPOo have increased to 3.33% compared to the POo OOC value of 0.04% only in the beginning of the reaction (Table 1). This OOC EPOo result is similar to the previous study

reported by Giita Silverajah et al. (3.23%) [34]. Meanwhile the saponification value of POo to EPOo was slightly reduced, 196.21 and 192.50 mg KOH/g oil, respectively. Further similarity was the slight reduction of ester value and ester percentage, which were recorded for the POo and EPOo (refer Table 1). This corresponds to the minor modification on triglyceride structure of POo by introducing epoxide ring to the POo's for producing of new triglyceride structure of EPOo [14, 35].

Table 1. Physico-chemical properties of the new precursors

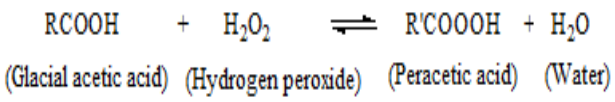
| **Conducted Test** | **Raw Material 1: Poo** | **Precursor 1: Epoo** | **Raw Material 2: OA** | **Precursor 2: Diol** |
|---|---|---|---|---|
| Acid value (%) | 0.56 | 8.09 | 0.56 | 67.32 |
| Iodine value (mg KOH/ g oil) | 61.47 | 0 | 83.91 | - |
| Oxirane oxygen content (%) | 0.04 | 3.33 | - | - |
| Saponification value (mg KOH/g oil) | 196.21 | 192.50 | 188.80 | 132.58 |
| Hydroxyl value (mg KOH/ g oil) | - | - | 231.07 | 114.53 |
| Ester value (mg KOH/ g oil) | 195.65 | 184.41 | 188.24 | 65.26 |
| Ester (%) | 43.98 | 41.45 | 42.32 | 14.67 |
| Viscosity (centipoise, cP) | 73.10 | 382.60 | 32.90 | 328.30 |



On the other hand, the saponification value of OA was decreased from 188.80% to 132.58% (Table 1) after the diol formation. This corresponds to the conversion of the carboxylic of OA to diol's ester, which was supported by the decrease in the ester value (or ester) of OA from 188.24 (or 42.32%) to 65.26 (or 14.67%) of diol, as well as the decrease of the hydroxyl value of OA to diol from 231.07 to 114.53, respectively (Table 1). The dynamic viscosity of POo and OA have increased drastically in EPOo and diol form, which showed initial confirmation of the formation of the new targeted precursors of EPOo and diol (Table 1). This result will be further confirmed by the analytical measurement presented in the following sections.

**The EPOo and Diol precursors' reaction mechanism**

The reaction mechanism for EPOo precursor formation is essential to be identified in order to understand the in situ epoxidation of POo with peracetic acid. In this study, POo was preferable as raw material due to its valuable physicochemical properties that consist of monounsaturated triacylglycerol (TAG), POP (42.8%), and diunsaturated TAG, POO (35.7%), where this TAG structures can be chemically or enzymatically modified to produce new green materials for utilization in industrial and pharmaceutical products applications [8-10, 14]. Furthermore, POo is derived from natural friendly source (a liquid fraction of palm oil), it's cheaper compare to petrochemical-based products and more importantly, POo is the largest renewable resources in Malaysia [8].



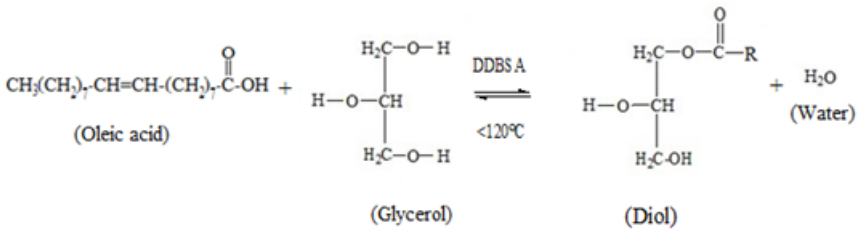
Moreover, the conventional chemical treatment method is the most widely used process of epoxidation compare to such as enzymes, metal catalysts and acid ion exchange resin methods [14, 36]. This chemical treatment method is also known as an efficient method for functionalization reactive group onto unsaturation sites (carbon double bonds) in organic compounds and resulted valuable properties of epoxides [14, 36, 37].

In this work, an established method called conventional chemical treatment by Ahmad et al. [20] is used and referred for the production of the EPOo where an alkene (POo) is reacted with peracetic acid [38-39] refer to reaction scheme (11). This epoxidation is known as an acid-catalyzed reaction [36]. The yield of reaction obtained using this method is 84.52%.

(11)

The peracetic acid solution was prepared from the glacial acetic acid (RCOOH) as an oxygen carrier and the hydrogen peroxide ($H_2O_2$) as an oxygen donor in the presence of catalytic inorganic sulphuric acid ($H_2SO_4$). The reaction mechanism of the peracetic acid formation is presented in scheme (12).

(12)



Acetic acid was found to be widely used as an oxygen carrier in the epoxidation process besides the formic acid [36]. The reaction conversion was found to be above 80% by using acetic acid, and also the higher conversion is still depends on the synthesis parameter such as temperature, reactants molar ratio, catalyst and mixing speed. In this work, the percentage of the relative conversion of the POo to EPOo, (conversion from double bonds to epoxide ring), by in situ epoxidation for 2.5 hours of reaction time is 89.04 ± 10.56 %. The theoretical value of the OOC is 3.74% [14] while the value obtained in this work is 3.33%. The OOC value was found to be different from the theoretical value probably due to the difference in the epoxidation parameters and reagent composition such as stirring speed, temperature, reaction time, type of reactants and reactants molar ratio [14, 36-37].

The catalytic inorganic of sulphuric acid have been chosen in this system because it was found to be more efficient in producing a high conversion of double bonds to epoxide ring when compared to other inorganic catalyst such as hydrochloric acid (HCI), nitric acid ($HNO_3$) and phosphoric acid ($H_3PO_4$) [36, 40]. Derawi and Salimon [14] worked on the epoxidation of POo using the performic acid reaction system [14]. They found that the conversion of epoxidation is 96.5% with a reaction yield of 91.3% for 2.5 hours of reaction time. However, this epoxidation process is considered as expensive compared to using the acetic acid because formic acid is more expensive than acetic acid [14].

However the purification method that we currently used in this work would require attentive washing and transferring in the recovery of the precursors in a way to obtain higher (maximum) yield as reported by other researchers [14, 36].

The average MW of the POo and EPOo were 860.21 and 912.64 g/mol, respectively, which were determined by titration method utilizing saponification value (an analytical method for measuring molecular weight of triglycerides in oils) and calculated using Equation (10).

We used acid-catalyzed homogeneous esterification reaction for diol production, in the absence of solvent [15-16, 18, 39]. In this study, OA was preferable as raw material due to its valuable chemical structure that consist of a carboxyl site and a carbon-carbon double bond at the ninth position, refer to scheme (13), which is reactive and can be further modified into high value-added products [16, 40-41], as well as its a plant or bio-based oil [an 18-carbon (C18) monounsaturated fatty acid] [16, 41]. This reaction system was conducted at temperature in the range of 115-118 $^{o}$C, in the presence of 3A molecular sieve as drying agent. The yield of reaction obtained was 72.65 % for 3 hours reaction time [refer Eq. (13)].

(13)

In this work, we used 4-dodecylbenzyl sulfonic acid (DBSA) as additive to homogenize the reaction system due to the reactants of OA and glycerol is not miscible. The DBSA was selected because it can act as emulsifier and catalyst (or known as a surfactant-type catalyst) compared to other surfactants such as cetyltrimethyl ammonium bromide (CTAB), tetradecyl trimethyl ammonium *bromide* (TTAB) and Esterquat [15-17]. In addition, DBSA is more efficient catalyst in water than other Bronsted acids such as HCl, $H_2SO_4$, $H_3PO_4$ and *p*-toluenesulfonic acid (PTSA). DBSA works well for dehydration reactions such as the esterification, etherification, thioetherification, and dithioacetalization in water, hence, gaining maximum yield of reaction (approximately 96%) [17]. This process was compared with the previous study by Kolvari et al. [17], where they conducted the condensation process of benzil (PhCOCOPh) and 1,2- diaminobenzene in $H_2O$ solvent at room temperature for 2 hours by using of 10% of the DBSA and resulted the reaction yield about a 96%. The results showed that the DBSA catalyst play important role to catalyze the reactions to obtain a high yield product above a 70% for at least a 3 hours reaction time. Besides, these reaction systems is considerable as green process, non-toxic, high product yields and cheap. However, the purification method of diol need carefully washing and transferred to gain maximum yield of reaction.

The average molecular weight of diol is expected in the range of 800 – 1000 g/mol [15] or less than 1500 g/mol [18], determined by GPC. The theoretical value of the average molecular weight of oleic acid is 282.47 g/mol. Further analysis of diol for chemical structure determination using nuclear magnetic resonance (NMR) spectroscopy, gas chromatograph (GC) or gas chromatograph-mass spectrometer (GC-MS) methods will be reported in future publications to identify the possibility of nearby functional group (neighbouring group participation) involvement in the reactions, especially the carbon double bond [39].

**FTIR analysis for EPOo and Diol precursors**

Figure 2 showed the spectra of the POo and EPOo in transmittance mode. The presence of epoxy group absorption in the EPOo at 834 $cm^{-1}$ corresponds to the formation of the epoxy ring in the EPOo molecular structure. In the previous study by few researchers [14, 19, 34, 42], the FTIR absorption of oxirane was identified at around 834 to 893 $cm^{-1}$. The absorption value was found to be slightly different for each of the researchers probably due to the difference in the synthesis parameters such as reactants, catalyst, temperature and mixing speed [14, 19, 34, 42]. In spite of that, the presence of the epoxy (oxirane) group in Figure 2 is strongly indicated that the EPOo was successfully synthesized via in-situ epoxidation of the POo from palm oil based.

Figure 3 showed the FTIR spectra of the OA and the diol. The O-H absorption was in the range of 3200 – 3600 $cm^{-1}$ corresponded to the hydroxyl group of the diol (broad). The hydroxyl value of the diol produced in this work was 114.53 (refer Table 1), which might represent at least two hydroxyl functionality in the diol, refer to scheme (13) and calculated according to Equation (9), which resulted approximately 2.78 of the hydroxyl number functionality. The average MW of the diol was taken as 1361 g/mol [18]. Five bands for the C-O absorptions in the range of 1000 – 1305 $cm^{-1}$ appeared in the spectra at 1010, 1038, 1124, 1182, 1304 $cm^{-1}$, which correspond to the ester functional group [16, 18]. Furthermore the carbonyl functional group (C=O) peak at 1716 $cm^{-1}$ has become shorter after the esterification due to diol formation and this has further confirmed the diol formation.

Based on the FTIR spectral analyses (refer Figure 2 and 3), the formation of EPOo and diol from POo and OA, respectively, are established. Numerous advantageous such as green renewable resources, cheaper and non-toxic were offered for utilizing a natural polymer as the raw material in designing polymeric drug vehicles [12]. Further

analysis on the thermal properties of the precursors are required to identify and understand their degradation and thermal transition properties which are the important aspect in the design and development of polymeric drug vehicles.

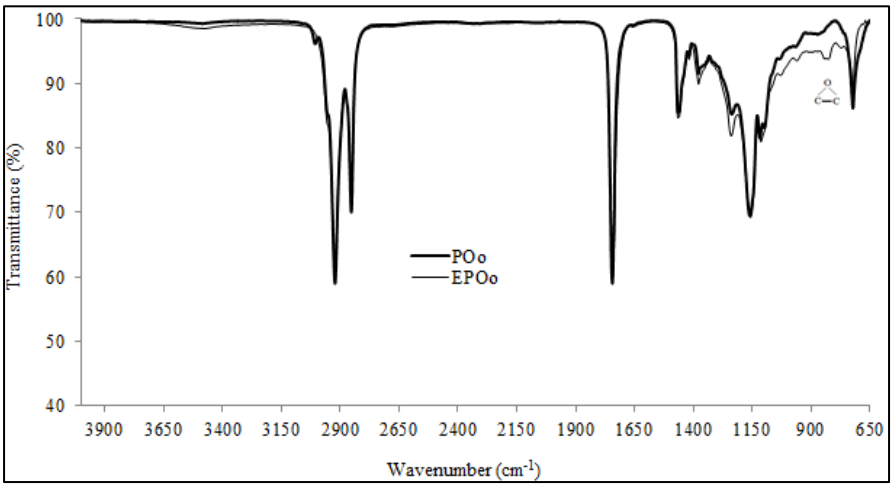


Figure 2. FTIR spectra of EPO in comparison to POo

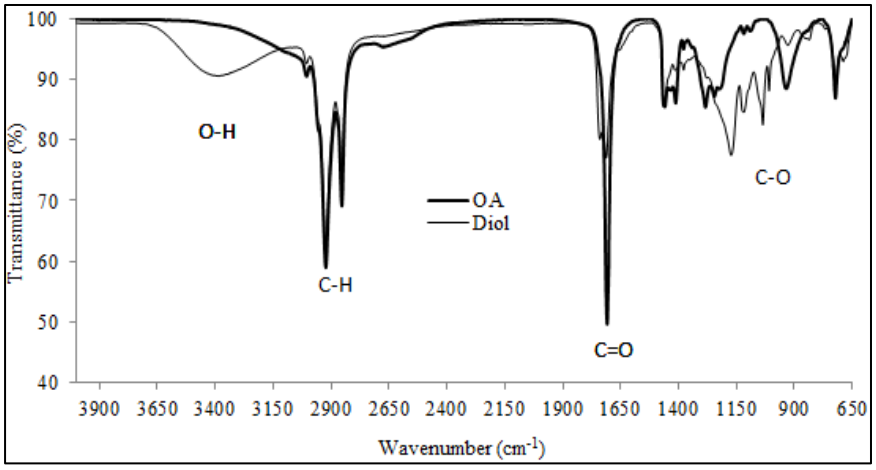

Figure 3. FTIR spectra of diol in comparison to OA

**Thermal analysis for EPOo and Diol precursors**

Figure 4 and 5 showed the thermal degradation (measured by TGA) and the corresponding derivative (DTG) thermograms of the POo and the EPOo, respectively. TGA thermogram curves of the POo and EPOo showed a single stage decomposition, for POo started at temperature 283 $^{o}$C to 479 $^{o}$C and for EPOo started at temperature 275 $^{o}$C to 523 $^{o}$C. Approximately about ~2% weight loss at the temperature of up to 300 $^{o}$C was observed, which was attributed to the loss of moisture content (Figure 5). The POo showed a degradation peak at the maximum temperature ($T_{max}$) of 440 $^{o}$C and the POo was fully degraded at higher temperature, 479 $^{o}$C. Meanwhile, the EPOo showed a slightly lower degradation peak at $T_{max}$ 407 $^{o}$C than the POo and the precursor was fully degraded at a higher temperature of 523 $^{o}$C, which is similar to the work reported by Tee et al. at 409 $^{o}$C [43] and Giita Silverajah

et al. at 405.1 $^{o}$C, respectively [34] for the peak degradation and was fully degraded at 491 °C and 504.3 °C for the EPO, respectively [34, 43]. The presence of oxirane ring have made the EPOo to have a slightly low thermal resistance compared to POo due to the plasticization effect (soft segment) of epoxide [34, 44] thus having a lower degradation peak (407 $^{o}$C) than the POo (at 440 $^{o}$C).

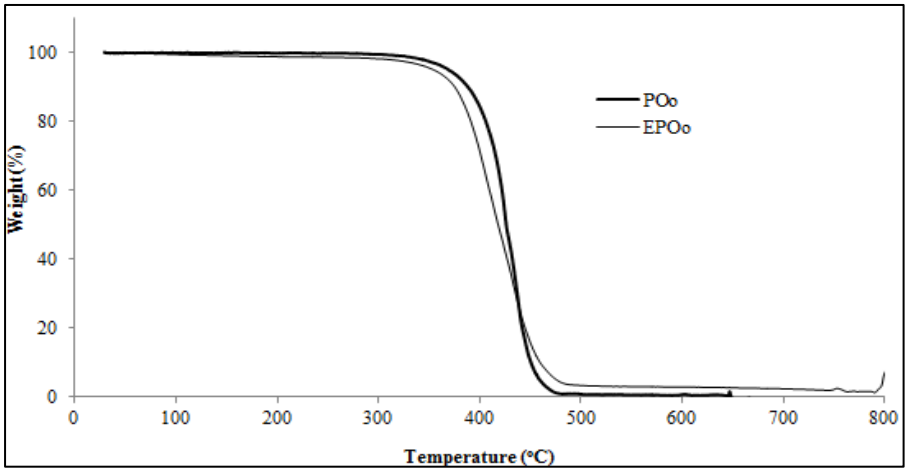

Figure 4. TGA thermograms of POo and EPOo

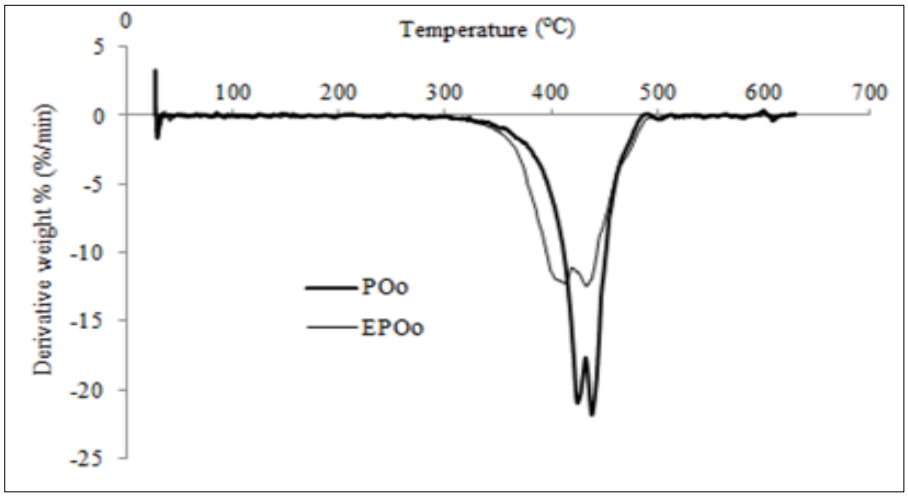

Figure 5. DTG thermograms of POo and EPOo

Figure 6 showed the DSC thermogram of the POo and the EPOo measured for the heating and cooling cycle (first heating cycle) from temperature -100 to 200 $^{o}$C. The DSC thermograms of POo and EPOo showed a single melting temperature ($T_m$) peak at 5 $^{o}$C and 15 $^{o}$C, respectively, almost in the range of the $T_m$ study reported by [34, 45-46]. The similarity on the $T_m$ for the palm olein is at 4.74 $^{o}$C, 6.94 $^{o}$C, 9 $^{o}$C and 17.79 $^{o}$C, as reported by Abdulkarim and Ghazali [45] and Zhang et al. [46], respectively. For the $T_m$ EPO is shifted to 24.46 °C and 37.69 °C, which is reported by Giita Silverajah [34].

Meanwhile three crystallization temperature ($T_c$) of POo were observed at $T_{max}$ -58 °C (in the range of -64 to -55 °C), -25 °C (in the range of -31 to -19 °C) and -3 °C (in the range of -7 to -1 °C), of which the different finding was reported by Zhang et al. approximately at −9.30 °C, 1.39 °C and 14.36 °C [46]. The EPOo thermogram also showed three $T_c$ peaks at $T_{max}$ -1 °C (in the range of -4 to 2 °C), 5 °C (between 2 – 8 °C) and 26 °C (in the range of 20 to 29 °C) when the sample is being cooled (Figure 6). This result is similar to the study reported by Tan and Chow where one of the EPO $T_c$ is at -0.97 °C, which is in the range of temperatures between $T_g$ and $T_m$ when the sample is being cooled [47].

The glass transition temperature ($T_g$) of EPOo was found approximately at $T_{max}$ -7 °C, occurred in the range of -16 to 2 °C (Figure 6). The $T_g$ of EPOo was found to be different from the finding reported by Tan and Chow at -18 °C [47] due to the difference composition of the palm oil been used such as from the palm oil by Tan and Chow and from the palm olein in our study. The $T_g$ of the POo could not be observed in the DSC thermogram (Figure 6), which is might due to the weak transition of $T_g$ especially for crystalline and low amorphous materials [47].

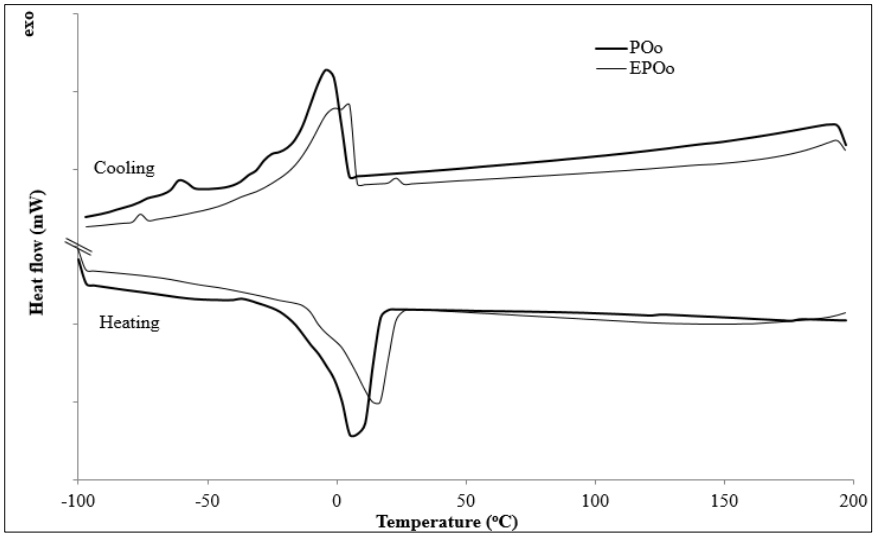

Figure 6. DSC thermograms of POo and EPOo

The TGA and DTG thermograms of the oleic acid and the diol are presented in the respective Figure 7 and 8. The thermogram patterns of both showed low thermal resistance of diol where the decomposition for OA started at temperature 180 °C to 438 °C. Meanwhile, the decomposition of diol started at temperature 108 °C to 516 °C. TGA curves of oleic acid and diol (Figure 7) showed two and three stages decomposition, respectively. In the oleic acid thermogram, the first stage represented the major degradation of the OA at $T_{max}$ 291 °C (in the range of 124 to 323 °C). This might be attributed to the loss of fatty acid in oleic acid, a carboxylic acid, which is about ~88 % from the total weight loss. The second stage occurred at $T_{max}$ 347 °C (in the range of 325 to 411 °C), which probably due to the total weight loss of carbon double bonds (C=C) and hydrocarbon (C-H) of about ~8 %. The OA was found to completely degrade at 438 °C.

Meanwhile the first stage degradation in the diol thermogram showed a slower decomposition process (than the OA) which is about ~14 % of the total weight loss at $T_{max}$ 125 °C (in the range of 79 to 200 °C). This might be attributed to the decomposition of hydroxyl group (O-H), which was produced from the hydroperoxide group (-OOH) (formed from oxidation of oil) and was found to be unstable at above 100 °C [48]. The decomposition of the hydroperoxide involved cleavage of the O-O bond in the hydroperoxide hence produced hydroxy-radical [48]. Based on this justification, the first stage decomposition temperature in the diol was strongly attributed to degradation of hydroxyl group.

In the second stage degradation, the major degradation of diol was recorded at $T_{max}$ 362 $^{o}$C (in the range of 204 to 426 $^{o}$C), which consist of about ~76 % of the major total weight loss. This involved bond cleavage on the carboxyl site which later produced ester group in the formation of ester radical. Thus, it can be concluded that this second stage decomposition pattern was possibly attributed to the degradation of the ester group (C-O) (Figure 7 and 8). The third stage degradation is about ~4 % weight loss at $T_{max}$ 492 $^{o}$C (in the range of 457 to 516 $^{o}$C), which might be attributed to bond cleavage of carbon double bond (C=C) and hydrocarbon (C-H) sides and further heating at 516 $^{o}$C showed a complete degradation of diol.

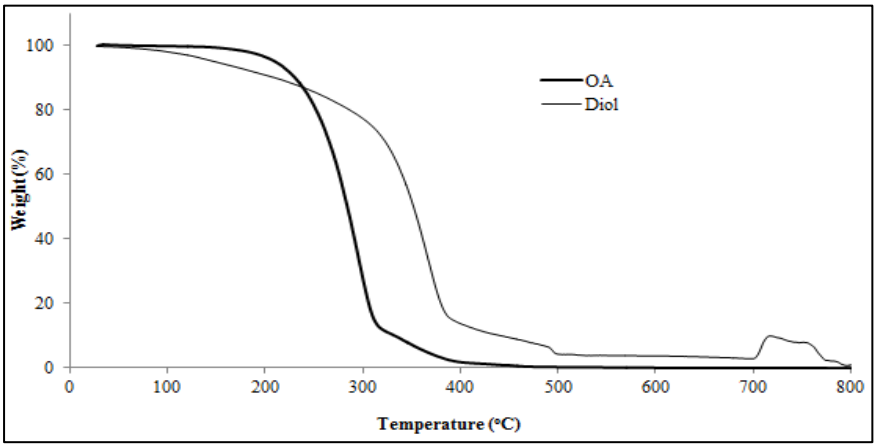

Figure 7. TGA thermograms of OA and diol

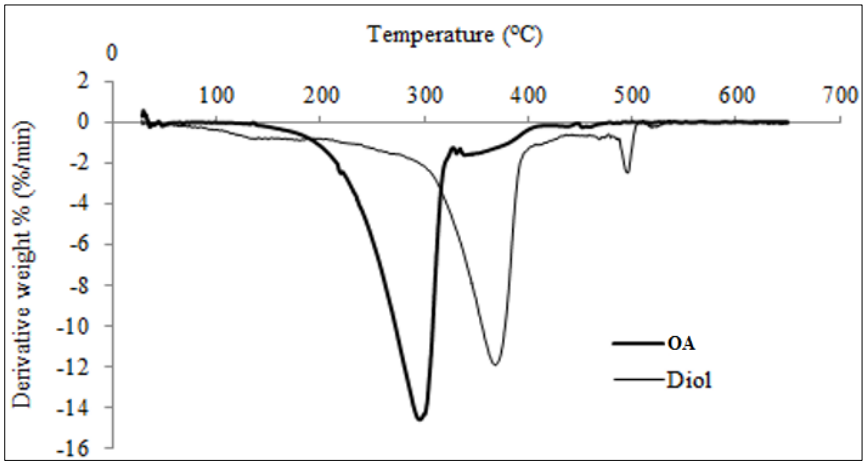

Figure 8. DTG thermograms of OA and diol

Figure 9 shows the DSC thermograms of the oleic acid and the diol. Two melting peaks of oleic acid were indicated at $T_{max}$ -25 $^{o}$C (in the range of -31 to -13 $^{o}$C) and 10 $^{o}$C (in the range of 2 $^{o}$C to 23 $^{o}$C) and also two $T_c$ peaks of oleic acid were occurred at $T_{max}$ -27 $^{o}$C (in the range of -31 to -22 $^{o}$C) and -5 $^{o}$C (in the range of -10 to -1 $^{o}$C) (Figure 9). The oxidative of oleic acid was associated with the thermal decomposition (Figure 7 and Figure 8) which was started from 124 $^{o}$C to $T_{max}$ at 151 $^{o}$C (in the range of 124 to 173 $^{o}$C), as shown in Figure 9.

Four peaks of the diol $T_m$ occurred at $T_{max}$ -40 $^oC$, -27 $^oC$, -4 $^oC$ (in the range of -49 to 5 $^oC$) and 133 $^oC$ (in the range of 112 to 142 $^oC$), as shown in Figure 9. The diol thermogram also showed one $T_c$ peak occurred at $T_{max}$ -21.81 $^oC$ (in the range of -36 to -13 $^oC$). The $T_g$ oleic acid is detectable at 2.18 $^oC$ (in the range of -0.67 $^oC$ to 5.18 $^oC$), as shown in the DSC thermogram. The $T_g$ of the diol was observed at $T_{max}$ -57 $^oC$ and -12.59 $^oC$ (Figure 9), which showed that the diol contains soft and hard segment of molecules structure where the $T_g$ peaks occurred in the range of $T_m$ and $T_c$ temperatures [16, 41]. Besides, the diol $T_g$ results is near to the range of the study reported by Mohd Mustafa et al. at -33.87 ºC, -18.29 ºC and -15.28 ºC [49]. The study reported the palm oleic acid based alkyd resins were prepared from oleic acid and glycerol with the presence of phthalic anhydride using the one step fatty acid process technique for two hours [49]. The similarity between these studies is the process systems are conducted in the absence of solvent.

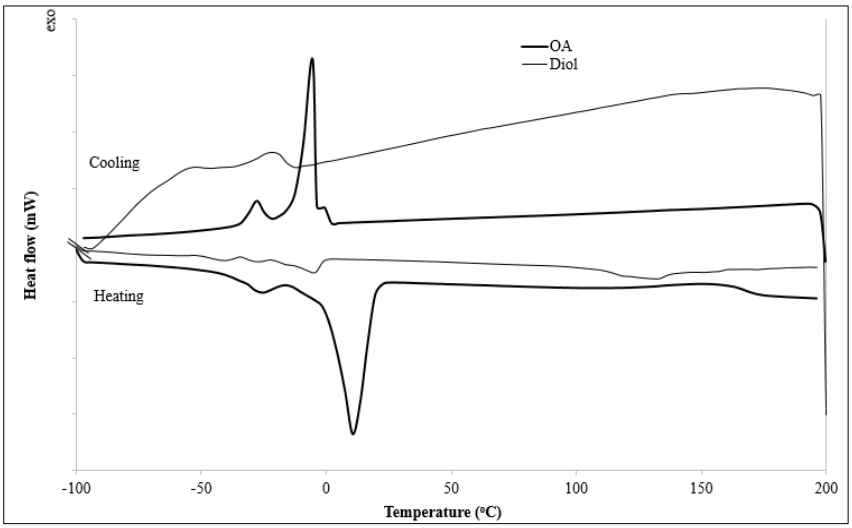

Figure 9. DSC thermograms of OA and diol

The thermal properties of the precursors in comparison to their raw materials found in this study (measured from the TGA, DTG and DSC analyses) are consistent and in line with the chemical properties obtained from the FTIR spectral analysis in Figure 2 and 3, such as the appearance of the functional groups of epoxy (oxirane) in the EPOo and hydroxyl and ester in the diol. This thermal property provided the overview of the degradation mechanisms and thermal transition ($T_g$, $T_c$ and $T_m$) of EPOo and diol. The thermal properties will be useful in elucidating the degradation and thermal behavior in designing and developing the future polymeric drug delivery vehicles.

## Conclusion

The synthesis of palm oil-based precursors namely EPOo and diol via in-situ epoxidation and esterification techniques using the respective POo and OA were successfully conducted. The procedures offer several advantages including cheap, cleaner reactions and high yields as confirmed by the proposed mechanism. The precursors exhibited promising physicochemical and thermal properties that could be used in designing new polymers such as acrylated palm oil (APOo) and polyol polyester for application in drug delivery system. These new precursors can be further investigated to be used in designing new concepts of biomaterial to create smart polymeric drug vehicle due to their soft, flexible and thermal resistance properties as confirmed by the FTIR, TGA, DTG and DSC analyses.

# CHARACTERIZATION OF SODIUM SILICATE DERIVED FROM SUGARCANE BAGASSE ASH

## (Pencirian Natrium Silikat yang Dihasilkan daripada Abu Hampas Tebu)

**Abstract**

This study explores the potential of sugarcane bagasse ash (SCBA) as a precursor in the extraction of sodium silicate. SCBA was obtained from sugarcane bagasse, residual waste from sugar industries. In the present study, sugarcane bagasse (SCB) was burnt with different temperatures 600 °C, 800 °C and 1000 °C for 2 hours and 4 hours and then the ash washed using hydrochloric acid (HCl) to remove metallic ions and impurities. The ash was characterized using X-ray Fluorescence (XRF). The result indicated that SCBA at 1000 °C for 4 hours using acid washing method gave the highest composition of silica which is 88.13%. Then, the ash with the highest silica composition was extracted using 3M of sodium hydroxide (NaOH) solution. During the process NaOH will bind with silicate to form sodium silicate ($Na_2SiO_2$) and water ($H_2O$). The formation of sodium silicate was characterized and compare with commercial sodium silicate using Fourier Transform Infrared Spectroscopy.

**Keywords**: sodium silicate, sugarcane bagasse ash, waste renewable

**Abstrak**

Kajian ini meneroka potensi abu hampas tebu (SCBA) sebagai pelopor dalam pengekstrakan natrium silikat. Abu hampas tebu ini telah diperolehi daripada industri gula. Dalam kajian ini, hampas tebu (SCB) dibakar dengan suhu yang berbeza iaitu pada suhu 600 °C, 800 °C dan 1000 °C selama 2 jam dan 4 jam dan kemudian abu dicampur dengan asid hidroklorik (HCl) dan ditapis untuk mengeluarkan ion logam dan kekotoran. Abu di analisis menggunakan pendarfluor Sinar-X (XRF). Hasilnya menunjukkan bahawa abu hampas tebu (SCBA) pada 1000 °C selama 4 jam dengan menggunakan kaedah basuhan asid memberikan komposisi silika tertinggi iaitu 88.13%. Kemudian, abu dengan komposisi silika yang paling tinggi akan diekstrak menggunakan 3M natrium hidroksida (NaOH). Semasa proses, NaOH akan bergabung dengan silikat untuk membentuk natrium silikat ($Na_2SiO_2$) dan air ($H_2O$). Pembentukan natrium silika dianalisis dan bandingkan dengan silika natrium yang digunakan dipasaran menggunakan Spektroskopi Inframerah Transformasi Fourier.

**Kata kunci**: natrium silikat, hampas tebu, sisa diperbaharui

## Introduction

Sugarcane or *Saccharum officinarum L*. is a perennial grass that thrives in hot and humid locations. It is originated in Papua, New Guinea and spread throughout Southeast Asia, India, the Mediterranean, Caribbean, Hawaii and the southern United States. According to Jorina [1], the structures of sugarcane comprised of stalks, leaves and a root system. The stalk contains the juice which used to make sugar and is broken up in segments called joints. The length and diameter of the joints and stalk vary by sugarcane species. Each joint has a node and an inter node and the leaves are attached to the node. The root system at the base of the plant anchors the grass to the soil and adsorb

in water and nutrients from the ground. When the top part of the sugarcane is cut, the roots remain intact, the plant will regrow from where it was cut. It can take about six to 24 months for the plant to grow to maturity [1]. Sugarcane is harvested when it reaches maturity and during the dry season of the particular sugar cane plantation. The sugarcane juice extract from the stalk is highly valued and is the source of 70 percent of the world's sugar and has the highest number of calories per unit area of any plant [1]. The sugars derived from sugarcane are commonly used in syrups, juices, and molasses. After juice was extract from stalks, the waste left is called sugarcane bagasse (SCB). The main constituents of SCB include cellulose, hemicellulose, ash and wax [2].

In Malaysia, large region of northern area is devoted to sugarcane plantation, which produces more than 700000 tonnes of sugarcane. This waste from sugarcane was abundance in Malaysia and usually used as a primary fuel source and additive in construction industries [3]. Normally for every metric ton of sugarcane production, 270 kg bagasse is generated. Approximately 50% amount of this waste generally will be reused for energy and bioethanol application, while the remaining 50% will be stockpiled or burnt that could pose environmental problem [4]. From biomass viewpoint, sugarcane plantation produces not only granulated sugar, but also bagasse, cane tops and dry leaves that potentially could be converted into useful energy and chemical feedstock. SCB itself contributes to the main biomass wastes, which represents 30 – 40% wastes from sugar production. Wide array of initiatives has been taken by researchers and scientist to utilize the SCB waste, one of which is sugarcane bagasse ash as the supplementary material in cement construction [5]. Several studies have investigated bagasse ash potential applications such as producing silica gel as adsorbent, raw material for ceramic, cements and concrete additives, catalyst, cosmetics, paint and coating, etc. based on its characteristics. SCB is a potential feedstock that can be convert to sugarcane bagasse ash (SCBA) by pyrolysis process which also known to be a renewable resource for silica content.

In local plantation it was a valuable by products that often uses as a primary fuel source to supply all the energy needs to power the plants. Burning bagasse as an energy source yields its ash, considered as a waste causing disposal problems. Therefore, this study will show that burning sugarcane bagasse will produce a valuable product through extraction process which is sodium silicate. Sodium silicate has been diligently produced from utilizing waste from sugar industry, SCBA. Currently in market, sodium silicate was synthesized by petroleum derivatives which are identified to be toxic and environmentally unfriendly. Moreover, the processing is very costly, in which total cost of raw material passes through different cycles of process is estimated to be expensive. Unlike the production of sodium silicate from SCBA, a green and economical approach has been developed to convert the SCB to ash through burning in laboratory furnace. It is then extracted and treated by simplified chemical methods to produce high purity of sodium silicate, and the cost involved is very minimal. The SCBA is preferable as a source for silicate production since it is renewable, available in Malaysia, cheap, natural, less toxic and high silica content. So, this seems to open a wide possibility of developing the silica precursor from SCBA. In order to achieve the goal of the study, the waste material which is Sugarcane bagasse was utilize as a source of silica and determine the potential of SCB as a source of silicate. However, this ash have a potential to be reused in other application due to it silica composition. According to Worthanakul et al., on the study of Characterization for Post-treatment Effect of Bagasse Ash for Silica Extraction, the silica content in SCBA might range from 60% to 89 %. The silica contents of bagasse and its ash vary depending on the type of soil, environment and harvesting period and process [6].

This study helps to determine the effect of varying parameters of temperature, curing time and acid washing method on the composition of silica present in the SCBA. Sodium silicate produced from this project can be utilized and applied in different applications i.e. detergent auxiliaries, adhesive use, concrete and cement treatment, as agent for drilling fluids, silica source for synthesis of mesoporous materials [7].

## Materials and Methods

### Materials

Silicate Supernatant Extraction was carried out using SCBA in order to extract silica for the further study. This study focus on the performance of thermochemical treatment to extract maximum amount of silica and also the performance of that sodium silicate as a silica source. Sugarcane bagasse were collected from juice processes industry (small industry). The bagasse was cut to ensure complete burning. Then SCB were pyrolysis in the laboratory furnace (CARBOLITE RHF 16-8 Chamber Furnace) at different heating temperature which is 600 °C,

800 °C and 1000 °C, respectively for 2 hours and 4 hours. The collected bagasse ash will be grinded and sieved to homogenize sample.

**Analysis of chemical composition in sugarcane bagasses ash**
The binder was used to compress SCBA into solid form (coin shape), by using hand compression at 40 psi. After that, the sample in solid form were put in X-ray Fluorescence (XRF) sample case and arranged in the prescribed positions in the machine, then the sample case was located in analysis hole and the result of the chemical composition of each sample was displayed after 1 minute on a monitor of a computer interfaced with the machine. Then, the ash with the highest silica composition was proceed with acid washing and silica extraction method.

**Acid washing to remove the impurities**
The process started with 5 gram of SCBA was dispersed into 50 mL of 1 M Hydrochloric solution (HCl), the suspension is then stirred for 2 hours at room temperature. The suspension obtain was filtered by Whatman No. 41 ashless filter paper and the solid residue was washed with 30 mL of distilled water to remove metallic ions completely. The washings are collected and dried for 24 hours at 60 °C for further process.

**Silica supernatant extraction**
Treatment with alkali is very effective in altering the chemical and physical structure and to remove metal impurities. The SCBA residue was dispersed in 50 ml of 3M of Sodium Hydroxide solution. The mixture was boiled for 4 hours at $80^{O}$C, vigorous stirred and reaction time was varied during this process to produce sodium silicate solution. The suspension was then filtered through an ashless Whatman No 41 in order to remove carbon residue. The filtrate solution obtain was characterized for determination of sodium silicate.

**Fourier transform infrared spectroscopy analysis**
Fourier transform infrared spectroscopy (FTIR Perkin Elmer, USA) was used to analyze the functional group of the sample. As the sample used was in liquid form, then the dropper was used to spread liquid sample over the plate and the sample was scan to identify specific functional group presence. Absorption bands were used to confirm the identity of a pure compound or to detect the presence of specific impurities.

## Results and Discussion

**Sugarcane bagasses ash**
The SCBA obtained from pyrolysis process in the laboratory furnace (CARBOLITE RHF 16-8 Chamber Furnace) at different heating temperature was shown in Figure 1.

600 °C 800 °C 1000 °C

Figure 1. Observation of SCBA colour at different temperature

The ashes obtained at 600 °C were dark in colour indicating the presence of unburnt carbon, while the ones heated at 800 °C and 1000 °C were slightly milky white and as temperature increases the amount of ash produced decreases

because they will be less carbon deposits. SCBA obtain after burning in laboratory furnace and have been analyze using X-ray fluorescent (XRF) analysis, the result was tabulated in Table 1.

Table 1. Compositions of silica in SCBA at different temperature and time

| Temperature (°C) | Composition of Silica in SCBA (wt. %) | | | |
|---|---|---|---|---|
| | Without Acid Washing | | After Acid Washing | |
| | 2 Hours | 4 Hours | 2 Hours | 4 Hours |
| 600 | 37.76 | 40.25 | 74.14 | 76.83 |
| 800 | 42.47 | 43.62 | 82.78 | 83.18 |
| 1000 | 52.39 | 53.05 | 86.72 | 88.13 |

**Effect of temperature and time on the silica composition**

The effect of times and temperature on the composition of silica present in the SCBA is shown in Table 1. Based on the overall analysis result without acid washing, 4 hours burning time were gave higher silica composition than 2 hours burning time. At temperature 600 °C without acid washing method, silica composition at 4 hour is 40.25% compare to 2 hours burning time which is only 37.76% of silica content. There are about 2.49% different of silica composition. While at temperature 800 °C the amount of silica was observed between 2 hours and 4 hours burning time are 42.47% and 43.62%, respectively which gave the different about 1.15%. Finally, at temperature 1000 °C, the composition of silica present at 2 hours and 4 hour are 52.39% and 53.05% respectively. So, the different is only 0.66%. Therefore, 1000 °C at 4 hours burning time without acid washing method give the highest silica composition which is 53.05%. But, there are does not much differences in composition between the 2 and 4 hour burning times.

**Effect of acid washing method on the silica composition**

The silica composition of SCBA which undergoes acid washing method at 600 °C, 800 °C and 1000 °C reveal that 4 hours burning time produce more silica amount compared to 2 hours burning time. Even there is a little difference in composition but both 2 and 4 hours burning time give the higher amount of silica content. By referring to the Table 1, amount of silica composition at 600 °C, 800 °C and 1000 °C at 2 hours are 74.14%, 82.78% and 86.72%, respectively. While quantities of silica observed at 600 °C, 800 °C and 1000 °C at 4 hours are 76.83%, 83.18% and 88.13% respectively. The pattern of the silica composition exists in the three different temperature was slightly increase from temperature 600 °C to 1000 °C. This is because at the higher burning temperature can improve the amount of silica present but the temperature must not exceed the silica melting point which is 1600 °C. Hence, from the Table 1, temperature at 1000 °C with 4 hours burning time with undergoes acid washing method give the highest silica composition which is 88.13%. Therefore, time and temperature are the most important parameter in order to achieve highest silica composition. Thus, suitable combination of time and temperature would help to improve the silica composition present.

As in the result, the composition of silica using acid washing method is higher than without using acid washing method for all samples, this is because the acid washing method helps to remove the impurities from the sugarcane bagasse ash. From the three temperature, 600 °C, 800 °C and 1000 °C, the composition of silica at 800 °C burning for 4 hours and undergoes acid washing was give highest composition which is 88.13%. The result was compared with Worthanakul et al. [6], on the study of characterization for post-treatment effect of bagasse ash for silica extraction, reveal almost the same result observed where acid washing method improved the composition of silica in the ash. But, the silica composition obtained by Worthanakul et al. was higher which is achieved at 89% [6]. Silica content of bagasse and its ash vary depending on the type of soil, environment and harvesting period and other process involve in sugarcane plantation.

**Fourier transform infrared spectroscopy analysis**

The functioning group for the commercial sodium silicate and extracted sodium silicate from SCBA was illustrated in Figure 2. The comparison spectrum structure of commercial sodium silicate and extracted sodium silicate was clearly shown. Theoretically, Fourier transform infrared spectroscopy measures the absorption of infrared spectrum radiation by the sample material versus wavenumber. The infrared absorption bands will identify molecular structures and components exist in the sample. When a sample is irradiated with infrared radiation, absorbed IR radiation usually excites molecules into a higher vibration state. The wavelength of light absorbed by a particular molecule is a function of the energy difference between the at-rest and excited vibration states. The wavelengths that are absorbed by the sample are characteristic of its molecular structure. The functioning group of the single molecules was represented according to the result, absorption bands in the range of 400 $cm^{-1}$ to 4400 $cm^{-1}$ wavenumbers are typically due to functional groups Si, O and H. The patterns of the result obtain almost the same, at peak 969 $cm^{-1}$, the wavenumber represent the Si-O-Si stretching. Both spectrums appear at peak 3239 $cm^{-1}$ confirms the presence of hydroxyl group in the sample. Peak observed at 1646 $cm^{-1}$ confirm the presence of H-O-H (water adsorption) and at peak 871 $cm^{-1}$ confirm the presence of $SiO_4$ tetrahedron. Absorption bands in this region are generally due to intramolecular phenomena and are highly specific to each material. Therefore, all peak that present in commercial sodium silicate also present in extracted sodium silicate from sugarcane bagasse ash.

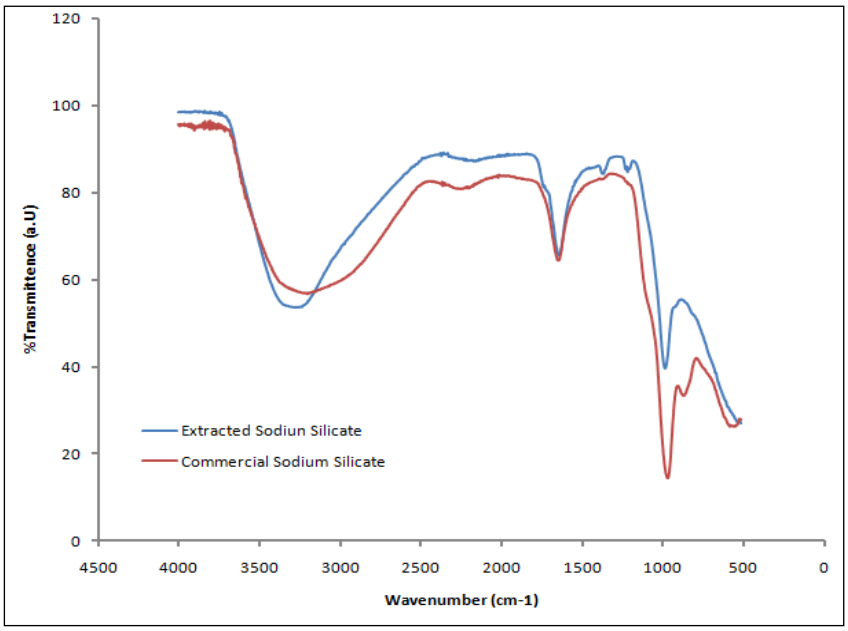

Figure 2. The FTIR spectrums of commercial sodium silicate and extracted sodium silicate from SCBA

**Conclusion**

Four hours burning time for all three different temperatures gave higher silica composition than 2 hours burning time. Amount of silica composition without acid washing method at temperature 600 °C, 800 °C and 1000 °C for 2 hour burning time are 37.76%, 42.47% and 52.38% respectively. While at 4 hours, the amount of silica recorded at 40.25%, 43.62% and 53.05%, respectively. On the other hand, the silica composition for the sugarcane ash that undergoes acid washing method was give the same result, while 4 hours burning time give higher silica amount than 2 hours. An amount of 88.13% is highest composition of silica obtain at temperature 1000 °C for 4 hour with acid washing method. The patterns of the result obtain from Fourier transform-infrared spectroscopy analysis was almost the same, the peak present at 969 $cm^{-1}$, 3239 $cm^{-1}$, 1646 $cm^{-1}$ and 871 $cm^{-1}$ wavenumbers are typically due to present of functional groups Si, O and H, hydroxyl group, Si-O-Si stretching, H-OH (water adsorption) and SiO4

tetrahedron, respectively. Therefore, the property and functional group exist in extracted sodium silicate from sugarcane bagasse ash (SCBA) was same as commercial sodium silicate in the market.

**Abstract**

This paper described the surface modification of screen-printed gold electrode using thiol self-assembled monolayer, in combination with enzyme-linked immunosorbent assay (ELISA) format for determination of benzo[a]pyrene (BaP) in water sample. All biomolecules were immobilized on the surface of working electrode to increase the sensitivity of the developed biosensor by applying different types of ELISA. Electrochemical characterizations using cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) were carried out to study the conductivity behavior of the developed biosensor. Based on the results, biomolecules were successfully immobilized and characterized optically and electrochemically. Optical immunoassay with indirect competitive ELISA were developed for the determination of BaP compound which showed the best performance compared to other assay. In optical measurement, normal assay exhibits higher absorbance, implying high bio complex formation. Modification of electrode using 11-MUA was successful due to highest blocking effect for electron transfer process. Determination of BaP in real water samples shows that there no BaP was detected in all samples collected, due to no presence of BaP in all samples.

**Keywords:** surface modification, screen-printed gold electrode, benzo[a]pyrene, water sample

**Abstrak**

Kertas kerja ini menerangkan pengubahsuaian permukaan elektrod emas skrin tercetak menggunakan lapisan mono tepasang menggunakan tiol, dengan kombinasi format ujian enzim-pengerap imuno (ELISA) untuk penentuan benzo[a]pirina (BaP) dalam sampel air. Semua molekul bio telah dipegunkan di atas permukaan elektrod bekerja untuk meningkatkan kepekaan biosensor yang dibangunkan dengan menggunakan pelbagai jenis ELISA. Pencirian elektrokimia menggunakan voltametri kitaran (CV) dan spektroskopi impedans elektrokimia (EIS) telah dilakukan untuk mengkaji tingkah laku kekonduksian biosensor yang dibangunkan. Berdasarkan keputusan yang diperolehi, molekul bio telah berjaya dipegunkan dan dicirikan secara optik dan elektrokimia. Ujian imuno optik dengan ELISA bersaing secara tak langsung telah dibangunkan untuk penentuan sebatian BaP menunjukkan prestasi terbaik berbanding ujian lain. Dalam pengukuran optik, ujian normal mempamerkan keserapan lebih tinggi, menandakan pembentukan kompleks bio yang tinggi. Pengubahsuaian elektrod menggunakan 11-MUA berjaya disebabkan oleh kesan halangan tertinggi bagi proses pemindahan elektron. Penentuan BaP dalam sampel air sebenar menunjukkan tiada BaP dikesan dalam semua sampel yang diambil, kerana ketiadaan BaP dalam semua sampel.

**Kata kunci:** pengubahsuaian permukaan, elektrod emas skrin tercetak, benzo[a]pirina, sampel air

## Introduction

Rapid growing of industries has contributed in the increasing of organic pollutants in the environment. Among the pollutants, polycyclic aromatic hydrocarbons (PAHs) have gained extra attentions in the past years from countless research in various fields. PAHs exist naturally in the environment through a carbonization process or can be man-made by pyrolytic processes [1]. However, most of the PAHs compounds in the environment today are the products from the infinite growing industries and human activities and they enter the environment through the incomplete combustion of fossil fuels such as crude oil or coal. Some compounds of PAHs have been recognized as carcinogenic, mutagenic and teratogenic. The simplest PAHs structure is naphthalene, which is the main ingredient in 'moth ball' or 'naphthalene ball', used to get of insects in closet.

Chromatographic technique such as liquid and gas chromatography were frequently selected to detect PAHs compounds in environment, especially in water samples. The method was certainly convenient for determining many targets analytes at one time, in addition of giving precise and accurate results. However, this method usually required large number of samples and complex sample preparation, which is time consuming. Thus, a lot of studies were conducted to develop simpler methods, yet give good results. The new developed method includes biosensor and immunosensor. Biosensors are analytical devices which are fabricated from the combination of two parts: a biological recognition element such as an antibody, enzyme, receptor, DNA, or cell and transducer that converts the biorecognition process into a measurable physical signal [2]. Immunosensors are one of the biosensors, which are widely investigated and developed over these past years. An immunosensor is an affinity-based biosensor designed to detect the direct binding of an antibody or an antigen [3]. The biological reactions on the surface of electrode will be detected by transducer and then converted into physical signal.

Enzyme-Linked Immunosorbent Assay (ELISA) principle is often used for immobilization of antibodies and antigen in immunoassay for biosensors development. The steps in ELISA involve the attachment of antigens to the surface, the application of antibody to the antigen, the antigen-antibody reactions and finally the addition of substrate. ELISA comes in several types namely indirect, direct, sandwich and competitive ELISA. ELISA is broadly applied in medical [4-6], food industry [7, 8], beverage industry [9] and environmental fields, for example detection of dioxins [10] and PAH compounds [11, 12].

In this study, we focused on the application of ELISA for detecting benzo(a)pyrene (BaP) in river water samples. Biological elements such as coating conjugate and antibodies were immobilized in 96-well plate and on the screen-printed gold electrode (SPGE) using indirect competitive ELISA. This type of assay is commonly applied for determination of 1-hydroxypyrene [13] and phenanthrene [14] because the assay usually gave higher sensitivity results compared to other assays. The performance of the immobilized biomolecules were measured optically and electrochemically. The purpose of this study is to determine the behavior of immobilized biomolecules on the SPGE as well as to test the sensitivity of the competitive assay towards real water samples. Optically, a normal competitive assay would display high selectivity and sensitivity towards BaP due to the interaction of 4D5 monoclonal antibody with BaP molecule. In addition, low current and high resistance were expected for electrochemical measurements due to thick layer embedded on the electrode surface, resulting a slow diffusion of redox probe ions.

## Materials and Methods

### Chemical and materials

Screen-printed gold electrode (SPGE) C220BT were purchased from DropSens, Spain. 11-mercaptoundecanoic acid (11-MUA), ethanol, isopropanol, acetone and isopropanol and acetone were purchased from Merck, Germany. Tris(hydroxymethyl)aminomethane (Tris) and bovine serum albumin (BSA) were purchased from Sigma-Aldrich, USA. Tween 20, diethanolamine, potassium chloride, potassium hexacyanoferrate (III) and potassium hexacyanoferrate (II) trihydrate were purchased from Merck, Germany. *p*-nitrophenyl phosphate was purchased from Sigma, USA. Both goat anti-mouse IgG alkaline phopshatase and 4D5 monoclonal antibody (specific for benzo[a]pyrene) were from Santa Cruz Biotechnology, USA. Adipic acid dihydrazide, N-(3-dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC), *N*-hydrosuccinimide (NHS), 9-phenanthrene carboxaldehyde and benzo[a]pyrene were purchased from Sigma-Aldrich, Germany. All reagents are of analytical grade or better.

**Instrumentations**
All experiments involving cyclic voltammetry and electrochemical impedance spectroscopy were conducted at room temperature using AUTOLAB PGSTAT30 (Metrohm, Utrecht, The Netherlands), located at School of Ocean Engineering, UMT. SPGE was connected to the potentiostat by DRP-CAC connector (DropSens, Spain). SPGE was cleaned with Ultrasonic Cleaner JAC Ultrasonic 2010P (Jin Woo Engineering Co. Korea). Mini incubator (VWR, China) was used to incubate samples at 37 °C. Ascent Multiskan ELISA reader (Thermo Scientific, USA), located at Institute of Marine Biotechnology, UMT was used for optical characterization.

**Preparation of gold electrodes**
The C220BT screen printed AuE was ultrasonic cleaned with acetone by isopropanol and lastly ultrasonic cleaned in deionized water for 5 minutes in each solution, respectively [15].

**SAM formation on gold electrodes**
SPGE was immersed in the freshly prepared 5 mM 11-MUA in ethanolic solution for 20 hours. The modified electrode was rinsed with ethanol to remove any unbound molecules. Activation of carboxylic acid terminated-group was done by coupling the modified electrode with 50 mM EDC and 50 mM NHS and this activated-modified SPGE was further used to detect BaP using ELISA principle.

**Preparation of buffer solutions**
Blocking buffer was prepared by dissolving 0.3029 g Tris in deionized water. Then, the prepared solution was used to dissolve 0.5 g BSA. For washing buffer, 0.3029 g Tris was dissolved in deionized water. A total of 50 µL Tris solution was pipetted out and replaced by 50 µL Tween-20. 1 mL *p*-nitrophenyl phosphate (*p*-NPP) substrate was diluted in 9 mL of diethanolamine (DEA).

**Control assays**
BSA-PHEN coating conjugate was synthesized by coupling the adipic acid dihydrazide with BSA, EDC and 9-phenanthrene carboxaldehyde [16]. Control assays were performed to evaluate the performance of optimized biomolecules optically and electrochemically (Table 1). *p*-NPP was only involved in optical measurement.

Table 1. Control assays

| Assay | *p*-NPP Only | Control 1 No Conjugate | Control 2 No Conjugate and 4D5 | Control 3 No 4D5 | Normal Assay |
|---|---|---|---|---|---|
| *p*-NPP (blank) | √ | √ | √ | √ | √ |
| AP Label | X | √ | √ | √ | √ |
| 4D5 | X | √ | X | X | √ |
| Blocking | X | √ | √ | √ | √ |
| BSA-PHEN | X | X | X | √ | √ |

**Indirect competitive assay for benzo(a)pyrene**
For optical characterization, the wells were coated with 50 µL bovine serum albumin-phenanthrene (BSA-PHEN) coating conjugate (n=3) and then incubated for an hour at 37 °C. After incubation, the plate was washed with washing buffer. 50 µL blocking buffer was added into each well and incubated again for one hour at 37 °C. After that, the plate was washed again. Serial dilutions of standard BaP were mixed with 4D5 monoclonal antibody and then were left for 15 minutes to react. The solutions were prepared at concentration two times higher than the desired concentration. Then, 50 µL of each solution was added into the wells and incubated at 37 °C for one hour. After washing, 50 µL of alkaline phosphatase (AP) label antibody was added and allowed to react at 37 °C for an hour. After that, the plate was washed and 200 µL of *p*-NPP substrate was added into each well. The absorbance was read at 405 nm after 60 minutes.

For electrochemical characterization, the working electrodes were coated with 5 µL BSA-PHEN coating conjugate (n=3) and then incubated for an hour at 37 °C. After incubation, the electrodes were washed with washing buffer. 5 µL blocking buffer was added onto each electrode and incubated again for one hour at 37 °C. After that, the electrodes were washed again. Then, 5 µL of serial dilution of standard BaP mixed with 4D5 were added onto the electrodes and incubate at 37 °C for one hour. After washing, 5 µL of AP label antibody was added and allowed to react at 37 °C for an hour. After one hour, the electrodes were washed and measured after 60 minutes.

CV measurements were carried out in 5 mM $[Fe(CN)_6]^{3-/4-}$ in 0.1 M KCl and the applied potential was in the range of -0.2 to 0.6 V versus Ag/AgCl. The scan rate applied was 50 $mVs^{-1}$. For impedance measurements, impedance behavior of the electrode is determined by analyzing the AC voltage and current response at frequencies ranging from 0.1 Hz to 10 kHz. Measurements were carried out in the presence of 5 mM $[Fe(CN)_6]^{3-/4-}$ in 0.1 M KCl at an applied potential of +0.025 V with amplitude of 0.1 V. All measurements were recorded at room temperature.

**Sampling site**

Water sampling was conducted at Semerak River in Tok Bali, Kelantan. The sampling was carried out in January 2016. Five sampling points were selected along the Semerak River (Figure 1). All water samples were collected using grab sampling. Triplicate of water samples were taken at each point. 1 mL of 2 M nitric acid ($HNO_3$) was added into the water samples for preservation. Then the bottles were wrapped with aluminium foil and stored in an ice box. The bottles then were transferred into a 4 °C chiller prior further analysis.

**Measurements on the river water samples**

Indirect competitive assay was applied for optical and electrochemical measurements of blank and spiked (50 and 100 ppm BaP) water samples.

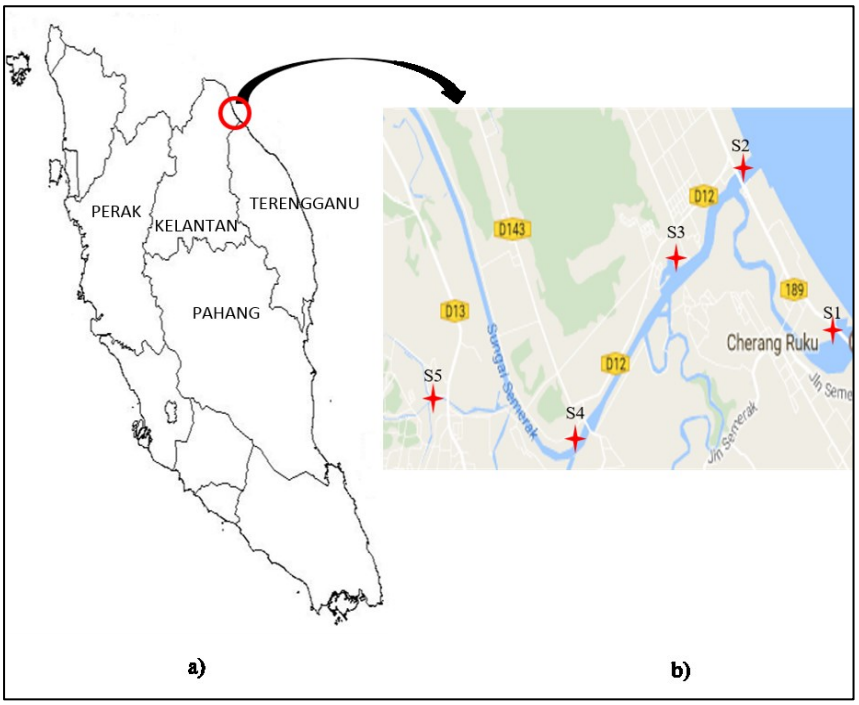

Figure 1. a) Map of Peninsular Malaysia and b) Map of five sampling points along Semerak River. [Scale 1 cm = 2 km]

## Results and Discussion

### Control assays: Optical characterization

Control assays were carried out in order to establish the optimal responses for different substances or antibodies immobilized on the 96 well plates. Figure 2 shows the absorbance for all assays. The effect of BSA-PHEN coating conjugate was studied in Control 1 and it was replaced with coating buffer. Control 2 was performed without BSA-PHEN coating conjugate and 4D5. The effectiveness of optimized AP label antibody was studied in Control 3. There was no specific binding observed for all the controls and it was as expected that the normal assay had the highest absorbance. Thus, it can be concluded that all bio elements must present in order to provide better absorbance reading.

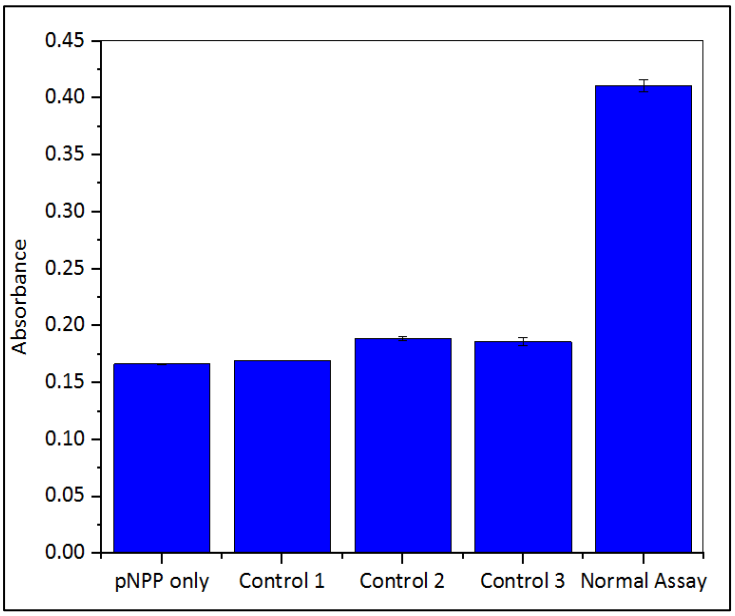

Figure 2. Control assays

### Electrochemical characterization

Electrochemical measurement of the control assay has been conducted without the presence of substrate. Figure 3 and Figure 4 shows the cyclic voltammogram and Nyquist plot of the control assay, respectively. From the voltammogram, low current reading was recorded for all control assays. Redox peaks were appeared in Control 2 and Control 3, which suggested that little redox reaction occurred on the electrode surface, due to formation of thin layers. As expected, normal assay displayed the lowest current reading, which implied high resistance for electron transfer process because of the thick layer appeared due to immobilization of several layers of biomolecules. The CV results were supported by the EIS results. The resistance recorded for normal assay was the highest, due to slow diffusion of the probe ions onto the gold surface [17].

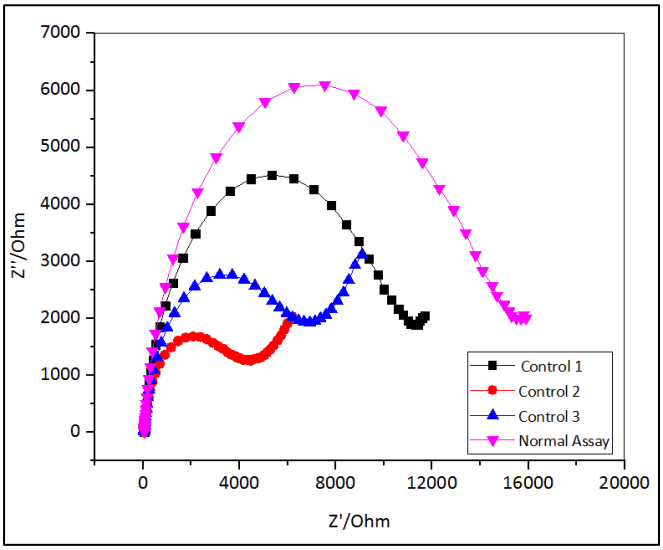

Figure 4. Nyquist plot of control assays on SPGE in 5 mM ferricyanide/ferrocyanide redox probe at 0.025 V and amplitude of 0.1 V

**Indirect competitive assay for benzo(a)pyrene**

The absorbance reading for competitive assay was shown in Figure 5. Different concentrations of BaP were tested to determine the sensitivity of the assay. At 20 ppm of BaP, the absorbance recorded the highest reading, which proved that indirect competitive assay was sensitive at low concentration of BaP. The reading became lower as the concentration of BaP decreased.

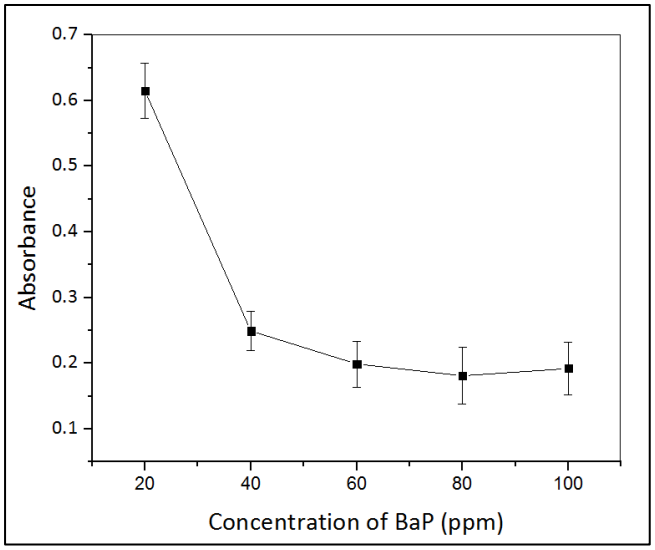

Figure 5. Optical measurement of indirect competitive assay for benzo(a)pyrene

**Measurements on river water samples**

The indirect competitive assay was conducted to study the capability of assay to detect BaP in real water samples. Figure 6 shows the absorbance reading of blank and spiked water samples at five different sampling stations. The lowest absorbance reading was recorded for blank water samples at each station. It is expected because no BaP was presence in the samples. This might be due to the possibility of absence of BaP in the river water during samples collection. However, after the water samples were spiked with 50 ppm and 100 ppm BaP, the absorbance reading significantly increased about two times higher than the blank reading at certain sampling points. In addition, the absorbance for water samples spiked with 50 ppm BaP were much higher than 100 ppm, where the reading was almost the same. The results proved that the assay was sensitive for BaP detection in lower concentration. This is due to less competition of BaP molecules to be attracted by the assay. As the concentration increased, more BaP molecules compete for the binding sites, resulting in low absorbance reading because more binding sites were unoccupied. Compared with lower concentration of BaP, the molecules moved more freely due to many space in the water samples, thus giving enough time for a complete bonding between the assay and the BaP.

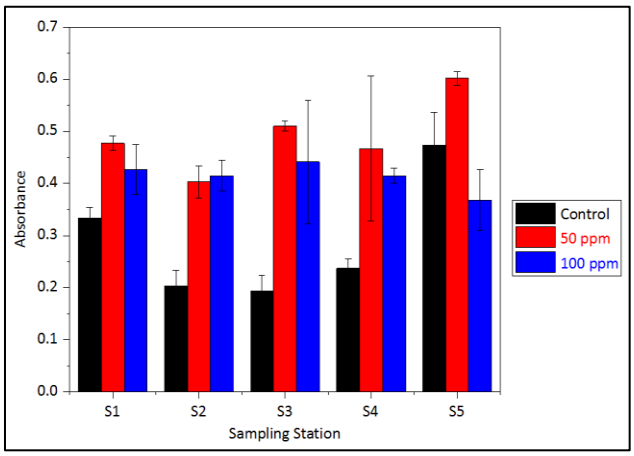

Figure 6. Indirect competitive assay for blank water samples and spiked water samples at five different sampling stations

## Conclusion

Biomolecules were successfully immobilized using indirect competitive ELISA. The optical results displayed active enzymatic reactions occurred with the presence of all biomolecules in the assay. The CV and EIS results verified the immobilization of all elements on SPGE, where high current and low resistance were recorded for normal assay. The immunoassay displayed surprising sensitivity for low concentration of BaP. The optical density recorded for 20 ppm BaP was far higher than other concentrations, which proves the reliability of the immunoassay for detecting the target analytes in lower concentrations of real samples. A test conducted in real water samples verify the sensitivity of the assay, where the optical intensity of lower concentration was higher in most water samples.

## Acknowledgement

The authors would like to extend their gratitude towards the Ministry of Higher Education of Malaysia for financial support through the Research Acculturation Grant Scheme (RAGS) Vote No. 57093 and Universiti Malaysia Terengganu for providing research facilities that were used in this research.

**Abstract**

Expanded poly(tetrafluoroethylene) (ePTFE) is used for many applications including in medical applications, such as for facial implants or as artificial vascular valves. However, due to its natural hydrophobic properties, it has limited efficacy in some applications. To be used as a facial implant, ePTFE must be biocompatible to the surrounding living tissues. Therefore, the modification of the ePTFE surface through a radiation-induced grafting technique was introduced in this study. Acetic acid (AA) was used as a monomer grafted onto ePTFE due to its hydrophilic properties. Monomer concentrations and radiation doses were observed to play an important role in the grafting outcomes. A dose of 15 kGy of γ-ray and 20% of AA concentration was observed to be an optimum grafting parameter in this study with the maximum grafting yield of 14 ± 4%. The result also showed a decrease of surface hydrophobicity for grafted ePTFE with the water contact angle decreased 18˚ (from 117˚ to 99˚). No extra band was observed in attenuated total reflectance infrared (ATR-FTIR) spectroscopy for grafted ePTFE, which indicated that grafting might occur only on the very top layer of ePTFE. Analysis from field emission scanning electron microscopy coupled with energy dispersive X-ray (FESEM/EDX) revealed a successful grafting as the oxygen peak can be seen on the treated sample.

**Keywords:** radiation-induced grafting, grafting, expanded poly(tetrafluoroethylene), acetic acid

**Abstrak**

Poli(tetrafluoroetilena) regangan (ePTFE) digunakan dalam pelbagai aplikasi termasuklah dalam aplikasi perubatan, contohnya sebagai implan pada wajah atau sebagai vaskular injap tiruan. Walau bagaimanapun sifat semulajadi ePTFE yang hidrofobik menyebabkan keberkesanannya adalah terhad dalam beberapa aplikasi. ePTFE mestilah mempunyai tahap integrasi biologi yang optimum untuk digunakan sebagai implan wajah. Justeru, pengubahsuaian permukaan ePTFE meggunakan teknik pengkopolimeran menggunakan sinar gama diperkenalkan dalam kajian ini. Asetik asid digunakan sebagai monomer untuk tujuan percantuman dengan ePTFE disebabkan sifatnya yang hidrofilik. Dos sinaran dan kepekatan monomer yang digunakan menunjukkan peranan yang penting dalam peratusan hasil pencantuman. Parameter optimum telah dikenalpasti dalam kajian ini (iaitu dos sinaran 15 kGy dan kepekatan AA sebanyak 20%) dengan menghasilkan nilai cantuman tertinggi sebanyak 14±4%. Hasil juga menunjukkan sifat hidrofobik permukaan ePTFE berkurang sebanyak 18˚ dengan menganalisis sudut permukaan air (iaitu daripada 117˚ menjadi 99˚). Hasil keputusan analisis (ATR-FTIR) tidak menunjukkan sebarang perubahan spektrum berkemungkinan disebabkan pencantuman berlaku pada permukaan ePTFE sahaja. Manakala hasil keputusan daripada analisis (FESEM/EDX) menunjukkan ada pertambahan puncak oksigen di dalam analisis sampel yang telah disinar dan dicantum dengan AA, justeru menunjukkan percantuman berjaya berlaku.

## Introduction

Poly(tetrafluoroethylene) (PTFE) is widely used in many different industries, such as petrochemical and chemical, electrical, semiconductor, food and beverage, pharmaceutical, and medical industries. The variety of applications of these polymers is possible because PTFE possesses high thermal and chemical stability [1]. This is due to the helical structure of the polymer chain caused by the relatively larger size of fluorine atoms compared to carbon atoms. The PTFE is also naturally hydrophobic, non-reactive, non-polar, and has low surface tension.

Expanded poly(tetrafluoroethylene) (ePTFE) is relatively similar to PTFE, but the difference is in morphology and surface conditions. The ePTFE is proven to be more favourable than the non-expanded version because it has a more porous membrane, excellent dielectric properties, and a drastic reduction in creep, which is a weakness of standard PTFE [2]. In addition, ePTFE is used to make lightweight, waterproof, and breathable fabrics, micro-porous membranes, medical tubes and implants, microwave carriers, industrial sealants, and high-tensile fabrics and cords. Moreover, ePTFE has been reported to perform well as a vascular graft, where its porous property is sufficient to promote endothelial healing with cellular and capillary growth. These properties also make ePTFE one of the best resorbable materials to be used as a tissue implant in the face [3]. However, high hydrophobicity of ePTFE limits the use of this polymer, especially as biomaterial where it is required to make a good integration with the surrounding living tissues. Therefore, its surface properties need to be altered so that it will match the uses of its intended applications [4].

Surface modification of a polymer via grafting techniques can be used to change the properties of any polymer surface so that the desired characteristics can be achieved. Grafting can be described as the covalent attachment process. Currently, there are various grafting techniques available to modify a polymer surface, including chemical treatment [5], photografting [6], radiation [7, 8], and plasma techniques [9]. Radiation-induced graft copolymerisation is one of the grafting techniques that has been well established for almost half a century [10]. These techniques can alter the initial surface of polymeric materials by introducing new functional groups on the backbone of the carbon chain. Many studies have been conducted using the radiation-induced grafting technique in which various monomers have been successfully introduced onto ePTFE, such as acrylic acid [8], itaconic acid [7], and methoxyacrylate phosphate [11]. In the current study, acetic acid (AA) was chosen as the grafting monomer to introduce the carboxylic acid group onto the surface of the ePTFE. The effects of the concentration of the monomer and radiation dose on the grafting outcomes were investigated using various characterisation techniques, including attenuated total reflectance infrared (ATR-FTIR) spectroscopy, field emission scanning electron microscopy (FESEM) coupled with energy dispersive X-ray (EDX) and water contact angle measurements.

## Materials and Methods

### Materials

The ePTFE membranes (0.022 mm thick, dimension of 15 x 10 $mm^2$) were obtained from Pall Corporation under the trade name Zefluor$^{TM}$ (0.5 µm). The membranes were pre-treated with methanol overnight at 40 ˚C to remove contaminants before being dried in the oven to a constant weight. Methanol was obtained from MERCK; AA was purchased from Systerm, and ammonium iron (II) sulphate hexahydrate (Mohr's salt) was obtained from Honeywell Riedel-de Haen.

### Grafting procedure

For the AA grafting experiment, 4 mL of deionised water and 40 mg of Mohr's salt were added to different AA concentrations (2, 10, and 20 w/v %) to form the monomer solution. The ePTFE samples (weight 2 – 3 mg) were placed in the monomer solution. All test tubes were covered using parafilm, and the solution was degassed with nitrogen for 15 minutes to remove the dissolved oxygen from the solution. The test tubes were sealed with caps and parafilm. Samples were then irradiated at ambient temperature using γ-rays (gamma cell 220 excel) with doses of 2 kGy, 5 kGy, 10 kGy, and 15 kGy at a dose rate of 1.8 kGy/h. After the irradiation process, the samples were washed with hot methanol at 40 ˚C for 1 hour to remove any occluded homopolymer or unreacted monomer. Then, the grafted sample was further washed with deionised water three times for 1 hour each and finally left in the water

overnight. The grafted samples i.e., ePTFE-grafted polyacetic acid (ePTFE-g-PAA) were dried in the desiccator jar over 3 days until a constant weight was achieved. The sample grafted with AA was named AA(*m*)*d* where *m* refers to concentration of the monomer and *d* to the dose (e.g., samples grafted in 2% AA at dose of 15 kGy were named AA(2)15).

**Characterisation**

The graft yield was determined from the initial and final weight of samples obtained using the electronic balance (Scaltex SBA31). The graft yield was measured using the formula:

$$\text{Graft yield (\%)} = \left[\frac{(Wf - Wi)}{Wi}\right] \times 100\%, \quad (1)$$

where $W_i$ is the initial weight of the sample and $W_f$ is the weight of grafted sample. The average and standard deviation are reported on triplicate samples.

Water uptake was obtained by immersing the ePTFE and grafted ePTFE in water overnight. The samples were removed from the water, and filter paper was used to remove any surface water before the sample weight was determined. The equilibrium water uptake was calculated using the formula:

$$\text{Water uptake (\%)} = \left[\frac{(Ws - Wd)}{WPAA}\right] \times 100\%, \quad (2)$$

where $W_s$ is the weight of the swollen sample, $W_d$ is the weight of dry sample, and $W_{PAA}$ is the mass of PAA on the grafted membrane. The average and standard deviation are reported on triplicate samples.

The contact angle measurement was performed via a custom-built setup, as previously described [8], using an automated angle goniometer machine (Rama Hart). Samples were placed on a Teflon stage, and 5 µL drops of deionised water were delivered onto the sample surface via a 50 µL glass flat-tip syringe. The measurements were taken at least five times for each sample, and the average measurement was taken.

Attenuated total reflectance infrared (ATR-FTIR) spectroscopy (model Perkin Elmer Spectrum BX) with a resolution of 8 $cm^{-1}$ and wavenumber range 400 $cm^{-1}$ – 4000 $cm^{-1}$ were used in this analysis. A FESEM/EDX analysis (Merlin compact model) was performed on the sample. All samples were coated with platinum for 5 min until a 15 nm thick layer had formed to make the material conductive. The FESEM/EDX analysis was performed under the standard high vacuum mode with the voltage at 3 kV. The morphology of each sample was obtained with various magnifications: 1.00 K x, 3.00 K x, 5.00 K x, and 10.00 K x.

## Results and Discussion

**Effects of grafting parameters on ePTFE and grafted ePTFE**

The increased graft yield after radiation-induced grafting of AA onto ePTFE possibly indicated the success of the grafting process. Table 1 shows the increased graft yield of grafted samples with increased radiation doses and monomer concentrations. At similar concentrations of AA (i.e., 20 w/v %), samples irradiated at higher doses (sample AA(20)15 and AA(20)10) showed higher grafting outcomes at approximately 14% compared to samples that have been irradiated at lower doses (sample AA(20)2) with a graft yield at approximately only 5%. The increased graft yield with higher doses, possibly due to the number of radicals produced at higher doses of radiation, initiated the primary radical of the polymer and monomer unit [12]. Thus, the increased radicals that could take part in the grafting reaction caused the degree of grafting to be increased [13].

In addition, the graft yield was observed to be increased with the increased AA concentrations at 5, 10, and 15 kGy. The percentage of grafting increased approximately 2 – 5% when AA concentrations increased from 2 to 20 w/v% for 5, 10, and 15 kGy. The increased graft yield with monomer concentrations was possibly because the grafting proceeds by a diffusion controlled mechanism, which takes place at the surface of the sample and gradually proceeds further by progressive diffusion of the monomer through the medium of the swollen grafted layer. It is also

assumed that the grafting begins at the polymer surface, then gradually proceeds inward as the grafting zone is swollen by the monomer solution [10, 14].

However, the percentage of grafting in these experiments was lower compared to the study conducted by Hidzir et al. [8], which used acrylic acid as the monomer that showed the highest grafting yield of 36 ± 3% at 20% monomer concentration with a 15 kGy dose. The differences of the percentage of grafting obtained from the previous study compared to the current study were possibly due to the characteristic of the monomer. As AA consists of two carbons that could covalently attach to ePTFE, whereas an acrylic acid has three carbons (Figure 1), only a few carbons of AA can form a bond to the carbon chain of ePTFE, which resulted in lower grafting yield from this monomer. In addition, acrylic acid has an unsaturated bond (i.e., double bond) that could easily break upon irradiation; therefore, more grafting onto ePTFE could easily be obtained with the used of acrylic acid as a monomer.

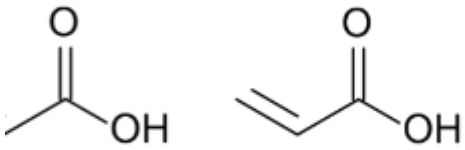

Figure 1. Chemical structure of acetic acid (left) and acrylic acid (right)

Table 1. Characterisation of ePTFE grafted membranes

| Sample | Dose (kGy) | Monomer Concentration (w/v%) | Graft Yield (%) | Water Uptake (%) | Contact Angle $\theta$(°) |
|---|---|---|---|---|---|
| ePTFE | 0 | 0 | 0 | 0 | 117 |
| AA(2)2 | 2 | 2 | 7±4 | 233±58 | na |
| AA(10)2 | 2 | 10 | 7±3 | 250±87 | na |
| AA(20)2 | 2 | 20 | 5±0 | 533±208 | na |
| AA(2)5 | 5 | 2 | 9±3 | 317±161 | na |
| AA(10)5 | 5 | 10 | 7±4 | 600±265 | na |
| AA(20)5 | 5 | 20 | 11±5 | 444±236 | na |
| AA(2)10 | 10 | 2 | 9±4 | 250±132 | 111 |
| AA(10)10 | 10 | 10 | 10±2 | 333±29 | 106 |

| AA(10)15 | 15 | 10 | 10±4 | 733±333 | 103 |
| AA(20)15 | 15 | 20 | 12±2 | 967±76 | 99 |

*na – data not available

**Water uptake and water contact angle analysis of ePTFE and grafted ePTFE**

The percentage of water uptake increased with the increased monomer concentrations and doses. At the highest grafting parameter (i.e., highest dose and monomer concentration used in this study), sample AA(20)15 showed the highest water uptake with 967 ± 76% compared to untreated ePTFE (0% water uptake) and samples that have been grafted at lower doses and monomer concentrations (e.g., sample AA(2)10 with water uptake of 250 ± 132%). This result was in line with the measurement obtained from water contact angle analysis where high hydrophobicity of

ePTFE (117˚) decreased significantly by ~18˚ to became less hydrophobic for grafted samples (sample AA(20)15 with water contact angle of 99˚). The increased water uptake and decreased water contact angle showed that the carboxylic functional group from the AA has successfully grafted onto ePTFE. At higher AA concentrations, more grafting of this carboxylic acid group occurred, thus resulting in a higher percentage of water uptake. The results in this study were similar to the previous studies reported by Wu et al. [4] and Hidzir et al. [8]. According to Wu et al. [4], the ePTFE surface angle can be reduced from 125˚ to 72˚ using the AA plasma deposition procedure. In addition, Hidzir et al. [8] reported that the surface water contact angle obtained is 92˚ for the grafted sample (ePTFE that has been irradiated at a dose of 10 kGy and 40% concentration of acrylic acid).

**Chemical characterisation of ePTFE and grafted ePTFE**

Figure 2(a) shows an FTIR spectra for untreated ePTFE, which displays the σ band at 1208 $cm^{-1}$ and 1154 $cm^{-1}$, which were assigned as the $CF_2$ stretching mode, and the band at 637 $cm^{-1}$ and 555 $cm^{-1}$, which were assigned to the $CF_2$ wagging mode and $CF_2$ deformation mode [8]. No additional band was observed on the sample that has been grafted with AA (e.g., sample AA(20)15) (Figure 2(b)) compared to the untreated sample. In the study by Hidzir et al. [8], the carbonyl band of the carboxylic acid group can be seen at 1716 $cm^{-1}$ , and the hydroxyl groups are present on the band 3000 – 3600 $cm^{-1}$. The undetected presence of the carbonyl group and hydroxyl groups on the spectrum of the current study (sample AA(20)15) is possibly because grafting may only have occurred on the top surface of the ePTFE. The penetration of the FTIR analysis was at the micrometre scale, whereas grafting may have occurred only on the very top surface of the ePTFE. In addition, the grafting obtained in this study was much lower compared to a previous study reported by Hidzir et al. [8].

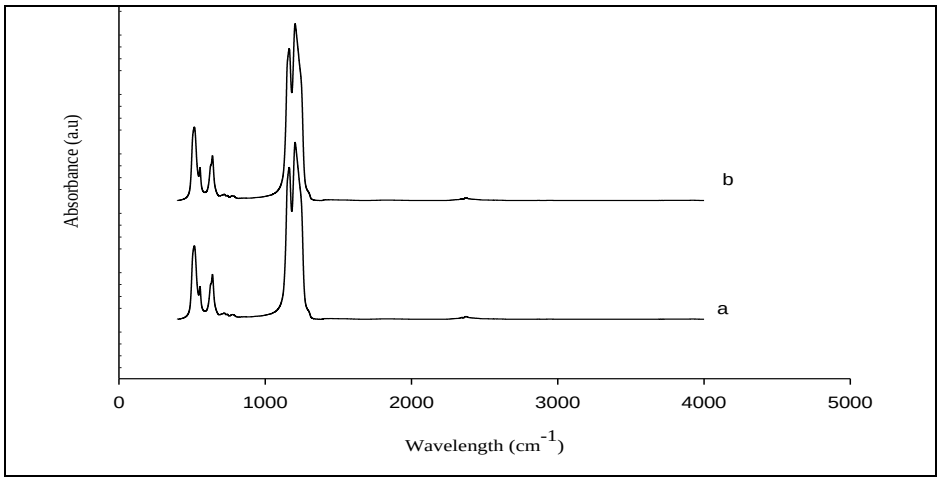

Figure 2. FTIR spectrum sample (a) untreated sample ePTFE and (b) AA(20)15

**Morphology and chemical composition analysis of ePTFE and grafted ePTFE**

Figure 3(a) shows the morphology of the ePTFE, which consists of islands and fibrils. The morphology of the grafted samples was observed to change, with less pores seen after grafting (Figure 3(b-f)). The change of this morphology was because the AA has been covered on the top surface of the ePTFE, resulting in less pores observed.

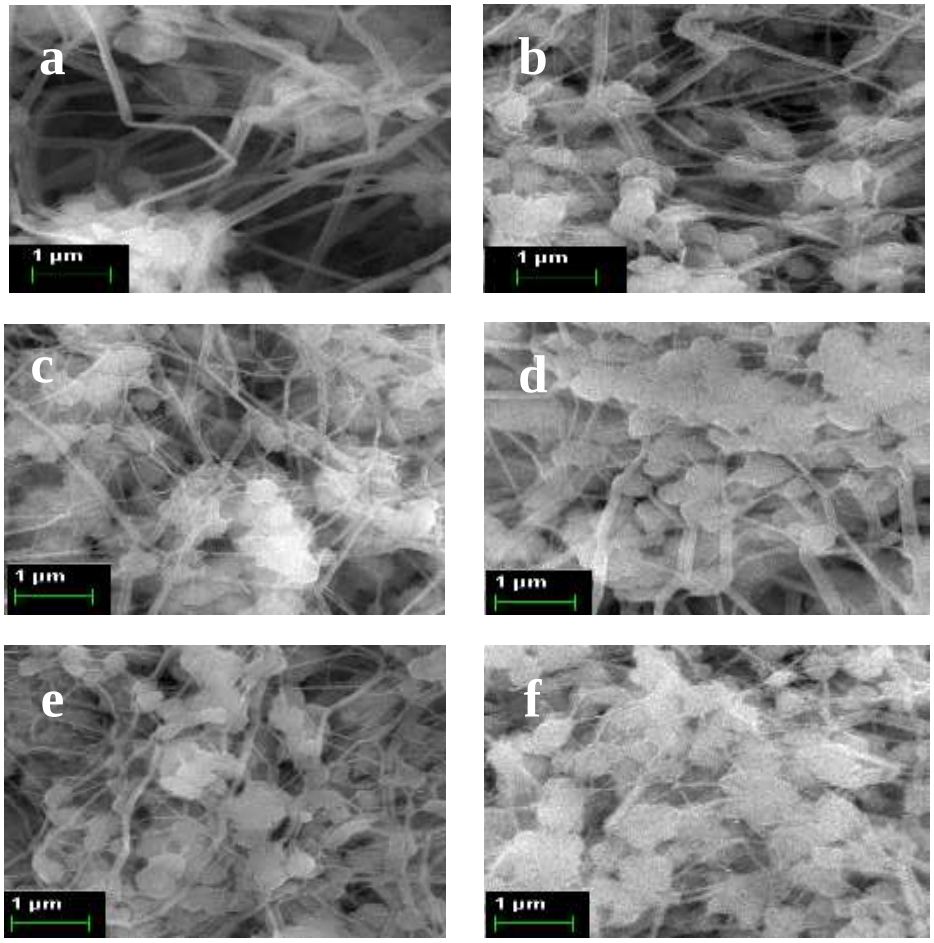

Figure 3. FESEM/EDX analysis of (a) untreated ePTFE, (b) AA(2)10, (c) AA(10)10, (d) AA(20)10, (e) AA(10)15 and (f) AA(20)15. Magnification for all images is 5000x

In addition, more island morphology was observed compared to fibril morphology in samples that have been grafted with higher doses and monomer concentrations (i.e., sample AA(20)15). Morphological changes are possibly due to the increased grafting percentage of AA. High doses and monomer concentrations allows more grafting of the AA onto the ePTFE surface. It was reported that the polymerisation could take place on the membrane surface and inside the pores, particularly when a high grafting degree was obtained [15, 16].

The EDX analysis shows the untreated ePTFE, which only consists of carbon and fluorine (Table 2). Oxygen was observed for the grafted sample (sample (AA(20)15) (Table 2)). In addition, the percentage of carbon weight for the grafted sample was observed to decrease from 22.66% (untreated ePTFE) to 18.92% (Table 2). Similarly, the ratio of carbon to fluorine (C:F) was observed to decrease for the grafted sample (sample AA(20)15) compared to the untreated ePTFE (Table 2). Through previous studies, the ratio of carbon to fluorine (C:F) was reported to decrease, but the ratio of carbon to oxygen (C:O) was increased due to the defluorination and oxidation occurring on the surface and shows the formation of hydrophilic ions on the surface [17].

Table 2. Comparison of elements on untreated ePTFE and sample AA(20)15 from the EDX analysis

| Sample | Element | Weight (%) | Atom (%) |
|---|---|---|---|
| ePTFE | C | 22.66 | 31.67 |
| | F | 77.34 | 68.33 |
| | Total | 100.00 | 100.00 |
| AA(20)15 | C | 18.92 | 26.92 |
| | O | 0.74 | 0.79 |
| | F | 80.34 | 72.29 |
| | Total | 100.00 | 100.00 |

## Conclusion

This study represents the first thorough investigation into gamma irradiation-induced grafting of AA onto ePTFE. It was found that grafting AA increased with higher doses and monomer concentrations. From FESEM/EDX analysis, it was found that grafting was successfully achieved. This grafting has resulted in the change of high hydrophobicity of ePTFE to less hydrophobicity with high water uptake for the grafted sample. This resulted in the desired characteristics of this ePTFE to be used in biomaterial applications, such as for bone tissue, bypass grafts, and artificial valves. However, further analysis, such as *in-vitro* mineralisation and protein adsorption studies, could provide more details on the biocompatibility of this polymer for such applications.

**Abstract**

In this study, *Pleuronectes yokohamae (P. yokohamae)* were exposed to the sediment mixed with mixture of nonylphenol (NP), octylphenol (OP), estrone (E1) and 17β-estradiol (E2) which makes up Endocrine Disrupting Chemicals (EDCs). The target compound was detected in water sample, and NP and OP concentrations were found to be the highest, 7.66 µg/L and 0.63 µg/L respectively (E1 and E2 concentrations were below the limit of detection). In pore water on the other hand, NP concentrations recorded the highest with 35.3 µg/L, while concentrations of OP, E1 and E2 were 4.08 µg/L, 0.06 µg/L and 0.18 µg/L respectively. *P. yokohamae* shown rapid and maximum accumulation of NP and OP on day 3, where NP recorded to be 2200 ng/g d.w. and OP 168 ng/g d.w. The recorded BAF values in low and high exposure groups were 0.010 and 0.065 for NP, and 0.065 and 0.084 for OP. The BAF findings recorded, being less than 1 indicated that there were no bioaccumulations in the tested fish of both groups. However, due to their nature of being more predisposed to accumulating EDCs than the water column, the bioaccumulation of contaminant in benthic fish should be continually monitored.

**Keywords**: bioaccumulation, sediment, endocrine disrupting chemical, *Pleuronectes yokohamae*, marbled flounder

**Abstrak**

Dalam kajian ini, campuran bahan kimia pengganggu endokrin (EDC) terdiri daripada nonilfenol (NP), oktilfenol (OP), estron (E1) dan 17β-estradiol (E2) telah dicampur ke dalam sedimen dan didedahkan kepada *Pleuronectes yokohamae (P. yokohamae)*. Sebatian sasaran telah dikesan dalam sampel air dengan kepekatan NP dan OP tertinggi iaitu masing-masing 7.66 µg/L dan 0.63 µg/L (kepekatan E1 dan E2 adalah di bawah had pengesanan), manakala kepekatan tertinggi di dalam air liang ialah 35.3 µg/L untuk NP, 4.08 µg/L untuk OP, 0.06 µg/L untuk E1 dan 0.18 µg/L untuk E2. Kepekatan NP dan OP di dalam *P. yokohamae* meningkat dengan mendadak pada hari 3 dan mencapai kepekatan maksimum 2200 ng/g d.w. dan 168 ng/g d.w. Nilai BAF dalam kumpulan kepekatan rendah dan tinggi ialah 0.010 dan 0.065 untuk NP, dan 0.065 dan 0.084 untuk OP. BAF telah dikira kurang daripada 1 menunjukkan tiada biopenumpukan EDC dalam ikan untuk kedua-dua kumpulan kepekatan. Walaupun begitu, biopenumpukan bahan cemar kepada ikan bentik harus sentiasa dipantau melalui sedimen berikutan kebolehannya menumpuk bahan EDC adalah lebih tinggi berbanding kolum air.

**Kata kunci**: biopenumpukan, sedimen, bahan kimia pengganggu endokrin, *Pleuronectes yokohamae*, marbled flounder

## Introduction

Endocrine Disrupting Chemicals (EDCs) are either estrogenic or natural – the estrogenic chemicals such as nonylphenol (NP), and octylphenol (OP) are mostly industrial byproduct of surfactants in detergents and paints, agricultural dispersing agents, and other industrial applications [1] while natural forms which include 17β-estradiol (E2) and estrone (E1) excreted by humans and livestock, are discharged from sewage treatment works and agricultural run-off into the aquatic ecosystems [2]. As a result, these compounds were frequently reported to disturb the reproductive system in fish such as reduced in testicular growth and formation of eggs in testis [3].

Endocrine disruption in fish occurs as a result of the binding of natural and manmade compounds in the aquatic environment to estrogen receptors, in place of endogenous hormone. The EDCs then alter the enzyme system controlling steroidogenesis, causing mimicking or blocking effects that disrupt normal endocrine pathways [4]. Researchers hypothesised that EDCs could be hydrophobic substances with affinity to bind to particles and accumulate on bottom sediments [5]. EDCs tend to get adsorbed into sediment due to high octanol-water partition coefficient (log Kow), resulting in vulnerability of aquatic organisms to accumulation [6].

*P. yokohamae* resides in sandy-mud bottoms less than 100 m depth [7] and recognised as commercially important species [8]. In Japan, winter is the breeding season of *P. yokohamae*. Both male and female fish reach maturity at the age of 1 year [9]. *P. yokohamae* prey mainly on benthic animals and were reported to accumulate organic compounds such as tributyltin (TBT) [10], 1,1-dichloro-2,2-bis(p-chlorophenyl) ethylene (DDE), hexachlorobenzene (HCB) and polychlorinated biphenyls (PCBs) [11] in the liver. Thus, *P. yokohamae* can serve as a good indicator of EDCs accumulation from sediment.

Bioaccumulation of EDCs has been demonstrated in both field and laboratory-based experiment [12, 13]. To date, nearly all experiments conducted on EDCs apply either the waterborne [14] or intraperitoneal exposure methods [15]. Very few studies adopted dietary and sedimentary exposure. Following this observation, this experiment aims to determine the bioaccumulation factor of EDCs through direct sedimentary uptake. Realising the significance of fisheries as an important commodity and main sources of diet for Japanese people, investigation on potential bioaccumulation of EDCs in fish is undeniably necessary.

## Materials and Methods

### Test organism (*P. yokohamae*)

*P. yokohamae* were purchased from Regional Government Aquaculture Center in Yamaguchi, Japan. They were acclimatized in the laboratory condition for six months to the desired body size and fed with commercial diet. *P. yokohamae* were kept in the water temperature below 25°C as it will die in warm water.

### Sampling of sediment

Approximately ten kilograms of sediment were collected randomly around the Amori River mouth in Kagoshima Bay (Figure 1) on 24 October 2012. Upon arrival at the laboratory, all sediment samples were dried under the sunlight and at room temperature for one week. Prior to spiking with EDCs, the sediment samples were combined and mixed well after sieving using sized 1- mm mesh sieve.

### Preparation of EDCs spiked sediment

Three kilograms of the sieved sediment were transferred into each glass aquarium (60 x 30 x 40 cm) of control, low and high test groups. The mixture of EDCs was then prepared according to Table 1.

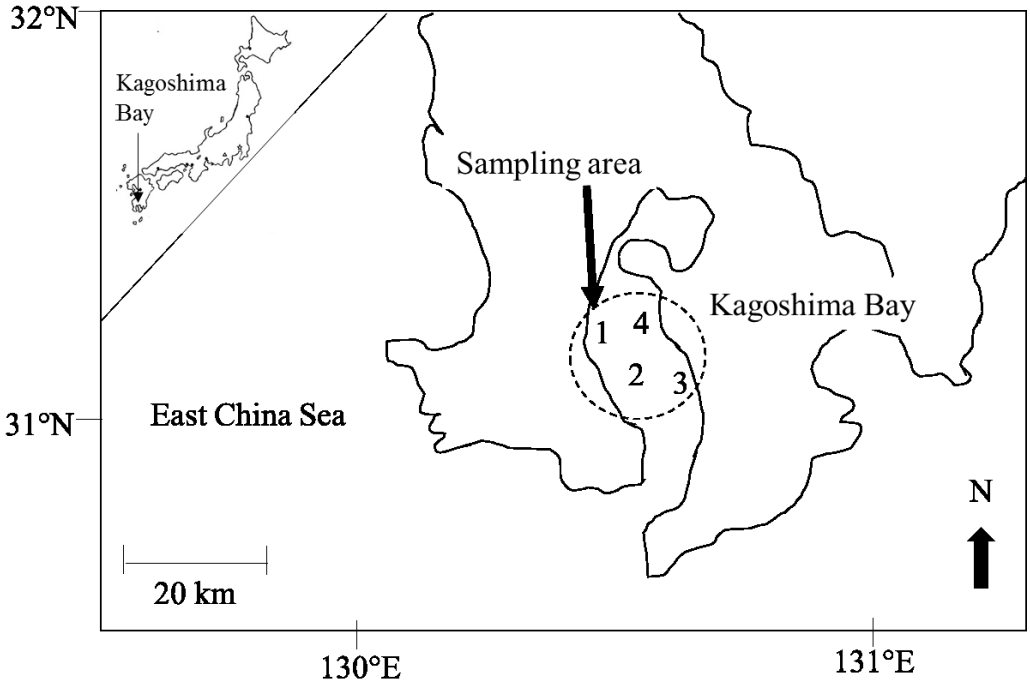

Figure 1. Sediment sampling stations (1, 2, 3 and 4) located in Kagoshima Bay

Table 1. Mean EDCs concentration, ng/g dry weight (d.w.) in control and spiked sediment, n = 2

| EDCs | ng/g dry weight (d.w.) | | |
|---|---|---|---|
| | Control | Low | High |
| NP | 5.09 | 2750 | 30,400 |
| OP | 0.63 | 169 | 1,210 |
| E1 | 2.36 | 1.90 | 10.8 |
| E2 | n.d | 0.83 | 6.70 |

n.d – Not detected

**Exposure scheme**

Before introducing *P. yokohamae*, the sediment in each aquarium (60 x 30 x 40 cm) was flooded and inundated with 60 L of seawater for a week. This condition was maintained in a water-flow-through system. After one week, fifteen of *P. yokohamae* were introduced into each aquarium including the control group. They were fed ad libitum with commercial fish diet twice daily for 14 days of the experimental duration. Sampling of *P. yokohamae* were done on days 0, 3, 7 and 14 while water sampling was done on days 4, 8, 10 and 13. At the end of exposure, sediment and pore-water samples were gathered. The body weight of individual *P. yokohamae* at the initial of exposure ranged from 7.30 g and 8.70 g. During sampling, *P. yokohamae* were anaesthetized using 0.05% 2-phenoxyethanol. The body length and weight were recorded prior to storage of the samples in freezer (-18 °C) until analysis stage. Water parameters such as temperature, dissolved oxygen, pH and salinity were measured periodically using the YSI multiprobe meter.

**Pre-treatment of samples**

After thawing, each benthic fish was weighed into a glass bottle to record the wet weight. The fishes were then freeze dried at -48 °C and 7.8 Pa for 7 days, and immediately after that, the dry weights of fishes were recorded. Sediment samples were treated the same way as benthic fishes. Wet and dry weights of sediments were recorded before and after freeze drying process. Water and pore water samples were analysed on the day of collection.

**EDCs analysis**

EDCs were analysed according to the published procedures in Nurulnadia [16]. After addition of external standard of *p*-n-NP-d4, target chemicals in the freeze-dried benthic fish (weights of homogenate sample ranged from 0.78 to 3.05 g) were ultrasonically extracted twice with 20 mL of methanol for 15 minutes. After centrifugation (4 °C, 760 x g, 10 minutes), the organic layer was collected and transferred into a separating funnel. Later, 3 mL Milli-Q water and 3 mL hexane were added. As lipid interfere with the measurement, they were removed from methanol using 20 mL hexane with 5 minutes shaking. This step was repeated three times. After shaking, hexane layer was discarded, while methanol (denser than hexane) was collected and combined. Methanol was put into the separating funnel again and mixed with 50 mL of 5% sodium chloride (NaCl) and 0.2 mL concentrated hydrochloric acid. The mixture of solvents was extracted twice using 20 mL dichloromethane and 10 min shaking and concentrated to 0.5 mL using a rotary evaporator and gentle stream of nitrogen ($N_2$). The concentrated extract was then replaced with 3 mL hexane and concentrated again to 0.5 mL using $N_2$. This step was repeated three times. Cleaning up process was performed in a 5 mL glass pipette (6 mm i.d. x 17 cm) filled with florisil (containing 3% water) and prewashed with 30 mL hexane. The target chemicals were then eluted with 50 mL hexane-isopropyl alcohol (9:1, v/v). The eluate was later concentrated to dryness using a rotary evaporator and gentle stream of $N_2$. Finally, internal standard (E2-16,16,17- d3) and acetonitrile were added to achieve the final volume of 0.2 mL before liquid chromatography-tandem mass spectrometry (LC-MS/MS) measurement.

Similar procedures were applied for sediment, water and diet samples.

**Measurement using LC-MS/MS-ESI**

LC–MS/MS analysis was carried out using Agilent 1200 LC system (Agilent Technologies, USA) coupled to an API-2000 triple stage quadruple mass spectrometer (Applied Biosystems, USA). The ESI was employed in negative mode. The optimized parameters were set as follows: curtain gas (40 psi), turbo gas (80 psi) and auxiliary gases (80 psi) using nitrogen, CAD gas, 5 psi; ion spray voltage, -4,500 V; and turbo temperature, 400°C. MS/MS measurements were performed in multiple reactions monitoring mode and target chemicals were four EDC compounds as shown in Table 2. The EDCs were analysed by gradient liquid chromatography using a reverse-phase Extend C-18 column (2.1 mm i.d. 9100 mm, 3.5 µm of particle size, Agilent) kept at 40 °C. The mobile phase consisted of solvents A (100% acetonitrile) and B (water containing 0.1% triethylamine, (v/v)).

Quality assurance test was performed using fish diet spiked with 100 ng/g of each EDC standards and internal standard (E2-16,16,17-d3). The EDCs standard extraction and measurement were done as above procedures. Mean percent recovery, as determined from an estimate of the amount of added and recovered, were between 70.0 % and 102.3 %. Analysis were conducted in triplicate (n = 3) with error of all analysis were within ±20 %.

Table 2. Precursor and daughter ions of EDCs and limit of detection by LC-MS/MS-ESI

| EDCs | Precursor Ions, m/z (amu) | Daughter Ions, m/z (amu) | Limit of Detection (ng/g) | |
|---|---|---|---|---|
| | | | Diet (ng/g)[a] | Water (µg/L)[b] |
| NP | 219.0 | 132.9 | 2.67 | 0.54 |
| OP | 205.0 | 132.9 | 0.31 | 0.05 |
| E1 | 269.1 | 145.0 | 1.01 | 0.05 |
| E2 | 271.1 | 144.9 | 1.50 | 0.10 |

[a]Detection limit using 0.3 g diet sample; [b]Detection limit using 0.5 L seawater

**Data analysis**

BAF (bioaccumulation factors) were calculated as the ratio of concentration in biota to sediment [17, 18] using the formula stated below:

$$BAF = \frac{\text{(EDCs concentration at steady state in } \textit{P. yokohamae}\text{)}}{\text{(EDCs concentration in sediment)}} \quad (1)$$

## Results and Discussion

**Water parameters and control sediment**

In the present study, range of water temperature and dissolved oxygen were 12.8 to 14.6 °C and 5.93 to 8.48 mg/L respectively, whereas pH and salinity were 8.01 to 8.08 and 36 to 38 psu respectively. Sediment sample collected from Amori River contains three of the target EDCs as shown in Table 1 (control). Amori River is one of the longest (42.5 km long) river, flowing into Kagoshima Bay, hence it receives large amount of effluent from residential and municipal activities daily. This most likely contributed to some concentrations of NP, OP and E1 in the control sediment. The total organic carbon and total organic nitrogen in sediment were 1.43±0.0.6% and 0.11±0.004% (n=5) respectively.

The concentration of EDCs was measured in the water sample during the exposure test, showing a range of 0.85 and 7.66 µg/L for NP, and 0.49 µg/L and 0.63 µg/L for OP, respectively whereas E1 and E2 concentrations were below the limit of detection. Low concentrations of EDCs were expected to be released into the water as *P. yokohamae* dwell onto the sediment. Low concentrations of EDCs were also recorded in pore water collected right after the exposure period ended (Table 3). In laboratory controlled uptake studies for NP, Bioconcentration factors (BCFs) yielded ranged from 200 to 300 [19, 20] whereas, OP were recorded to be from 250 to 350 [21, 22]. If *P. yokohamae* in this study has bio accumulated the target compound from water, the estimated concentration of NP and OP from maximum value would be approximately 2,300 and 221 ng/g w.w., respectively. However, the maximum wet weight concentrations of NP (532 ng/g w.w.) and OP (45.4 ng/g w.w.) in *P. yokohamae* in this study were recorded much lower than those estimated concentration. Thus, it was assumed that *P. yokohamae* in the present study accumulated EDCs from the spiked sediment.

Table 3. EDCs concentration (µg/L) in pore water, n = 2

| Exposure Group | NP | OP | E1 | E2 |
|---|---|---|---|---|
| Control | 16.9 | n.d | n.d | n.d |
| Low | 11.7 | 0.15 | n.d | n.d |
| High | 35.3 | 4.08 | 0.06 | 0.18 |

n.d – Not detected

**NP and OP concentrations in *P. yokohamae***

As reported in previous study [23], E1 and E2 could not be detected in *P. yokohamae* due to rapid metabolism of the substance in the fish. The accumulation of NP and OP in *P. yokohamae* from the sediment is shown in Figure 2. The concentration is calculated in dry weight (d.w.) basis to ease the determination of bioaccumulation factor (BAF). On day 0, NP and OP were detected in *P. yokohamae* with 114±91 and 34.4±15 ng/g d.w., respectively. Both compounds probably accumulated from commercial diet fed during the acclimatization period [24] as they were measured 27.9±1.77 ng/g d.w of NP and 3.02±0.34 ng/g d.w of OP in the control diet. *P. yokohamae* rapidly accumulated NP and OP on day 3 of exposure period and reached the maximum concentration. The highest concentration of NP in low and high exposure groups were 249 and 2200 ng/g d.w. respectively, whereas the recorded OP concentrations were 56.3 and 168 ng/g d.w. respectively. After day 3, observations shown that the

concentrations declined consistently until the end of experiment. Hence, day 3 was decided as the point at which steady state was reached for both NP and OP and these concentrations were used for the BAF computation.

**Bioaccumulation factors (BAF)**

BAFs were calculated using the concentration of NP and OP at day 3 of each group relative to measured concentration of the respective compound in the spiked sediment (Table 4). BAF values were similar between the low and high exposure groups indicating that the difference in concentration does not affect the bioaccumulation. However, NP and OP were not bio accumulated in *P. yokohamae* as the BAF values less than 1 [23].

Table 4. BAF in low and high exposure groups

| EDCs | Low | High |
|---|---|---|
| NP | 0.010 | 0.065 |
| OP | 0.065 | 0.084 |

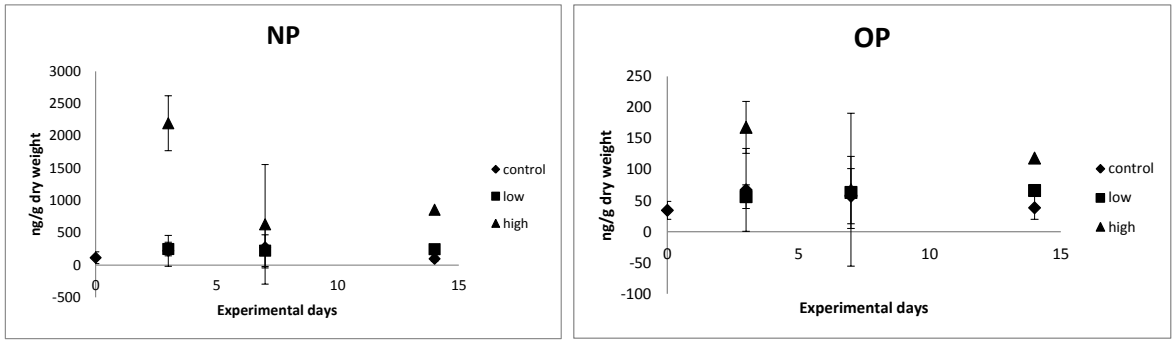

Figure 2. Accumulation of NP and OP (ng/g dry weight) in *P. yokohamae* in control, low and high exposure groups. Error bars indicate the standard deviation (n = 3)

BAF from previous studies are tabulated in Table 5. Based on the values, NP was discovered to be bio accumulated in bluegill, flounder and goby with BAF of 2.33, 6.24 and 27.0, respectively. These fishes were collected near sewage treatment water effluent; thus, it was probable that they may have accumulated NP from the water as well. NP was also found to be bioaccumulated in worm, mussel and bivalve. As sediment-dwelling organism, worms are in direct exposure to the pollutant in sediment – which may cause bioaccumulation [25]; higher concentration of NP in benthic worm compared to sediment was also observed in our previous field study [26]. Meanwhile, mussel and bivalve were sampled in urban and industrial areas [16, 27], hence received NP at frequent term which could lead to bioaccumulation. However, many other studies reported the same results as the present study that NP was not bioaccumulated in fish. In the case of OP on the other hand, no bioaccumulation was observed either in fish or invertebrate.

NP and OP did not bioaccumulate in *P. yokohamae* through the sediment as suggested by BAF values. However, certain aquatic organisms could probably accumulate EDCs (e.g. bluegill, flounder, and goby). This provides an impression that accumulation is probably influenced by species specific. This study was conducted to investigate the extremely high BAF values of EDCs measured in benthic worm compared to sediment samples of Osaka Bay [16]. If the worm accumulated EDCs from the sediment, the fish might accumulate the same compounds. Following this hypothesis, the EDCs have great potentials to be transferred into human as they consume the fish. Therefore, the EDCs measurement in fish from Osaka Bay should be conducted in order to prove the hypothesis.

## Conclusion

*P. yokohamae* in this study rapidly accumulated NP and OP from the sediment until day 3. After that the concentrations of both EDCs decreased to constant level until the end of experiment. E1 and E2 could not be detected in *P. yokohamae* due to rapid metabolism which were proven in our recent study [23]. BAF values for both compounds (NP and OP) indicated bioaccumulation did not occur in *P. yokohamae* after being exposed to EDCs spiked sediment. However, bioaccumulation of EDCs to benthic organism should be continually investigated as sediment can concentrate higher levels of pollutant than the water column.

## Acknowledgement

The present study was partly funded by the EXTEND 2010 Program, Ministry of Environment, Japan.

**Abstract**

Binding studies of metal complexes with DNA has attracted many interests due to their importance in cancer therapy and molecular biology. In this study, N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine and its metal Ni(II) and Cu(II) complexes have been synthesized and characterized. The complexes were structurally characterized using standard spectroscopic 1D $^{1}$H, 2D COSY, HMQC and $^{13}$C NMR spectroscopy, FTIR spectroscopy and ESI-MS spectrometry. The binding interaction between synthesized metal complexes and G-quadruplex DNA has been investigated using UV/Vis DNA titration study. Ni(II) and Cu(II) complexes bind strongly to G-quadruplex DNA (Kb = (5.42 ± 2.48) x $10^{6}$ $M^{-1}$ and (1.42 ± 2.48) x $10^{6}$ $M^{-1}$ respectively) via end stacking mode. Both complexes show selectivity for G-quadruplex DNA over CT- DNA by 2.15- and 1.82-fold, respectively.

**Keywords**: metal complexes, DNA binding, G-quadruplex DNA

**Abstrak**

Kajian mengenai pengikatan kompleks logam bersama DNA telah menarik perhatian penyelidik disebabkan kepentingannya dalam perubatan terapi kanser dan molekular biologi. Dalam kajian ini, N, N'-bis [4-[1-(2-hidroksietoksi)] saliksalidin]-fenildiamina bersama logam Ni(II) dan Cu(II) kompleks telah berjaya disintesis dan dicirikan. Struktur kompleks telah dicirikan menggunakan spektroskopi piawai 1D $^{1}$H, 2D COSY, HMQC dan spektroskopi $^{13}$C NMR, spektroskopi FTIR dan spektrometri ESI-MS. Pengikatan antara kompleks logam yang disintesis bersama DNA G-kuadruplek telah dikaji dengan menggunakan kajian titratan DNA UV/Vis. Ni(II) dan Cu(II) kompleks memberikatan nilai ikatan yang tinggi kepada DNA G-kuadruplek ((5.42 ± 2.48) x $10^{6}$ $M^{-1}$ dan (1.42 ± 2.48) x $10^{6}$ $M^{-1}$) melalui mod penyusunan akhir. Ni(II) dan Cu(II) kompleks menunjukkan pemilihan pengikatan terhadap G-kuadruplek DNA berbanding CT- DNA dengan 2.15 dan 1.82 kali ganda setiap satu.

**Kata kunci:** kompleks logam, pengikatan DNA, DNA G-kuadruplek

## Introduction

Over this past two decades, DNA have been regarded as primary molecular target for antitumor and antimicrobial drugs [1]. Recently, G-quadruplex DNA have been proposed to be alternative and attractive targets for the development of anticancer drugs. G-quadruplex DNA are found in biologically important regions such as proto-oncogene promoter region, immunoglobulin switch regions and telomeres [2]. Telomere is the end of chromosome

consist of single strand of guanine-rich DNA sequence [3]. The guanine-rich sequences of DNA can fold into quadruply stranded structures known as G-quadruplex DNA [4]. Stabilization of quadruplex DNA by small molecules can inhibit telomerase, an enzyme overexpressed in 85 – 90% of cancerous cell which play important role in cancer cell immortalization [5]. Consequently, there is growing interest in development of G-quadruplex DNA stabilizers. Researchers are focusing on stabilizer that can bind to G-quadruplex DNA with high affinity and selectivity over duplex DNA. Organic compounds have been reported to be a good G-quadruplex DNA stabilizers such as such as anthracene, naphthalene, bipyridine or pyrine [6]. Most of G-quadruplex stabilizers share similar properties such as planar geometry to enable them to π-π stack on the surface of guanine quartet and high solubility in water [7].

Metal complexes have recently emerged to be a new class of G-quadruplex stabilizers. Thus far, metal complexes have included copper, platinum, manganese, nickel, zinc and ruthenium in their design [8-10]. A clear advantage of metal complexes over organic molecules is their varied geometry. The presence of metal ions play a vital role in coordinating ligands into the optimal geometry for G-quadruplex interaction. Metal centre also often possesses a positive charge, which can interact with the electron-rich channel at the centre of the G-quadruplex.

Nickel(II) and copper(II) salphen complexes had been synthesized before and showed ability to selectively stabilize G-quadruplex DNA [4]. Both complexes are reported to have planar geometry with aromatic group that allowed π-π stacking interactions with G-quadruplex DNA [11]. In addition, the presence of substituents such as amines and amino acid group to the metal complexes gave high affinity when interact with G-quadruplex DNA [12]. This is because the substituents played an important role to increase the solubility of the complexes in aqueous media as well as enhancing their ability to bind to G-quadruplex DNA. The attachment of hydroxyl groups to metal complexes have been proposed before by Nurul Huda [13]. The presence of hydrogen bonding can increase the solubility of the complex in buffer and binding energy to G-quadruplex DNA. Thus, a successful strategy to improve the selectivity of complexes have included planar geometry to stack on the surface of guanine quartet and hydroxyl subtituents to improve the solubility of the complexes in water.

Research are still ongoing in finding G-quadruplex DNA with high affinity and selectivity towards G-quadruplex DNA. In this research, we report the synthesis of nickel(II) and copper(II) salphen complex with hydroxyl substituent in order to get good solubility and high binding energy with G-quadruplex DNA. To date, the synthesis and G-quadruplex DNA binding studies of the complexes have not been reported yet. The finding of the research could be useful in designing anticancer drug based on G-quadruplex DNA interaction.

## Materials and Methods

### Chemicals

The chemicals used in this work such as 1,2-phenyldiamine, 2,4-dihydroxybenzaldehyde, nickel(II) acetate tetrahydrate, copper(II) acetate hydrate, 2-chloroethanol and potassium carbonate were purchased from Sigma-Aldrich. Human Telomeric DNA (H-Telo) and Calf thymus DNA (CT-DNA) was purchased from Sigma (USA).

### Physical measurement

The nuclear magnetic resonance (NMR) spectra were recorded in DMSO-d6 by using JEOL JNM-ECP 400 MHz spectrometer. IR spectra were recorded using FTIR Perkin-Elmer GX Model in the spectral range of 4000 – 400 $cm^{-1}$. The mass spectrometry were carried out using Electrospray ionization Mass Spectrometry Bruker Daltonics. DNA binding experiments were carried out in Tris-Potassium chloride (Tris-KCl) buffer at pH 7.4 using PHM 210 measurement, while the UV/Vis absorption spectra were measured on a Shimadzu UV-1650 spectrophotometer using a 1 mL cuvette.

### Synthesis of N,N'-bis-4-(hydroxysalicylidene)-phenylenediamine-nickel(II) complex, [1]

Complex **[1]** was prepared following previous work of the group [4, 14]. All spectroscopic data for the complex are in accordance to literature [14]. 1,2-Phenyldiamine (0.135 g, 1.25 mmol) and 2,4-dihydroxybenzaldehyde (0.345 g, 2.50 mmol) were dissolved in methanol (40 ml) and the reaction mixture was stirred at reflux for 30 min. $Ni(OAc)_2.4H_2O$ (0.622 g, 2.50 mmol) was then added to mixture. A brick-red solid precipitated form immediately.

The reaction was then heated at reflux for a further 4 hour. The solvents was filtered to get brick-red precipitate solid. The solid was washed with ethanol (100 mL), diethyl ether (50 mL) and water (50 mL).

**Synthesis N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-nickel(II) complex, [2]**
Complex **[2]** was prepared following previous work of the group [14]. All spectroscopic data for the complex are in accordance to the literature. A complex nickel(II) salphen (0.251 g, 0.62 mmol), 2-chloroethanol (0.252 g, 3.09 mmol) and $K_2CO_3$ (0.691 g, 4.98 mmol) in DMF solutions (30 mL) was heated at 90 $^oC$ overnight. After that 2-chloroethanol with the same mole was added and the reaction was heated for another 24 hours. After this time the excess salts were removed by filtration and the DMF evaporated under reduced pressure. The resulting dark red solid was recrystallised with DMF: diethylether (1:3) to give as brown red solid.

**Synthesis of N,N'-bis-4-(hydroxysalicylidene)-phenylenediamine-copper(II) complex, [3]**
Synthesis complex copper(II) salphens followed the published method [4]. 1,2-Phenyldiamine (0.135 g, 1.25 mmol) and 2,4-dihydroxybenzaldehyde (0.345 g, 2.50 mmol) were dissolved in methanol (40 mL) and the reaction mixture was stirred at reflux for 30 minutes. $(CH_3COO)_2Cu.H_2O$ (0.499 g, 2.50 mmol) was then added to mixture. A dark green solid precipitated form immediately. The reaction was then heated at reflux for a further 4 hours. The solvents was filtered to get dark green precipitate solid. The solid was washed with ethanol (100 mL), diethyl ether (50 mL) and water (50 mL).

**Synthesis N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-copper(II) complex, [4]**
A complex copper(II) salphen (0.253 g, 0.62 mmol), 2-chloroethanol (0.252 g, 3.09 mmol) and $K_2CO_3$ (0.688 g, 4.98 mmol) in DMF solutions (30 mL) was heated at 90 $^oC$ overnight. After that 2-chloroethanol with the same mole was added and the reaction was heated for another 24 hours. After this time the excess salts were removed by filtration and the DMF evaporated under reduced pressure. The resulting dark green solid was recrystallized with DMF: diethylether (1:3) to give as a dark green solid.

**DNA binding experiments**
The stock solution of DNA was prepared by dissolving DNA in 10 mM of Tris–HCl/ 100 mM KCl buffers at pH 7.4. H-telo DNA was dissolved in 10 mM Tris-HCl/100 mM KCl (pH 7.4) buffer solution. The oligonucleotide were annealed by heating it to 90 ºC for 5 minutes and then cooled to room temperature overnight. CT-DNA dissolved overnight in a 10 mM Tris-HCl /100 mM KCl (pH7.4) buffer solution. Then, the complexes was diluted to 5 mM using DMSO. The absorbtion titration experiments were performed by diluting the complex with buffer to the 30 μM concentrations while increasing DNA concentrations. The intrinsic binding constant (Kb) values were calculated by the following equation 1 [15]:

$$\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)} = \frac{[DNA]}{(\varepsilon_b-\varepsilon_f)} + \frac{1}{Kb(\varepsilon_b-\varepsilon_f)} \quad (1)$$

where [DNA] is the concentration of DNA in base pairs, εa, εf, and εb correspond to the $A_{observed}$/[complex], the extinction coefficient of free complex and the complex in fully bound form, respectively, and Kb is intrinsic binding constant. A plot of [DNA]/ (εa – εf) versus [DNA] will have a slope of 1/(εb – εf) and intercept equal to 1/Kb(εb – εf). Kb is the given ratio of the slope to the intercept.

Percentage hypochromacity was determined using the following equation 2:

$$\text{Hypochromacity (\%)} = \frac{(\varepsilon_b-\varepsilon_f)}{\varepsilon_b} \text{ x } 100 \quad (2)$$

From the equation, Kb of complexes with G-Quadruplex DNA and CT- DNA can be calculated

## Results and Discussion

**Characterization study: N,N'-bis-4-(hydroxysalicylidene)-phenylenediamine-nickel(II) complex**
Yield 0.386 g (77 %). $^1$H NMR (400 MHz, DMSO-$d_6$): δ 6.21 (s, 1H, $H^6$), 6.22 (d, $^3J_{HH}$ = 8.8 Hz , 1H, $H^5$), 7.19 (dd, $^3J_{HH}$ = 6.0 Hz, $^4J_{HH}$ = 3.0 Hz, 1H, $H^1$), 7.41 (d, $^3J_{HH}$ = 8.8 Hz, 1H, $H^4$), 7.99 (dd, $^3J_{HH}$ = 6.0 Hz, $^4J_{HH}$ = 3.0 Hz, 1H,

$H^2$), 8.54 (s, 1H, $H^3$) $^{13}C$ NMR (100 MHz, DMSO-$d_6$) 103.8, 108.4, 114.8, 116.0, 127.1, 136.2, 143.3, 154.9, 165.4, 167.7. IR ($cm^{-1}$): 3527 (OH alcohol/phenol), 3082 (C-H $sp^2$), 1578 (C=N), 1450 (C=C aromatic), 1121 (C-O), 1209 (C-N). ESI(+)-MS m/z calcd for $C_{20}H_{14}N_2NiO_4$ ($M^+$): 404 a.m.u. The a.m.u. Found: $[M+Na]^+$= 427 a.m.u.

**N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-nickel(II) complex, [2]**
Yield: 0.161 g, 64%. $^1H$ NMR (400 MHz, DMSO-d6): δ 3.72 (t, $^3J_{HH}$ = 4.00Hz , 1H, $H^8$), 4.00 (t, $^3J_{HH}$ = 4.00Hz , 1H, $H^7$), 4.96 (s, 1H, $H^9$), 6.32-6.39 (m, 2H, $H^4H^6$), 7.24-7.26 (dd, $^3J_{HH}$ = 8.0 Hz, $^4J_{HH}$ = 4.0 Hz, 1H, $H^1$), 7.46-7.48 (d, $^3J_{HH}$ = 8.6 Hz, 1H, $H^5$), 8.02-8.05 (d, $^3J_{HH}$ = 8.0 Hz, 1H, $H^2$), 8.64 (s, 1H, $H^3$) $^{13}C$ NMR (100 MHz, DMSO-$d_6$) δ 59.79, 70.05, 102.01, 108.02, 115.19, 116.02, 127.23, 135.74, 142.71, 154.86, 165.25, 167. IR ($cm^{-1}$): 3352 (OH alcohol / phenol), 3039 (C-H $sp^2$), 2878 (C-H $sp^3$) 1577 (C=N), 1515 (C=C aromatic), 1127 (C-O), 1196 (C-N). ESI(+)-MS m/z calcd for $C_{24}H_{22}N_2NiO_6$ (M+): 492 a.m.u. The a.m.u. Found: $[M+K]^+$=531, $[M+Na]^+$=515 a.m.u.

**N,N'-bis-4-(hydroxysalicylidene)-phenylenediamine-copper(II) complex, [3]**
Yield 0.386 g (80 %). IR (cm-1): 3350 (OH alcohol / phenol), 3150 (C-H sp2), 1581 (C=N), 1448 (C=C aromatic), 1122 (C-O). ESI(+)-MS m/z calcd for $C_{20}H_{14}CuN_2O_4$ ($M^+$): 409 a.m.u. The a.m.u. Found: $[M+Na]^+$=432 a.m.u.

**N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-copper(II) complex, [4]**
Yield: 0.161 g, 74%. IR (cm-1): 3350 (OH alcohol / phenol), 3100 (C-H $sp^2$), 2929 (C-H $sp^3$) 1575 (C=N), 1482 (C=C aromatic), 1187 (C-O). ESI(+)-MS m/z calcd for $C_{24}H_{22}CuN_2O_6$ ($M^+$): 497 a.m.u. The a.m.u. Found: $[M+K]^+$=536 a.m.u.

The N,N'-bis-4-(hydroxysalicylidene)-phenylenediamine-nickel(II) complex had been successfully synthesized characterized. The attachment of hydroxyl was then carried out by adding 2-chloroethanol in presence of potassium carbonate. The reaction scheme of hydroxyl substituted Nickel(II)- and Copper(II)- salphen complexes **[2]** and **[4]** are illustrated in Figure 1. The synthesis and characterization of complex **[1]**, **[2]** and **[3]** have been reported in our previous work [14]. Synthesis of complex **[4]** yielded 74% product as dark green solid. Complex **[4]** was characterized by means of FTIR and mass spectrometry. Based on IR spectra of the complex **[4]**, absorption bands corresponding to Cu(II) salphen due to stretching vibrations of some functional group such as imine, C-O hydroxyl and C=C for aromatic group are presence. The expected band for imine C=N appears at 1575 $cm^{-1}$ suggested the formation of the salphen complex. The IR spectrum also displayed bands at 3352 $cm^{-1}$, 1482 $cm^{-1}$ and 1187 $cm^{-1}$ for hydroxyl, C=C aromatic and C-O respectively. The attachment of hydroxyl side chain to complex **[2]** to yield complex **[4]** was successful evidence by the presence of absorption band at 2929 $cm^{-1}$ which can be assigned to C-H $sp^3$. The electrospray ionization mass spectrometry (ESI-MS) was carried out to determine the mass-to-charge ratio of complex **[4]**. Spectrum showed that one peak corresponding to complex with adducts ion, which is $[M+K]^+$=536 a.m.u. Since the copper(II) complex is paramagnetic, NMR spectroscopy could not be used to analyze the complex.

**UV-Vis DNA titration**
UV-Vis spectroscopic titration were carried out to gain inside into the binding mode and binding affinity of the complexes with G-Quadruplex and CT- DNA. When a compound exhibit a high binding affinity, it is said to be a powerful binder to DNA and a promising candidate as an anticancer drug. The UV-vis spectra for titration study complex **[2]** with G-Quadruplex DNA is given in Figure 2. As shown, complex **[2**] at 30 μM showed maximum absorption peak at 388 nm. The intensity of complex decreases with addition of G-Quadruplex DNA and red shift can be seen with further addition of DNA. Obviously hypchromicity of 53% was observed along with 10 nm bathochromic shift. The hypochromism effect and bathochromic shifting suggest end stacking for the binding mode of the complex toward G-quadruplex DNA [16].

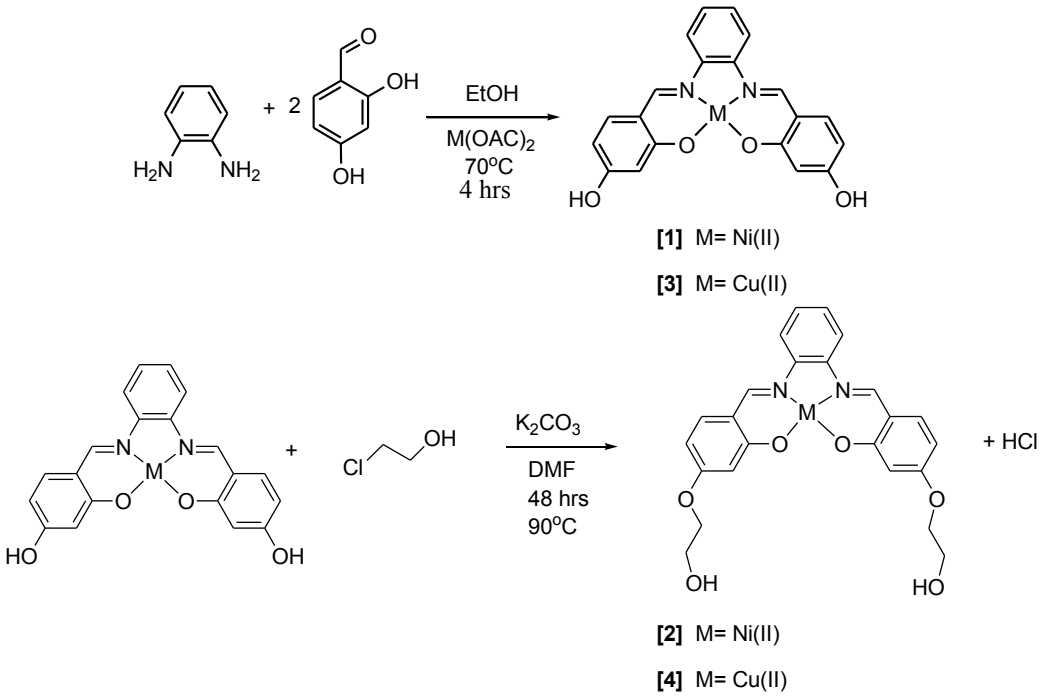

Figure 1. Reaction scheme for N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-nickel(II) and copper(II) complex

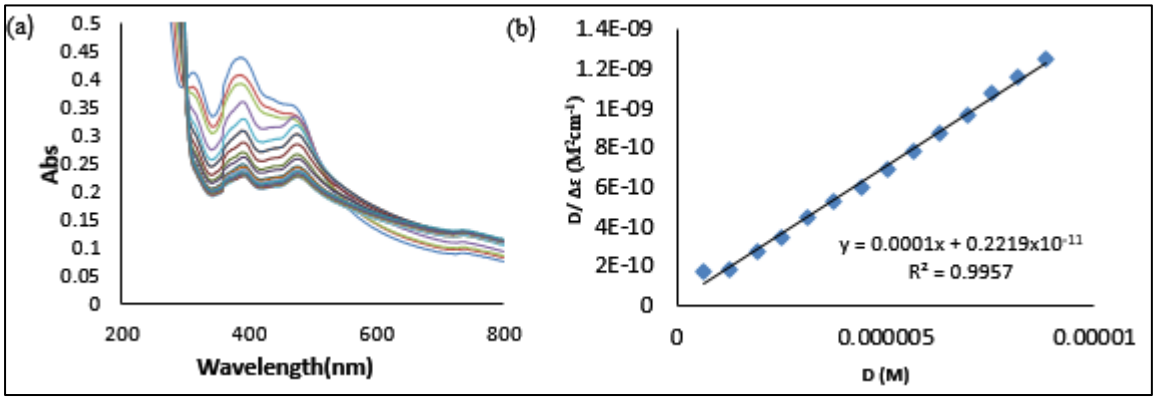

Figure 2. (a) Absorption spectral changes of complex **[2]** (30 μM) in Tris/KCl buffer (pH 7.4) in the absence and presence of increasing concentration of H-Telo (6.30 x $10^{-3}$ mM – 1.3 x $10^{-3}$ mM), (b) The reciprocal plot that fits the absorbance data to obtain the binding constant.

The next binding study is complex **[4]** with G-Quadruplex DNA (Figure 3). Referring to the spectra, complex **[4]** alone at 30 μM showed maximum absorption peak at 385 nm. The intensity of complex decrease with addition of G-Quadruplex DNA and small red shift appeared with further addition of DNA. A hypochromic effect 16% was observed along with 6.5 nm bathochromic shift. The hypochromism effect and bathochromic shifting suggesting the complex possesed end stacking mode binding which is same mode with complex **[2]** when binding to G-quadruplex DNA.

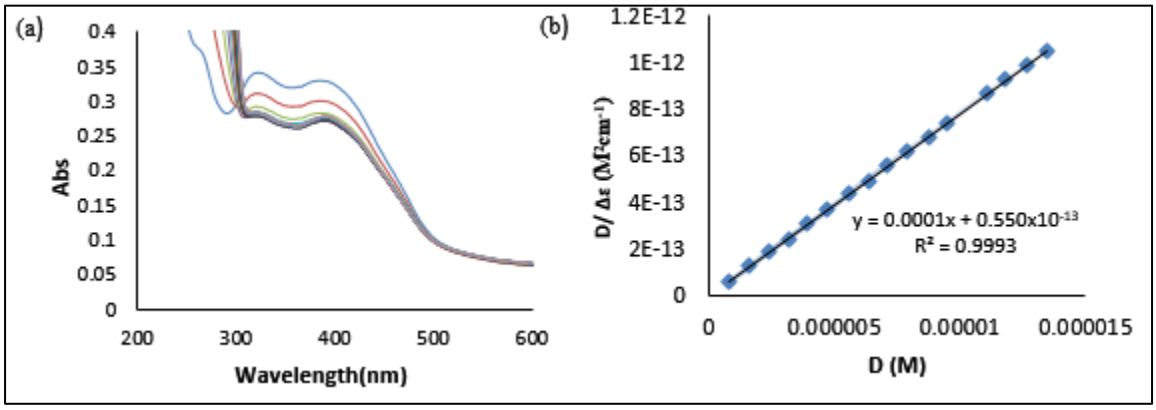

Figure 3. (a) Absorption spectral changes complex **[4]** (30 μM) in Tris/KCl buffer (pH 7.4) in the absence and presence of increasing concentration of H-Telo (7.9 x $10^{-3}$ mM – 13.4 x $10^{-3}$ mM), (b) The reciprocal plot that fits the absorbance data to obtain the binding constant

By using the Scatchard equation (the plot of D/Δεap versus D) the binding constant (Kb) values of the compounds to G-quadruplex DNA were calculated. Complex **[2]** was found to bind to G-quadruplex DNA with higher affinity (Kb= 5.42 ± 2.48 x $10^6$ $M^{-1}$) compared to the complex **[4]** (Kb = 1.42 ± 2.48 x $10^6$ $M^{-1}$). Both new salphen complexes with hydroxyl substituted showed significant improvement on G-quadruplex DNA stabilization ability compared to piperidine substituted metal complexes that have been reported before [5].

For comparison, we also study the binding affinity of both complexes with duplex calf thymus DNA (CT-DNA). The concentration of CT-DNA was determined from UV absorbance at 260 nm (ε = 6600 $cm^{-1}$). The absence of any protein contamination with CT DNA was confirmed from absorption ratio at 260 and 280 nm which was found to be 1.86 [17]. In Figure 4, we can see that upon addition of CT- DNA to complex **[2]**, hypochromicity (29%) of peak absorption can be observed with small red shift (3 nm). From the observations, it is concluded that complex **[2]** have been intercalated to the base pairs of CT-DNA [18].

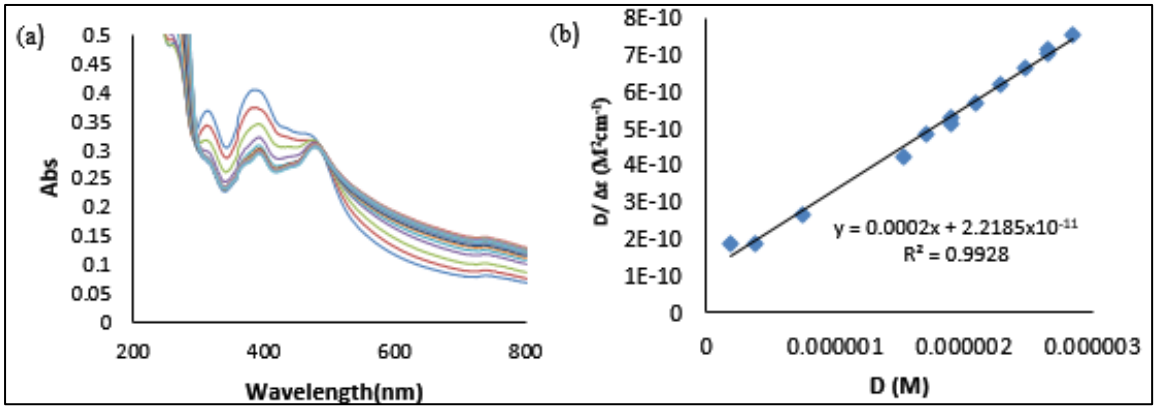

Figure 4. (a) Absorption spectral changes of complex **[2]** (30 μM) in Tris/KCl buffer (pH 7.4) in the absence and presence of increasing concentration of CT-DNA (0.19 x $10^{-3}$ mM – 3.61 x $10^{-3}$ mM), (b) The reciprocal plot that fits the absorbance data to obtain the binding constant

The binding study of complex **[4]** with CT-DNA was shown in Figure 5. Upon addition of CT-DNA to solutions of complex **[4]** the hypochromic (13%) followed by small bathochromic effect (3.5 nm) can be seen. These spectral characteristics suggested moderately intercalative mode binding.

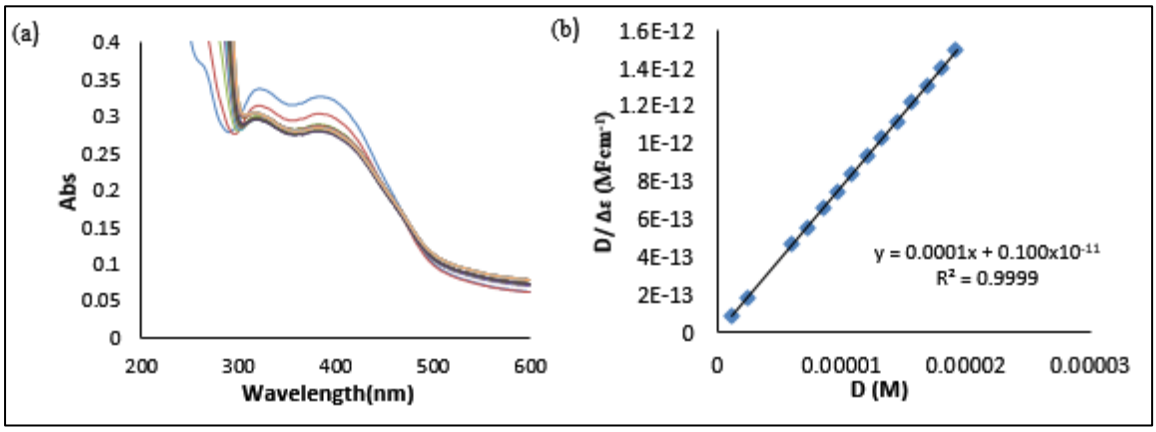

Figure 5. (a) Absorption spectral changes of complex **[4]** (30 µM) in Tris/KCl buffer (pH 7.4) in the absence and presence of increasing concentration of CT-DNA (1.2 x $10^{-3}$ mM – 20.4 x $10^{-3}$ mM), (b) The reciprocal plot that fits the absorbance data to obtain the binding constant.

From the equation, calculated intrinsic binding constant, Kb of complex **[2]** and **[4]** with CT- DNA are 2.51 x $10^6$ ± 0.65 $M^{-1}$ and 7.80 x $10^5$ ± 0.65 $M^{-1}$. Both complexes show selectivity for G-quadruplex DNA over CT- DNA by 2.15- and 1.82-fold, respectively. The presence of hydroxyl substituent on the metal salphen complexes seems to have little effect in the selectivity towards G- quadruplex DNA over CT- DNA.

## Conclusion

N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-nickel(II) complex and N,N'-bis[4-[1-(2-hydroxyethoxy)]salicylidene]-phenyldiamine-copper(II) complex have been successful synthesized and characterized. The DNA binding of complex with G-quadruplex DNA and CT-DNA examine by absorption spectral technique. From the results, the binding constant interaction between complex **[2]** and **[4]** with G quadruplex DNA are (5.42 ± 2.48) x $10^6$ $M^{-1}$ and (1.42 ± 2.48) x $10^6$ $M^{-1}$. Meanwhile, the binding constant of complex **[2]** and **[4]** with CT-DNA are (2.51 ± 0.65) x $10^6$ $M^{-1}$ and (7.80 ± 0.65) x $10^5$ $M^{-1}$ respectively. The UV-Vis titration study suggested that complex **[2]** binds selectively to G-quadruplex DNA over CT-DNA by two folds. Complex **[2]** showed the potential to be a good candidate for anti-cancer drug development via inhibition of telomerase activity.

# MARKOV CHAIN MONTE CARLO METHOD FOR HANDLING MISSING DATA IN AIR QUALITY DATASETS

## (Kaedah Rantai Markov Monte Carlo Untuk Mengurus Data Hilang Di Dalam Data Kualiti Udara)

**Abstract**

Missing data are a common problem in raw data especially in air quality datasets. Incomplete data due to machine or instruments failures, changes in the sitting air station monitors, calibration, routine maintenance and human error handling dataset. Multiple imputation of missing value technique was used to deal with selective air quality data by using Markov Chain Monte Carlo (MCMC). Expectation-maximization (EM) algorithm was used to compute the maximum likelihood estimate (MLE), assuming a multivariate normal distribution for the data. In this paper, the air quality monitoring stations selected namely Kemaman, Terengganu and Petaling Jaya, Selangor. The parameters selected were carbon oxide, ground level ozone, sulphur dioxide, nitrogen oxide, nitric oxide and nitrogen dioxide. A total of annual hourly data is 52,704 (8784 x 6 parameters) observations. Result shows that the coefficient of determination for all annual hourly monitoring data is consistently high ($R^2$ = 0.49 – 0.91) and small error (0.0001 – 0.3). Therefore, the multiple imputation technique by using MCMC method provides a good fit imputation and unbiased result of missing value to this data.

**Keywords**: missing data, air quality, multiple imputation, Markov Chain Monte Carlo

**Abstrak**

Data hilang ialah masalah biasa dalam data mentah terutamanya data kualiti udara. Data yang tidak lengkap disebabkan oleh kegagalan alat atau mesin, perubahan tempat stesen udara, kalibrasi, rutin penyelenggaraan dan kesilapan pekerja mengurus data. Teknik pelbagai imputasi digunakan untuk mengisi nilai hilang bagi data kualiti udara yang terpilih dengan menggunakan Markov Chain Monte Carlo. Jangkaan maksimum (EM) algoritma digunakan untuk menjangka kemungkinan maksimum dengan andaian taburan normal dari pelbagai pembolehubah. Dalam kajian ini, stesen kualiti udara yang dipilih ialah Kemaman, Terengganu dan Petaling Jaya, Selangor. Pembolehubah yang dipilih ialah karbon dioksida, ozon paras tanah, sulfur dioksida, nitrogen oksida, nitrik oksida dan nitrogen dioksida. Jumlah data jam tahunan ialah 52,704 (8784 x 6 pembolehubah) pemerhatian. Keputusan menunjukkan penentuan pekali untuk semua data jam tahunan ialah tinggi dan kesilapan kecil. Oleh sebab itu, teknik pelbagai imputasi dengan menggunakan kaedah MCMC menyediakan imputasi yang sangat bagus dan keputusan yang tiada keraguan bagi nilai hilang.

**Kata kunci:** data hilang, kualiti udara, pelbagai imputasi, rantai Markov Monte Carlo

## Introduction

The air pollution in Malaysia has yet reached a critical level at the some areas [1]. However, even outside haze periods, pollution levels occurred despite tight regulations and this is exacerbated by the increase in the number of vehicle, distance travelled and growth in industrial production [1]. The haze phenomenon in Malaysia which contribute to the air pollutant reading including ozone concentration exceeds Malaysian standard [2] have already been observed in some urban [3] and industrial regions of Malaysia [4]. The air quality data was collected from the Air Quality Division of the Department of Environment, Ministry of Natural Resources and Environment of Malaysia. The National Continuous Air Quality Monitoring Network, manual air quality monitoring stations using high volume samplers were also established at the all air monitoring stations [1]. The main pollutants recorded at the Malaysian air quality monitoring stations are ground level ozone ($O_3$), carbon monoxide (CO), nitrogen dioxide ($NO_2$), sulphur dioxide ($SO_2$) and particulate matter of less than 10 microns in size ($PM_{10}$) [1].

Continuously sampling system is necessary to obtain a more reliable and accurate information about the air quality in atmosphere. However, real data are not usually complete that contain missing data. Missing data arise in almost real life datasets especially in air quality dataset. Incomplete data might be because of machine failures or break-down of measurement instruments, changes in the sitting air station monitors, calibration, routine maintenance and reading invalidation or human error handling dataset. Missing data are problematic in statistical analysis; the data will loss of information and efficiency [5], several problems related to data analysis, and bias due to systematic differences between observed and unobserved data [6]. According to Little and Rubin [5], rate of missing data less than 1% are considered trivial, 1 – 5% are manageable, 5 – 15% need powerful method to handle and more than 15% may harm the model's result.

There are various techniques of handling missing data such as interpolation techniques (linear, quadratic, cubic and nearest neighbor interpolation) [7], mean imputation techniques (mean-before after, mean before) [8], hot-deck imputation [9], regression imputation [10], k-nearest neighbor imputation [11]. Multiple Imputation (MI) provides a useful technique for dealing missing value in environmental research [12]. MI technique replaces each missing value with a plausible value that represents the uncertainty the right value to impute [13]. MI gives much better results to handle missing data [14]. The example for multiple imputation is Markov Chain Monte Carlo method [15]. Markov Chain Monte Carlo (MCMC) method was used for the MI procedure because of assuming multivariate normality [16]. Markov chain is a sequence of random variables in the distribution of each variable depends on the value of the previous variable. The expectation-maximization (EM) algorithm is a technique that estimates maximum likelihood for MCMC method [17]. Therefore, the aim of this study focuses on MI technique to replace missing value for air quality data.

## Materials and Methods

This section explains the source of data and process of constructing the multiple imputation technique. We have designed a SAS version 9.0 codes for MI technique.

### Study area

This study involving real secondary data that obtained from the Department of Environmental, Malaysia managed by a private company, Alam Sekitar Malaysia Sdn. Bhd (ASMA). There are two air monitoring stations were studied for this research; Kemaman, Terengganu (S1) and Petaling Jaya, Selangor (S2). Kemaman is developing Malaysian town located at the industrial Kertih Petrochemical Industrial Area in the North and the industrializing and urbanizing Gebeng Industrial Area in the South. The monitoring station was located at Sekolah Rendah Bukit Kuang with coordinate (4°14'21.9"N 103°11'31.8"E). Petaling Jaya, Selangor is located within Klang Valley region and covers an area of 97.2 $km^2$. It's surrounded by residential, commercial and industrial areas leads to a high volume of traffic. The monitoring station was located at Sekolah Rendah Sri Petaling with coordinate (3°08'16.7"N 101°36'29.7"E). Both stations were classified as industrial area although different geographical area. The locations of the continuous air quality monitoring stations for this research are shown in Table 1 and Figure 1.

Table 1. Air quality monitoring stations description

| Air Monitoring Station | Location | Background | Coordinates | |
|---|---|---|---|---|
| | | | Latitude | Longitude |
| S1 | Kemaman, Terengganu | Industrial | $4^0$14'21.9'' N | $103^0$11'31.8''E |
| S2 | Petaling Jaya, Selangor | Industrial | $3^0$08'16.7''N | $101^0$36'29.7''E |

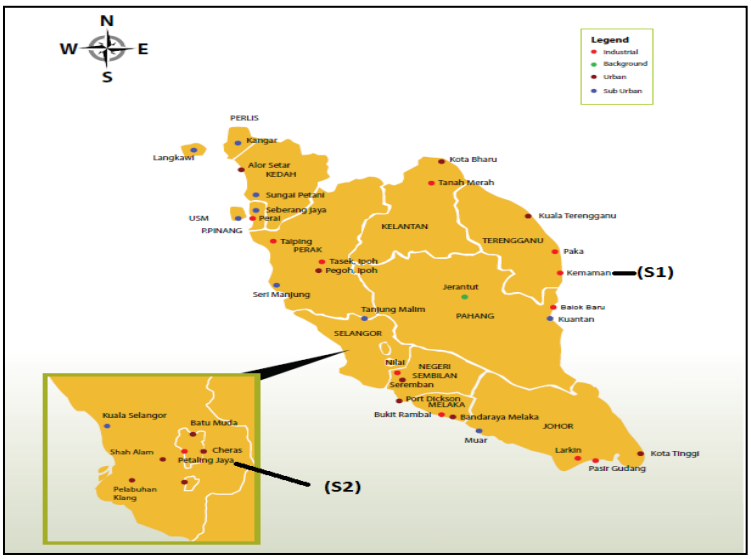

Figure 1. Location of Air Quality Monitoring Stations in Peninsular Malaysia, 2012

**Data acquisition**

Six air pollutants were selected to carry out replacing missing value. The overall air quality data used was collected from January to December for year 2012. The total number of observations is 52,704 records corresponding to the hourly value for each one of the following 6 parameters (8,784 observations x 6 parameters). The highest percentage missing data of parameter for S1 is NO (45.1%) and S2 is $O_3$ (20.4%). Table 2 show the parameters used in this study and percentage of missing data.

Table 2. Parameters used during period of study

| Station | % Missing Data | | | | | |
|---|---|---|---|---|---|---|
| | CO | $O_3$ | $SO_2$ | $NO_X$ | NO | $NO_2$ |
| S1 | 6.9 | 5.3 | 34.4 | 8 | 45.1 | 10.1 |
| S2 | 5.8 | 20.4 | 8.8 | 5.3 | 5.6 | 5.3 |

*CO-Carbon Monoxide, $O_3$-Ozone, $SO_2$-Suphur Dioxide, $NO_x$-Nitrogen oxide, NO-Nitrogen Oxide, $NO_2$-Nitrogen Dioxide*

**Multiple imputation**
The imputation has been performed by Monte Carlo simulation of MCMC method. The expectation-maximization (EM) [17] is a technique that finds maximum likelihood estimates for MCMC method to replace missing data. MCMC method is based on Bayesian inference with missing data by following several steps:

1. Imputation step. Estimate mean and covariance matrix, then simulates the missing values for each observation.
2. Posterior step (P-step). P-step simulates the mean vector and covariance matrix from the imputed step. This is the posterior distribution.

A current parameter estimate $\theta^{(t)}$ at $t^{th}$ iteration, the I-step draws $Y_{mis}^{(t+1)}$ from $p(Y_{mis} \mid Y_{obs}, \theta^{(t)})$ and the P-step draws $\theta^{(t+1)}$ from $p(\theta \mid Y_{obs}, Y_{mis}^{(t+1)})$. Therefore, a Markov chain is created as shown below:

$$(Y_{mis}^{(1)}, \theta^{(1)}), (Y_{mis}^{(2)}, \theta^{(2)}) \tag{1}$$

which converges in distribution to $p(Y_{mis}, \theta \mid Y_{obs})$.

**Performance indicators**
There are four performance indicators were used to explain the efficiency of the imputation method used in this study. The observed data and theoretical data were compared to show the goodness of method for replacing missing values. Four performance indicators were used namely; coefficient of determination ($R^2$), prediction accuracy (PA), mean absolute error (MAE) and root mean squared error (RMSE).

**Coefficient of determination**
The coefficient of determination ($R^2$) explains how much the variability of the imputed data that related with observed data. The value of $R^2$ is between 0 and 1, with value closer to 1 implying a better fit model. The $R^2$ is computed using the following equation 2 [16]:

$$R^2 = \left[ \frac{1}{N} \frac{\sum_{i=1}^{N} \left(P_i - \overline{P}\right)\left(O_i - \overline{O}\right)}{\sigma_p \sigma_o} \right]^2 \tag{2}$$

where N is the number of observations, $O_i$ is observed data, $P_i$ is the imputed data, $\overline{P}$ and $\overline{O}$ are the average of imputed data and observed data, and $\sigma_P$ and $\sigma_O$ are the standard deviation of the imputed data and observed data respectively.

**Prediction accuracy**
The Prediction accuracy (PA) takes on value range from 0 to 1 with closer to 1 describing a better fit model. The equation of PA is given as follows [18]:

$$PA = \sum_{i=1}^{N} \frac{\left[\left(P_i - \overline{P}\right)\left(O_i - \overline{O}\right)\right]}{(N-1)\sigma_P \sigma_O} \tag{3}$$

where N is the number of observations, $O_i$ is observed data, $P_i$ is the imputed data, $\overline{P}$ and $\overline{O}$ are the average of imputed data and observed data, and $\sigma_P$ and $\sigma_O$ are the standard deviation of the imputed data and observed data respectively.

**Mean absolute error**
Mean absolute error (MAE) is the average of the difference between observed data and predicted data. The MAE is computed by Schafer [16]:

$$MAE = \frac{1}{N}\sum_{i=1}^{N}\left|P_i - O_i\right| \tag{4}$$

where N is the number of observations, $O_i$ is observed data, $P_i$ is the imputed data, $\overline{P}$ and $\overline{O}$ are the average of imputed data and observed data, and $\sigma_P$ and $\sigma_O$ are the standard deviation of the imputed data and observed data respectively.

**Root mean squared error**
The root mean squared error (RMSE) is one of the common errors that measure for building of model and testing accuracy of the model. The small value explains the good performance of the model. This error is evaluated by the equation 5 [16]:

$$RMSE = \left(\frac{1}{N}\sum_{i=1}^{N}\left[P_i - O_i\right]^2\right)^{\frac{1}{2}} \tag{5}$$

where N is the number of observations, $O_i$ is observed data, $P_i$ is the imputed data, $\overline{P}$ and $\overline{O}$ are the average of imputed data and observed data, and $\sigma_P$ and $\sigma_O$ are the standard deviation of the imputed data and observed data respectively.

**Multiple imputation efficiency**
The relative efficiency is computed by using $m$ imputation and $\lambda$ as shown in equation 6

$$RE = (1 + \frac{\lambda}{m})^{-1} \tag{6}$$

## Results and Discussion

Table 3 gives the summary of parameters for air quality data. The mean values for both stations and for all parameters are higher than median which indicates that the parameters distributions are skewed to the right. The variance value shows the variability of parameter concentration. The station 1 explained the distribution for CO (sk = 1.36), $SO_2$ (sk = 6.947), $NO_x$ (sk = 2.14), NO (sk = 4.15), and $NO_2$ (sk = 2.08) are highly skewed to the right. Meanwhile, the distribution for $O_3$ (sk = 0.922) is slightly skewed to the right. For the station 2, the distribution for $O_3$ (sk = 1.36), $SO_2$ (sk = 5.23), and NO (sk = 1.55) are highly skewed to the right. Meanwhile, the distribution for CO (sk = 0.93), $NO_x$ (sk = 0.99), and $NO_2$ (sk = 0.94) are slightly skewed to the right. Hence, all parameters are skewed to the right because of nonnegative values. The data was analyzed assuming missing at random because the air quality data was missing being due to the monitoring site down [19].

MI technique was performed by using SAS version 9 with the imputation of m = 5 values for each missing record hence creating five complete datasets. Table 4 shows the relative efficiency of missing data for both stations. The result shows that all parameters are high efficiency very close to 1. This indicates that imputations with five replications are needed for simulation of this data.

Table 5 shows that the parameters give the close fit between the actual data and imputed data because of high value for $R^2$ and PA implying closer to 1. Meanwhile, the errors of the model for both stations are small and closer to 0 for parameters. According to the performance of $R^2$, the highest $R^2$ for both stations is CO parameter in S2 which is 0.906. Meanwhile, the highest performance of PA is NO in S2 which is 0.9513. The smallest RMSE is NO for S1

which is 0.0005 and the smallest MAE is also for NO in S1 which is 0.0002. Although $R^2$ value is quite low for $SO_2$ (0.497) in S1 but the performance of PA is quite high and also given small error. Therefore, this assures us that the MI technique by using MCMC method produced consistent result and suitable for the replace missing value for air quality datasets. It is supported with [20] reported that MI is suitable method to solve the high ratio of missing values for example 43.5% missing data. Another study from [21] shows that MCMC method was more effective than simple mean for the monthly rainfall data in the northern region of Thailand.

Table 3. Details of the two original datasets

| Station | US | CO | $O_3$ | $SO_2$ | $NO_x$ | NO | $NO_2$ |
|---|---|---|---|---|---|---|---|
| S1 | M | 0.35 | 0.021 | 0.0017 | 0.005 | 0.002 | 0.004 |
| | Med | 0.34 | 0.018 | 0.001 | 0.004 | 0.001 | 0.003 |
| | Var | 0.018 | 0.0002 | 0.00001 | 0.00002 | 0.000003 | 0.00001 |
| | Sk | 1.36 | 0.922 | 6.947 | 2.14 | 4.15 | 2.08 |
| S2 | M | 1.17 | 0.015 | 0.0034 | 0.05 | 0.03 | 0.03 |

| | $NO_x$ | 0.9013 | 0.9494 | 0.0149 | 0.0031 |
| | NO | 0.9050 | 0.9513 | 0.0084 | 0.0015 |
| | $NO_2$ | 0.8859 | 0.9413 | 0.0074 | 0.0016 |

## Conclusion

This paper discussed the use of multiple imputation technique to replace missing values in air quality dataset. The MCMC technique was used. The hourly air quality data was used to test the performance of the imputation technique. The relative efficiency was calculated to examine the accuracy technique for replacing missing values. The result shows that the relative efficiency is high and more than 0.9. Based on the result of performance indicators shows that the MCMC method give the good linear relationship because of $R^2$ and PA are high approaches to 1 for both stations and followed with small errors for RMSE and MAE. Therefore, it can be concluded that MCMC method is suitable method for replacing missing air quality data. MCMC method is also reliable to replace missing value either low or high percentage of missing data. Missing values are always arises, but a proper imputation can help remedy the analysis as much as possible.

**Abstract**

Rare earth complexes can exhibit higher coordination numbers while rare earth metals have the ability to form a multitude of geometries with organic ligands. The ligands, [Sm(III) $(4Acpy4MTSC)_2(4H_2O)Cl]Cl_2$ and [Sm(III) $(4Acpy4ETSC)(5H_2O)Cl_2]Cl$ [4Acpy4MTSC = 4-acetylpyridine 4-methyl-3-thiosemicarbazone; 4Acpy4ETSC = 4-acetylpyridine 4-ethyl-3-thiosemicarbazone] have been synthesised by condensation method. The compounds were structurally characterised by elemental analysis (CHNS), molar conductivity, Fourier Transform Infrared (FT-IR), Nuclear Magnetic Resonance (NMR), Ultraviolet-Visible (UV-Vis), and Thermo-Gravimetric Analysis (TGA). The elemental analysis for the compounds were in a good agreement with the theoretical values. The molar conductivity of the complexes showed electrolyte behaviour and confirmed the presence of counter ions in the structures. The proposed structures of the compounds have been confirmed by NMR, UV-Vis, and TGA. Based on the analysis, the ligands were coordinated to the metal ions through azomethine N and thione S thus, producing bidentate complexes. From the TGA, it is confirmed that a few water molecules have coordinated with metal ions. The X-ray crystallographic structures for the 4Acpy4ETSC, the C=S bond length is shorter than the single bond C-S which is 1.82 Å. It shows that in the solid state, the ligand exists in the thione form. The 4Acpy4ETSC adopted a monoclinic system, $a$ = 10.5922(7), $b$ = 8.9597(6), $c$ = 13.0407, Z = 4. *In vitro* antibacterial tests showed that the complexes have an effective inhibitory effect compared to the ligands because the presence of chloride ions, $Cl^-$ which caused the complexes to be more acidic, can inhibit bacterial growth.

**Keywords**: thiosemicarbazone, samarium(III), antibacterial screening

**Abstrak**

Sebatian kompleks nadir bumi boleh wujud dengan nombor koordinatan yang lebih tinggi dan logam nadir bumi berkeupayaan membentuk pelbagai geometri dengan ligan organik. Sebatian ligan, [Sm(III) $(4Acpy4MTSC)_2(4H_2O)Cl]Cl_2$ dan [Sm(III) $(4Acpy4ETSC)(5H_2O)Cl_2]Cl$ [4Acpy4MTSC = 4-asetilpiridin 4-metil-3-tiosemikarbazon; 4Acpy4ETSC = 4-asetilpiridin 4-etil-3-tiosemikarbazon] telah disintesiskan melalui kaedah kondensasi. Kesemua struktur sebatian telah dicirikan dengan analisis unsur (CHNS), kekonduksian molar, spektoskopi Inframerah Transformasi Fourier (FTIR), Resonans Magnet Nukleus (NMR), Ultralembayung-Sinar Nampak (UV-Vis), dan analisis termogravimetrik (TGA). Data analisis unsur bagi semua sebatian adalah hampir sama dengan nilai-nilai teori. Kekonduksian molar bagi sebatian kompleks menunjukkan sifat elektrolit dan

membuktikan kehadiran ion pembilang dalam struktur sebatian. Struktur jangkaan bagi sebatian telah dibuktikan dengan NMR, UV-Vis, dan TGA. Berdasarkan kepada analisis, ligan berkoordinat dengan ion logam melalui N azometina dan S tion dengan menghasilkan sebatian kompleks bersifat bidentat. Analisis TGA membuktikan kehadiran beberapa molekul air yang berkoordinat dengan ion logam. Struktur kristalografi sinar-X bagi 4Acpy4ETSC, panjang ikatan C=S adalah lebih pendek daripada ikatan tunggal C-S iaitu 1.82 Å. Ini menunjukkan bahawa dalam keadaan pepejal, ligan wujud dalam bentuk tion. 4Acpy4ETSC menghablur dalam sistem monoklinik, $a$ = 10.5922(7), $b$ = 8.9597(6), $c$ = 13.0407, Z = 4. Ujian antibakteria *in-vitro* ke atas sebatian kompleks mempamerkan kesan perencatan yang lebih tinggi berbanding dengan ligan kerana kehadiran ion klorida, Cl- yang menyebabkan kompleks bersifat asid, boleh menghalang pertumbuhan bakteria.

**Kata kunci:** tiosemikarbazon, samarium(III), penyaringan antibakteria

## Introduction

The study of thiosemicarbazone and their complex properties have favoured diverse researches that are related to the biological purposes [1-3]. Previous studies have reported that varied substitutions at the thioamide N atom have a powerful effect on the biological efficiency of the compounds [4]. The restructuring of the thiosemicarbazone framework is intended to get new compounds that will enhance their biological activity and be more reactive as an antibacterial agent [5]. 4-acetylpyridine complexes have the ability to inhibit bacteria cell growth where the activity greatly depends on the nature of the *N*-heterocyclic ring [6]. According to a study conducted by Rosu et al. [7], thiosemicarbazones do not show any bacterial inhibitor properties compared to their complexes against some microorganisms. This is due to chelation between thiosemicarbazones with metal ions that will reduce the metal ion polarity because of the shared positive charge between the donor atoms and metal ions. Moreover, the dispersion of the electrons in the rings may also influence the reactivity of thiosemicarbazones as an antibacterial agent. Thiosemicarbazones consist of C=N and C=S moieties which show favourable coordination towards metal ions [8]. Thiosemicarbazones consist of soft donor atoms; imine N and thiolate S where they act as δ-donor and π-acceptor atoms that can stabilise the oxidation state of metal ions [9]. Thiosemicarbazone commonly reacts with the transition and lanthanide metals to form stable complexes through amine N and thiocarbonyl or thiolate S atoms in which have a few bonding modes such as monodentate, bidentate, and polydentate [10].

In this study, the ligands and Sm(III) complexes were synthesised and characterised by an elemental analysis, molar conductivity, UV-Visible, FT-IR, TGA, NMR and single crystal X-ray diffraction technique. In addition, the antibacterial activity of the compounds were investigated.

## Materials and Methods

All reagents and reactants are of analytical grade and were used as received without further purification. The melting points of the synthesised compound were determined using the Electrothermal IA 9100. The elemental analysis was performed on the CHNS/O Model Fision EA 1180 and Thermo Finnigan Flash EA 1112 Series. 13C and 1H NMR spectra were recorded on a 600 MHz FT-NMR Cryoprobe using DMSO-$d_6$ as solvent and tetramethylsilane as the internal reference. Chemical shifts were recorded in parts per million (δ). Infrared spectra of the ligands were recorded as KBr discs on FTIR Perkin Elmer model GX spectrophotometer in the 4000-400 $cm^{-1}$ range. The thermogravimetric analysis (TGA) of the complexes was recorded on Mettler Toledo model TGA.SDTA 851e. The electronic absorption spectra were recorded on a Shimadzu UV-1650 PC and measured in the range of 200-800 nm in DMF. The molar conductivity was measured with DMF at room temperature using SI Analytic Lab 970 conductivity meter at the concentration of 1 x $10^{-3}$ M.

The determination of the crystal structures of the ligand was carried out on a Bruker Smart APEX CCD area detector diffractometer equipped with graphite mono-chromatised Mo-Kα (λ=0.71073Å) [11]. All data collection was carried out at 296K. Data collection: SMART [12]; cell refinement: SAINT [13]; data reduction: SAINT; program(s) used to solve structure: SHELXTL [14]; program(s) used to refine structure: SHELXTL [14] molecular graphics: SHELXTL [14]; software used to prepare material for publication: SHELXTL and PLATON [15]. Crystallographic data for the compounds Is2MTSC have been deposited with the Cambridge Crystallographic Data Centre, CCDC reference numbers (1007736). This information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK.

**Synthesis of 4Acpy4MTSC and 4Acpy4ETSC**

4Acpy4MTSC: A methanolic solution (10 mL) of 4-acetylpyridine (0.121 g, 10 mmol) was added to a methanolic solution (10 mL) of 4-methyl-3-thiosemicarbazide (0.105 g, 10 mmol) followed by the addition of a few drops of acetic acid. The solution was heated under reflux for 2 hours, filtered and left to dry at room temperature to get the white precipitate which formed after 2 weeks. The 4Acpy4ETSC was synthesised following the same method as 4Acpy4MTSC. Colourless crystals suited for X-ray Crystallography were obtained from methanol by slow evaporation at room temperature after a few weeks. The purity of ligands was checked by TLC and verified by elemental analysis.

**Synthesis of Sm(III) complexes**

$[Sm(III)(4Acpy4MTSC)_2(4H_2O)(Cl)]Cl_2$*:* A methanolic solution (30 mL) of 4-acetylpyridine 4-methyl-3-thiosemicarbazone (0.625 g, 3 mmol) was added dropwise into a methanolic solution (5 mL) of Sm(III) chloride hexahydrate (0.364 g, 1 mmol). The solution was heated under reflux for 3 hours. The yellow precipitate was filtered, rinsed with hot methanol, and dried in the desiccator. The $[Sm(III)(4Acpy4ETSC)_2(5H_2O)(Cl_2)]Cl$ was synthesised following the same method as $[Sm(III)(4Acpy4MTSC)_2(4H_2O)(Cl)]Cl_2$. Their reactions were difficult to be confirmed by the TLC method because of their insolubility in a few organic solvents.

**Antibacterial screening**

Antibacterial activity of the synthesised compounds was tested against Gram-positive bacteria with different species by convenient, low cost, and ease of use method which was disc diffusion. The types of bacteria used for antibacterial screening are as follows: i. *Bacillus subtilis (B. subtilis)*, ii. *Staphylococcus epidermidis (S.epidermidis)*, iii. *Staphylococcus auerus (S. aureus)*, iv. *Bacillus thuringiensis (B. thuringiensis)*, and v. *Methicillin-resistant Staphylococcus aureus (MRSA)*.

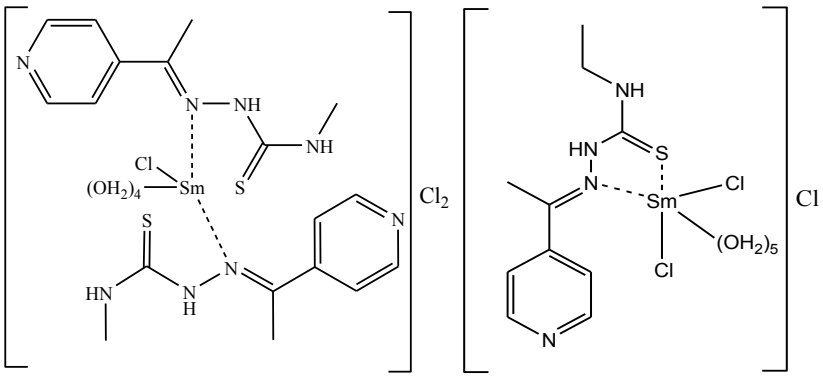
## Results and Discussion

**Chemical properties**

The results of the elemental analysis of the compounds are shown in Table 1. The molar conductivity for the complexes was measured in DMF ($10^{-3}$ M) at room temperature. The molar conductance for $[Sm(III)(4Acpy4MTSC)_2(4H_2O)Cl]Cl_2$ showed that the complex was 1:2 electrolyte, while $[Sm(III)(4Acpy4ETSC)(5H_2O)Cl_2]Cl$ was 1:1 electrolyte behaviour. It shows that the complexes have anions, $Cl^-$ outside the metal coordination sphere [16]. The proposed structures for the Sm(III) complexes are shown in Figure 1.

Table 1. Chemical properties of the compounds

| Compounds | Colour | Yield (%) | Composition Percentage, % (Calculated) | | | |
|---|---|---|---|---|---|---|
| | | | C | H | N | S |
| 4Acpy4MTSC | White precipitate | 90 | 51.11 (51.90) | 5.52 (5.81) | 25.48 (26.90) | 14.28 (15.39) |
| 4Acpy4ETSC | Colourless crystal | 92 | 53.64 (54.03) | 5.82 (6.35) | 25.08 (25.20) | 14.08 (14.42) |
| $[Sm(III)(4Acpy4MTSC)_2(4H_2O)(Cl)]Cl_2$ | Yellow precipitate | 83 | 28.89 (29.01) | 4.11 (4.33) | 14.78 (15.03) | 7.69 (8.60) |
| $[Sm(III)(4Acpy4ETSC)_2(5H_2O)(Cl_2)]Cl$ | Yellow precipitate | 89 | 21.82 (22.62) | 4.98 (4.66) | 10.01 (9.59) | 5.27 (5.49) |



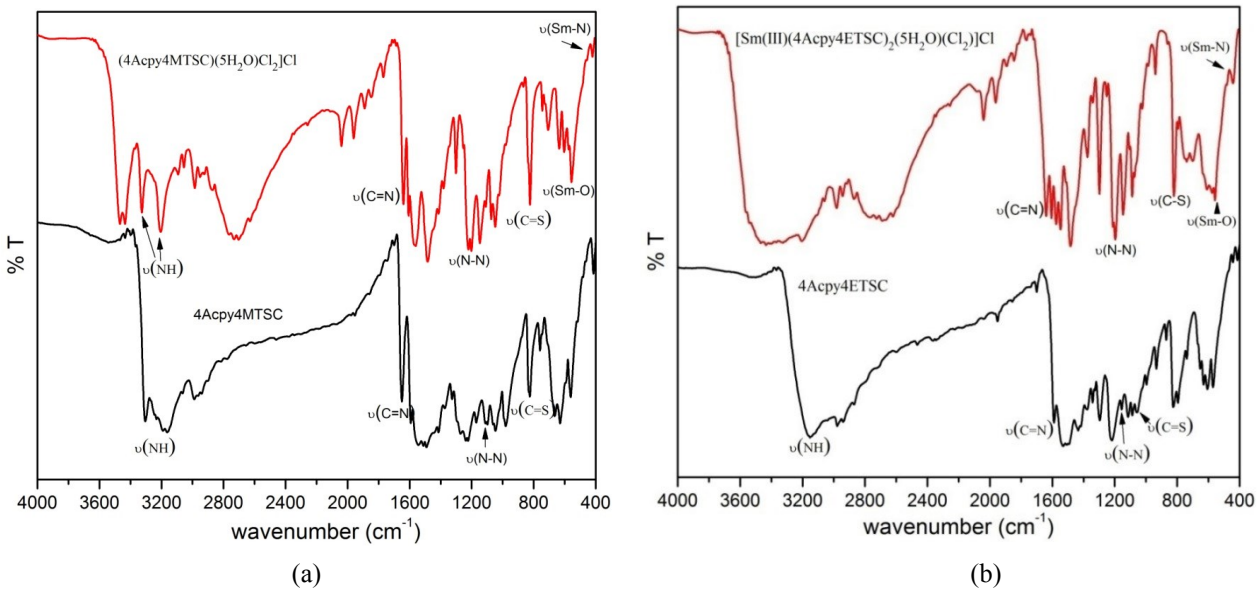


Figure 1. The proposed structures of the Sm(III) complexes

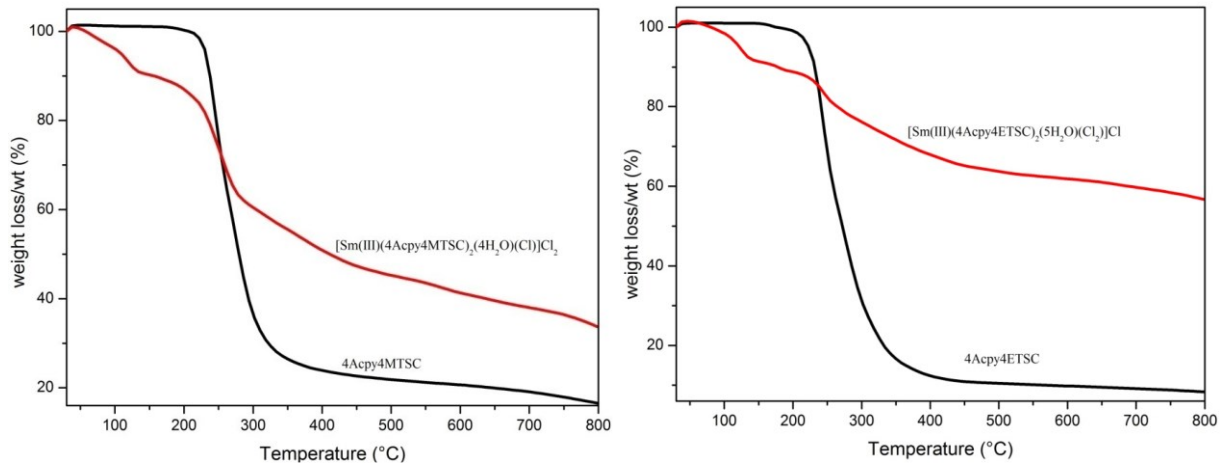
**Infrared spectra**

The infrared spectra of complexes and ligands were reported in the range of 200 – 400 and 400 – 4000 $cm^{-1}$, respectively, as shown in Figure 2. The comparison of stretching bands between the compounds is important to certify the coordination that occurs in the formation of complexes. The stretching band of ν(S-H) in the range of 2600 to 2800 $cm^{-1}$ implies that the ligands exist as tautomeric thione in the solid state [17, 18]. In addition, the presence of an amine group stretching band, ν(NH) in the range of 3150 – 3320 $cm^{-1}$ for the spectra of ligands also proved that ligands remain as thione tautomeric when in the solid state [19]. The absence of thiol stretching band, ν(S-H) in the range 2600 – 2800 $cm^{-1}$ and the existence of thiocarbonyl, ν(C=S) stretching band imply that the ligands will be presented as thione tautomeric in the solid state. Besides that, the existence of an amine, ν(N-H) stretching band at 3193 $cm^{-1}$ (4Acpy4MTSC) and 3151 $cm^{-1}$ (4Acpy4ETSC) also verified that the ligands remain as thione tautomers in the solid state. The stretching band ν(C=N) for the ligands exists at 1589 $cm^{-1}$. While for the complexes, the stretching band of ν(C=N) was shifted to higher wavenumber due to the coordination between the ligands to the metal ion through donor atoms, N-imine [20]. The stretching bands ν(C=S) for the ligand 4Acpy4MTSC and 4Acpy4ETSC showed up at 822 and 826 $cm^{-1}$, respectively. The stretching band was shifted to lower wavenumber, 821 $cm^{-1}$ for [Sm(III) (4Acpy4ETSC)($5H_2O$)$Cl_2$]Cl due to the coordination that occurred between thiocarbonyl sulfur with a metal ion. While the stretching band, ν(C=S) in [Sm(III) (4Acpy4MTSC)($5H_2O$)$Cl_2$]Cl was not shifted as it proved that no coordination occurred through S [21]. The coordination between azomethine, N and thiocarbonyl sulfur to metal ion was verified with the presence of stretching bands, ν(Sm-N) in the range 420 – 442 $cm^{-1}$ [22] and ν(Sm-S) at 353 $cm^{-1}$ [23]. In addition, the existence of two new stretching bands, ν(Sm-Cl) and ν(Sm-O) also showed that chloride ions and water molecules are also coordinated to metal ion to form high stability complexes.



**Thermogravimetric analysis**

The thermogravimetric analysis (TGA) (20 – 800 °C) was recorded for the prepared ligands and complexes to distinguish between the coordinated and hydrate water molecules and study the thermal stability of the compounds. In order to evaluate the thermal stability of the prepared Sm(III) complexes, the TGA plot of the ligands was compared with Sm(III) complexes. The decomposition of the prepared complexes was not fully completed compared to the ligands as the instrument constraints only allow combustion of up to 800 °C. Referring to Figure 3, these complexes will be fully decomposed above 800 °C to produce $MS_2$ or $MO_2$ as a residue. Moreover, water molecules evaporate at less than 100 °C, which is likely that the complexes are not completely dry. Meanwhile, the temperatures between 100 – 300 °C are referred to the loss of water molecules coordinated with Sm(III) ion which can be supported by the proposed structures [24]. The complexes have a higher thermal stability than the ligands because the thermal stability is enhanced when the complexation occurred. Besides that, the decomposition of chloride, $Cl^-$ and nitrate ions, $NO_3^-$ also occurred in this temperature range [25].

**Absorption spectra**

The absorption spectra of the ligands and Sm(III) complexes were determined in DMSO solution ($c$ = 1 x $10^{-5}$ M). The spectra of 4Acpy4MTSC and 4Acpy4ETSC displayed almost similar diagrams in the range of 200 – 400 nm regions. The absorption spectra for 4Acpy4MTSC were composed of three intense absorption peaks at 205.50, 237.50, and 315.50 nm which appointed to n→σ*, π→π*, and n→π*, while 4Acpy4ETSC was composed of four intense bands at 211.00 (n→σ*), 243.50, 253.00 (π→π*), and 320.50 (n→π*). The electronic transitions refer to the presence of azomethine, thioamide, and benzene rings. In addition, according to Tulay et al. [26], electronic

transition, $\pi \rightarrow \pi^*$ refers to the transition of electrons in imine, C = N. The formation of the Sm(III) complexes led to the change in the absorption region (200-400 nm). This is probably because of the conjugation effect caused by the deprotonation of the ligands upon coordination. The spectra of $[Sm(III)(4Acpy4MTSC)_2(4H_2O)(Cl)]Cl_2$ were composed of three intense absorption peaks at 206.00, 233.00, and 315.50 nm which appointed to $n\rightarrow\sigma^*$, $\pi\rightarrow\pi^*$, and $n\rightarrow\pi^*$, while $[Sm(III)(4Acpy4ETSC)_2(5H_2O)(Cl_2)]Cl$ was composed of three intense absorption peaks at 203.50, 235.00, and 315.50 nm which appointed to $n\rightarrow\sigma^*$, $\pi\rightarrow\pi^*$, and $n\rightarrow\pi^*$. The slight shifting of absorption peaks proves that the coordination occurred through azomethine N and thiocarbonyl S [27]. No absorption peak for *f-f* transition appeared in the visible region presumably due to the very weak transition. Besides that, Taha et al. [28] reported that Sm(III) ion is not involved in the absorption of complexes as the *f-f* transition is a Laporte forbidden transition, which is assumed to be too weak to appear in the visible range with low molar absorption coefficient.

**Nuclear Magnetic Resonance analysis**

The results of the Nuclear Magnetic Resonance of the ligands are shown in Table 2.

Table 2. NMR spectra data of the ligands

| Compounds | Type of Protons | Chemical Shift δ (ppm) | Type of Carbons | Chemical Shift δ (ppm) |
|---|---|---|---|---|
| 4Acpy4MTSC | N-$CH_3$ (d) | 3.04-3.05 | -$CH_3$ | 31.65 |
| | N(1)H (s) | 2.49 | C=S | 179.31 |
| | N(2)H (s) | 10.39 | C=N | 150.22 |
| | $CH_3$C=N (s) | 2.28 | $CH_3$C=N | 13.80 |
| | Aromatic (m) | 7.87-8.59 | Aromatic | 121.09, 145.21 |
| 4Acpy4ETSC | -$CH_3$ (t) | 1.13-1.17 | -$CH_3$ | 14.85 |
| | N-$CH_2$ (m) | 3.59-3.66 | -$CH_2$ | 39.05 |
| | N(2)H (s) | 10.30 | C=S | 178.27 |
| | N(1)H (t) | 8.63-8.66 | C=N | 150.23 |
| | $CH_3$C=N (s) | 2.28 | $CH_3$C=N | 13.84 |
| | Aromatic (m) | 7.86-8.59 | Aromatic | 121.09, 145.20, 145.30 |

Based on Table 2, the chemical shift for N(2)H appeared at downfield, 10.39 and 10.30 ppm for 4Acpy4MTSC and 4Acpy4ETSC, respectively, with singlet multiplicity. For 4Acpy4MTSC, the spin multiplicity of N(1)H is a singlet different from the theory, as it should be generating quartet. This is because the presence of $D_2O$ has caused nitrogen protons to exchange with deuterium, then indirectly; the resonance disappears and exists as a singlet. Besides that, from the NMR data, it was revealed that the ligands exist as thione form caused by the absence of S-H protons and existence of C=S and C=N bonds. The protons of the phenyl group also appeared at downfield due to the presence of magnetic anisotropy and resonance effect. The chemical shifts for DMSO deuterated appeared in the range of 2 – 5 ppm. The NMR data proved the proposed structures of ligands as recommended. The complexes have paramagnetic properties and are not suitable for NMR analysis.

**X-ray structure determination**

The molecular structure of the ligand along with the atomic numbering scheme is shown in Figure 4. The crystal data and structure refinement and H-bonding parameters of the ligand are shown in Tables 3 and 4, respectively.

For 4Acpy4ETSC, pyridine ring N1/C1/C2/C3/C4/C5, as shown in Figure 4, is planar with a maximum deviation of 0.014 Å for the C5 atom from the least square plane. Thiourea moiety, S1/N3/N4/C7 is planar with a maximum deviation of atoms at 0.009 Å C7 from the least square plane. 4Acpy4ETSC ligand is connected with hydrogen bonds as listed in Table 2 to form 1D chain along the *b* axis. Referring to Table 5, for azomethine moiety, C(6)-N(2) and S(1)-C(7) is a double bond in which the bond length varies with the theoretical value. This is due to the effect of conjugation and delocalisation of electron density in the molecule [29].

**Antibacterial screening**

The synthesised compounds tested for their *in vitro* antibacterial activity against Gram-positive bacteria by disc diffusion method and their diameters of the zones inhibition are listed in Table 6. From the observation, it can be concluded that the complexes are more active as antibacterial agent compared to the ligands. This phenomenon is caused by the presence of chelation between metal ion with the ligands in which will lower the polarity of metal ion caused by the partial sharing between positively charged metal ions with the donor atoms, N and O [30]. This will increase the chelation lipophilic properties of the metal ion which will indirectly increase the penetration abilities of the complexes through the cell walls of microorganisms. Increasing the lipophilic properties of the complexes will inhibit the growth of bacteria [31]. In addition, when the metal ions or complexes were adsorbed onto the bacteria wall, they will indirectly inhibit the respiration cell and protein production process. Hence, this phenomenon will inhibit the growth of the bacteria. Besides that, the complexes showed that the inhibitory activities are more active compared to the ligands due to the presence of chloride ions, $Cl^-$ that are acting as electron withdrawing group

which causes them to be more acidic. In addition, due to the high degree of solubility of these compounds in the solvent DMSO, they are easily absorbed into the cells of bacteria through the membrane [32].

## Conclusion

Two ligands and complexes were successfully synthesised and the proposed structures were supported by the elemental analysis, infrared, UV-Vis, molar conductivity, TGA, and X-ray Crystallographic study. The ligands exist as thione form in the solid state, which were proven by the X-ray Crystallographic study. The complexes showed 1:2 and 1:1 electrolytic behaviour for 4Acpy4MTSC and 4Acpy4ETSC, respectively, with molecular formula of $[Sm(III)\ (4Acpy4MTSC)_2(4H_2O)Cl]Cl_2$ and $[Sm(III)\ (4Acpy4ETSC)(5H_2O)Cl_2]Cl$. From the infrared and UV-Vis spectra, it can be seen that the ligands are coordinated with Sm(III) through azomethine N and thiocarbonyl, S as recommended by the proposed structures. The existence of coordinated $H_2O$ molecules with Sm(III) was proven by TGA which supported the proposed structures. An antibacterial screening implies that the Sm(III) complexes exhibit higher antibacterial activity compared to the ligands. These performances are due to the presence of chloride ions, $Cl^-$ which caused the complexes to be more acidic and therefore, inhibit bacterial growth.

## Acknowledgement

**Abstract**

In the present work, hydroxyapatite (HAP) powder was successfully synthesized *via* the thermal decomposition and subsequent wet precipitation (with different experimental reaction times of 3, 5, 24, 48, and 72 hours of bulk seashells. We found that the reaction time during wet precipitation stage affected the physical and chemical properties of HAPs adsorbents. HAP synthesized with a reaction time of 48 hours showed the highest removal of $Pb^{2+}$ ions (99.1%) and is highly potential to be used as bio adsorbent material in heavy metal wastewater treatment.

**Keywords**: hydroxyapatite, seashell, wet precipitation, lead

**Abstrak**

Di dalam kajian ini, serbuk hidroksiapatit (HAP) telah berjaya disintesis dari kulit kerang melalui proses penguraian termal dan diikuti oleh teknik pemendakan basah (dengan masa tindakbalas kajian 3, 5, 24 dan 72 jam). Kajian mendapati masa tindakbalas mempengaruhi ciri-ciri fizikal dan kimia penjerap HAP. HAP yang disintesis dengan masa tindakbalas selama 48 jam menunjukkan peratusan penyingkiran ion $Pb^{2+}$ tertinggi (99.1%) dan berpotensi untuk digunakan sebagai bahan penjerap-bio bagi pemulihan logam berat di dalam air sisa.

**Kata kunci**: hidroksiapatit, kulit kerang, pemendakan basah, plumbum

## Introduction

Water contamination often occurs due to anthropogenic activities such as manufacturing industries and agriculture. The untreated wastes from these activities are discharged directly into the environment, causing adverse impact on both the environment and human. Lead is one of the harmful pollutants which can cause irreversible neurological harms, e.g. kidney diseases, nervous disorders and reproductive toxicity [1]. The main factors contributing to lead contamination are from pipes, batteries, cable sheathing, and lead sheets [2]. The Ministry of Health Malaysia set the benchmark for both raw and drinking water quality index, with a maximum acceptable value of lead at 0.05 mg/L and 0.01 mg/L, respectively [3]. Various conventional methods have been introduced to remove heavy metals from wastewater, including chemical precipitation, membrane filtration, ion exchange, carbon adsorption, and co-precipitation/adsorption [4]. However, due to operational demerits, high cost of the treatment, the generation of

toxic chemical sludge and incomplete removal of the pollutants, the conventional methods are least favourable [5]. Therefore, in search of alternatives, many researchers have applied regenerated natural wastes to produce an efficient and low cost treatment technology for heavy metal treatment.

Nowadays, studies using hydroxyapatite, $Ca_{10}(PO_4)_6(OH)_2$, (HAP) are being rapidly conducted and due to its versatility, it is applied in various fields such as biomedical application [6, 7], bone tissue engineering [8, 9], and wastewater treatment [10 – 12]. In addition, HAP has appealed a great deal of attention as a good adsorbent. It is highly stable under reducing and oxidizing conditions and possesses various favourable surface characteristics, such as surface functional groups, acidity and basicity, surface charge, hydrophilicity and porosity. The heavy metal sorption takes place through ionic exchange reaction, surface complexation with phosphate, calcium and hydroxyl groups and/or co-precipitation of new partially soluble phases [13].

HAP, also commonly known as calcium phosphate ceramic or bioceramic, exhibits similar structure and composition to the mineral phase of bones and teeth. Every year, 63,000 metric ton of shell fish wastes are generated worldwide and about 70% of this total weight is represented by clam shells. Easily available and abundant in nature, a renovation of these clam shell wastes into value-added HAP can be highly profitable [14]. HAP can also be produced from other natural calcium sources, e.g. corals, eggshell [15], cuttlefish shells, natural gypsums, bovine bones and seashells [16]. Various HAP production methods are developed: preparation methods such as hydrothermal method [17], microwave-assisted hydrothermal rapid synthesis [18], combustion method [19], precipitation, sol-gel technique, multiple emulsion, biomimetic deposition technique and electro deposition approach [20]; experimental conditions can also be modified according to the needs of applications prior to use. The type of source, method of preparation and different conditions will create HAP with different chemical and physical properties.

Therefore, in the present work, HAP was produced from marine waste *via* straightforward analysis technique by controlling the reaction time taken to produce high quality of HAP adsorbent in optimum condition. The changes of physical and chemical characteristics of the resulting HAP were discussed. The produced HAP is a potential lead-removal adsorbent, removing lead from contaminated water, thus curbing water pollution due to anthropogenic activities by converting wastes into valuable material.

## Materials and Methods

### Instrument

The purity of HAP adsorbents was examined by X-ray diffraction (XRD) using Cu Kα radiation (λ¼1.5406 Å) on a SmartLab X-ray diffractometer (Rigaku). Fourier Transform infrared (FTIR) spectroscopy technique using potassium bromide (KBr) pellet method was conducted using Perkin Elmer Spectrum 2000 FT-IR Spectrometer to define the information functional groups of HAP present in adsorbents. The adsorbent surface morphologies were studied using scanning electron microscope (SEM) (JEOL model JSM-6360 LA), and analysed using Brunauer, Emmett, and Teller (BET) analysis (Micromeritics, ASAP-2020). An Inductively Couple Plasma-Optical Emission Spectroscopy (ICP-OES) Shimadzu was used for $Pb^{2+}$ analysis.

### Raw material and chemical

Bulk seashells were randomly collected from Teluk Ketapang beach, Terengganu. Standard solution (1000 mg/L of lead) was prepared from lead (II) nitrate, $Pb(NO_3)_2$ (Merck, Germany) and used as stock solution of Pb(II). The working solutions of lower concentrations were prepared by dilutions series. All standard solutions were stored in refrigerator at 4 °C. Ammonium hydrogen dibasic was supplied by Merck, Germany. Deionised water was purified by Purelab Ultra, ELGA with Millipore 18.2 μΩ. All reagents used were of analytical grade.

### Synthesis of hydroxyapatite

Bulk seashells were cleaned and dried in oven at 60 °C overnight. After crushed and pulverized, the seashell powder was calcined at 1000 °C for 1 hour in a furnace. HAP 3 was synthesized by slowly adding 150 mL of dissolved diammonium hydrogen phosphate solution to the 150 mL of calcined seashell powder with a Ca/P ratio of 1.68. The solution was then stirred at room temperature for 3 hours. The resulting precipitate was filtered using nylon cellulose filter paper (pore size = 0.25 μm) and extensively washed with deionized water to neutralize the

precipitate. Subsequently, the HAP 3 was dried in oven at 100 °C overnight. Finally, the HAP 3 was sieved at a size range of less than 38 µm before being stored in tight container for further analyses. This experimental procedure was repeated to produce HAP 5, HAP 24, HAP 48 and HAP 72 by changing the reaction time during stirring from 3 to 5, 24, 48 and 72 hours. The physical and chemical characterizations of the HAPs powders produced were examined. The chemical reaction involved in the experiment is stated as equation 1 and 2 below:

$$CaCO_3 \xrightarrow{1000\ ^\circ C} CaO + CO_2 \quad (1)$$

$$10CaO + 6(NH_4)_2HPO_4 + 4H_2O \longrightarrow \underset{\text{Hydroxyapatite}}{Ca_{10}(PO_4)_6(OH)_2} + 12NH_4OH \quad (2)$$

**Adsorption method**

Batch adsorption experiment was conducted to study the $Pb^{2+}$ ions adsorption performance of different types of HAPs adsorbents. The experiments were conducted by mixing HAP adsorbent (0.4 g) in 200 mL of lead (II) nitrate solution (25 mg/mL) in a 250 mL Schott bottle. The solutions were equilibrated using controlled mechanical shaker at 150 rpm in room temperature. The aliquot supernatant was collected at fix time intervals (0, 15, 30, 60, 120, 150, 180, 210 and 240 minutes). The concentration changes of $Pb^{2+}$ were determined using ICP-OES.

The percentage of lead removal (% R), quantity adsorbed by adsorbent ($q_t$) and adsorption capacity of adsorbent ($q_e$) were calculated using equation 3, 4 and 5, respectively:

$$\% R = [(C_0-C_e)/C_0] \times 100\% \quad (3)$$
$$q_e = (C_0-C_{eq})\ V/\ (M) \quad (4)$$
$$q_t = (C_0-C_t)\ V/\ (M) \quad (5)$$

where, $C_0$, $C_t$ and $C_{eq}$ are the initial, at time t (min) and equilibrium concentration of heavy metal ion in the solution (mg/L), respectively. The $q_e$ is the adsorption capacity in (mg/g), $q_t$ is the amount of lead adsorbed at time (mg/g), V is the total volume of the solution (L) and M is the amount of composite adsorbent (g).

**Kinetic and equilibrium modelling**

The effect of initial concentrations of adsorbate, $Pb^{2+}$ (25, 50, 75, 100, 125, 150, and 200 mg/L) was observed. In each batch experiment, 200 mL of aqueous metal ion solution of desired concentration was prepared and a fix weight of adsorbent, 0.4 g was added. The mixed solution was equilibrated with controlled mechanical shaker at 150 rpm. Supernatants were collected at various time intervals (0, 15, 30, 60, 120, 150, 180, 210 and 240 minutes), and the concentration of lead was determined using ICP-OES analysis. All experiments were carried out in triplicates and the mean values were presented.

Study of kinetic models is important to define the mechanism involved in the adsorption process of adsorbate onto adsorbent in aqueous solution. The kinetic models by Lagergren's pseudo-first order and McKay and Ho's pseudo-second order models were used to the analysis data [5]. The linear equation of pseudo-first and pseudo-second are expressed in equation 6 and 7, correspondingly.

$$\log (q_e - q_t) = \log q_e - (k_1/2.303)t \quad (6)$$
$$t/q_t = 1/k_2 q_e^{\ 2} + t/q_e \quad (7)$$

where $q_e$ is the amount of lead adsorbed by the absorbent at equilibrium at specific time $q_t$ (mg/g). $k_1$ ($min^{-1}$) is the biosorption rate constant of pseudo-first-order sorption. The graph of pseudo-first order was plotted as log ($q_e$-$q_t$) versus t, and the linear graph for pseudo-second-order was plotted as t/qt against t. The pseudo-second order model rate constant, $k_2$ (g/mg min) and $q_e$ was obtained from the intercept and slope of the linear graph plotted. From the equation 8, the initial biosorption rate, h (mg/g min) was calculated from the value obtained using pseudo-second-order as stated below:

$$h\ (mg/g\ min) = k_2 q_e^2 \quad (8)$$

The equilibrium adsorption isotherm is important in designing a biosorption system. The relationship between the adsorbent and adsorbate in equilibrium can be described from the type of adsorption isotherms data plotted. In this study, the lead adsorption of HAP 48 adsorbent was tested using Langmuir and Freundlich isotherm models. The Freundlich and Langmuir isotherm are represented in equation 9 and 10 as below:

$$\log q_e = \log K_F + (1/n) \log C_e \quad (9)$$
$$C_e/q_e = (1/Q_0 b) + (C_e/Q_0) \quad (10)$$

where $q_e$ is the amount of adsorbate adsorbed at equilibrium (mg/g) and $C_e$ is the equilibrium solute concentration (mg/L). Value of $K_F$ and 1/n are Freundlich constants, that related to the adsorption capacity and adsorption intensity of the adsorbent which are can be directly obtained from the intercept and slope of the linear plot of log $q_e$ against log $C_e$. Value of b is the Langmuir constant related to the energy of biosorption (L/mg), $q_m$ is the maximum sorption capacity corresponding to complete monolayer coverage (mg/g). These b and $Q_0$ were obtained from the intercept and slope, respectively from the linear plot of $C_e/q_e$ over $C_e$.

The favourable nature of adsorption can be expressed in terms of dimensionless separation factor of equilibrium parameter, which is shown in equation 10 below [22].

$$R_L = 1/1+bC_0 \quad (11)$$

## Results and Discussion

### Physical characterizations

Figure 1 depicts the diffractograms of different types of HAPs produced at different reaction times. The broad peaks indicate an amorphous structure. This result is consistent with previous study, in which non-calcined HAP produced broad peaks as a result of poor crystallinity structure [23]. The reflection patterns of HAP 3, HAP 24, HAP 48 and HAP 72 matched the XRD pattern of hydroxyapatite [$Ca_{10}(PO_4)_6(OH)_2$] (JCPDS standard No. 74–565). HAP 5 powder showed the presence of calcite peak matching the XRD pattern of carbonate hydroxyapatite, syn [$Ca_{10}(PO_4)_3(CO_3)_3(OH)_2$] (JCPDS standard No. 19–272). The highest peak of HAP was at $31.9^0$ and the adsorbent of HAP 48(315) showed the highest intensity, indicating the high purity of HAP 48 compared to others adsorbents (i.e. HAP 24(313), HAP 72(295), HAP 3(286) and HAP 5(258)). The calcite peak of HAP 5 at 29.42° is considered as an intermediate product in the conversion of seashell (calcium carbonate) to calcium oxide. The production of HAP increased with reaction time and conversion is completed with the disappearance of the diffraction line of calcite [24].

Figure 2 illustrates the FTIR spectra of different types of HAP. A broad peak at 1031 – 1033 $cm^{-1}$ demonstrated the stretching modes of P-O bonds of phosphate group ($PO_4^{3-}$) in the HAP structure. The peak at 602 $cm^{-1}$ and 563 $cm^{-1}$ were due to the bending modes of P–O bonds in phosphate groups [25]. A broad peak at 3421 – 3441 $cm^{-1}$ were assigned to the hydroxyl group (-OH) vibration [26]. A weak band of functional group of carbonate, $CO_3^{2-}$ exhibited in the region 1419 – 1455 and 873 – 875 $cm^{-1}$ corresponded to the B-type carbonate substitution of the $PO_4$ groups in the HAP structure [27]. The lower intensity of the carbonate bands of HAP 72 and HAP 48 showed that they were purer compared to other HAPs.

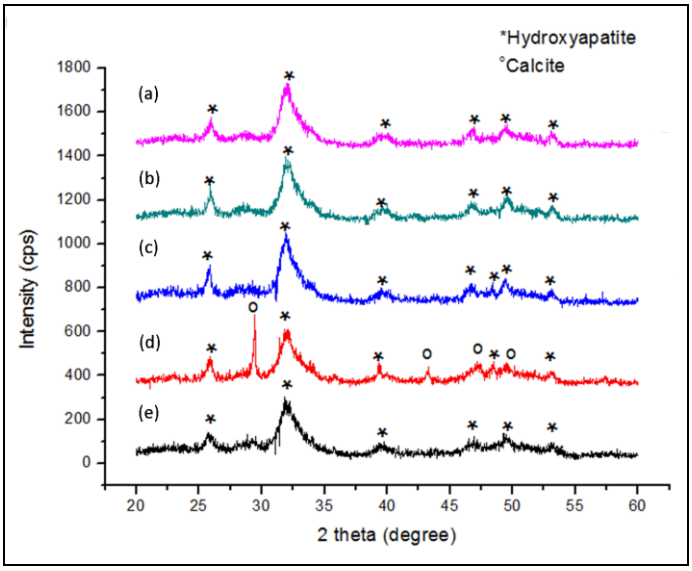

Figure 1. The XRD diffractogram of the HAP adsorbents. (a) HAP 72, (b) HAP 48, (c) HAP 24, (d) HAP 5 and (e) HAP 3

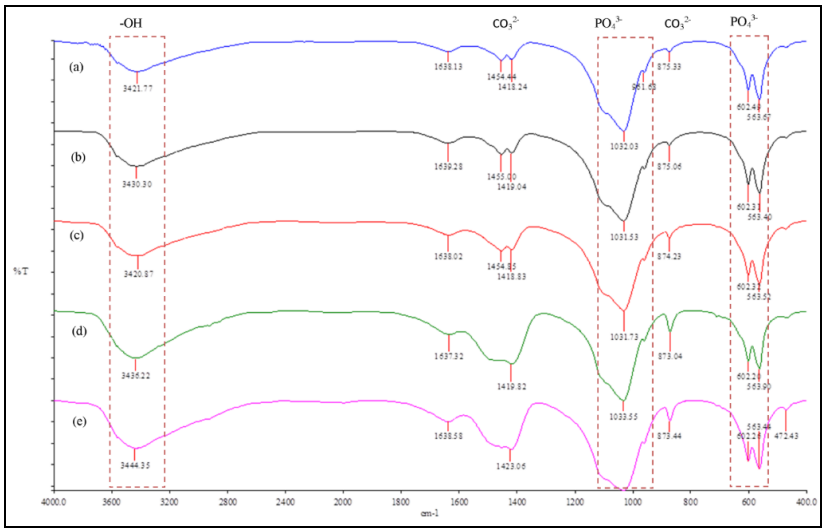

Figure 2. The FTIR spectra of HAP adsorbents. (a) HAP 72, (b) HAP 48, (c) HAP 24, (d) HAP 5 and (e) HAP 3

Based on these observations, the synthesis of HAP was successful based on the existence of the main functional groups of HAP, i.e. the hydroxyl group and phosphate group in each spectrum of HAP adsorbents. The reaction time exerted effects on the composition of the resulting HAP, which was clearly reflected from the band intensity of functional groups that appear in all spectra. A reaction time of 48 hours and 72 hours produced purer HAP structure, indicating that the reaction time is positively correlated with the conversion process of calcium carbonate, $CaCO_3$ to hydroxyapatite, HAP molecule.

The surface and texture porosity of the HAPs were determined by nitrogen adsorption/desorption measurements at 77 K and the results of BET analysis are presented in Table 1. The data have shown that the reaction time was

inversely proportional to the value of BET surface area. The HAP 3 exhibited the highest surface area, 126.51 $m^2/g$ while HAP 72 = gave the lowest value of BET surface area, 66.91 $m^2/g$. A possible explanation for this might be due to the agglomerate process that produced larger cluster of particles [28].

Table 1. The BET surface area, average pore volume and pore diameter of HAPs

| Type of Adsorbent | BET Surface Area ($m^2/g$) | Average Pore Volume ($cm^3/g$) | Average Pore Diameter (nm) |
|---|---|---|---|
| HAP 3 | 126.6 | 0.482 | 13.05 |
| HAP 5 | 87.8 | 0.330 | 12.77 |
| HAP 24 | 76.6 | 0.438 | 20.53 |
| HAP 48 | 74.6 | 0.389 | 17.99 |
| HAP 72 | 66.9 | 0.347 | 17.12 |

Figure 3 presents the isotherm graphs of HAPs produced at different reaction times. As shown in this figure, all the HAPs illustrated the physisorption isotherm type IV, indicating a mesoporous structure (2 – 50 nm in diameter). This type of isotherm was determined based on the shape of hysteresis loop formed during capillary condensation process occurred in the mesoporous structures [29]. Based on Figure 3, the hysteresis loops of HAPs at relative pressure ($P/P_0$) from 0.55 to 1.0 were of Type H4, thus indicating the presence of narrow-slit like pore pattern in the absorbents' structures.

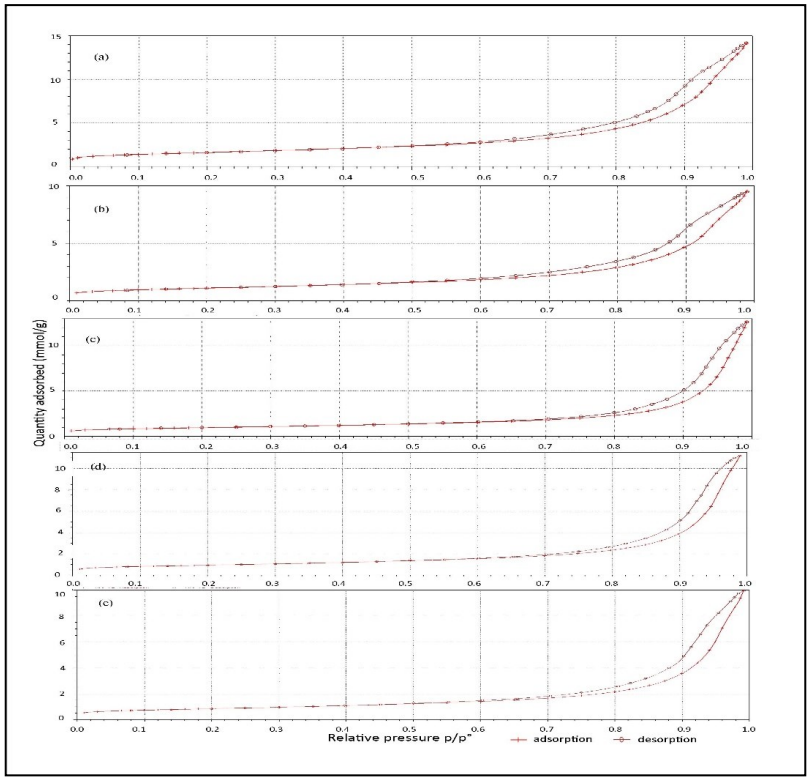

Figure 3. The nitrogen adsorption and desorption isotherm of HAP adsorbents. a) HAP 3, b) HAP 5, c) HAP 24, d) HAP 48 and e) HAP 72

The HAP formation was governed by the nucleation and growth process. By increasing the reaction time, more spaces are available for HAP particles growth, thus producing more surface for the attachment of nucleate particles [30]. Figure 4 showed the typical SEM images of the prepared HAP adsorbents. All the synthesized HAPs showed irregular shapes and were accumulated in bulky sizes due to the uneven surface of HAP and the formation of plat-like shape that overlapped each other. The morphology of HAP varies when using high temperature, carbonate sources, and the solvent extraction [31].

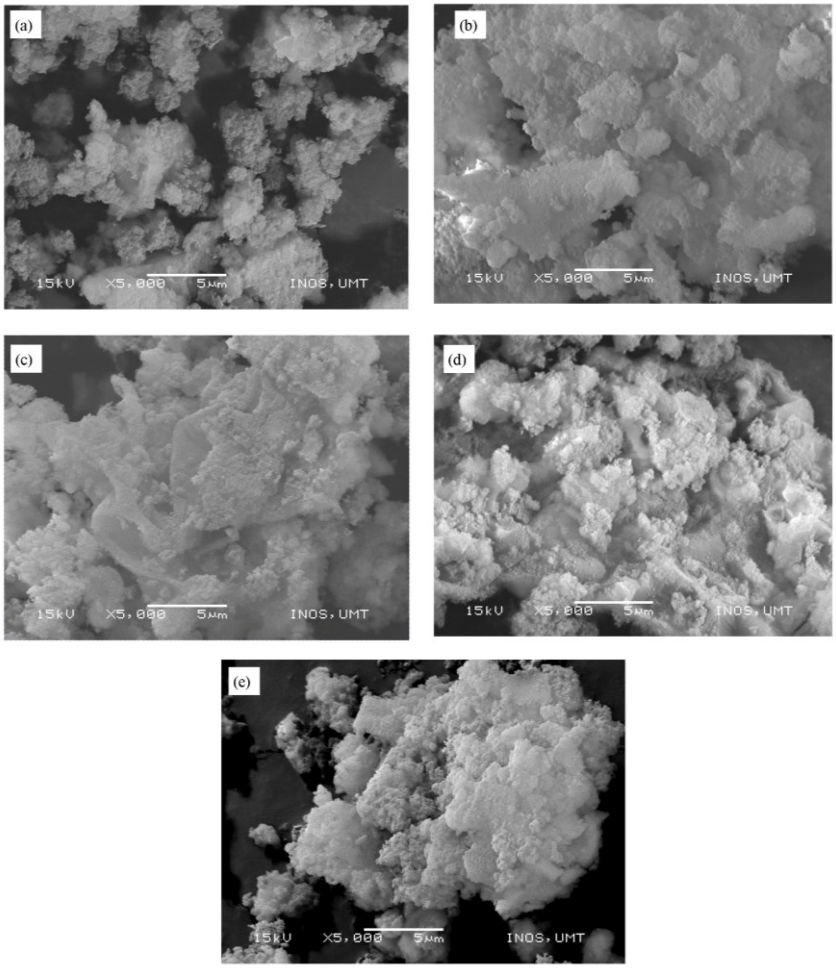

Figure 4. The scanning electron microscope (SEM) micrograph image of HAPs adsorbent at 5,000x magnifications. a) HAP 3,b) HAP 5, c) HAP 24, d) HAP 48 and e) HAP 72

**Selection of optimum HAP adsorbent**

The removal of lead ($Pb^{2+}$) by synthesized HAP adsorbents showed similar trends due to the similarities in their main chemical compositions (Figure 5). The selection of optimum adsorbent was based on the slope of the graph during the first 50 minutes of contact time, with HAP48 showing the steepest of slope followed by HAP72 > HAP3 > HAP24 > HAP5.

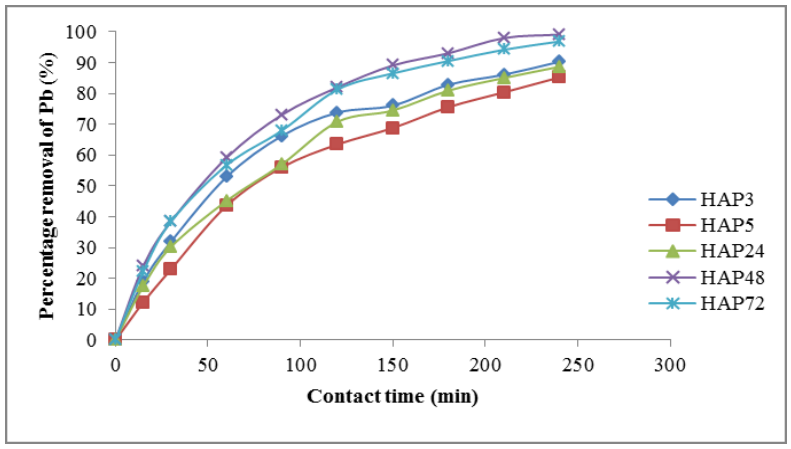

Figure 5. Removal of lead ($Pb^{2+}$) (%) by prepared HAP adsorbents. (adsorbent dose: 0.4 g; initial concentration and volume of $Pb^{2+}$: 25 mg/L, 200 mL)

The capability of HAP48 to absorb metal ($Pb^{2+}$) was the highest (12.28 mg/g), followed by HAP72 (11.62 mg/g), HAP3 (11.6 mg/g), HAP24 (10.28 mg/g) and HAP5 (10.4 mg/g). This result is similar to the XRD diffractogram (Figure 1), demonstrating the purity of HAP48 compared to the other adsorbents. It is clear that the time of reaction affected the chemical properties of HAP adsorbent by influencing the availability of active sites to adsorb the metal ions. Consequently, HAP48 adsorbent was determined as the optimum adsorbent for subsequent studies. HAP derived from seashells are used in wastewater treatment as fluoride removal [32], sulfur removal [33], and dye removal [34]. The HAP produced from similar source is also applied in other fields such as fluorescence-quenching platform for cancer cell detection [35], bone tissue engineering [36], and body implant application [37].

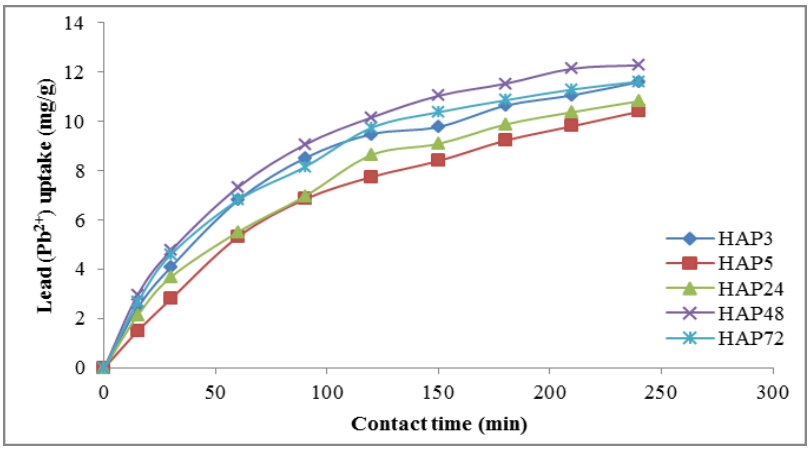

Figure 6. Effect of contact time on metal uptake ($Pb^{2+}$) by HAP adsorbents. (adsorbent dose: 0.4 g; initial concentration and volume of $Pb^{2+}$: 25 mg/L, 200 mL)

**Effect of initial metal ions concentration and contact time**

Metal adsorption by the absorbent is influenced by the initial concentration of $Pb^{2+}$ ion. Form the Figure 7, the adsorption of lead has occurred rapidly in the first 30 min and can be seen from the steep of slope at 0 to 30 minutes of contact time and subsequently, the system achieved equilibrium point after 90 minutes. This situation was due to the reduced availability of binding sites and the external sites were occupied [38].

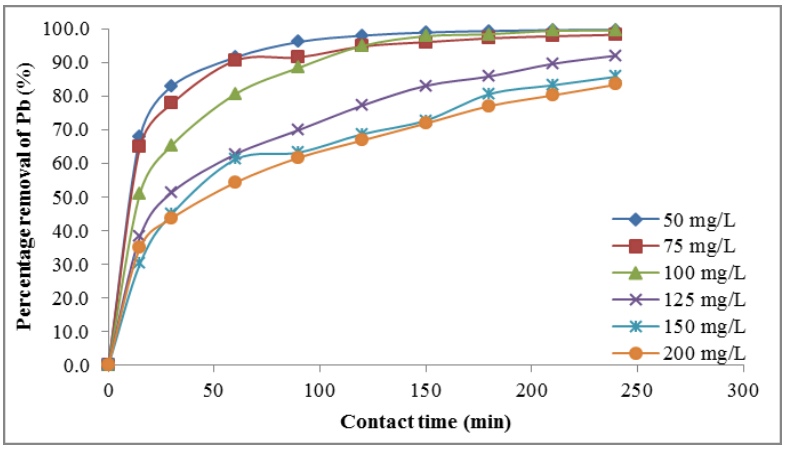

Figure 7. Effect of initial concentration of Pb on the percentage removal of ($Pb^{2+}$) (mg/g) by HAP48 adsorbent. (adsorbent dose: 0.4 g; volume of $Pb^{2+}$: 200 mL)

From Figure 8, the lowest initial concentration of $Pb^{2+}$ (50 mg/mL) achieved equilibrium in the shortest time compared to other higher initial concentrations in terms of the quantity of metal adsorbed ($Pb^{2+}$). During low initial concentration, metal ions are adsorbed by HAP on specific active sites. As the initial concentration of metal increases, so was the adsorption rate. The lowest initial concentration of $Pb^{2+}$ achieved equilibrium fastest is due to the static weight of adsorbent [39].

The maximum uptake of $Pb^{2+}$ by HAP48 achieved equilibrium at 60 minutes of contact time for initial concentration of 50 mg/L (20.87 mg/g) and 75 mg/L (31.18 mg/g). However, higher initial concentration required longer contact time to achieve equilibrium, 120 minutes for concentration 100 mg/L, 150 minutes for 125 mg/L, 180 minutes for 150 and 200 mg/L with the increased of adsorption capacity, 43.94 mg/g, 49.09 mg/g, 58.31 mg/g, and 73.77 mg/g, respectively. This similar pattern was also reported from previous study on methylene blue adsorption using activated carbon discovered from pineapple leaf [22].

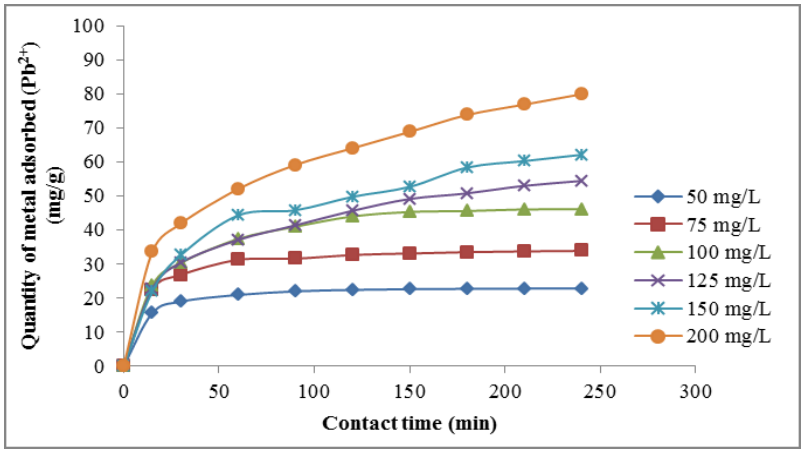

Figure 8. Effect of initial concentration of Pb on the quantity of metal adsorbed ($Pb^{2+}$) (mg/g) by HAP48 adsorbent. (adsorbent dose: 0.4 g; volume of $Pb^{2+}$: 200 mL)

**Kinetic adsorption study**

The adsorption experiment data of lead was fitted to pseudo-first-order and second-order as shown in Figure 9. The value of $R^2$ of linear equation approaches value 1 designates that the respective equation corresponds well to the experimental data [22]. Therefore, the kinetic adsorption was fitted well to the pseudo-second-order model, with $R^2$ value of 0.9994 for the bio adsorption system. This model, based on the chemisorption mechanism for metal ions interaction with adsorbent surface, was suggested as the rate-limiting step in HAP48 adsorbent [40]. This mechanism also described the physicochemical interactions between the two phases [41].

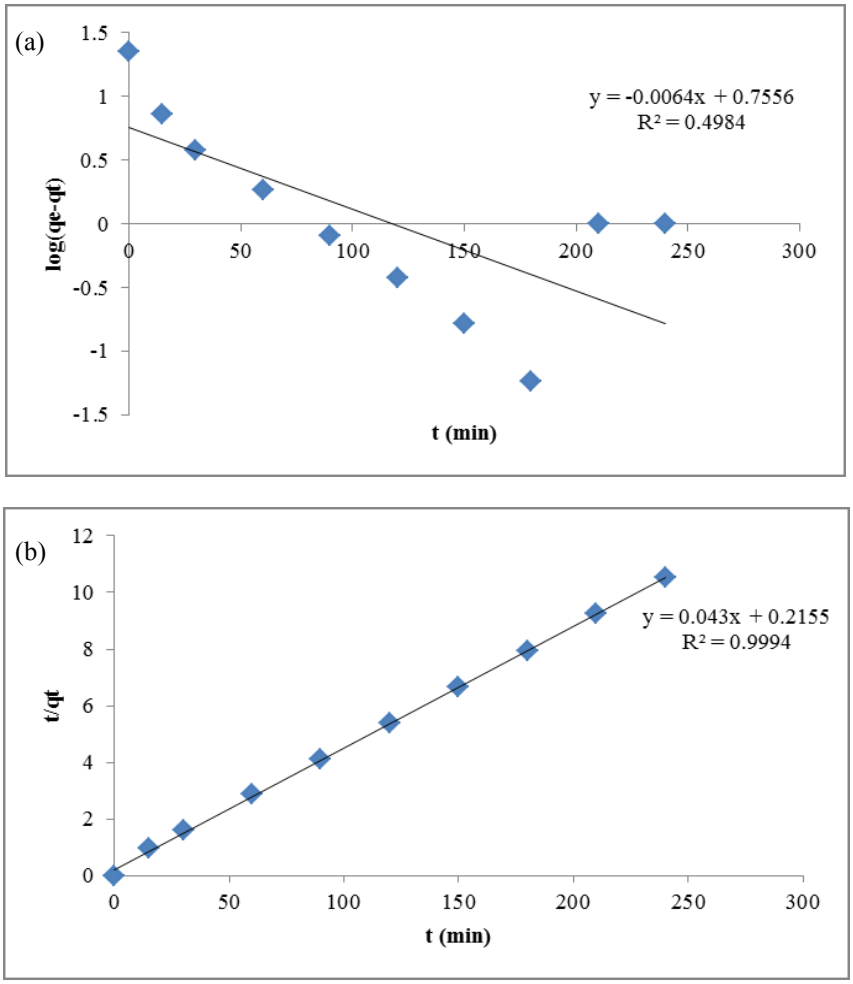

Figure 9. Pseudo-first-order (a) and pseudo-second-order (b) for kinetics model of $^{Pb2+}$ adsorption onto HAP48

Initial concentration was inversely proportional to the adsorption rate, $k_2$ and displayed in Table 2. Even increasing of initial concentration was decreasing the rate constant, $k_2$, the adsorption capacity, $q_e$ was showed increasing trend. Similar pattern to the work on lead removal using modified coconut shells [42].

**Equilibrium adsorption study**

The linear plots for both isotherms are shown in Figure 10. It clearly presented that the adsorption data were well fitted with Langmuir isotherm, with $R^2$= 0.973 compared to Freundlich isotherm ($R^2$ = 0.865). The Langmuir model describes the formation of a monolayer adsorbate on the outer surface of the adsorbent, and no more adsorption

takes place once a saturation value is reached [43]. The $R_L$ value of 0.013 (Table 3) indicates that the adsorption of $Pb^{2+}$ onto HAP48 was favourable ($0 < R_L < 1$) and had strong interaction with each other.

Table 2. The pseudo-second-order kinetic parameters for lead removal by HAP48 adsorbent

| $C_{0\ (mg/L)}$ | $q_{e\ (mg/g)}$ | $k_2$ (g/mg min) | h (mg/ g min) | $R^2$ |
|---|---|---|---|---|
| 50 | 23.26 | 0.0086 | 4.640 | 0.999 |
| 75 | 34.48 | 0.0047 | 5.593 | 0.999 |
| 100 | 48.54 | 0.0016 | 3.837 | 0.996 |
| 125 | 57.47 | 0.0008 | 2.493 | 0.984 |
| 150 | 65.79 | 0.0006 | 2.488 | 0.978 |
| 200 | 84.03 | 0.0005 | 3.285 | 0.978 |

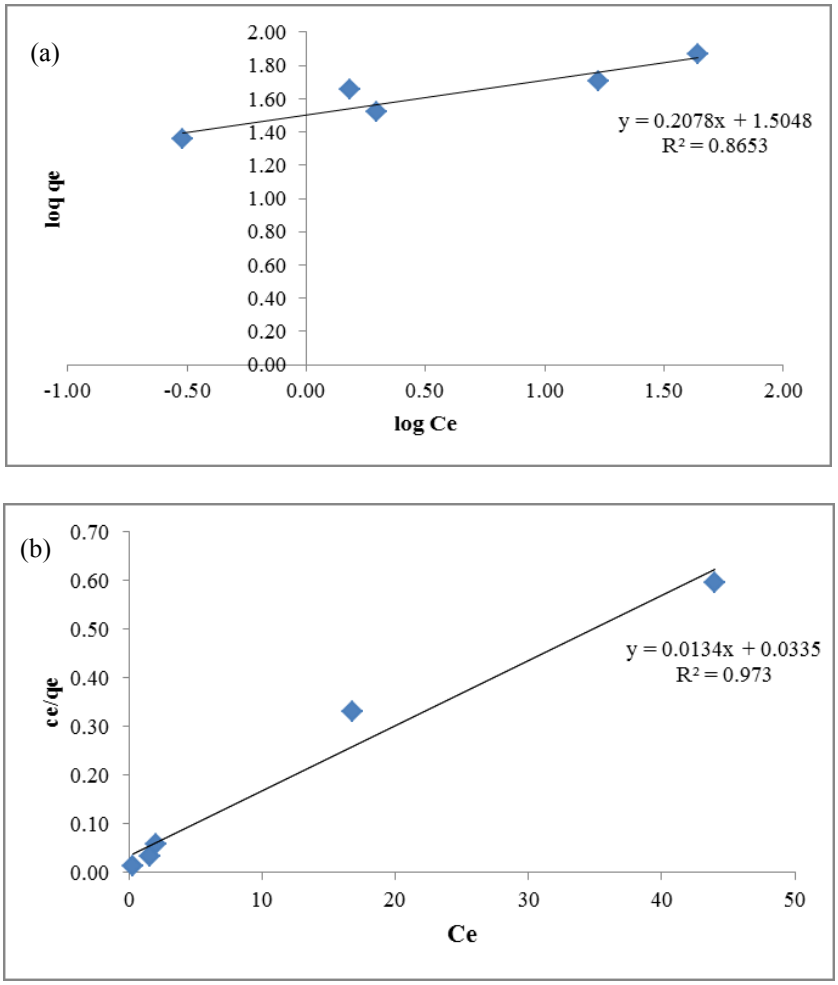

Figure 10. Freundlich (a) and Langmuir (b) adsorption isotherm models of $Pb^{2+}$ adsorption onto HAP 48

Table 3. Freundlich and Langmuir isotherms constants of lead ($Pb^{2+}$) biosorption onto HAP 48 adsorbent

| **Freundlich Constants** | | | **Langmuir Constants** | | | |
|---|---|---|---|---|---|---|
| **$K_F$** | **n** | **$R^2$** | **$q_m$ (mg/g)** | **b (L/mg)** | **$R^2$** | **$R_L$** |
| 31.97 | 4.812 | 0.8653 | 74.63 | 0.4 | 0.973 | 0.013 |

The maximum sorption capacity, $q_m$ of HAP48 was 74.63 mg/g. Using dead calcareous skeletons (CS) as calcium carbonate source, maximum adsorption capacities of 26.5 and 38.5 mg/g for the Cd(II) and Pb(II) column, respectively were achievable [44]. However, *Anadara inaequivalvis* seashells powder had higher biosorption capacity of Cu(II) and Pb(II) (330.2 and 621.1 mg/g, respectively) [38]. The obtained result was postulate to be affected by the orthorhombic crystal structure of aragonite and the condition of the experiment conducted.

The interaction mechanism between $Pb^{2+}$ ions and HAP48 adsorbent was determined via dissolution and precipitation process. The chemisorption interaction had occurred via the formation of new chemical bonding between adsorbate and adsorbent surface and was explained in the chemical reactions below [45]:

$$Ca_{10}(PO_4)_6(OH)_2 + 14H_2^+ \longrightarrow 10Ca^{2+} + 6H_2PO_4^- + 2H_2O \text{ (Dissolution process)} \quad (12)$$

$$10Pb^{2+} + 6H_2PO_4^- + 2H_2O \longrightarrow 14H_2^+ + Pb_{10}(PO_4)_6(OH)_2 \text{ (Precipitation process)} \quad (13)$$

## Conclusion

In this study, a worthwhile bio adsorbent from marine bio-waste, HAP48 bio-adsorbent was successfully synthesized with optimal characteristics for the application of the removal of lead from contaminated water. Though the resulting HAP resembles that found naturally in terms of its composition, this continuous research efforts have produced new economic synthesis approaches and can be applied in future research. For subsequent study, the produced HAP will be combined with other potential adsorbents, as well as its absorbent ability in other multi-metal ions, adsorbent reusability and its production on pilot scale.

## Acknowledgement

The authors would like to Thank and gratitude to Universiti Malaysia Terengganu for providing the facilities to conduct this research.

# THE ANALYSIS OF THERMAL DECOMPOSITION PRODUCTS GENERATED FROM PORCINE TISSUES EXPOSED TO OUTDOOR BURNING CONDITIONS

## (Analisis Produk Penguraian Haba Yang Terhasil Daripada Tisu Khinzir Yang Terdedah Kepada Pembakaran Terbuka)

**Abstract**

Volatile products commonly known as pyrolytic products, are thermal decomposition products generated from the various fuels that are present at a fire scene due to heat exposure. When a fire scene involves human remains, the volatile species generated from the remains can be mistaken with others residues due to the presence of interfering products or ignitable liquid residues from the fire scene. Knowledge of the type of products generated from human remains in real life fire scenarios is crucial under these circumstances. Thus, this study was executed to test the robustness and validity of the pyrolytic data generated from porcine tissue under indoor laboratory burning conditions to those generated under outdoor burning conditions. Porcine bone samples were burnt under outdoor conditions until the ignition of fat occurred (temperatures exceeding 250 °C). The pyrolytic products generated were absorbed onto activated carbon tablets that were incubated in an oven for 16 hours at 80 °C and then desorbed with pentane and injected into the Gas Chromatography-Mass Spectrometry (GC-MS). The 60 pyrolytic profiles obtained were in the range of *n*-alkanes, *n*-alkenes, *n*-aldehydes, aromatics and nitriles, similar to those obtained from the indoor laboratory burning data but with the additional presence of *n*-aldehydes. Results from this study has indicated that the human pyrolytic data model generated indoors is a good representative of outdoor burning conditions and has also successfully clarified the inconsistencies in terms of the presence and absence of *n*-aldehydes from porcine and human pyrolytic data.

**Abstrak**

Sebatian meruap mudah kebiasaannya dikenali sebagai produk pirolitik merupakan produk penguraian menggunakan haba yang terhasil daripada pelbagai jenis bahan api yang terdapat di sekitar kawasan kebakaran disebabkan oleh pendedahan kepada haba. Apabila terdapat sisa kebakaran yang melibatkan tulang manusia, spesis sebatian mudah meruap yang dikesan boleh disalah anggap dengan sisa lain disebabkan produk luar atau pun sisa cecair mudah terbakar. Oleh yang demikian, kajian ini bertujuan untuk mengenalpasti ketepatan dan kesahihan data pirolitik yang terhasil daripada tisu khinzir melalui pembakaran secara tertutup di dalam makmal dengan pembakaran secara terbuka. Tulang khinzir dibakar secara terbuka sehingga suhu nyalaan pembakaran lemak tulang berlaku (suhu melebihi 250 °C). Produk pirolisis yang dijana diserap menggunakan penjerapan karbon teraktif dalam bentuk tablet dengan menggunakan inkubator selama 16 jam pada suhu 80 °C dan seterusnya dinyaherap dengan pentana dan dianalisis menggunakan Kromatografi Gas-Spektrometri Jisim (GC-MS). Sejumlah 60 jenis produk pirolitik yang terhasil adalah sebatian kompaun *n*-alkana, *n*-alkena, *n*-aldehid, aromatik dan sebatian nitril. Produk yang terhasil adalah sama dengan data pembakaran di dalam makmal tetapi dengan penambahan kehadiran *n*-aldehid. Keputusan kajian ini menunjukkan bahawa model data pirolitik manusia yang terhasil daripada pembakaran dalam makmal boleh menjadi rujukan yang baik untuk

situasi kebakaran terbuka, dan berjaya menjelaskan percanggahan dari segi kehadiran dan ketiadaan *n*-aldehid daripada data pirolitik khinzir dan manusia.

**Kata kunci:** penguraian menggunakan haba, tulang khinzir, produk pirolitik, penjerapan karbon teraktif, kromatografi gas-spektrometri jisim

## Introduction

Fire is often used as a tool to conceal and destroy evidence of a crime, particularly in terms of obscuring the detection of human remains [1, 2] as it is commonly believed that fire or the effects of fire can completely destroy any forensic evidence present. When a human body is exposed to fire, a variety of physical, chemical and biological changes are exerted to the muscles, tissues and bony structure of the body [3 – 5]. These changes can indefinitely pose difficulty to a fire investigator, in locating and identifying human remains, if any, at a fire scene. Moreover, it is a daunting task to differentiate between small fragments of bone or teeth that are severely burnt and/or dismembered from charred fragments of fire debris [3, 4], even for trained anthropologies [3]. This is due to the similarity in overall appearance for both components, especially when mixed together with various fuel loads at the fire scene. The lack of knowledge and experience in locating these burnt remains, in addition to the limited research data available in identifying the pyrolytic profile of burnt human remains [6] as opposed to the vastly known and readily available pyrolytic database of ignitable liquid residue (ILR) could potentially lead investigators to a false positive or false negative conclusion [7].

Previous work in the field of pyrolytic data from human and porcine tissue were conducted by DeHaan et al. [8], in which they determined the presence of *n*-alkanes, *n*-aldehydes, *n*-alkenes and aromatic compounds from these samples burnt in a contained microfurnace at 300 °C, 500 °C and 700 °C, respectively. In the recent work conducted by Agu [9] and Gabriel [7] on human and porcine tissue exposed to an open flame but under controlled laboratory conditions, identified the consistent presence of volatile compounds in the range of *n*-alkanes, *n*-alkenes, aromatic alkenes, *n*-alkyl-benzenes and nitriles when exposed to temperatures between 500 °C to 800 °C. No *n*-aldehydes were present at these temperature ranges as opposed to DeHaan et al.'s [8] work. However, both Gabriel [7] and Agu [9] identified the presence of *n*-aldehydes at pre-ignition temperatures (below 300 °C). Variations in temperature, methodologies and particularly exposure conditions (indoor and outdoor, contained and open) could certainly cause these documented discrepancies in the pyrolytic profile obtained from human and porcine tissue.

This paper addresses these issues, by testing the robustness of the pyrolytic data and key indicators established from porcine tissue under controlled laboratory conditions to those generated from outdoor conditions. The similarity and differences in terms of the chemical fingerprint of thermal decomposition products from porcine tissue; as a representation of human tissue [7, 8], exposed under both; indoor laboratory and outdoor conditions were analysed, compared and reported.

## Materials and Methods

This study is an extension of the work executed by Gabriel [7], who conducted indoor laboratory burning using porcine bone. This study adapted similar experimental procedures but varied the conditions to outdoor burning.

### Standard test mixture

A 1 mg/mL standard solution (Sigma Aldrich, UK) containing 12 high purity compounds; benzene, toluene, octane, ethyl-benzene, *p*-xylene, propyl-benzene, decane, butyl-benzene, dodecane, tridecane, tetradecane and pentadecane, were prepared and placed into six individual gas chromatography (GC) vials (Agilent, UK). The six vials were then placed into an auto-sampler of a Gas Chromatography-Mass Spectrometry (GC-MS) (Shimadzu, UK) and injected into the instrument. Information from the individual peak area and retention time of each compound provided data that was then used to test the robustness of the instrument and analysis by revealing the relative standard deviation (RSD) values.

### GC-MS condition

The temperature of the injector was maintained at 250 °C, set to splitless mode with a 20:1 split ratio and 32.7 mL/min split flow. A 128-0122 DB-1MS column (22 mm length × 0.2 mm inner diameter × 0.33 $\mu$m film

thickness) (Crawford Scientific, UK) was used in this experiment. Helium was used as a carrier gas, flowing at a constant rate of 1 mL/min. The oven temperature was set at 40 °C and held for five minutes, then ramped at 15 °C/min to reach the final temperature of 280 °C and held for two minutes. The temperature of the detector was maintained at 250 °C. Data collected from the GC-MS analysis were identified based on their *m/z* values that were matched against the standard test mixture and National Institute of Standards and Technology (NIST) (NIST/EPA/NIH Mass Spectral Library).

**Sample preparation**

Porcine femur bones in the range between five to six months of age were utilised in this work, purchased from the Kajang Wet Market, Selangor. The bones were labelled according to the date purchased and stored in a laboratory freezer at -21°C. Before cutting, the bones were defrosted at room temperature for 30 to 40 minutes. The epiphysis of each bone was detached using a bench vice and a hacksaw in order to reduce variations in the composition of the bone samples that could potentially alter the resultant pyrolytic data [7]. Scissors and tweezers were used to remove any residual soft tissues on the bone. The remaining diaphysis was then cut into 25 ± 1.5 g sizes as recommended in the indoor laboratory burning experiment, to be the optimum size for best pyrolytic data. Each 25 ± 1.5 g bone fragment was then placed into individual 125 mL aluminium tin can (WA Products, UK) respectively. The process above was repeated until six 25 ± 1.5 g bone samples were obtained.

**Thermal decomposition process**

The outdoor burning experiment was set up at the Forensic Science Simulation Site, UKM, Bangi, Selangor. A retort stand was placed on a flat ground and the tin can (with the lid removed) containing the bone sample was clamped onto it to hold it in place during the burning process. The sample was heated using a portable gas canister burner (Sigma Aldrich, UK) placed under the tin can at approximately 3 cm from the tip of the canister to the base of the tin. A k-thermocouple connected to a digital thermometer model 6802 II (Signstek Ltd, London) was used to monitor the temperature of the bone sample during pyrolysis. The sample was allowed to burn until the ignition of fat occurred and was allowed to burn for five minutes thereafter. Ten seconds before the five minute mark, the gas canister and k-thermocouple were removed swiftly and an empty lid was placed over the tin can in order to extinguish the flame. The covered tin can containing the burnt sample was then left to cool at room temperature for four minutes as recommended in the indoor laboratory burning experiment.

The empty lid was then replaced with another lid containing an activated carbon tablet, which was hooked onto a paper clip and held on the lid with the use of magnets. The tin was sealed shut and incubated in oven for 16 hours at 80 °C [10]. After the incubation process, the activated carbon tablet was removed and placed into a 1 mL GC vial (Agilent, UK) and desorbed with 1 mL of pentane. The GC vial containing the desorbed activated carbon in pentane was then introduced into the GC-MS. The entire process was repeated until six sets of results were obtained. The similarities and differences in terms of volatile compound detected in outdoor burning conditions were then compared to the results obtained from the indoor laboratory burning conditions.

## Results and Discussion

Porcine tissue was chosen as a representative of human tissue as Gabriel [7], Agu [9] and DeHaan et al. [8] identified clear similarities with minor differences in the pyrolysis products generated across both tissues. Porcine bone, in particular, possesses the closest resemblance to human bone as compared to other animals [11] in terms of its morphology, bone remodelling process and structure [12, 13], diameter and the area of femoral cross-sectional, structure of lamella bones and regeneration rate [11].

Across the six replicates, volatile compounds in the range of $C_7$ to $C_{17}$ *n*-alkanes and $C_4$ to $C_{17}$ *n*-alkenes as well as *n*-cycloalkanes, aromatics, *n*-alkyl-benzenes, $C_5$-$C_6$ *n*-aldehydes, nitriles, furans, disulfide alcohol and dienes were detected, as displayed in Table 1. Table 1 also shows the volatile compounds that are consistently present across all six replicates of burnt porcine bone samples, namely; $C_8$ to $C_{15}$ *n*-alkanes and $C_4$ to $C_{16}$ *n*-alkenes together with *n*-cycloalkanes, aromatics, *n*-alkyl-benzenes, $C_5$ *n*-aldehyde and a nitrile. Six individual Total Ion Chromatograms (TIC) for each set are illustrated in Figure 1 till Figure 6, respectively.

Table 1. Volatile compounds generated from six outdoor burning of porcine bone samples. A tick represents that the compound is present in the sample

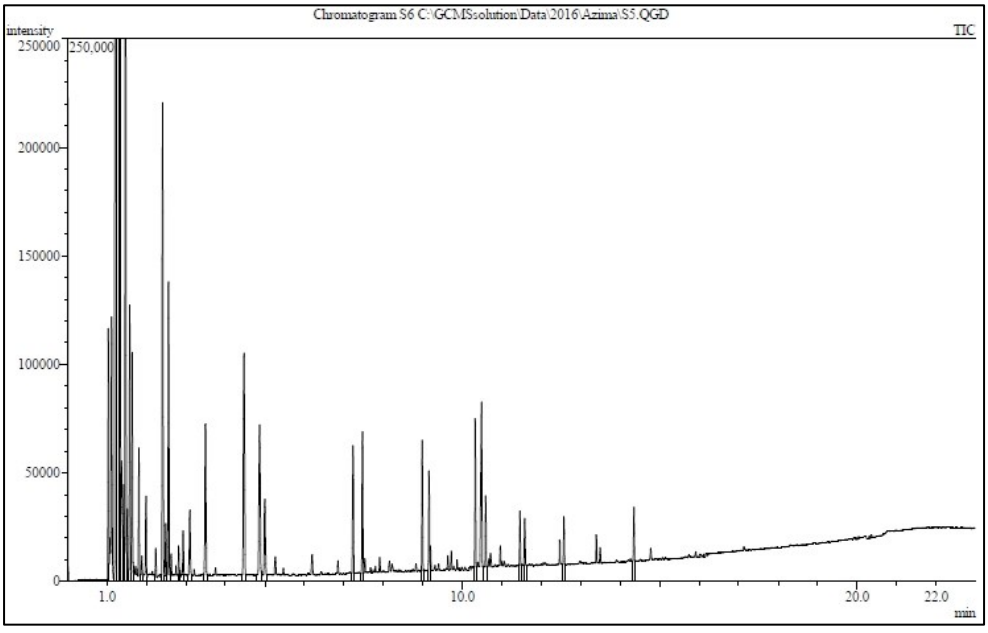

Figure 5. TIC of burned porcine bone (Set 5)

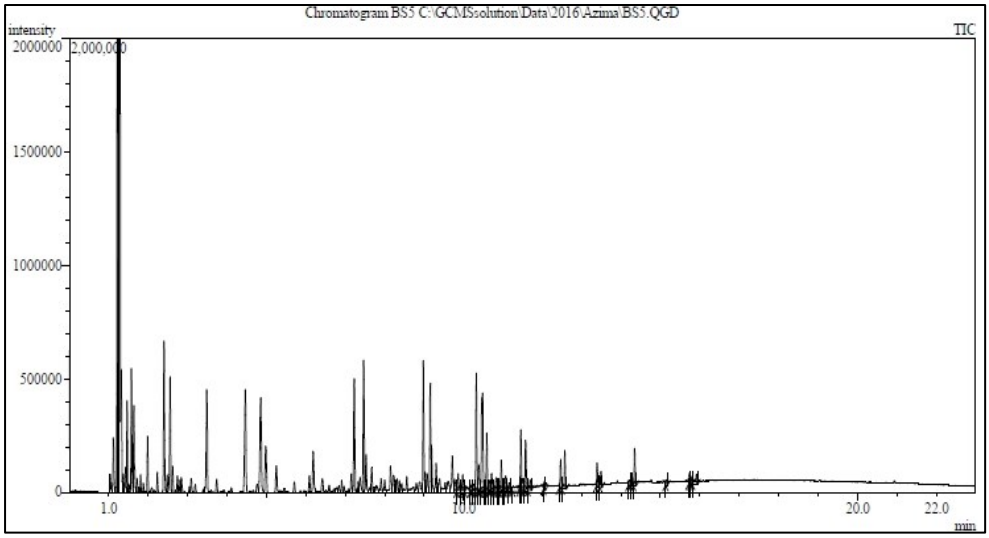

Figure 6. TIC of burned porcine bone (Set 6)

While majority of the compounds appeared in at least four of the total six repetitions, alcohol (nonanol), *n*-alkene (1-pentadecene) and nitrile (hexadecanitrile) only appeared in three or less repetitions. Meanwhile, hexadecanitrile was only present in three out of the six repetitions, although a small peak in every chromatogram with *m/z* values of 38 and 44 were consistently detected across six repetitions. It's absence could potentially be due to the decomposition and fragmentation of hexadecanitrile into smaller daughter fragments that rendered it undetectable in the GC-MS. Similar to the indoor burning data in Gabriel's research [7], this work (Table 1) also documented the presence of dimethyl-disulfide and dienes, although inconsistently across the repetitions. The present of furan in this work could be due to the variation in the environmental conditions exposed particularly the auto-ignition of fat that occurred multiple times in one complete cycle of burning as shown in Figure 7(a).

Higher temperature with broader exposure durations have been documented in the literature to cause the volatilization of low vapour pressure (higher molecular weight) *n*-alkanes and *n*-alkenes [14]. Although this experiment attained sufficient temperatures to volatilise these compounds, the inconsistencies in the presence of high molecular weight *n*-alkanes and *n*-alkenes in this work (Table 1) could be due to the short length of exposure and multiple ignitions experienced, as illustrated in Figure 7(a).

The differences in the time-temperature profiles of six replicates of porcine bone samples across indoor laboratory and outdoor burning conditions are illustrated in Figure 7. The initial temperature of all laboratory samples in Figure 7(b) increased rapidly and attained temperatures above 250 °C after seven minutes. This was not the case for outdoor samples in Figure 7(a) as most samples attained temperatures of 250 °C within one minute. In Figure 7(a), it is clearly seen that the ignition of fat occurred several times for sets 1, 2 and 4, but died down almost instantly before the final ignition that lasted for five minutes. It is noted that the ignition of fat in set 2 occurred once at 300 seconds but instantly died off and ignited again at 500 seconds. This was not the case for laboratory burning as the ignition of fats occurred once and could sustain itself for five minutes as shown in Figure 7(b). This occurrence could be due to the variation in the concentration of oxygen that is largely controlled by wind conditions in outdoor burning [15]. On the contrary, in indoor burning, the supply of oxygen was steady and controlled throughout the entire experiment, facilitating a steady and long-lasting flame [16]. It is also noted in Figure 7(b) that the maximum temperature attained in indoor burning was above 700 °C. As for the outdoor burning, the maximum temperature attained as illustrated in Figure 7(a) was only 580 °C. The differences in temperatures attained could also be due to the variations in oxygen availability that could alter the burning efficiency [15, 16].

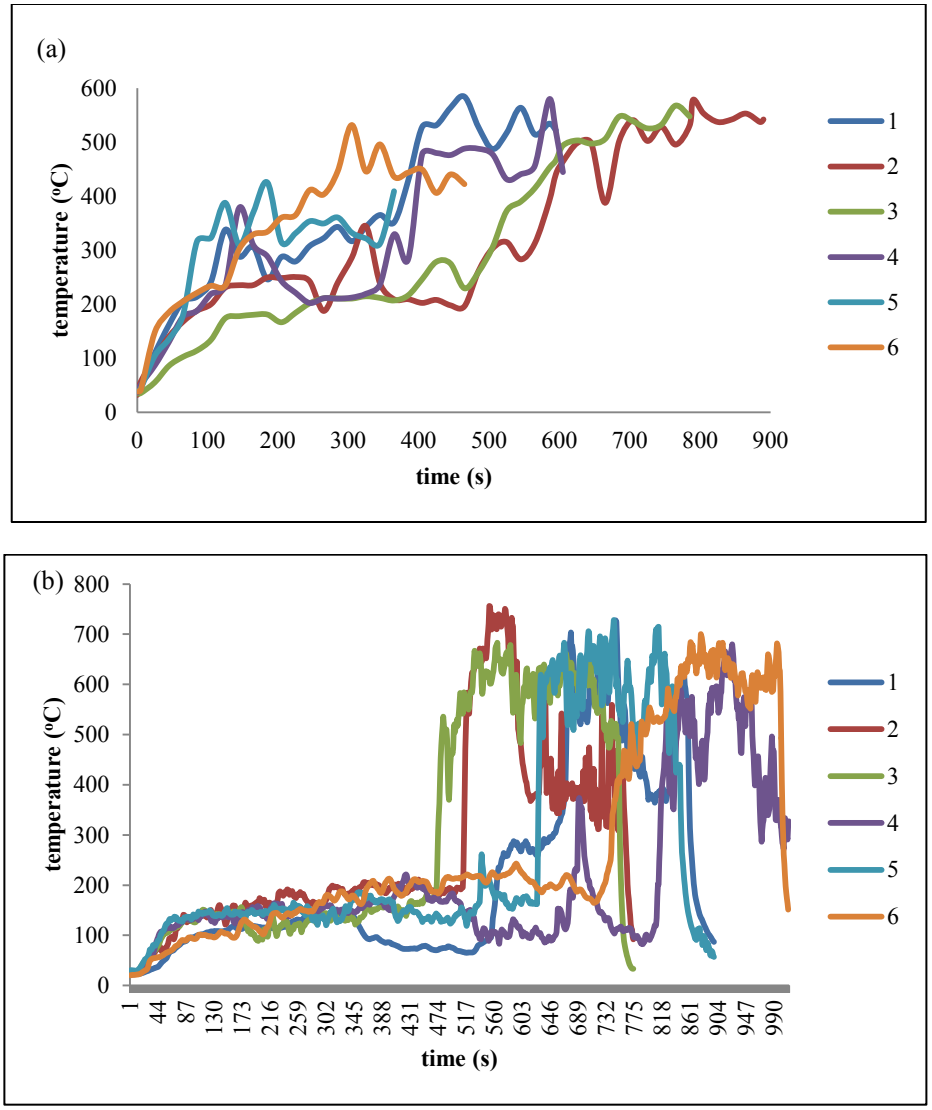

Figure 7. Overlay of six time-temperature profiles of **(a)** outdoor burning condition and (b) indoor laboratory burning condition [7]

Pyrolysis products generated from the outdoor burning of porcine bone samples that consistently appeared across six repeats were found to be similar with those generated from indoor laboratory burning condition as displayed in Table 2. These include $C_8$ to $C_{16}$ *n*-alkanes and *n*-alkenes (1-octene, octane, 1-nonene, nonane, 1-decene, decane, 1-undecene, undecane, 1-dodecene, dodecane, 1-tridecene, tridecane, 1-tetradecene, tetradecane, pentadecane, 1-hexadecene) and aromatic compounds (benzene, toluene, ethyl-benzene, propyl-benzene). Five volatile compounds that were detected consistently in this work but not consistent in indoor laboratory burning are methyl-cyclopentane, 3-methyl-butananitrile, 2-octene, butyl-benzene and pentyl-benzene. The presence of *n*-aldehydes (pentanal and hexanal) in this work was the major differences noted in terms of pyrolytic profiles when compared to indoor laboratory burning condition. No *n*-aldehydes were detected from indoor laboratory burning of porcine bone samples that were exposed to temperatures above auto-ignition (250 °C) [7] under longer burning durations above 900 seconds.

Similar findings were also noted by Purevsuran et al. [17] for their samples that were exposed to temperatures above 500 to 700 °C under extended burning durations of about 4 to 5 hours. However, *n*-aldehydes were detected in the pre-ignition samples (temperatures below 300 °C) in Gabriel's work [7] under indoor laboratory burning conditions. Contrary to Gabriel [7] and Purevsuran et al.'s [17] finding, DeHaan et al. [8] detected the present of straight chain *n*-aldehydes at high temperature (above 700 °C) but with shorter burning durations of ten seconds. The presence or absence of *n*-aldehydes as a by-product of pyrolysis from porcine bone samples is largely related to the temperature in which the samples were exposed; higher temperature induces the decomposition and oxidation of *n*-aldehydes into smaller compounds and renders it undetectable by the instrument [8, 9]. The presence of *n*-aldehyde in this work may be due to the lower temperature profiles experienced by the sample and the multiple ignitions as illustrated in Figure 7(a). Besides temperature, the exposure duration also plays an important role in the detection of *n*-aldehydes [7]. In the indoor laboratory burning conditions [7] and in Purevsuren et al.'s [17] work, burning occurred for extended periods of more than 900 seconds and 4 hours respectively as compared to DeHaan et al.'s work [8] (ten seconds) and the outdoor burning conditions in this work (800 seconds), where burnings were shorter, thus preserving the *n*-aldehydes from being decomposed or totally consumed during the burning process [7].

Table 2. Comparison of pyrolysis products that were detected consistently across six sets of repeats between indoor and outdoor burning conditions [7]

| No. | Compound (Outdoor Burning) | Compound (Indoor Laboratory Burning) |
|---|---|---|
| 1. | 1-butene | **benzene** |
| 2. | methyl-cyclopentane | **toluene** |
| 3. | **benzene** | **1-octene** |
| 4. | pentanal | **octane** |
| 5. | 3-methyl-butanitrile | **ethyl-benzene** |
| 6. | **toluene** | *p*-xylene |
| 7. | **1-octene** | **1-nonene** |
| 8. | **octane** | **nonane** |
| 9. | 2-octene | **propyl-benzene** |
| 10. | **ethyl-benzene** | **1-decene** |
| 11. | **1-nonene** | **decane** |
| 12. | **nonane** | **1-undecene** |
| 13. | **propyl-benzene** | **undecane** |
| 14. | **1-decene** | **1-dodecene** |
| 15. | **decane** | **dodecane** |
| 16. | butyl-benzene | **1-tridecene** |
| 17. | **1-undecene** | **tridecane** |

## Conclusion

Indoor laboratory burning conditions generated consistent results in terms of the pyrolysis products generated and the time-temperature profiles in comparison to outdoor burning conditions. Pyrolytic data generated in this work were determined to be in the range of *n*-alkanes, *n*-alkenes, *n*-aldehydes, aromatics and nitrile compounds, similar to those obtained from indoor laboratory burning but with the additional presence of *n*-aldehydes. Results from this study has indicated the human pyrolytic data model generated indoors to be a good representative of outdoor conditions and has also successfully clarified the inconsistencies in terms of the presence and absence of *n*-aldehydes from porcine and human pyrolytic data. The use of activated carbon tablet as a substitute of activated carbon strip (ACS) for the adsorption of pyrolytic products is also highlighted in this work.

In terms of future prospects, pyrolytic experiments using other parts of the porcine carcass would be an advantage. This will reveal further information about the type and consistency of pyrolysis products generated by different types of tissues in a fire. In addition, it would also be particularly interesting to explore the origin of porcine tissues that have been subjected to burning in the presence of ignitable liquids and clothing material. Data generated from this process would be helpful in identifying the effects of interfering products that can possibly be generated, if any, on the key indicators of human remains in the presence of contaminants.

## Acknowledgement

The authors would like to appreciate Faculty of Health Sciences, Universiti Kebangsaan Malaysia for the facilities and support that are provided for this study. We would also like to extend our gratitude to The Centre for Water Research and Analysis (ALIR), UKM for collaboration in providing the facilities which is a freezer to store the bone samples.

**Abstract**

Bivalve, such as marsh clam (*Polymesoda expansa*) feed by filtering most of the suspended particle in water that surrounding them. Lots of elements being trap into their body via this feeding habit including pollutant such as trace metals. Unfortunately, these marsh clams were taken directly by human as their daily diet. Due to its ability to filter water, marsh clam was used to monitor the level of trace metals in aquatic system in significant place such as industrial area. Therefore, this study was carried out at Kelantan River near to the industrial area in Pengkalan Chepa, Kelantan, Malaysia. A total of 80 marsh clams were collected from 4 different sites to represent a different environmental condition. The in-toto of the marsh clam were dissected and digest with suprapur nitric acid by using Teflon Bomb method. Six metals were determined by using Inductively Coupled Plasma Mass Spectrometry including chromium, iron, copper, cadmium, lead and zinc. The highest mean concentration of all metals studied (Cr 45.03 µg/g dry weight; Fe 1.28 µg/g dry weight; Cu 21.8 µg/g dry weight; Cd 1.15 µg/g dry weight; Pb 2.31 µg/g dry weight; Zn 898 µg/g dry weight) in the marsh clam tissue was recorded at station 4 which is near to the industrial area discharge. Whereas, those concentration were lower at Station 1 and Station 2, which located at the upstream and far from the industrial area discharge. On the other hand, the size of marsh clam does not significantly correlate to the concentration of selected trace metals. Level of selected metals in some the samples were exceeded the permissible limit provide by Malaysia Food Safety and Food Regulation 1985 especially marsh clam collected from station near to industrial area. Therefore, marsh clam collected for consumption near to industrial area need to be continuously monitor to prevent any acute effect on human health risk.

**Abstrak**

Kerang seperti lokan (*Polymesoda expansa*) memperolehi makanan melalui proses penapisan zarah-zarah terampai di dalam air di sekeliling mereka. Banyak unsur-unsur elemen yang terperangkap di dalam badan mereka melalui tabiat makan ini termasuklah logam surih. Malangnya, lokan ini telah diambil oleh manusia dan dijadikan sebagai diet harian mereka. Disebabkan keupayaan lokan ini untuk menapis air, lokan telah digunakan untuk memantau tahap pencemaran logam berat di dalam persekitaran akuatik terutamanya di kawasan perindustrian. Oleh itu, kajian ini telah dijalankan di Sungai Kelantan berhampiran dengan kawasan perindustrian di Pengkalan Chepa, Kelantan, Malaysia. Sebanyak 80 lokan yang dikutip dari 4 kawasan

penyampelan untuk mewakili keadaan persekitaran yang berbeza. Keseluruhan tisu lembut lokan tersebut telah dikeluarkan dan dicerna dengan menggunakan kaedah Teflon bom dengan bantuan asid nitric suprapur. Kepekatan 6 logam telah ditentukan menggunakan spekrometri jisim gandingan aruhan plasma termasuk logam kromium, ferum, kuprum, cadmium, plumbum dan zink. Purata kepekatan logam yang dikaji (Cr 45.03 µg/g berat kering; Fe 1.28 µg/g berat kering; Cu 21.8 µg/g berat kering; Cd 1.15 µg/g berat kering; Pb 2.31 µg/g berat kering; Zn 898 µg/g berat kering) di dalam tisu lokan tersebut dicatatkan di stesen 4 yang terletak berhampiran dengan pelepasan sisa kawasan perindustrian. Kepekatan logam adalah lebih rendah di dalam lokan yang dikutip dari Stesen 1 dan Stesen 2 yang terletak di hulu sungai dan jauh daripada kawasan pelepasan sisa perindustrian. Selain itu, saiz lokan tidak mempengaruhi kadar kepekatan logam yang dikaji. Tahap kepekatan logam yang dikaji didapati melebihi had yang ditetapkan oleh Peraturan Makanan Malaysia 1985 terutamanya lokan yang dikutip dari stesen berhampiran kawasan perindustrian. Oleh itu, lokan berhampiran kawasan perindustrian perlu dipantau untuk mengelakkan apa-apa kesan akut kepada risiko kesihatan manusia.

**Kata kunci**: Sungai Kelantan, lokan, logam berat, had dibenarkan, risiko kesihatan manusia

## Introduction

Heavy metals are a metallic chemical element that has a high density and are toxic or poisonous at low concentrations [1]. Living organisms need a certain amounts of some metals, including calcium, copper, iron, manganese, molybdenum, vanadium, strontium, and zinc in order to keep the metabolism activities inside the body functioning well [2,3]. However, heavy metals are also dangerous because they tend to bio-accumulate in the body of the organism [4].

Heavy metals have been recognized as a severe pollutant to the environment due to its hazardous effects. Industrial and agricultural activities were reported as the major sources of the accumulation of pollutants in the aquatic environment, including the sea [5, 6]. These lethal wastes in the sea are highly probable to be accumulated in the sediments and marine organisms, including shellfish and consequently transfer to human beings through the food chain [7]. Shellfish are consumed by human beings and if accumulate large quantities of some metals from the water through daily consumption. It is important to determine the concentration of heavy metals in shellfish in order to evaluate the possible risk of the consumption for human health [8]. Shellfish contain quite great concentrations of carotenoids [9], low levels of fat and essential amino acids and also possess a relatively high content of vitamins and minerals [10]. For an example, bivalves have a much higher concentration of vitamins such as folate, cobalamin and minerals [10]. Today, it is generally accepted that fish and shellfish are important in a healthy and balanced human diet [11].

However, the evaluation of the risks and benefits of the consumption of these products has been particularly controversial. Even though, shellfish are very important human foods, but they exposed to chemicals in polluted and contaminated waters [12]. Toxicologists tend to relate shellfish as a major vector for toxic substances of metal trace elements and persistent organic pollutants [13]. The bioaccumulation of heavy metals by fish and shellfish make these food items can be a rich source of metal [14]. The interactions of heavy metals with usual elements form diet have an important role in acute and chronic toxicity [15].

Among the common approaches used to study environmental contamination, the use of bivalve mollusk as bio-indicator species has proved to be a valuable and informative technique [16]. This approach has been particularly developed in temperate areas, whereas in sub-tropical and tropical areas the scarcity of available information makes the identification of species that could be used as suitable bio-indicators is difficult [17]. This study was conducted to evaluate the concentration of selected heavy metals accumulated in the seashell and beside to determine the size of seashells toward the concentration of metals in the seashell.

## Material and methods

### Sample collection

The seashells, ranged from 54 to 80.9 mm were collected in the mangrove area of the Kelantan River, located in Kota Bharu, Kelantan (Figure 1) during June 2013 in four different sampling stations. Sampling station 1 and 2 locate before industrial area, meanwhile station 3 and 4 locate near to industrial area. Various type of industries

including food canning and manufacture of plastics. Sediment attached to the seashell was washed thoroughly by the *in-situ* water. All samples were stored in low temperature before the seashells were dissected in the laboratory.

**Sample analysis**

In the laboratory, the sample was washed with distilled water. Prior to analysis, the samples were classified, weighted, and the length measured using vernier caliper and all of the soft tissue were removed from their shells by using ceramic scalpel blades and then thoroughly rinsed to remove any extraneous impurities. The total weight and wet weight were recorded on the data sheet.

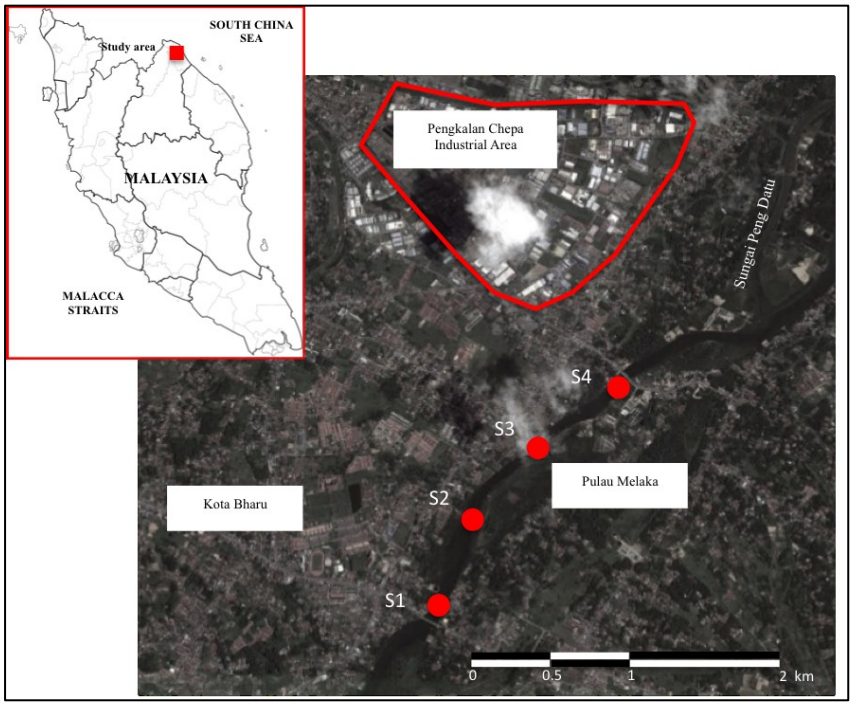

Figure 1. The sampling stations (Sungai Peng Datu, Kelantan) near to Kota Bharu city and Kampung Pulau Melaka

**Analytical method**

The soft tissue is weighted approximately to 0.05 g (dry sample) in Teflon digestion container. Suprapur nitric acid was added into each of the samples and let to predigest. Standard reagent, SRM1566 Oyster Tissue and blank were done simultaneously. After that, the container is covered and place in a stainless steel bomb, which is sealed with screw closure to avoid any acid leakage and store in the oven. The sample was heated in oven temperature for 7 hours at 100 °C in order to digest the sample completely. After cooling, the solution is transferred into a centrifuge tube diluted with deionized water to 10 mL. The metals content, then measured by inductively-coupled plasma mass spectrometry (ICP-MS).

**Statistical analysis**

The statistical analysis, t-test of SPSS software is used to investigate the variation in trace elements concentration in the organisms and the sampling site. The levels of significance of the statistical analyses are set at 0.05.

## Results and Discussion

### Average concentration of heavy metal in marsh clam

Table 1 shows the overall results obtained from this study. Generally, cadmium (Cd), lead (Pb) and zinc (Zn) relatively are higher in station 4. Station 4 is the station that locates near to the end of the river and also near to the industrial area. However, concentration of chromium (Cr) in station 2 is the lowest among all. Approaching to industrial area, the concentrations of metal seem to be increased. This shows the industrial area may affect the selected metal concentration inside the river and uptake by the clam.

Table 1. The average concentration of each metals in each station

| Sample ID | Cr (μg $g^{-1}$) | Fe (μg $g^{-1}$) | Cu (μg $g^{-1}$) | Cd (μg $g^{-1}$) | Pb (μg $g^{-1}$) | Zn (μg $g^{-1}$) |
|---|---|---|---|---|---|---|
| Station 1 (non-industrial area) | | | | | | |
| Average | 44.60 ± 0.05 | 0.50 ± 0.05 | 13.10 ± 0.05 | 0.54 ± 0.05 | 1.17 ± 0.05 | 323.65 ± 0.05 |
| Std. Dev. | 32.06 ± 0.05 | 0.50 ± 0.05 | 9.72 ± 0.05 | 0.45 ± 0.05 | 0.61 ± 0.05 | 296.60 ± 0.05 |
| Station 2 (non-industrial area) | | | | | | |
| Average | 25.05 ± 0.05 | 1.08 ± 0.05 | 17.89 ± 0.05 | 0.88 ± 0.05 | 1.89 ± 0.05 | 510.86 ± 0.05 |

Previous study shows the significant value that has been done in certain areas which may be affected by different physical and biological factor. Differences of value between the current study and previous study determined the toxicity of the area and may give harmful to human society and community through ingestion and consumption. Previous report shows there are four metals that have been studied along the Strait of Malacca. Several fishes have been catch and well preserved together with several cockles (*Anadara granosa*) [18]. However, there are only two same metals which previous report and this report have used include cadmium and lead. Previous study shows higher concentration of cadmium rather than in this study range from 25.1 μg $g^{-1}$ to 47.0 μg $g^{-1}$ [18]. This could be due to the fact that the habitat of *Anadara granosa* that are living at the bottom of the sea, nearly in the sediment where various kinds of hazardous and toxic substances are accumulated [19]. Lead in previous study showed much lower than the current study (0.19 μg $g^{-1}$ to 0.28 μg $g^{-1}$). *Anadara granosa* from Malacca's Straits was used as background comparison as there is no study that's been established around the Kelantan River.

A previous study in 1998, the report shows that the heavy metal concentrations of the bivalve *Anadara (Senilia) senilis* show a clearly distinct effect of size, small individuals having greater concentrations than large cockles [19]. Results should therefore be normalized for size before attempting any geographical or temporal comparison. In this study, statistically significant differences in metal concentrations of cockles between localities and years are explained by differences in the size distribution of the samples. Five types of metals studied in previous study show that than this study as the concentration is 309 μg $g^{-1}$. In the previous study conduct during 1980, the concentration in the cockles is much lower than in this research [20].

Generally, the levels in industrial area were higher compared to non-industrial area station. For example, the average concentration of Cu was 18 μg $g^{-1}$ at Station 2 and 25 μg $g^{-1}$ at Station 3, respectively. This clearly indicates the influence of aquatic environments [21] as well as surrounding human activities at a specific point of time may contribute to the accumulation of trace metals in marine organisms. Copper is one of the metals that is introduced

into the aquatic environment through a number of natural methods. Copper is also a very useful substance for man. When these uses occur, some of that Cu is also presented in the aquatic environment [22]. In this study, the concentration of Cu in each sample is still below 30 μg $g^{-1}$ and in safety level. Highest level of Cu was observed at station 4. Thus, the accumulation of heavy metals in the aquatic environments has been associated with urban runoff, sewage treatment plants, industrial effluents and wastes, mining operations, boating activities, domestic garbage dumps and agricultural fungicide runoff [23].

On the other hand, the concentration of Cr is high and almost the same except for Station 2. The decrease of concentration may influence by the degradation of Cr by the biological process of marine organisms [24] or there are less human activity and production that contribute to the increase of Cr concentration. Although the graph shows the high concentration in both non-industrial area, yet it is considered as low. Besides, Cr has low toxicity and no adverse effects were observed at intakes of 1000 to 2000 μg/day by human [25]. Due to the lack of adequate data, the EU Scientific Committee for Food (2003) has not suggested a Tolerable Upper Intake Level (UL) for Cr. The same conclusion was reported by the US Food and Nutrition Board and the UK Expert Group on Vitamins and Minerals [25].

For the iron (Fe) in the clam samples, the highest percentage of concentration can be observed in samples at station 4. Similar with other metals, Fe also was carried through the stream and accumulates at the end of the river bank. Station 2 and 3 shows almost same value, probably due to the station located close to the industrial area. Surface and river runoff from the industrial area may contribute to the amount of the Fe present in the river.

The concentration pattern of cadmium (Cd) is likely same as concentration of Fe and Pb. The highest concentration of Cd exceeding safety level can be found in station 4 and lowest concentration of Cd can be found in station 1. Although Cd is not widely used in human activities, but Cd is the essential component in the manufacture of solder, electrical supplies, batteries, phosphors in the production of televisions, anti-corrosive coatings for metals and bearing alloys [26]. However in this study, the Cd may come from natural resource as there are no specific industries utilized Cd present in the area of sampling located.

For lead metal (Pb), the highest level was observed in an industrial area in station 4 and exceeding safety levels of human consumption while in lowest level can be found at Station 1. Station 4 has the highest concentration of Pb because of the accumulation of the heavy metal at the end of river bank [27]. It is because the industrial area may also contribute to the amount of the Pb concentration at Station 4. Pb is well known metal used in industry as paint, coating agent and storage of batteries. Although Pb is not harmful to human at low level, but if the amount takes more than the body can handle, the body will show some of the known symptoms of Pb poisoning such as headache, irritability, abnormal pain and various symptoms related to the nervous system.

The data about the zinc metal (Zn) show that all sampling stations exceed the safety level of human consumption, 150 μg $g^{-1}$. Station 4 in industrial area shows the highest concentration of Zn in each sample. Excess level Zn has been accumulating at the end of the river and the source may come from the industrial area. The evidence in station 3 shows the concentration of zinc in higher than in non-industrial area (Station 1 and 2). Large doses of consuming zinc taken by mouth even for a short time can cause stomach cramps, nausea, and vomiting. Zinc is well known as metal that easily found dumped by villager in this river such as roof, barrel and component of car.

**Correlation of length and weight and the concentration of heavy metals**

From the tabular data of correlation between length of seashell and concentration of heavy metal, it was concluded that the heavy metal concentrations in the bivalve *Polymesoda expansa* are not related based on sample size (Figure 2 and 3). Small individuals having higher concentrations than large seashells and some small seashells also have lower concentration of metals than a large one or called as a growth dilution effect. The concentration of metals in samples is not directly proportional to the size, but regarding to the geographical or temporal comparison. In this study, statistically significant differences for concentration of metals in seashells between localities and years are clarified by differences in the size distribution of the samples. The areas itself give important in determining the status of metal toxicity in the current study. Moreover, the concentration levels of zinc, lead, cadmium and iron

shows that the highest concentration within the range of 60 mm to 70 mm of seashell's length, meanwhile for chromium and copper, the highest concentration can be found in the seashells with the range of 70 mm to 80 mm.

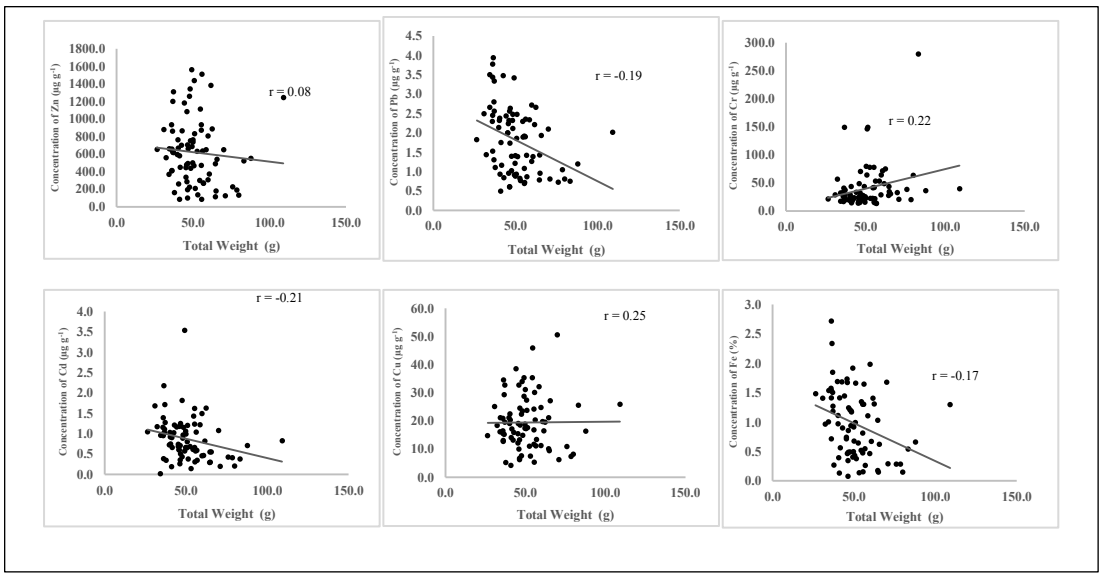

Figure 2. Correlation between weight of clam and the concentration of metals

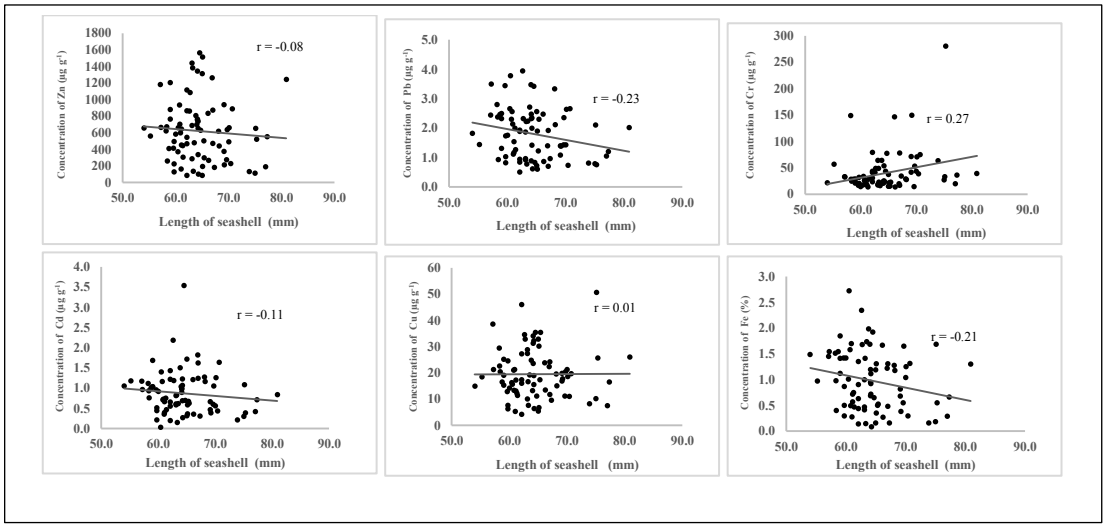

Figure 3. Correlation between length of clam and the concentration of metals

## Conclusion

The concentration of metal in non-industrial and industrial area is most likely same and can determine that the industrial area use safe and work in accordance with the standards set. The metals in the river is not totally come from the industries but may come from rural activities. Vehicle and metal-based barrel dumping are also contribute to the increase of the concentration. The size of clam also play role in determining the concentration of heavy metal

inside their body but limited to certain type of metals. From the correlation graph, some of metals are increase through size or length but some of metals are also decrease directly with size. However, there are some researchers claimed that the behavior of the seashell itself will 'consume' less if the area is really polluted. The gasping rate is decrease and less medium like water pass through the body. From the preliminary data obtained, the marsh clams at Kelantan River are still safe to be consumed. However, continuous consume the organism may lead to Zn poisoning due to the level of Zn is higher compare to standard values. Therefore, an intensive studies include water and sediment quality or other organism should be considered in order to obtain a better conclusion for metal pollution in Kelantan River.

**Acknowledgement**

This research was conducted with funding from the Ministry of Higher Education Malaysia (MOHE), under the Niche Area Research Grant Scheme (NRGS) project number 53131. The authors wish to express their gratitude to Oceanography and Biodiversity Laboratory, School of Marine and Environmental Sciences teams for their invaluable assistance and providing the facilities to carry out the research. We are grateful to our editors and referees for their invaluable comments that helped improve this manuscript.

# DEVELOPMENT AND VALIDATION OF A REVERSE PHASE-HIGH PERFORMANCE LIQUID CHROMATOGRAPHY-ULTRAVIOLET METHOD FOR SIMULTANEOUS DETECTION OF CAFFEINE AND PHENOLPHTHALEIN IN WEIGHT REDUCING SUPPLEMENTS

## (Pembangunan dan Pengesahsahihan Kaedah Fasa Terbalik-Kromatografi Cecair Prestasi Tinggi Ultraungu bagi Pengesanan Kafein dan Fenolftalein Dalam Suplemen Pengurangan Berat Badan)

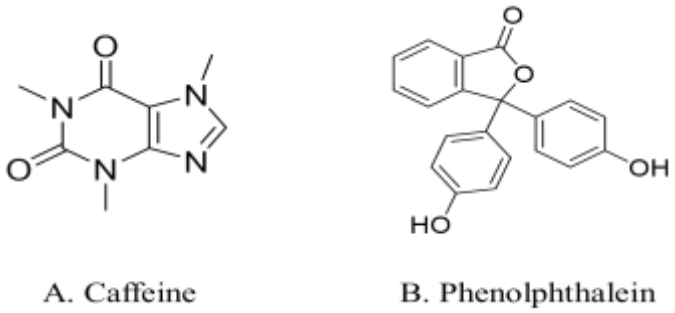
**Abstract**

A reversed-phase high performance liquid chromatography analytical method with variable wavelength detection was developed for the simultaneous detection of caffeine and phenolphthalein in weight reducing supplements. Chromatographic separation was achieved with a C18 reversed-phase column using a gradient elution of methanol and an ammonium acetate buffer (pH 5; 25 mM), with the detector wavelength set at 254 nm. The method was validated according to The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use guidelines. The method was proven to be linear over a concentration of 10 – 100 µg/mL for both caffeine and phenolphthalein, with mean correlation coefficients of 1.000 and 0.999, respectively. The limit of detection for caffeine and phenolphthalein was 0.77 µg/mL and 0.47 µg/mL respectively, while the limit of quantification for caffeine and phenolphthalein was 2.35 µg/mL and 1.44 µg/mL, resspectively. The percentage relative standard deviation for both intra and inter-day precision was less than 2%. The mean recovery values were calculated as 105.84% and 113.58% for caffeine and phenolphthalein. In addition, the method was proven to be robust when deliberate changes in flow rate, buffer pH and organic mobile phase composition were tested.

**Keywords**: caffeine, phenolphthalein, high performance liquid chromatography, validation, weight reducing supplement

**Abstrak**

Satu kaedah analitikal kromatografi cecair prestasi tinggi (KCPT) fasa terbalik dengan pengesanan pada pelbagai panjang gelombang telah dibangunkan untuk pengesahan kafein dan fenolftalein dalam suplemen pengurangan berat badan. Pemisahan kromatografik dicapai dengan turus fasa terbalik C18 menggunakan kecerunan elusi metanol dan penampan ammonium asetat (pH 5; 25 mM), pada panjang gelombong λ = 254 nm. Kaedah ini telah ditentusahkan mengikut garis panduan harmonisasi persidangan antarabangsa keperluan teknikal untuk pendaftaran famaseutikal bagi pengunaan manusia. Kaedah ini dibuktikan linear dalam julat kepekatan larutan piawai kafein dan fenolftalein di antara 10 – 100 µg/mL dengan nilai pekali korelasi ($R^2$) 1.000 dan 0.999 untuk masing – masing bagi kafein dan fenolftalein. Had pengesanan bagi kafein dan fenolftalein masing-masing ialah 0.77 µg/mL and 0.47 µg/mL. Keputusan had kuantifikasi bagi kafein dan fenolftalein masing-masing ialah 2.35 µg/mL and 1.44 µg/mL. Peratus relatif sisihan piawai bagi ketepatan intra dan antara hari yang diukur ialah kurang dari nilai 2%. Nilai min pemulihan semula yang dikira bagi kafein dan fenolftalein masing-masing ialah 105.84 dan 113.58%. Kaedah ini juga dibuktikan teguh apabila perubahan dalam kadar aliran, pH panampan dan komposisi fasa bergerak diuji.



**Kata kunci:** kafein, fenolftalein, kromatografi cecair prestasi tinggi, pengesahsahihan, suplemen pengurangan berat badan

## Introduction

Obesity is a worldwide health epidemic. It is reported that among adults aged 18 and above, 11% of men and 15% of women were obese in 2014 [1]. Because of the health risks associated from being overweight, and also pressure from society to have a slim and attractive body, weight reducing supplements are popular worldwide among both men and women. The majority of these weight reducing supplements are marketed as being derived from phytotherapeutic formulations and are advertised as being natural and safe. Unfortunately this is not the case in reality, as there have been many reports worldwide of weight reducing supplements being adulterated with undeclared prescription pharmaceuticals and banned substances to enhance their efficiency [2–11].

In the US, the Food and Drug Administration (FDA) has detected the presence of adulterants such as sibutramine, fenproporex, fluoxetine, bumetanide, furosemide, phenytoin, rimonabant, cetilistat and phenolphthalein in various weigh reducing products sold over the counter (OTC) and online [12]. We are interested in developing a simple and fast HPLC method to quantify caffeine and phenolphthalein, as these compounds are popular choices as adulterants due to their relatively cheap price and easy accessibility. Phenolphthalein, a synthetic compound, was a stimulant laxative used for the treatment of constipation and for bowel evacuation until 1999, when the FDA reclassified the drug as 'not generally safe and effective' after studies indicated that it presented a potential carcinogenic risk [13]. Since then, the United Kingdom has changed the status of phenolphthalein from OTC to prescription agent, while European countries such as Italy and France have suspended the use of it in prescription and OTC pharmaceutical preparations [14, 15].

Caffeine is a natural product found in the leaves, seeds, and fruits of more than 60 plants [16]. As a stimulant, caffeine was reported to be one of the most used drugs for slimming purposes [3]. Consuming caffeine increases energy expenditure, making the individual more alert and hence more active, leading to weight loss [17]. Caffeine has also been proposed to counteract the decrease in metabolic rates, and may also act as an appetite suppressant. Although complications due to caffeine toxicity are rare, excessive consumption of caffeine can lead to health problems such as sleep disruption, headache, nausea, anxiety, and even caffeine-induced cardiac arrhythmia [18,19]. The chemical structures of caffeine and phenolphthalein are shown in Figure 1 below.

A. Caffeine B. Phenolphthalein

Figure 1. Chemical structures of the adulterants of interest (a) Caffeine (1,3,7-trimethyl-3,7-dihydro-1H-purine-2,6-dione) and (b) Phenolphthalein (3,3-Bis(4-hydroxyphenyl)-2-benzofuran-1(3H)-one)

In this paper, the development and validation of a reversed-phase high performance liquid chromatography-ultra violet (RP-HPLC-UV) analytical method to detect caffeine and phenolphthalein in weight reducing supplements was investigated. The developed method was validated according to The International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) guidelines [20]. Among the existing analytical methods reported in the literature to detect caffeine and phenolphthalein simultaneously are ultra-high performance liquid chromatography (UHPLC) and liquid chromatography-mass

spectroscopy (LC-MS) [9, 21]. Recently, an article was published reporting a HPLC-UV method for quantitative determination of six adulterant drugs, including caffeine and phenolphthalein, in slimming supplements [22]. However, the published method uses different HPLC parameters from our study. The method which we have developed can be applied to analytical laboratories in developing countries which are only equipped with HPLC-UV instrumentation to screen and quantify for caffeine and phenolphthalein in weight reducing supplements.

## Materials and Methods

### Chemicals and reagents

Caffeine (≥99.0%) and phenolphthalein (ACS reagent), used as standards, were purchased from Sigma Aldrich and Merck, respectively. HPLC-grade methanol and ammonium acetate (>99%) was obtained from Fischer Scientific. The mobile phase was filtered through a 0.45 µm nylon membrane filter and ultrasonically degassed before use. Other reagents, including glacial acetic acid, were of analytical grade. Ultrapure water was prepared using an atrium® 611 Ultrapure Water System (Sartorius, Germany).

### Instrumentation and chromatographic system

Method development and validation was performed on a 1200 series HPLC (Agilent Technologies, US), interfaced with a binary pump (G1312A, Agilent Technologies, US), degasser (G1379B, Agilent Technologies, US), variable wavelength detector (VWD) (Agilent Technologies, US) and manual injector (G1328B, Agilent Technologies, US). The HPLC was interfaced to a Hewlett-Packard L1908 computer equipped with ChemStation System (version 2008) software.

The chromatography method was developed using a C18 Hypersil GOLD column (150 mm x 4.6 mm internal diameter, 5 µm particle size) at room temperature. The mobile phase was composed of (A) an ammonium acetate buffer 25 mM solution adjusted to pH 5 with glacial acetic acid and (B) methanol with a gradient elution programme, as shown in Table 1. The mobile phase was delivered at a flow rate of 1.1 mL/min. The injection loop volume was 20 µl. The detection wavelength was set at 254 nm.

Table 1. Gradient elution profile used in HPLC system

| Time (min) | 0 | 1 | 3 | 5 | 10 |
|---|---|---|---|---|---|
| A (%) | 90 | 90 | 60 | 45 | 45 |
| B (%) | 10 | 10 | 40 | 55 | 55 |

A = ammonium acetate buffer (pH 5; 25 mM); B = methanol

### Preparation of stock standard solution

Stock standard solutions of 1 mg/mL caffeine and phenolphthalein were prepared separately in HPLC grade methanol. The resulting stock solutions were sonicated and filtered using a 0.2 µm nylon syringe filter.

### Preparation of mixed standard and mixed working solution

Mixed standard solution in concentration 100 µg/mL was prepared from the stock standard solutions. Using this tertiary solution, mixed working solutions of 10, 20, 40, 60 and 80 µg/mL were prepared by diluting with the appropriate amount of methanol. All solutions were prepared in HPLC grade methanol, stored in a refrigerator (4 $^{o}$C) and brought to room temperature before use.

### Preparation of blank sample

The blank sample for validation of specificity was prepared according to methods modified from the literature [5, 10]. A herbal weight reducing supplement purchased from a local pharmacy was considered as a blank sample. The capsule was opened, and 0.1 g of powder was weighed. The powder was then extracted with 25 mL of HPLC grade methanol by sonication for 10 minutes. The mixture was then centrifuged at 10 000 rpm for five minutes, and the

supernatant was then collected and filtered through a 0.2 µm nylon syringe filter. The blank sample was stored at 4 ºC in the refrigerator and brought to room temperature before injection into the HPLC.

**System suitability tests**

System suitability tests were carried out before performing validation parameters. The following system suitability tests were performed: peak symmetry, number of theoretical plates, resolution and capacity factor.

**Method validation**

The method validation was performed according to ICH guidelines for the following parameters: specificity, linearity, limit of detection (LOD), limit of quantification (LOQ), accuracy, precision, and robustness. Stability of a mixed working solution at a 50 µg/mL concentration was also investigated.

**Specificity**

Specificity is defined as the ability to assess unequivocally the analytes in the presence of components which may be expected to be present. Specificity was determined by injecting blank samples into the HPLC system to test for interference of a complex matrix of the blank samples with caffeine and phenolphthalein peaks. Blank samples used were OTC weight reducing supplements.

**Linearity of the calibration curve**

The linearity of the calibration curves were constructed by analysing mixed working solutions of caffeine and phenolphthalein. Six concentrations of mixed working solutions containing them ranging from 10 µg/mL to 100 µg/mL were prepared. The linearity was obtained by the injection of the mixed standard working solutions at each concentration in triplicates (n = 3), and the results were expressed as the mean of the triplicates.

**Limit of detection and limit of quantification**

The LOD is defined as the lowest analyte concentration of a sample that can be detected by the analyst, while LOQ is the lowest analyte concentration which can be quantitatively detected with accuracy and acceptable precision. The LOD is expressed as 3.3δ/S, and LOQ is expressed as 10δ/S, where S refers to the slope of the calibration curve and δ refers to the standard deviation of the response. The value of δ was determined from the residual standard deviation of the calibration curve.

**Accuracy**

The accuracy of the method, expressed as percentage recovery (% recovery), was established via spiking studies. The % recovery values were evaluated by spiking blank samples with low, medium and high levels of caffeine and phenolphthalein standards. The concentrations of caffeine standard spiked into the samples were 11, 22 and 33 µg/mL, while the concentrations of phenolphthalein standard spiked were 10.44, 20.88 and 31.32 µg/mL. Each standards of the same concentration was injected into the HPLC in triplicates (n = 3) and the results are expressed as the mean of the triplicates. The % recovery values were established by calculating the ratio of the experimentally determined concentration of each analytes spiked into the blank samples to its theoretical amount (equation 1):

$$\% \text{ Recovery} = \frac{(\text{Recovered concentration of analytes})}{(\text{Theoretical concentration of analytes})} \text{ x } 100\% \quad (1)$$

**Precision**

Precision is the measure for the relative errors of the method and is expressed as the percentage relative standard deviation (% RSD) for intra-day precision (repeatability) and inter-day precision (intermediate precision). To find the intra-day precision, mixed working solutions at low, medium and high concentrations were injected consecutively in the same day. Each sample of a similar concentration was injected in triplicates (n = 3), and the results were expressed as the mean of the triplicates. To find the inter-day precision, the process to do so was repeated where injections of mixed working standard solutions at low, medium and high concentrations were performed over three consecutive days. Each sample of a similar concentration was injected in triplicates (n = 3), and the results were expressed as the mean of the triplicates.

**Stability of mixed standard solution**
A mixed working solution of concentration 50 µg/mL was prepared fresh. The stability of this solution was checked after 24 hours under refrigerated conditions (4 °C).

**Robustness**
The robustness of the method was determined by analysing the mixed standard solution after deliberate changes in flow rate (± 0.2 mL/min), buffer pH (± 0.2 units) and organic content of the mobile phase (± 2.0%). System suitability was applied after each of the above mentioned changes. The method is considered robust for the parameter tested if it conforms to the system suitability tests.

**Preparation of representative samples**
The representative samples were prepared according to similar method employed to prepare the blank sample. Five weight reducing supplements in the form of capsules and powder were purchased from the Kuala Lumpur area (products A, B, C, D and E). The filtered solution of product A was diluted by 10 times with HPLC grade methanol before injection into the HPLC to obtain concentrations within the calibration range. No dilutions were required for the other samples before injection into the HPLC. All solutions were injected in triplicate.

**Liquid-liquid extraction (LLE)**
To clean-up product E, 0.05 g of the product was weighed and dissolved in 20 mL sodium carbonate solution. Solids were removed by filtering, and the filtrate collected into a separating funnel. The filtrate was extracted with dichloromethane (20 mL x 3), the dichloromethane fractions pooled into a round bottom flask and the solvent removed using a rotary evaporator. The residue left in the round bottom flask was reconstituted with 10 mL of HPLC grade methanol and filtered through a 0.2 µm nylon syringe filter prior to injection into the HPLC.

## Results and Discussion

**Selection and optimisation of the method**
The chromatographic method was optimised during the method developing stage by trying different mobile phase compositions and flow rates. The final method was obtained using an ammonium acetate buffer (pH 5; 25 mM) as an aqueous mobile phase and methanol as an organic mobile phase at a flow rate of 1.1 mL/min. The buffer was used as an aqueous mobile phase to obtain good peak shape and a constant retention time, as caffeine and phenolphthalein contains pH sensitive functional groups [23, 24]. Additional peaks were observed when ammonium acetate buffer pH 5 was substituted with ammonium acetate buffer pH 3.8 and pH 5.8 (Figures 2a and 2b). The optimum wavelength allowing for sensitive detection for both caffeine and phenolphthalein was set at 254 nm based on literature [9, 10, 25].

The elution gradient begins with 10% methanol and 90% buffer. After one minute a linear gradient is started where 40% methanol composition is reached after 2 minutes from the time of gradient. A second linear gradient is then applied where methanol composition increases to 55% after 2 minutes and kept constant for 5 minutes until caffeine and phenolphthalein elutes out at 5.61 minutes and 8.78 minutes respectively. The separation achieved using the experimental conditions described are presented in Figure 2c. The following system suitability test parameters were performed: peak symmetry, number of theoretical plates, resolution and capacity factor (Table 2). All system suitability test parameters were found to be within the ICH requirements.

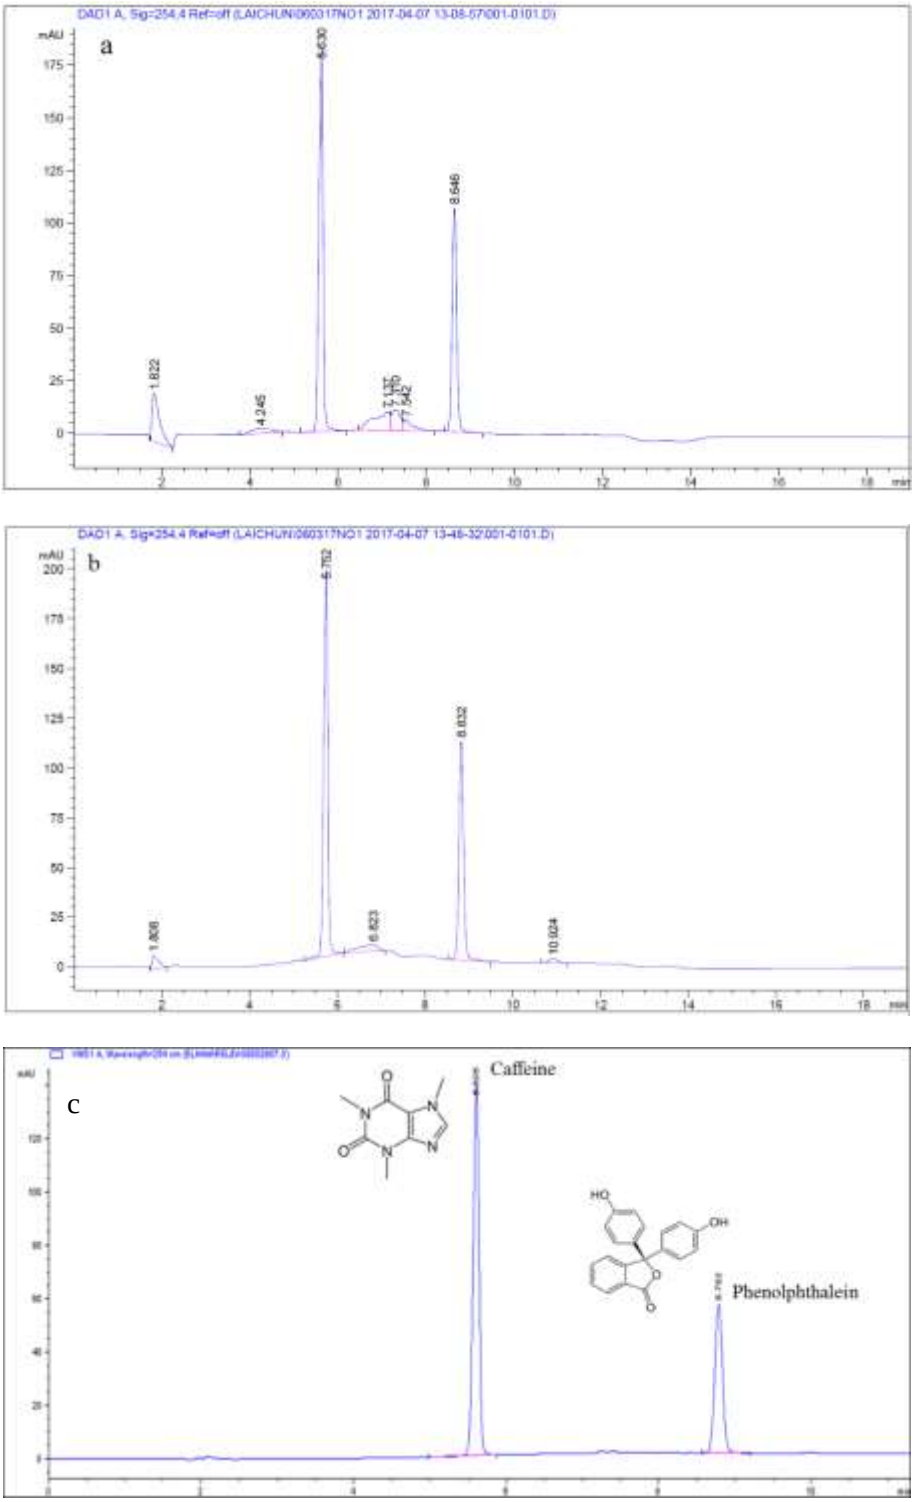


Figure 2. The HPLC chromatogram of mixed working solution (50 µg/mL) under chromatographic conditions of the developed method with ammonium acetate buffer at (a) pH 3.8; (b) pH 5.8 and (c) pH 5

Table 2. System suitability test parameters

| **Parameters** | **Caffeine** | **Phenolphthalein** | **ICH Requirement** |
|---|---|---|---|
| Numbers of theoretical plate | 43 442 | 58 100 | > 10 000 |
| Peak symmetry | 1.5 | 1.3 | < 2 |
| Retention factor (min) | 2.18 | 4.04 | - |
| Precision (%RSD, n = 6) | 1.32 | 1.49 | < 2 % |
| Resolution (R) | 26.125 | 26.125 | > 1.5 |

**Validation criteria of the HPLC method: Specificity**

Specificity was indicated by the absence of any endogenous interference at retention times close to the peaks of interest, as evaluated by chromatograms of blank samples and blank samples spiked with analytes. Retention times for caffeine and phenolphthalein in the spiked sample were 5.652 minutes and 8.987 minutes respectively. In the blank sample, no interfering peaks were found at the retention times of caffeine and phenolphthalein (Figure 3).

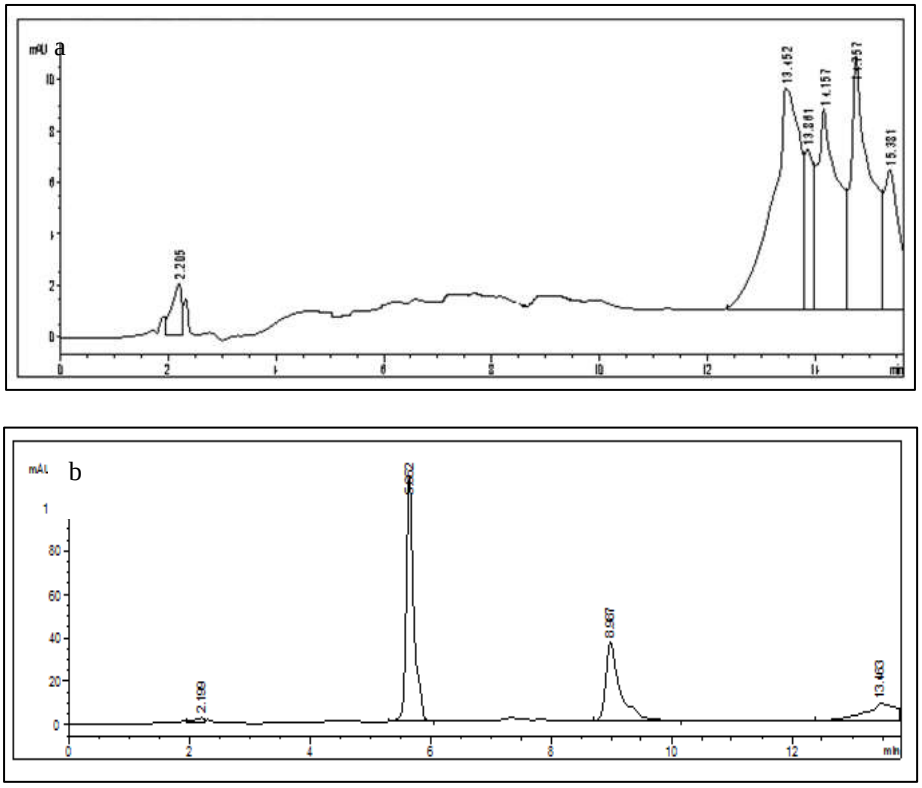

Figure 3. Representative chromatograms for (a) blank sample and (b) blank sample spiked with caffeine (50 µg/mL) and phenolphthalein (50 µg/mL)

**Linearity**

The calibration curves for caffeine and phenolphthalein were plotted using ordinary least-square linear regression over the concentration range 10 µg/mL to 100 µg/mL (Figure 4). A linear relationship was established between the peak area and analyte concentrations over the range tested, and it was confirmed by the correlation coefficient ($R^2$) value where $R^2$ values were higher than 0.990. The slope and intercept of the calibration curve was calculated, and the following linear equation was obtained: y = 22.751x + 66.613 for caffeine and y = 11.352x + 5.716 for phenolphthalein. Therefore, it can be concluded that the calibration curves for caffeine and phenolphthalein is linear within the range 10 µg/mL to 100 µg/mL.

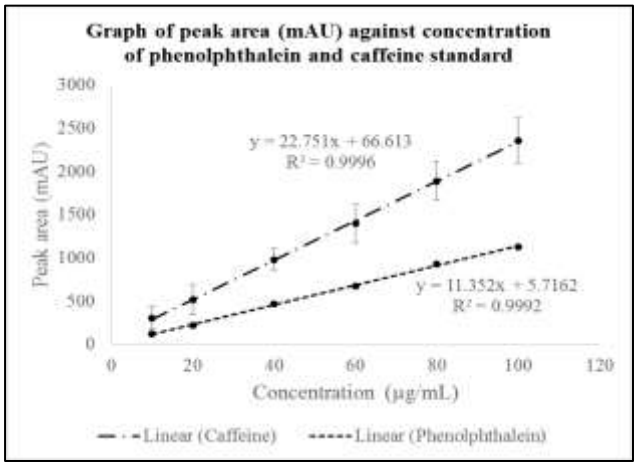

Figure 4. Calibration curve for caffeine and phenolphthalein in concentration range 10 – 100 µg/mL

**Limit of detection and limit of quantification**

The LOD for both caffeine and phenolphthalein determined from the residual standard deviation of the regression line was found to be 0.77 µg/mL and 0.47 µg/mL, respectively. The LOQ for caffeine and phenolphthalein determined from the residual standard deviation of a regression line was found to be 2.35 µg/mL and 1.44 µg/mL, respectively. The LOD and LOQ values for caffeine were found to be comparable with those reported in a previous study using HPLC-UV (0.75 µg/mL and 2.25 µg/mL respectively) [22]. However, the LOD and LOQ values for phenolphthalein obtained in this study were higher than the values reported in the previous study (0.1 µg/mL and 0.3 µg/mL, respectively) [22]. The higher LOD and LOQ values for phenolphthalein could be attributed by the different wavelength used in our study (254 nm) compared to the previous one (220 nm).

**Accuracy**

The percentage recovery values of caffeine and phenolphthalein at low, medium and high concentrations are summarised in Table 3. The mean percentage recovery values for caffeine and phenolphthalein in the range of concentration tested were found to 105.84% and 113.58% respectively. The method was proven to be accurate in measuring caffeine and phenolphthalein in the concentrations tested, where the measured concentration values were close to the true values.

**Precision**

The intra-day precisions for caffeine and phenolphthalein were found to be between 0.67 – 1.99% and 0.80 – 1.55%, respectively, while the inter-day precisions for caffeine and phenolphthalein over three consecutive days were between 0.67 – 1.99% and 0.80 – 1.79%, respectively. In both cases, percentage RSD values were found well within the 2% limit. Therefore, the method is proven to be repeatable and is capable of producing consistent results regardless of whether the analysis is made in the same or on different days. The percentage RSD values for precision are summarised in Table 4.

Table 3. Accuracy of the HPLC method expressed as percentage recovery (% recovery), determined using spiking (three spike levels) experiment

| Spike Levels | Compound | Spiked (Theoretical) µg/mL | Spiked (Found) µg/mL | % Recovery (n = 3) |
|---|---|---|---|---|
| Low | Caffeine | 11.00 | 11.49 | 104.45 ± 3.82 |
| | Phenolphthalein | 10.44 | 12.54 | 120.11 ± 4.50 |
| Medium | Caffeine | 22.00 | 23.78 | 108.07 ± 0.59 |
| | Phenolphthalein | 20.88 | 23.79 | 113.94 ± 0.43 |
| High | Caffeine | 33.00 | 34.65 | 105.00 ± 0.64 |
| | Phenolphthalein | 31.32 | 33.42 | 106.70 ± 0.93 |

Table 4. Intra-day and inter-day precision of the HPLC method to detect and quantify caffeine and phenolphthalein, measured on three consecutive days

| Day | Compound | % RSD |
|---|---|---|
| 1 | Caffeine | 0.68 – 1.14% |
| | Phenolphthalein | 0.84 – 1.55% |
| 2 | Caffeine | 1.22 – 1.48% |
| | Phenolphthalein | 1.00 – 1.52% |
| 3 | Caffeine | 1.41 – 1.85% |
| | Phenolphthalein | 0.93 – 1.79% |

**Stability of mixed working standard solution**

Mixed working standard solution (50 µg/mL) was found to be stable over up to 24 hours under refrigeration conditions (4 °C). Stability values for caffeine and phenolphthalein were 99.0 ± 0.9% and 97.4 ± 2.5%, respectively. The stability values are summarised in Table 5 below.

Table 5. Stability of mixed working standard solution at 4°C after 24 hours

| Solution | Compounds | Stability (%) (n = 3) |
|---|---|---|
| Mixed working solution (50 µg/mL) | Caffeine | 99.0 ± 0.9 |
| | Phenolphthalein | 97.4 ± 2.5 |

**Robustness**

System suitability parameters (precision, peak symmetry, number of theoretical plates, retention factor and resolution) remained within the acceptable limit range [20,26,27] after deliberate changes in the three robustness parameters tested (Table 6). This indicates robustness of method for flow rate ± 0.2 mL/min, buffer pH ± 0.2 units and organic content ± 2.0%.

**Analysis of representative samples**

Five herbal weight reducing supplements (products A, B, C, D and E) were purchased from the Kuala Lumpur area. All the products were advertised by the manufacturers to be derived from natural plant sources. The concentrations of caffeine and phenolphthalein quantified in the products are summarised in Table 7 below. Phenolphthalein was

detected in two of the five products. Product A was found to contain the highest amount of phenolphthalein, about 40 mg per capsule. The chromatogram of product A is shown in Figure 5 below. As the instruction on the product label recommends three capsules daily, a consumer may be ingesting up to 120 mg of phenolphthalein a day. The typical dose for adults before it was withdrawn as a laxative was 30 – 200 mg, and it was not recommended to exceed 270 mg [28]. Phenolphthalein has been detected as an undeclared drug in weight reducing supplements around the world in concentrations ranging from 48.20 – 1167 mg/capsule of mg/pill [2, 29] and 13.8 – 45.4 mg/g [5]. It is expected that adulteration of weight reducing products with phenolphthalein will be identified more frequently in the future, as phenolphthalein is widely available in laboratories and is cheap.

Table 6. System suitability parameters after deliberate changes in flow rate, buffer pH and buffer organic content of the mobile phase

| **Parameter** | | **Compound** | **Precision (% RSD) n = 6** | **Peak Symmetry** | **Number of Theoretical Plates** | **Retention Factor** | **Resolution** |

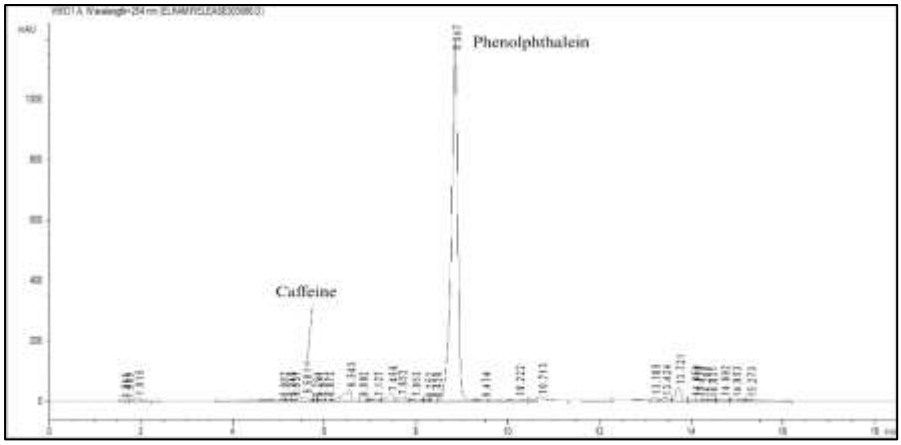

Figure 5. HPLC chromatogram of Product A. Caffeine and phenolphthalein elutes out at 5.581 and 8.847 minutes, respectively

Caffeine is classified by the FDA as generally recognised as safe (GRAS), with a toxic dose being over 10 g for an average adult. Caffeine was detected in two of the products, and the concentration measured to be within the safe limit. Further clean-up of product E was attempted by the LLE method to improve the reliability of caffeine measurement due to the complicated matrix in the product (Figure 6). The extraction method is as described in the materials and methods section. Product E was dissolved in basic solution prior to extraction of caffeine with dichloromethane. Water soluble impurities and tannins (if present) remained in the basic solution. As observed from the chromatogram in Figure 7, LLE may be an effective clean-up method for products with complicated matrices. However, it should be noted that products suspected to be adulterated with phenolphthalein should be dissolved in water instead of basic solution, as phenolphthalein contains acidic phenolic groups.

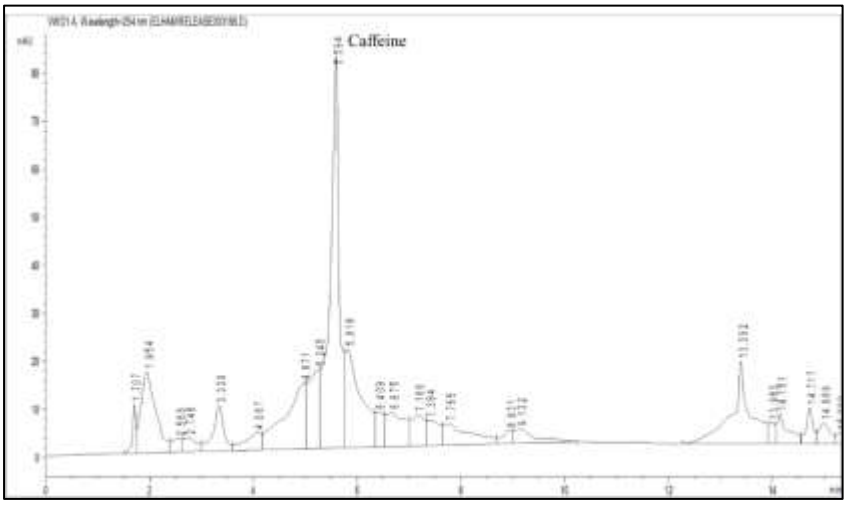

Figure 6. HPLC chromatogram of Product E before LLE. Caffeine elutes out at 5.594 minutes

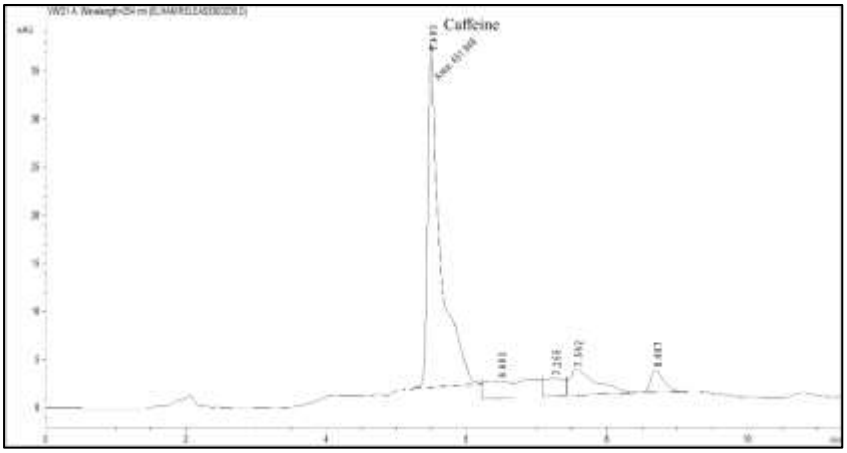

Figure 7. HPLC chromatogram of Product E after LLE. Caffeine elutes out at 5.493 minutes

## Conclusion

A RP-HPLC-UV analytical method with variable wavelength detection was developed and validated for the simultaneous detection of caffeine and phenolphthalein in weight reducing supplements. Out of five supplements screened, two products were found to be adulterated with phenolphthalein. The validation was performed according to ICH guidelines. The HPLC method developed is selective, accurate, precise, robust and relatively fast (10 minutes). Moreover, the use of ammonium acetate buffer combined with methanol allows the transfer to a mass spectrometer, leading to a more thorough investigation in case of any doubt. The method can be easily adapted for rapid detection of caffeine and phenolphthalein in herbal products in quality control laboratories with a HPLC instrument.

**Abstract**

This study aimed to prepare activated carbon nanofibers (ACNFs) from polyacrylonitrile (PAN) and zinc oxide (ZnO) via electrospinning process for removal of lead from aqueous solution. The ACNFs/ZnO were characterized in term of its morphological changes, specific surface area and functional groups analysis using Field Emission Scanning Electron Microscope (FESEM), Brunauer–Emmett–Teller (BET) and Fourier Transform Infrared (FTIR) analysis, respectively. The results showed that the specific surface area (SSA) of the ACNFs/ZnO were higher than the neat ACNFs which were 163.04 $m^2/g$ as compared to 67.6 $m^2/g$, accordingly. FESEM analysis illustrated that composite ACNFs possessed more compact fibers with presence of ZnO beads and smaller fiber diameter whereas neat ACNFs possessed more aligned nanofibers with larger fiber diameter. Adsorption study showed that the composite ACNFs possessed higher capacity which was 120.3 mg/g as compared to 77.6 mg/g of neat ACNFs. This excellent adsorption performance of ACNFs PAN/ZnO exhibits the potential of this composite adsorbent to solve the environmental issue of heavy metal contamination.

**Keywords**: activated carbon, activated carbon nanofiber, adsorption capacity, lead adsorption

**Abstrak**

Kajian ini bertujuan untuk menyediakan gentian-nano karbon teraktif (ACNFs) daripada poliakrilonitril (PAN) and zink oksida melalui proses putaran-elektro untuk menyingkirkan plumbum (II) daripada larutan akues. ACNFs/ZnO dicirikan berdasarkan perubahan morfologi, luas permukaan spesifik, dan analisis kumpulan berfungsi mengunakan Mikroskopi Elektron Pengimbasan Pancaran Medan (FESEM), Brunauer–Emmett–Teller (BET) dan Inframerah Transformasi Fourier (FTIR). Keputusan kajian menunjukkan luas permukaan spesifik (SSA) komposit ACNFs adalah lebih tinggi berbanding ACNFs tanpa logam oksida iaitu 163.04 $m^2/g$ berbanding 67.6 $m^2/g$. Analisis FESEM menunjukkan komposit ACNFs mempunyai gentian lebih padat dengan kehadiran manik zink oksida and mempunyai diameter gentian lebih kecil manakala ACNFs tanpa logam oksida mempunyai gentian lebih tersusun dengan diameter gentian yang lebih besar. Ujian penjerapan menunjukkan bahawa penyingkiran Pb(II) menunjukkan kapasiti penjerapan yang lebih tinggi, iaitu 120.0 mg/g berbanding 77.6 mg/g oleh ACNFs tanpa ZnO. Hasil kajian ini menunjukkan potensi PAN/ZnO ACNFs sebagai penjerap untuk menyelesaikan isu pencemaran logam berat dalam persekitaran.

**Kata kunci:** karbon teraktif; gentian nano karbon teraktif, kapasiti penjerapan, penjerapan plumbum

## Introduction

Recently, contamination of water by heavy metals has becomes a major concern among researchers. Their exposure towards human and enviroment could cause acute effects due to their non-degradable property and their rapid bio-accumulation into body system [1]. In water, some heavy metals that are commonly present are cadmium, arsenic, copper, iron, manganese and lead. Out of these hazardous heavy metals, the removal of lead (Pb) has been extensively studied. In general, the major athrophogenic source of Pb disposal is mainly from industry, such as from leaded gasoline, leaded pipes, building construction, radiation shields, battery industries as well as lead smelting and bearings [2]. The effects of Pb exposure are well documented in which even a very small amount of Pb will results acute effects to nervous system, hematopoeitic system, cardicac and vascular system, metabolism, reproductive system and immune system [3]. To date, the maximum contaminant level (MCL) of Pb in drinking set by World Health Organization (WHO) and US Environmental Protection Agency (USEPA) is 15 µg/L [3]. With the increasing development of industrilization, the amount of Pb being released into water streams will aggravate. Therefore, the elevated amount of Pb in water is an important matter to be concerned.

Due to hazardous exposure of Pb on human and environment, there are various techniques have been implied for its removal from water streams; such as coagulation-flocculation, precipitation, ion exchange, membrane technology and adsorption [4]. Among the mentioned methods, adsorption stands as a promising techniques for removing heavy metals in which the process is relatively simple, effective and economic. In brief, adsorption is a process whereby the adsorbents are attached on the surface of solid or adsorbent [4]. There are wide range of adsorbents have been used for removal of Pb(II) such as natural products, zeolite, aluminosilicate, peat, clay, and activated carbon [5]. Among the wide range adsorbents, carbon-based materials particularly activated carbon (ACs) has become as one of the commonly used adsorbent for Pb(II) adsorption ascribed by their highly porous and high specific surface area [5]. In recent years, studies have been focusing on the development of activated carbon in nanofiber form (ACNFs). The developed ACNFs have been reported to possess smaller pore diameter with more concentrated pore size distribution which this properties are required for adsorption process [5].

There are several methods can be used to fabricate nanofibers such as melt fibrillation, island-in-sea, electro-spinning and gas jet technique [6]. Nevertheless, it seems that electro-spinning process as shown in Figure 1 provides more advantages in term of high production rate and relatively low in cost as compared to the other techniques mentioned previously. To prepare electrospun ACNFs, polymer polyacrylonitrile (PAN) serves as an excellent carbon precursor as it has high carbon yield as compared to other carbon precursors [6]. Recently, many researchers had focused on incorporating various metal oxides such as magnesium oxide, iron oxide, zinc oxide, aluminium oxide and manganese oxide as additive in the dope suspension of ACNFs [7]. Adding metal oxides such as zinc oxide can enhance adsorption capacity as it is reported that these additives can improve the properties of the ACNFs [8,9]. Thus, the aim of this study is to fabricate ACNFs based polyacrylonitrile (PAN) as carbon precursor and zinc oxide as additive by electrospinning process. The prepared ACNFs were evaluated based on its physicochemical properties as well as it adsorptive performance towards Pb(II) from aqueous solution.

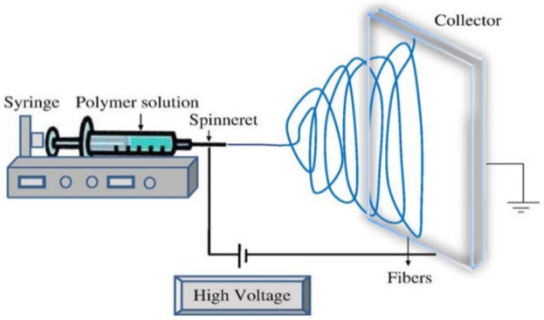

Figure 1. Schematic setup for electrospinning process [7]

## Materials and Methods

### Materials

Polyacrylonitrile (PAN) with molecular weight of 150kDa was purchased from Sigma Aldrich (USA). Similarly, N,N-Dimethylformamide (DMF) and zinc oxide (ZnO) powder with 99% purity were purchased from Alfa Aesar. Stock solution of Pb(II) was prepared using lead nitrate ($Pb^2NO^3$) powder (Sigma Aldrich, USA) while the pH of heavy metal solution was adjusted by using 0.1mol of NaOH and HCl.

### Preparation of PAN-ZnO nanofibers by electrospinning

Initially, dope solution of PAN-ZnO was prepared by stirring 5 wt.% of ZnO powder with N-N dimethylformamide (DMF) for 5 hours followed by addition of 10 wt.% polyacrylonitrile (PAN). The mixture was again continuously stirred for another 24 hours to obtain a homogenous solution. The dope solution was later subjected to electrospinning process under the electric field of 12kV, suspension rate of 1.0mL/hour and distance of 20 cm. The collected nanofibrous mats were allowed to dry for at least a day prior to carbonization and activation process.

### Preparation of PAN-ZnO ACNFs

The PAN-ZnO nanofibrous mats were later subjected to three pyrolysis processes: 1) stabilization; 2) carbonization and 3) activation following procedure [10]. The nanofibers were stabilized in pure air at temperature of 250 $^oC$ for 4 hours with heating rate of 1 $^oC$/min. For the carbonization process, the process was carried out in nitrogen gas at temperature of 325 $^oC$ for 1.5 hours with heating rate of 3 $^oC$ /min. Lastly, the carbonized nanofibers were activated at a heating rate of 3 $^oC$/min with under carbon dioxide until temperature at 425 $^oC$. The physicochemical properties of the end product which is activated carbon nanofibers (ACNFs) was characterized as described in section 2.4. Figure 2 shows the procedures of ACNFs fabrication.

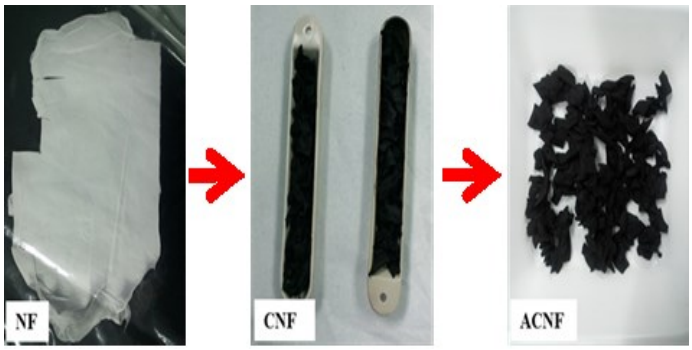

Figure 2. Preparation of nanocomposite ACNFs/ZnO

### Characterization

In this study, characterizations were carried out in term of specific surface area (SSA), morphological structures and functional groups analysis by BET, FESEM-EDX and FTIR, respectively. To analyze the specific surface area of NFs and ACNFs, the specific surface area was determined by using automatic Tristar 3000 volumetric system.The surface morphologies of the ACNFs were examined using Field Emission Scanning Electron Microscopy (FESEM) respectively. The samples were placed on a staph and were sputtered with gold prior of FESEM analysis. The distribution and presence of Zn particles were analyzed by EDX, which was conducted by using the images captured by FESEM analysis. The functional groups present in PAN-ZnO ACNFs were identified using ATR-FTIR spectrometer (Model: IRTRACE100, Shimadzu). The samples were scanned by single-reflectance ATR accessory with IRTRACER100. The sample was prepared by cutting it into a small pieces and scanning at a wavelength 400 $cm^{-1}$ to 4000 $cm^{-1}$.

**Pb(II) adsorption study**

The adsorptive performance of ACNFs on lead removal was conducted by studying the effect of initial pH and initial concentration. In every sample, 0.01 g of neat ACNFs and composite ACNFs was added into 10 mL Pb(II) solution. The solution was agitated for 48 hours in rotary shaker. The pH was adjusted using 0.1 mol of NaOH and HCI. The equilibrium concentrations of each samples was measured by filtering the samples and analyzed using Atomic Absorption Spectrometer (AAS) (model 4100ZL, Perkin Elmers).

The removal efficiency, R(%) and adsorption capacity of prepared PAN-ZnO ACNFs were calculated using equation 1 and 2, respectively [9]:

$$R(\%)= (C_o-C_e)/C_o \times 100 \quad (1)$$

$$q_e\ (mg/g)=(C_o-C_e)V/m \quad (2)$$

where $C_o$ is initial concentration of metal (mg/L); $C_e$ is equilibrium concentration of metal (mg/L); $V$ is volume of solution in (L) and $m$ is mass of adsorbent.

**Adsorption isotherm**

Adsorption isotherm analysis was conducted to analyze the adsorption behavior of ACNFs for the removal of Pb(II) ions from aqueous solution. The linear equations of Langmuir and Freundlich models are described from equation 3 and 4, respectively [9].

$$C_e/q_e = 1/Q_{max}b + C_e/Q_{max} \quad (3)$$

where $q_e$ is amount of Pb (II) adsorbed to adsorbent (mg/g); $C_e$ is equilibrium concentration of metal (mg/L). $Q_{max}$ is maximum adsorption capacity (mg/g) and $b$ is the Langmuir constant.

$$\ln q_e = \ln KF + (1/n) \ln C_e \quad (4)$$

$q_e$ is amount of Pb (II) adsorbed to adsorbent (mg/g); $C_e$ is equilibrium concentration of metal (mg/L); $K_F$ is the Freundlich constant (mg/g) and $1/n$ is parameter related to adsorption intensity.

## Results and Discussion

**Characterizations of PAN-ZnO ACNFs**

***Specific surface area***

Table 1 shows the specific surface area (SSA) of ACNFs and ACNFs/ZnO after activation process. From the table, it can be seen that addition of ZnO in the ACNFs increased the specific surface area from 67.60 $m^2/g$ for neat ACNFS to 163.04 $m^2/g$ for composite ACNFs/ZnO. The larger specific surface area could be resulted from the role of metal oxides (in our study, ZnO) that acts as catalyst that accelerates the process of carbonization and activation. As results, more pores were created which contributes to larger specific surface area [8]. Nevertheless, the SSA obtained by both ACNFs were lower as compared to the studies reported elsewhere [9]. It is believed that the carbonization and activation process of the ACNFs might be incomplete, and thus contributed to low SSA when analyzed by BET analysis. Thus, longer duration of activation and carbonization might be required.

Table 1. Specific surface area of NFs and ACNFs

| Sample | Specific Surface Area (S.S.A) ($m^2/g$) | |
|---|---|---|
| | Before Activation | After Activation |
| Neat ACNFs | 9.13 | 67.60 |
| ACNFs/ZnO | 8.91 | 163.04 |

***SEM/FESEM – EDX analysis***

The structural morphologies of neat ACNFs and composite ACNFs are shown in Figure 3. It can be seen that the neat ACNFs possessed more aligned and straight fibers while the PAN-ZnO ACNFs showed more compact arrangement with bent surfaces. The result obtained is in agreement to study conducted by Imtiaz et al. where the activation process and the presence of ZnO led to cross-sectional shrinkage and causing the surface of fibers became rougher and more compact [11]. It can also be seen that there are white spots present alongside the fibers (as indicated by circle marks) which this could be referred as ZnO which is dispersed as beads alongside the PAN-ZnO nanofibers. Dispersion of ZnO beads further supported with EDX mapping as depicted in Figure 4 confirmed that ZnO exists in the ACNFs.

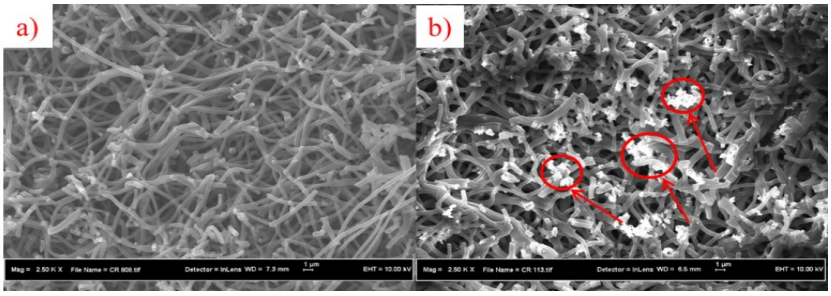

Figure 3. Structural morphologies of a) neat ACNFs and b) PAN-ZnO ACNFs

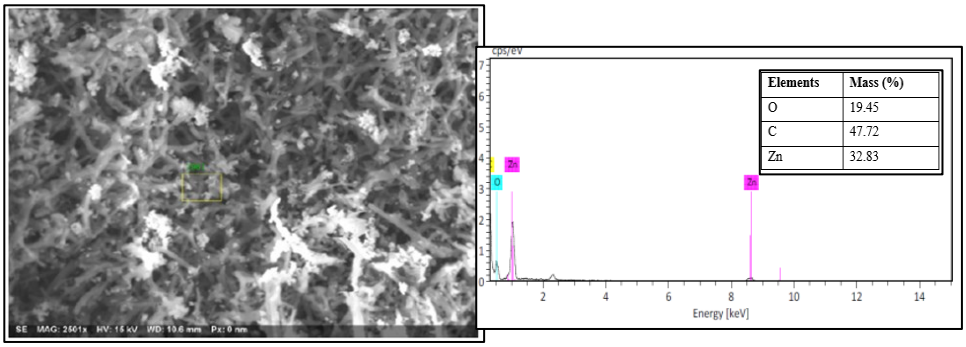

Figure 4. EDX mapping and elemental analysis of PAN-ZnO ACNFs

***FTIR analysis***

Figure 5 displays the FTIR spectrum of neat and PAN/ZnO based ACNFs. It can be seen that the activation process removed nitrile groups (C≡N) and methylene group ($CH_2$), only carbon and hydrogen remain as observed at wavelength peaks of 1573 $cm^{-1}$ and 1250 $cm^{-1}$ indicating aromatic C-C groups and alkyl halides C-H groups [9]. In addition, absorption peak at 436.5$cm^{-1}$ was identified as Zn-O, indicating the presence of ZnO nanoparticles in the composite ACNFs [11]. The result is supported by EDX-mapping as displayed by Figure 4 previously, which showing the presence of elements Zn.

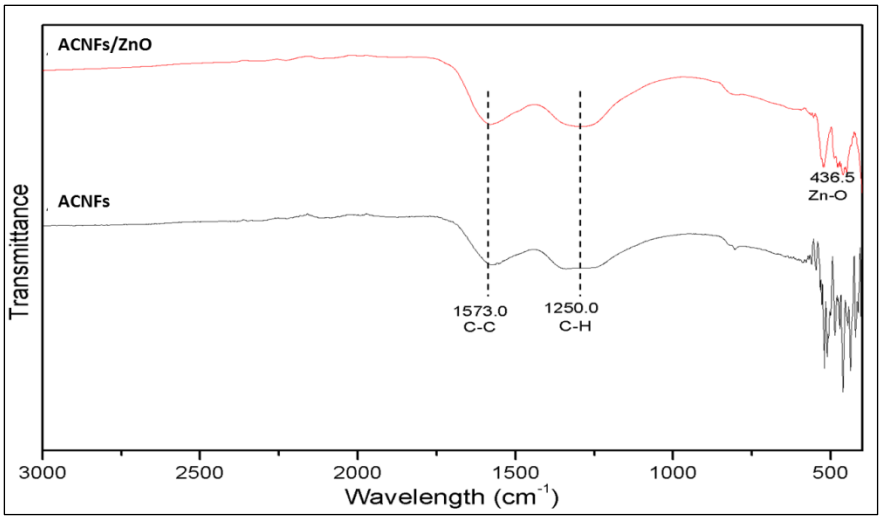

Figure 5. FTIR spectrum of ACNFs and ACNFs/ ZnO

**Adsorptive performance of ACNFs on Pb removal**

***Effect of pH***

The adsorption of Pb(II) on ACNFs/ZnO at different pH (1.0 to 6.0) was conducted and the results are shown in Figure 6. The pH values higher than 6 was not tested in order to avoid precipitation of Pb(II) with $OH^-$ ions which will form lead salts as well as to avoid any inaccuracy [11]. It can be seen from the figure that increasing pH of the Pb solution increased the removal efficiency. For neat ACNFs, the removal efficiency of Pb is 20.1% (pH 1.0) to 99.4% (pH 4.0). After pH 4.0, there is no increment of removal was obtained. Therefore, the optimum pH of Pb(II) removal on ACNFs is from pH 4.0 to pH 6.0. Similarly, for ACNFs/ZnO, increasing the pH caused a gradual increase of Pb(II) removal from 20.0% (pH 1.0) to 99.4% (pH 6.0) in which the optimum pH for removal of Pb on ACNFs/ZnO is at pH 6.0. From the pH study, it can be seen that both ACNFs and ACNFs/ZnO have good removal efficiency which was more than 99.0%. From the trend shown by both ACNFs, it is evident that the removal of Pb(II) is strongly related to pH which is related to the protonation of the functional groups existed in ACNFs. In acidic condition, low adsorption efficiency was achieved due to the competition between H+ and metal ions for active sorption sites while at higher pH value, thus permitting the attraction between the metal ions and the surface of the adsorbent [8, 9].

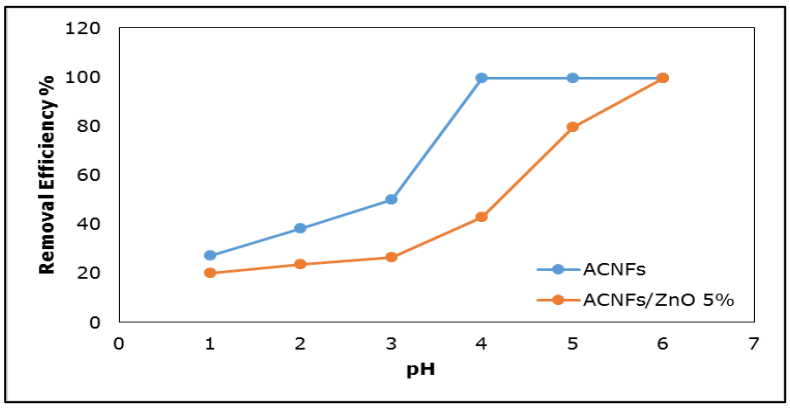

Figure 6. Effects of pH on removal of Pb(II)

***Effect of initial concentration***

Figure 7 depicts the removal of Pb(II) by neat and PAN-ZnO ACNFs with respect to different initial concentration (10 – 121 mg/L) of Pb(II) solution. For both ACNFs, it can be seen that the percentage of adsorption capacity increased with the increase of initial concentration. The highest adsorption capacity achieved for neat ACNFs was 77.60 mg/g. whereas the highest adsorption capacity achieved for ACNFs/ZnO 5% was 120.3 mg/g. For carbon-based adsorbents, the adsorptive capabilities are contributed surface area, pore volume as well as minor role of surface functional groups which adsorb the ions. For the adsorption process, enhancing the former features is necessary as higher SSA and pore volume facilitate the adsorption process due to the availability of more binding sites [11]. As discussed in the previous section, the SSA of ACNFs/ZnO were higher than the neat ACNFS. Thus, the higher adsorption capacity may be attributed to the higher number of active sites provided by ZnO. It is possible that addition of ZnO increased the active adsorption sites that increase the adsorption capacity of composite ACNFs towards Pb(II) [9]. The satisfactory adsorption capacity also contributed due to the fact that ZnO itself is adsorbent and very favorable towards sorption of heavy metals [9].

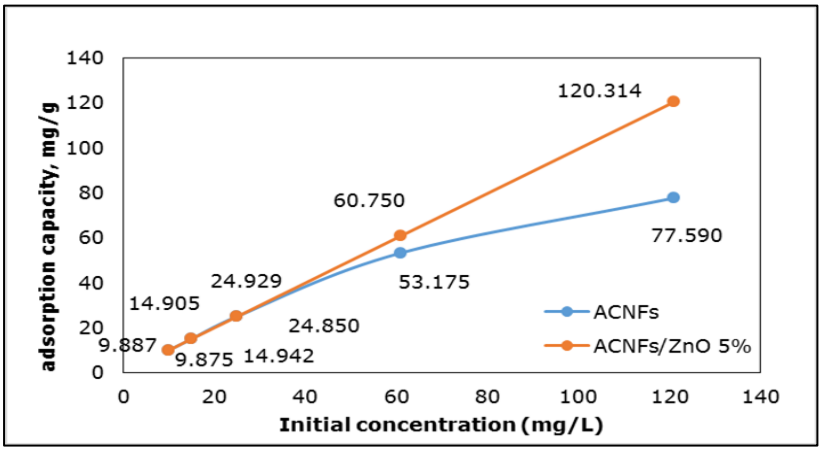

Figure 7. Effect of initial concentration

**Adsorption isotherm study**

In order to evaluate the mechanism of adsorption occurred on the surface of adsorbent, Langmuir and Freundlich isotherm models were applied and the results are presented in Table 2. As refer to Table 2, the $R^2$ values from Freundlich model (0.960) for ACNFs was higher than Langmuir model (0.608). Similar results were obtained for ACNFs/ZnO in which the $R^2$ values from Freundlich model (0.958) was higher than Langmuir model (0.939). Thus, Freundlich isotherm model is best fitted to describe the adsorption behaviour that took place between the ACNFs and ACNFs/ZnO with Pb(II) ions. From that, it is assumed that the attachment of Pb(II) ions occurred at heterogeneous surface of the neat ACNFs and ACNFs/ZnO [11].

Table 2. Langmuir and Freundlich isotherm parameters

| Adsorbent | Langmuir Model | | | Freundlich Model | | |
|---|---|---|---|---|---|---|
| | $Q_{max}$ (mg/g) | b (L/mg) | $R^2$ | K (mg/g) | 1/n | $R^2$ |
| ACNFs | 54.6 | 0.778 | 0.608 | 9.314 | 0.882 | 0.960 |
| ACNFs/ZnO | 169.5 | 1.594 | 0.939 | 2.920 | 0.011 | 0.958 |

## Conclusion

In this study, the feasibility of ACNFs/ ZnO to remove Pb(II) from aqueous solution was demonstrated. The specific surface area was increased by addition of zinc oxide in the ACNFs component. Under SEM analysis the ACNFs/ZnO were found to have compact arrangement with dispersion of Zn beads. The adsorption studies revealed that the removal was dependant on pH and the adsorption mechanism were best fitted to be described by Freundlich model with the highest adsorption capacity in this study was 120.3 mg/g.

**Abstract**

Tissue engineering has emerged to provide a new medical therapy in helping tissue regrowth and regeneration by employing scaffold as an artificial supporting structure for cellular growth. Many polymers have been utilized in the fabrication of these artificial scaffolds, but there is still a need to fabricate hydrophilic nanofibrous scaffold with appropriate degradation rate. In this study, polycaprolactone (PCL) and polycaprolactone/gelatin (PCL/Ge) 70:30 nanofibrous scaffolds were fabricated using electrospinning technique and compared on *in vitro* degradation rate to determine a more suitable scaffold for skin tissue engineering application. *In vitro* degradation was evaluated by morphological changes, water uptake, and chemical bonding until 12 weeks. Result shows that both PCL and PCL/Ge (70:30) nanofibrous scaffolds were degraded after 8th week. However, the degradation rate of PCL nanofibrous scaffold is slower and does not has obvious morphological changes. PCL/Ge (70:30) nanofibrous scaffold with faster degradation rate have the potential for skin tissue engineering application.

**Abstrak**

Kejuruteraan tisu muncul untuk menyediakan terapi perubatan baru dalam membantu pertumbuhan semula tisu dengan menggunakan perancah sebagai struktur sokongan tiruan untuk pertumbuhan selular. Banyak polimer telah digunakan dalam penghasilan perancah ini, namun masih wujud permintaan terhadap penghasilan perancah gentian hidrofilik yang bersaiz nano dengan kadar degradasi yang sesuai. Dalam kajian ini, gentian perancah nano polikaprolakton (PCL) dan polikaprolakton/gelatin (PCL/Ge) 70:30 telah dihasilkan dengan teknik putaran elekron dan kadar degradasi *in vitro* dibandingkan untuk menentukan perancah yang lebih sesuai bagi aplikasi kejuruteraan tisu kulit. Degradasi *in vitro* telah dinilai melalui perubahan morfologi, penyerapan air, dan ikatan kimia kedua-dua gentian perancah nano sehingga 12 minggu. Keputusan menunjukkan kedua-dua PCL dan PCL/Ge (70:30) gentian perancah nano telah degradasi selepas minggu ke-8. Walau bagaimanapun, kadar degradasi gentian perancah nano PCL adalah lebih perlahan dan tiada perubahan morfologi yang jelas. Gentian perancah nano PCL/Ge (70:30) dengan kadar degradasi yang lebih cepat mempunyai potensi dalam bidang kejuruteraan tisu kulit.

**Kata kunci:** kejuruteraan tisu, perancah gentian nano, degradasi *in vitro*, polikaprolakton, polikaprolakton/gelatin

## Introduction

Tissue engineering is an interdisciplinary field that uses life sciences and engineering principles to develop biological substitutes for example fibrous scaffold for improving, maintaining and restoring the function of tissues

or organs. Skin tissue engineering has been developed recently due to the limitations of autografts and allografts such as availability of healthy autologous skin, infections, and scarring. The emergence of skin tissue engineering facilitates the treatment of patients with deep dermal injuries, deep skin burns, and skin related disorders [1]. Skin tissue engineering aims to promote the healing of wounds [2], repair, and promote the regeneration of skin tissue with reduced scarring [1] by applying fibrous scaffold on the wounds.

There are many techniques of scaffold fabrication. One of the techniques which is simple and cost effective for fibrous scaffold fabrication is electrospinning technique [3]. Electrospinning, a technique that utilises electrostatic forces to produce fibers has been emerging from 100 years ago [4]. This technique is versatile to spin a wide range of materials such as polymers, composites, and ceramics into extremely thin fibers ranging from micrometers to a few nanometers [5]. These thin fibers mimic the structural dimension of extracellular matrix (ECM) of tissues and organs [4]. Moreover, small dimension of fibers provides high surface area to volume ratio for cellular growth [4]. The product of electrospinning is called electrospun fiber or electrospun membrane or fibrous scaffold. Electrospinning technique is able to fabricate nano-sized fibrous scaffolds which mimic ECM of skin for skin tissue engineering.

To fabricate scaffold, biomaterials such as biodegradable polymers are widely used as the material of scaffold. Using biodegradable polymer as scaffold, it will provide an adequate support for cells and degrade at a rate coincide with tissue growth. Biodegradable polymers are divided into biodegradable synthetic polymers and natural polymers. In this study, biodegradable synthetic polymer, polycaprolactone (PCL) and natural polymer, gelatin (Ge) were used. Both polymers were Food and Drug Administration (FDA) approved to be safe for human body [6, 7].

Some studies observed that PCL fibrous scaffolds caused a reduction in the ability of cell attachment, migration, proliferation, and differentiation [8]. Cell affinity towards synthetic polymer is usually poorer than natural polymer. PCL has the advantages of biodegradable and biocompatibility, but it has lower hydrophilicity, slower degradation rate, and lack of surface cell-recognition sites [9]. Ge is a natural polymer derived from collagen, the main structural component of ECM of skin. It is hydrophilic and has faster degradation rate. Previous study had investigated Ge and blending of Ge with poly(L-lactic acid)-co-poly(ε-caprolactone) (PLACL) for the application of skin tissue engineering [10, 11]. Ge fibrous scaffold has the potential for dermo-epidermal composite skin substitute [10]. Blending of poly(L-lactic acid)-co-poly(ε-caprolactone) (PLACL)/Ge is favorable for cell infiltration [11]. However, an appropriate degradation rate is also an important characteristic for skin tissue engineering application. In this study, Ge is selected to be blended with PCL to achieve a desired fibrous scaffold for the aim to increase the degradation rate. PCL and PCL/Ge (70:30) nanofibrous scaffolds were compared on *in vitro* degradation to choose a suitable scaffold for skin tissue engineering application.

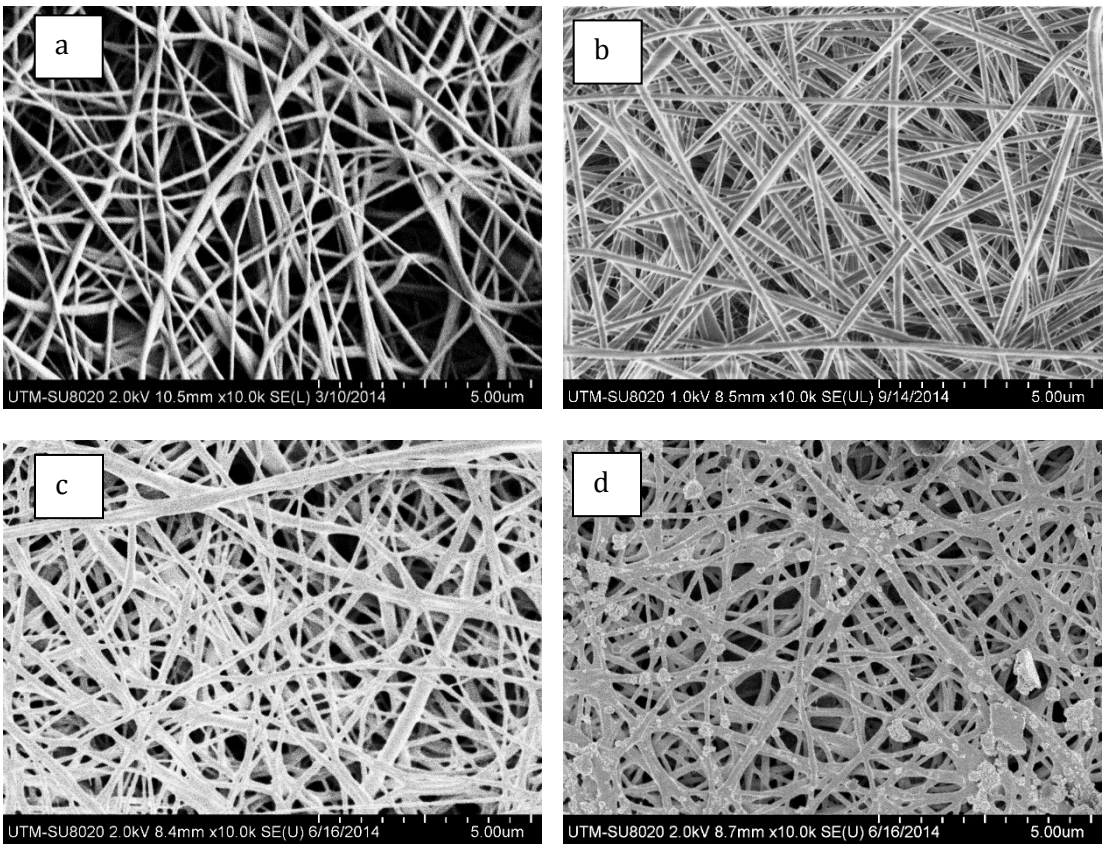
## Materials and Methods

Polymer Ge Type A in powder form (~300 g Bloom) from porcine skin, PCL with molecular weight 70,000 – 90,000, formic acid (≥ 95%), and phosphate buffered saline (PBS, P-3813, pH 7.4) were obtained from Sigma Aldrich (St. Louis, MO). PCL and PCL/Ge with weight ratio 70:30 were dissolved in formic acid. Both solutions were electrospun to fabricate nanofibrous scaffolds by using electrospinning technique. Degradation of PCL and PCL/Ge (70:30) nanofibrous scaffolds was evaluated by morphological changes and water uptake. Nanofibrous scaffolds were sectioned into 1 x 1cm$^2$, weighted, and incubated at 37 ºC in 10 ml PBS. After 4, 8, and 12 weeks of incubation, nanofibrous scaffolds were washed with distilled water to remove residual buffer salts. Nanofibrous scaffolds were blotted dry with tissue paper to remove excess water and weighted. Water uptake of nanofibrous scaffolds was calculated using the following equation 1 [12].

$$\text{Water Uptake } (\%) = \frac{W_w - W_d}{W_d} \times 100 \quad (1)$$

where $W_w$ is weight of scaffold after incubation, $W_d$ is weight of scaffold before incubation.

This process was repeated for three times for each time point. The average and standard deviation of water uptake was plotted against degradation time. Nanofibrous scaffolds were dried at room temperature until a constant weight



had achieved and coated with gold for the preparation to be viewed under field emission scanning electron microscope (FESEM). Morphological changes of the fibers after degradation for 8 and 12 weeks were determined by FESEM images.

Chemical bonding analysis of both PCL and PCL/Ge nanofibrous scaffolds was performed by using an attenuated total reflectance (ATR) spectroscopy (Perkin-Elmer Series, USA Modal) in the range of 4000 – 400 $cm^{-1}$.

## Results and Discussion

PCL and PCL/Ge (70:30) scaffolds were fabricated using electrospinning technique by using formic acid as solvent. 14% w/v of PCL and PCL/Ge (70:30) in formic acid formed fibrous scaffold with nanosized diameter. Previous study had reported that the average fiber diameter of PCL and PCL/Ge (70:30) fibrous scaffolds were 88.02 ± 27.83 nm and 155.60 ± 41.13 nm [13]. The contact angle of as-fabricated PCL was 112.30 ± 8.14 and 43.83 ± 0.06 for PCL/Ge. Both nanofibrous scaffolds were compared on *in vitro* degradation. Biodegradable scaffolds are usually degraded and replaced by new tissue. Ideally, the rate of degradation should match the rate of tissue regeneration or tissue growth in vitro and in vivo [9, 14, 15]. In this study, PCL and PCL/Ge (70:30) nanofibrous scaffolds were incubated in PBS at 37 ºC for 12 weeks.

Figure 1 illustrates the morphological changes of PCL and PCL/Ge (70:30) nanofibrous scaffolds before incubation and after 8 and 12 weeks of incubation. From the FESEM images, there was no broken fiber was observed. The fiber diameters of PCL and PCL/Ge increased after absorbing water at different degradation period which is referred as "swelling".

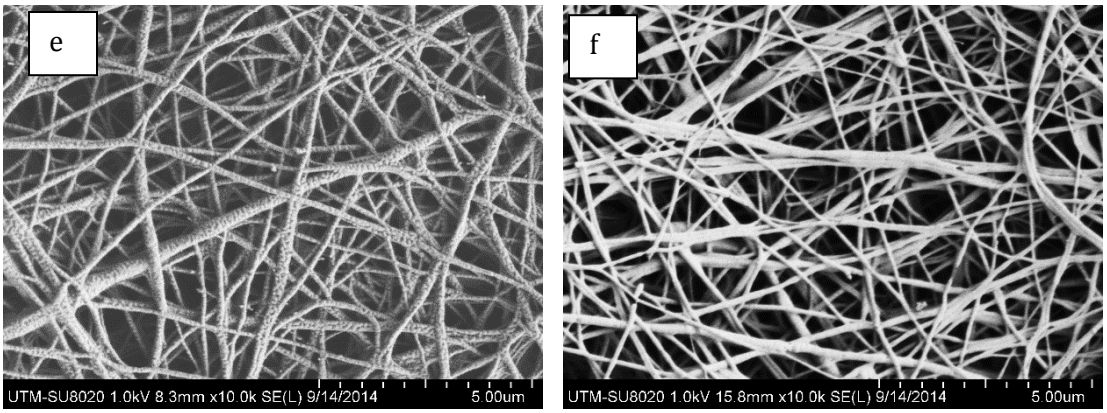


Figure 1. FESEM images of PCL (left) and PCL/Ge (70:30) (right) nanofibrous scaffolds for *in vitro* degradation (a, b) before degradation, (c, d) after 8 weeks, (e, f) after 12 weeks

Water uptake percentage of PCL and PCL/Ge (70:30) nanofibrous scaffold was also studied for 4, 8, and 12 weeks to evaluate the rate of degradation. Figure 2 shows the percentage of water uptake.

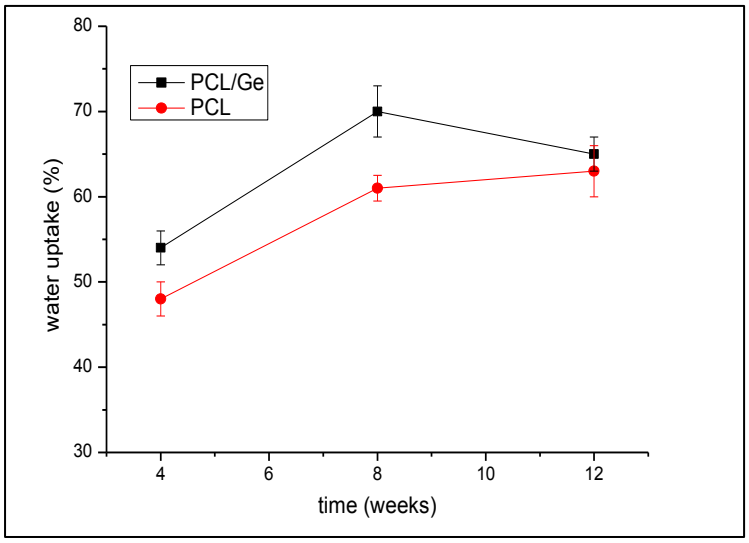

Figure 2. Water uptake percentage of PCL and PCL/Ge (70:30) nanofibrous scaffolds after degradation for 4, 8, and 12 weeks

With increasing time, water uptake percentage of PCL nanofibrous scaffold was increasing, but water uptake percentage of PCL/Ge (70:30) nanofibrous scaffold decreased at week 8. In overall, percentage of water uptake of PCL/Ge nanofibrous scaffold was higher than PCL nanofibrous scaffold due to the presence of an amide bond. Amide bond of Ge presence in PCL/Ge scaffold is able to form hydrogen bonds with water molecules. Hence, PCL/Ge nanofibrous scaffold is hydrophilic and takes up more water. However, from the result, percentage of water uptake decreased at week 8 as nanofibrous scaffolds were started to degrade. Degradation of amide bond decreases its ability to form hydrogen bonds with water molecules. Hence, percentage of water uptake was decreased.

Chemical structure of both PCL and PCL/Ge (70:30) nanofibrous scaffolds are investigated using ATR. Figure 3 shows the ATR spectra of PCL and PCL/Ge nanofibrous scaffolds before and after degradation.

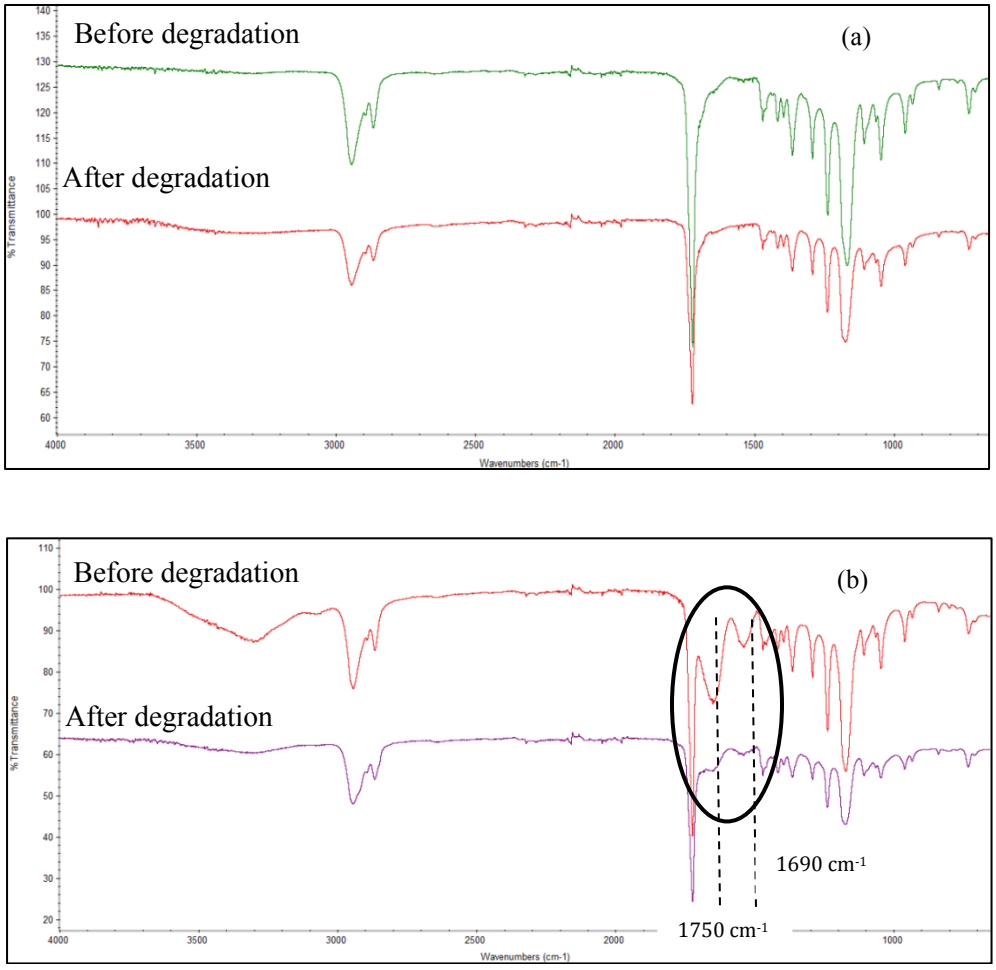

Figure 3. Chemical structure analysis of nanofibrous scaffolds before and after degradation for 8 weeks (a) PCL and (b) PCL/Ge

PCL is a polyester containing ester (C=O-O) groups and cyclic alkyl groups. It can be observed in Figure 3 (a) that there are three prominent absorption peaks displayed in both polycaprolactone (PCL) spectra before and after degradation. Absorption band at around 2900 and 2800 $cm^{-1}$ are attributed to asymmetric and symmetric $sp^3$ C-H stretching, 1730 – 1750 $cm^{-1}$ is assigned to C=O-O, and 1150 $cm^{-1}$ is indicated the presence of C-O group. The difference between these two spectra is that the loss of concentration of PCL proven by decreasing of the PCL intensity in the spectrum after degradation.

In Figure 3 (b), it is clearly seen that the absorption peak of carboxylate group (C=O-O, around 1730 – 1750 $cm^{-1}$), amide group (C=O-N, 1690 $cm^{-1}$) and carbonyl group (1150 $cm^{-1}$) reduced after the 8$^{th}$ week. It is proven that the PCL/Ge degraded in PBS solution. Hence, the water absorption capacity was decreased due to the loss of carboxylate, amide and carbonyl groups which can form hydrogen bonding with water molecules.

Both PCL and PCL/Ge nanofibrous scaffolds were degraded after 8$^{th}$ week. However, the degradation rate of PCL nanofibrous scaffold is slower and does not has obvious morphological changes. PCL has been known for its slow

degradation rate which can degraded up to 3 – 4 years [6]. After adding Ge, degradation rate has increased. Type of the chemical bond and water uptake are the most important factors that will influence the rate of degradation of a scaffold [15, 16].

## Conclusion

In this study, nanofibrous scaffolds of PCL and PCL/Ge with weight ratio 70:30 were produced. The results reported in this study demonstrated that the degradation rate of PCL/Ge (70:30) nanofibrous scaffold was faster than PCL nanofibrous scaffold. PCL nanofibrous scaffold with slow degradation rate is more suitable to be used for long-term implantation and long-term drug delivery carrier while PCL/Ge (70:30) nanofibrous scaffold might have the potential to be used for skin tissue engineering application.

**Abstract**

The present work is aimed to study the influence of membrane internal structure on the extracting performance of hollow fiber membrane contactor system in removing free fatty acid (FFA) from crude palm oil (CPO). Polyphenylsulfone (PPSU) hollow fiber membrane were prepared via wet spinning method. Different bore fluid composition were employed mainly consisted of distilled water in combination with 0, 20, 30 and 40 wt.% N-methyl-2pyrrolidone (NMP). The resulting membranes structure were characterized for membrane morphology, membrane wettability and membrane pore size. The used of pure distilled water as membrane BF had created a large macrovoid structure with uniform and tiny finger-liked morphology at the outer membrane layer. Meanwhile, the present of NMP in BF composition had obviously changed the internal layer of 14PPSU membrane to more interconnected double-layers of finger-liked morphology. However, there are not much different in membrane wettability and pore size of 14PPSU membrane were recorded. All PPSU hollow fiber membranes were further evaluated for deacidification performance through membrane contactor with sodium hydroxide (NaOH) as liquid extractant. 14PPSU-100:0 membrane contactor that prepared from100% distilled water as BF composition demonstrated the highest FFA removal of 16.54% without soap formation in oil permeate stream.

**Keywords**: polyphenylsulfone, membrane contactor, sodium hydroxide, free fatty acids, crude palm oil

**Abstrak**

Hasil kerja ini bertujuan untuk mengkaji pengaruh struktur dalaman membran kepada prestasi pengekstrakan gentian geronggang membran kontaktor sistem dalam mengeluarkan asid lemak bebas (FFA) daripada minyak sawit mentah (MSM). Membran polifenilsulfona gentian geronggang telah disediakan melalui teknik fasa balikan basah. Komposisi cecair lubang yang berbeza telah digunakan dimana sebahagian besarnya terdiri daripada air suling dengan kombinasi 0, 20, 30 dan 40 wt.% berat N-metil-2pirolidon (NMP). Struktur membran yang dihasilkan telah diperincikan kepada morfologi membran, kebolehbasahan membran dan saiz liang membran. Penggunaan air suling tulen sebagai cecair lubang telah mewujudkan struktur ruang makro dengan morfologi seperti jejari kecil dan sekata pada lapisan luar membran. Sementara itu, kehadiran NMP dalam komposisi cecair lubang dengan jelas telah mengubah lapisan dalaman membran 14PPSU untuk saling berhubung diantara dua lapisan morfologi jejari. Walau bagaimanapun, tiada perbezaan ketara pada kebasahan dan saiz liang membran 14PPSU telah direkodkan. Semua membran PPSU gentian geronggang telah dinilai pada prestasi penyahasidan melalui membran kontaktor bersama natrium hidroksida (NaOH) sebagai cecair pengekstrak. Membran 14PPSU-100:0 kontaktor yang dihasilkan daripada 100% air suling

sebagai komposisi cecair lubang telah menunjukkan penyingkiran FFA tertinggi sebanyak 16.54% tanpa pembentukan sabun dalam aliran minyak.

**Kata kunci:** polifenilsulfona, kontaktor membran, natrium hidroksida, asid lemak bebas, minyak sawit mentah

## Introduction

In palm oil industry, refining process involves the removal of undesirable constituents such as FFA, phospholipid, colour pigment and trace elements from crude palm oil (CPO) in order to achieve the required quality and stability of refined oil. Chemical and physical refining processes are the most common methods that has been applied in palm oil industry. Deacidification or the removal of free fatty acid (FFA) are conducted at different processing stage between these two refining approached. In chemical refining, the FFA is removed during neutralization stage in the formed of soapstock after reacted with sodium hydroxide (NaOH). In physical refining, the FFA is removed during deodorization stage by steam distillation at high temperature of 260 – 265 °C [1]. However, several drawbacks are identified from conventional refining processes such as high energy usage, losses of neutral oil and large amount of water and chemical usage had heavily produced a contaminated effluents [2].

Membrane technology is one of new deacidification approaches that can be further explore in order to overcome the drawbacks of conventional deacidification practices. It is due to advantages of low energy consumption, mild temperature operation and retention of nutrients and other desirable components [3]. Nevertheless, FFA in principle is almost impossible to be removed by membranes itself due to smaller molecular size of FFA (<300 Da) than the triglycerides (~900 Da). Theoretically, the ideal process would be to use a precise membrane pores size that could effectively separate the FFAs from the triglycerides [4].

In order to overcome the abovementioned limitation, membrane contactor technology is chosen for deacidification of CPO due to the advantages of liquid-liquid mass transfer without dispersion of one phase within another. In membrane contactors system, the membrane separation is fully integrated with another separation technology called extraction process in order to exploit the benefits of both technologies in improving the removal of FFA from CPO. The fluids to be contacted are flowed on the opposite sides of the membrane and the fluid/fluid interface forms at the mouth of each membrane pore. Mass transfer occurs by diffusion across the interface. The driving force for separation is a concentration rather than a pressure gradient; indeed only a very small pressure drop across the membrane is required to ensure that the fluid/fluid interface remains immobilized at the mouth of the pore [5].

Polyphenylsulfone (PPSU) membrane was chosen as a main polymer for membrane contactor system. Although PPSU is relatively new in the polysulfone family, it has a vast potential in various membrane applications, such as fuel cell [6], pervaporation [7], gas separation [8] and water treatment process [9]. PPSU that comprises sulfone moieties, ether linkages and biphenyl group in its repeat group have the highest impact strength compared with the other family members [10]. It presents superior resistant to hydrolysis and plasticization of stress cracking. The robustness of PPSU membrane in terms of physical durability and high tolerance to chemical resistance has standout as a remarkable polymer candidate, which could be potentially developed for further use in CPO deacidification [7].

A dry-jet wet spinning method usually employed a tube-in-orifice spinneret that transfer the nascent fiber through an air gap before it enters the coagulation bath. The shell surface structure can be controlled by the air gap length and the environment of the surrounding including relative humidity, temperature, organic vapor etc. Whereas, the bore fluid (BF) composition controlled the bore side structure [11]. Dong et al. [12] investigated the effect of various membrane fabrication parameters on the structure and separation performance of hollow fiber (HF) membrane for gas separation. They found that increasing NMP to water in BF composition had suppressed the finger-liked macrovoids and the sponge-like structure becomes predominant. Feng et al. [13] investigated on the PVDF-HF membrane fabrication using various N-methyl-2-pyrrolidone (NMP) aqueous solutions as an inner coagulant. They found that the PVDF membrane morphology had gradually shifted from a double-skin to a single-skin structure with the increased in NMP concentration.

The aimed of current research work is to study the influence of membrane internal structure at different BF composition (water/NMP) on the extracting performance of membrane contactor. It is generally known that changing the BF composition will change the membrane internal structure due to low solvent/non solvent exchange rate upon addition of solvent into bore fluid. The addition of NMP into BF composition could delay the demixing process, produce more porous membrane structure and better mass transport of solute (FFA) towards the liquid extractant for effective deacidification of CPO. NaOH is used as liquid extractant in PPSU membrane contactor system due to high affinity towards FFA. The interfacial contact between NaOH and CPO that immobilized in the membrane pores could serve as a good platform in extracting the FFA without contaminating the CPO with soap formation. Hence, it could prevent the oil loss throughout the process as well as an attractive solution towards "solvent-free" technology.

## Materials and Methods

### Materials

PPSU membrane polymer was purchased from Sigma-Aldrich. N-methyl-2pyrrolidone (NMP) was bought from Merck and used as a solvent in membrane dope solution and bore fluid composition. CPO was obtained from Sime Darby Jomalina Sdn. Bhd. (Telok Panglima Garang, Selangor,Malaysia). Sodium Hydroxide (NaOH) was used as liquid extractant for membrane contactor system. All chemicals used in this work were received without further treatment.

### Preparation of dope solution

Three membrane dope solution were prepared from a combination of 14% PPSU membrane and 86% NMP. Both polymer and solvent were mixed thoroughly under constant mechanical stirring at 60 $^{o}$C for 1 day in order to produce a homogenous solution. Then the formulated dope solution was degassed before spinning to remove the micro-bubbles.

### Fabrication of PPSU hollow fiber membrane

The HF membranes were fabricated according to the well-known wet spinning method. The dope was place in a stainless steel dope reservoir (volume: 1 liter) that was subsequently pump to the spinneret by a gear pump. The dope reservoir that contains polymer solution was kept under nitrogen pressure as a precaution against cavitation in the line to the pump. Then a pulse-free BF was fed into the inner tube of the spinneret by a syringe pump. Once the spinning dope and the BF met at the tip of the spinneret, they went into the external coagulation bath after going through zero air gap. The details spinning parameter of HF membrane is shown in Table 1. The nascent fibers were then passed through the washing/treatment bath before collected properly by a wind-up drum.

### Membrane post-treatment

The as-spun fibers were cut in pieces of approximately 40 cm in length and immersed in water bath at room temperature for 1 day to remove residual solvent from the membrane structure. Then the nascent HF membrane were post-treated with water/ ethanol (1:1) solution for 30 minutes, followed by pure ethanol solution for another 30 minutes to prevent fiber shrinkage. Finally, the fibers were hang vertically and air dried at room temperature for about 1 day before membrane characterization and preparation of membrane module.

### Membrane contactor module

A total of 100 pieces of HF membrane were potted inside the PVC pipe for membrane contactor performance testing. An epoxy adhesive resin (Polyurethane E-30CL Loctite) was used as the potting resin. This resin was chosen due to its suitable cure times, low viscosity and proper adhesion with the PVC and steel tubing. Table 2 shows the detail specification of HF membrane contactor module.

### Membrane characterization

PPSU membrane cross-sectional images was observed using table-top scanning electron microscope (SEM, Model: TM 3000, Hitachi). All specimens were freeze-dried and coated with an ultra-thin layer of gold before characterisation. Prior to analysis, a piece of hollow fiber was immersed in a liquid nitrogen and fractured carefully in order to create a perfect cross section.

Table 1. Spinning parameters for fabrication of PPSU-HF membrane

| Spinning Parameter | Composition |
|---|---|
| Spinning solution | 14PPSU/86NMP |
| Bore fluid composition | Distilled water/ NMP |
| (a) 14PPSU-80:20 | 80/20 |
| (b) 14PPSU-70:30 | 70/30 |
| (c) 14PPSU-60:40 | 60/40 |
| Inner diameter of spinneret (mm) | 0.55 |
| Outer diameter of spinneret (mm) | 1.25 |
| Air gap (mm) | 0 |
| Dope extrusion rate ($cm^3$/min) | 7.2 |
| Bore fluid flow rate (ml/min) | 2.2 |
| Take-up rate (rpm/min) | 24 |
| Spinning temperature (°C) | 27 |
| External coagulant | Distilled water |
| Coagulation bath temperature (°C) | 25 |

Table 2. Specification of HF membrane contactor module

| Membrane Specification | Value |
|---|---|
| Module i.d. (mm) | 35 |
| Module length (mm) | 400 |
| Fiber o.d. (mm) | 0.55 |
| Fiber i.d. (mm) | 1.25 |
| Effective fiber lengh (mm) | 330 |
| No. of fibers | 100 |

The membrane wettability property of HF membrane was evaluated by sessile drop method using contact angle goniometer (Model: OCA15Plus, Dataphysics, Germany) equipped with images processing software. A total of 10 contact angle measurement were recorded from each sample to get more accurate and average reading.

The field emission scanning electron microscopy (FESEM) (Hitachi model S-900) was used to capture the membrane images with magnifications ranging from 10,000 to 50,000. The electron beam was accelerated under a 3.0 kV in the vacuum chamber. The images obtained from the FESEM were analyzed by the software 'AnalySIS' provided by Soft Imaging System. The pores area was measured by encircling the membrane pores.

**Lab-scale hollow fiber membrane contactor system**

Figure 1 shows a schematic diagram of membrane contactor system for CPO deacidification. The pressure was set at 0.1 bar for both CPO stream (1) and NaOH stream (2). Initially, CPO was subjected to pre-treatment process to remove gums (phospholipids) before deacidification process. The treated CPO was heated and maintained at 50 to 60°C when passing through membrane contactor module within the membrane housing (shell-side), whereas the NaOH was circulated inside the lumen (tube-side) of PPSU membrane (Figure 2). The interfacial contact between CPO and NaOH occurred at the mouth of membrane pores for FFA extraction towards the liquid extractant. 200 ml permeate oil was collected every 30 min time interval for 3 hours for FFA and soap content analysis.

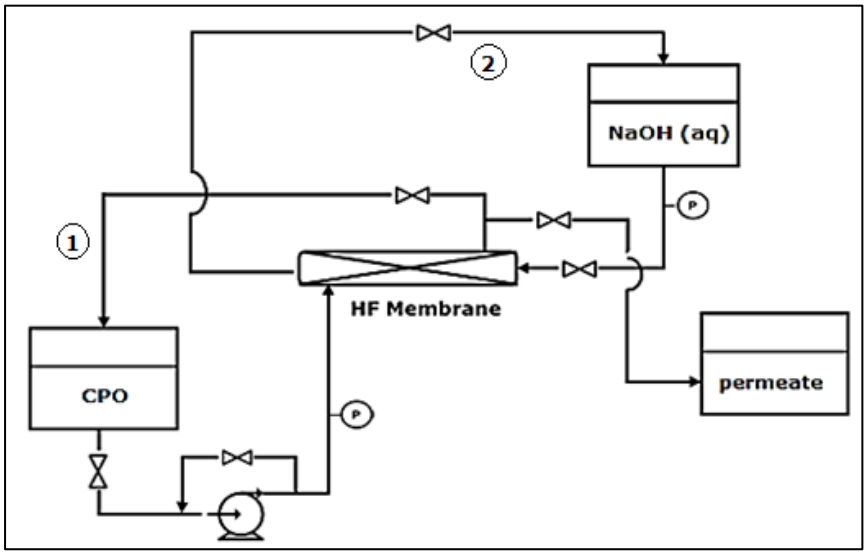

Figure 1. Schematic diagram of HF membrane contactor system

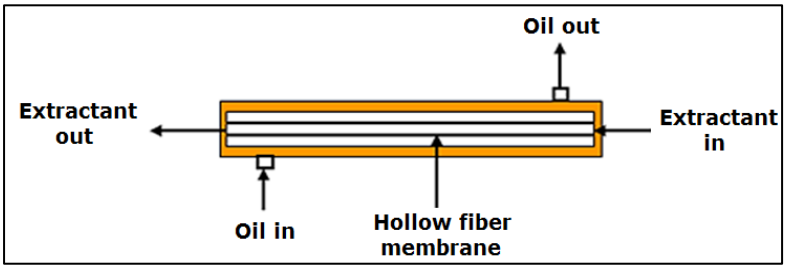

Figure 2. Flow direction of CPO stream and NaOH stream within a membrane housing

**Oil analysis**

Free fatty acid (FFA) and soap content in the oil samples was determined according to the American Oil Chemists' Society (AOCS) Official Method – Ca 5a-40 and Cc 17-95, respectively.

**Statistical analysis**

Statistical analysis software (Minitab 17) was used to perform statistical analysis for R-square and P-value. The analysis of variance (ANOVA) with Tukey pairwise comparison was performed to determine the significant difference at $P < 0.05$. Analysis was conducted in triplicates.

## Results and Discussion

**Membrane morphology**

The influence of internal coagulant on HF membrane properties has been investigated by many researchers. It was found that the addition of solvent into the internal coagulant significantly reduced the precipitation rate. The formation of hollow fiber is based on the solvent/non-solvent exchange mechanism. The used of distilled water as membrane BF due to significant concentration gradient results in a rapid exchanged mechanism. The exchanged mechanism is significantly slower when the BF contains solvent [14, 15].

The most two important parameters that influences the membrane properties are type of solvent and polymer concentration in membrane dope solution. 14PPSU-100 HF membrane that fabricated using 100% distilled water as BF composition had produced a tiny finger-liked morphology near the outer membrane surface with a large macrovoid structure in the central core membrane layer as shown in Figure 3 (a). The present of 20% NMP in combination with 80% distilled water as BF composition had changed the internal structure of 14PPSU-80:20 HF membrane to a prominent double-layer finger-liked morphology with bigger microvoid structure at the inner membrane layer compared to the outer part (Figure 3b). Apparently, the double-layer finger-liked morphology of 14PPSU-70:30 HF membrane became thicker especially at the inner membrane layer with the present of 30% NMP in membrane BF while the bottom structures of skin layer remains unchanged (Figure 3c). Further increased of solvent (40%NMP/ 60% distilled water) in membrane BF composition made 14PPSU-60:40 HF membrane became more porous compared to 14PPSU-70:30 HF membrane with more uniform and interconnected finger-liked morphology between the inner and outer membrane layers.

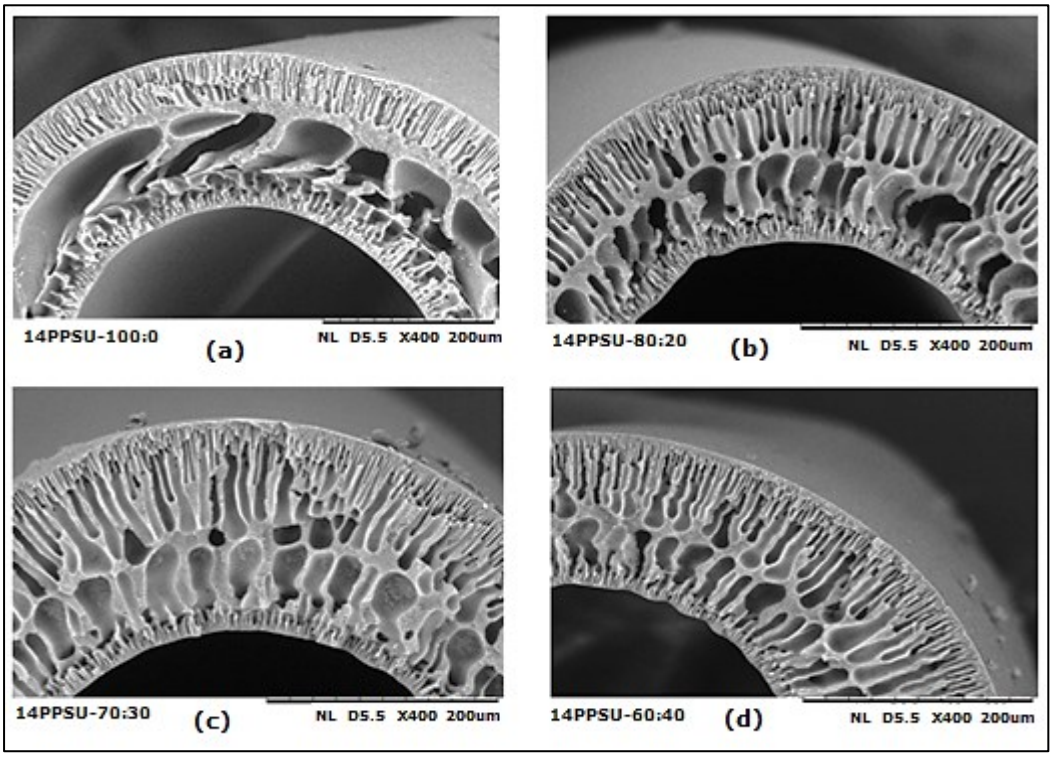

Figure 3. SEM cross-sectional images (400X magnification) of 14PPSU with different bore fluid ratio of water: NMP (a) 100:0 (b) 80:20 (c) 70:30 (d) 60:40

These is an agreement with Rahbari-sisakht et al. [15] which explained that as NMP concentration in the BF increased, the inner surface becomes more porous because the solvent out flux from the polymer solution phase to the coagulant phase is suppressed in the presence of solvent (NMP) in the coagulant. As the consequences, a large amount of NMP remains at the polymer solution/coagulant interface, preventing the formation of dense skin layer. However, the results obtained was contradict with finding from Feng et al. [13].They found that increased in NMP concentration had shifted a double-skin to a single-skin structure of PVDF hollow fiber membrane. It may due to different membrane polymer have different membrane morphology that acted differently although membrane fabrication is subjected to similar BF composition.

**Membrane wettability**

Table 3 shows the membrane contact angle of 14PPSU membrane at different water/NMP as BF composition. It can be observed that more than 20% NMP present in BF composition had significantly ($P<0.05$) reduced the hydrophobicity of 14PPSU membrane from 85.23° (0% NMP) to 81.46°(30% NMP) and 81.11° (40% NMP), respectively.

Table 3. Membrane contact angle of 14PPSU membrane at different bore fluid composition of water: NMP

| Membrane | Contact Angle (0) |
|---|---|
| 14PPSU-100:0 | $85.23 \pm 0.77^{A}$ |
| 14PPSU-80:20 | $83.54 \pm 1.57^{A}$ |
| 14PPSU-70:30 | $81.46 \pm 0.70^{B}$ |
| 14PPSU-60:40 | $81.11 \pm 1.52^{B}$ |

Each value in table represents the mean ± standard deviation of sample analysis from triplicate analysis. Mean within column with different superscripts letter A, B are significantly different ($P < 0.05$).

**Membrane pore size**

Table 4 shows the range and mean pore size of 14PPSU membrane characterized by images analysis from FESEM micrograph. Statistically, the present of 20%NMP in BF composition had significantly ($P<0.05$) increased the mean pore size of 14PPSU membrane from 24.81nm to 30.49nm, respectively. However, further increased in NMP composition resulted in a fluctuation of membrane pore size but it has no significant different ($P<0.05$) from 14PPSU produced from 100% distilled water as BF composition. A poor correlation ($R2=0.2898$) was recorded between the different in BF composition and membrane pore size of 14PPSU membrane.

Table 4. Membrane pore size of 14PPSU membranes at different BF composition (H2O: NMP)

| Membrane | Range Pore Size (nm) | Mean Pore Size (nm) |
|---|---|---|
| 14PPSU-100:0 | 22.3 to 31.3 | $24.81 \pm 3.07^{B}$ |
| 14PPSU-80:20 | 22.3 to 35.7 | $30.49 \pm 6.51^{A}$ |
| 14PPSU-70:30 | 17.8 to 26.8 | $23.59 \pm 2.78^{B}$ |
| 14PPSU-60:40 | 22.3 to 32.97 | $26.01 \pm 3.92^{AB}$ |

Each value in table represents the mean ± standard deviation of sample analysis from triplicate analysis. Mean within column with different superscripts letter A, B are significantly different ($P < 0.05$).

**PPSU membrane contactor performance: FFA removal and soap formation**

The selection of proper BF composition had a big impact on the membrane contactor performance in removing the FFA. As shown by Figure 4, 14PPSU-100 had the most promising results with high initial FFA removal of 12% after 30 min, followed by 12.86% FFA removal after 120 min and up to 16.54% FFA removal after 180 min of permeate collected throughout the process although there are some fluctuation in between the time intervals. Unfortunately, changing the internal membrane structure by adding the NMP into BF composition had tremendously reduced the deacidification performance of membrane contactor system. It can be seen clearly a significant ($P<0.05$) reduction in FFA removal when NMP was added into BF composition. 14PPSU-80:20 did not favour FFA removal at all. Meanwhile both 14PPSU-70:30 and 14PPSU-60:40 had only 2.5% and 2.3% FFA removal, respectively after 3 hours permeate collection. Although the present of NMP in BF composition had

slightly changed the membrane hydrophobicity and membrane pore size, a predominant changed in internal membrane structure from a large macrovoid with tiny finger-like morphology on the upper membrane layer (BF: 100% distilled water) to interconnected double-layers finger-like morphology had reduced the immobilisation of CPO towards NaOH at the mouth of membrane pores. It may due to the reduction in CPO volume localisation inside the internal membrane structure. Besides, the present of central core skin layer that separated double-layer finger-liked morphology had created a barrier and obstructing the mass transfer of FFA towards NaOH.

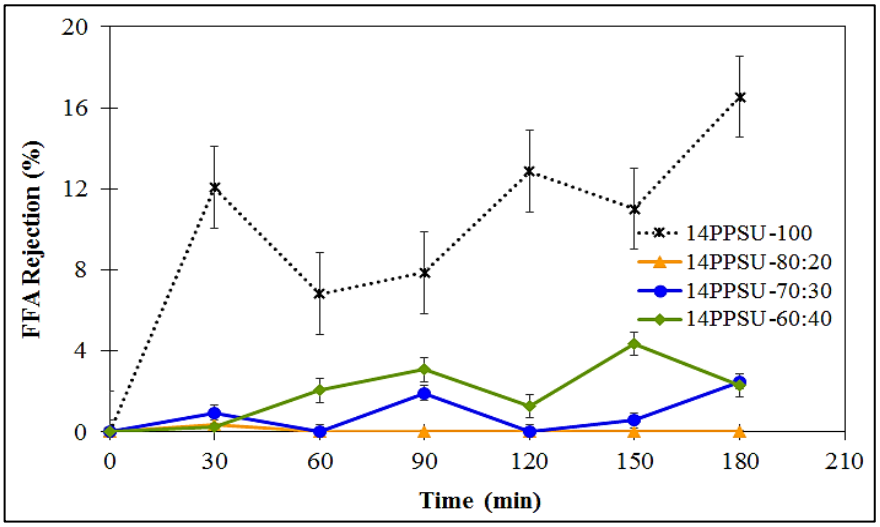

Figure 4. FFA rejection of 14PPSU membranes at different bore fluid composition

For the practical application, it is of great importance to ensure that the membrane contactor system could remove FFA from feed CPO without contaminating the permeate oil with soap formation to avoid neutral oil loss. PPSU is chosen in this study due to its hydrophobicity that allows the oil to wet the membrane layer and prevent the NaOH from penetrating into CPO stream. Besides, the operating pressure for both CPO and NaOH stream was properly established to facilitate FFA extraction and limit the penetration between the two separated streams at the membrane interface only. Although the deacidification performance was not favourable with the present of NMP in BF composition, but the robustness of all PPSU membrane with regards to chemical resistance cannot be denial. Table 5 showed that no soap formation was detected in all permeate samples throughout 3 hours operation.

Table 5. Soap content analysis of permeate oil sample collected from membrane contactor performance

| **Membrane Modules** | **Soap Content (ppm)** | | | |
|---|---|---|---|---|
| | **14PPSU-100 (water)** | **14PPSU-80:20 (water: NMP)** | **14PPSU-70:30 (water: NMP)** | **14PPSU-60:40 (water: NMP)** |
| Feed oil | n/a | n/a | n/a | n/a |
| Permeate: After | | | | |
| 30 min | nil | nil | nil | nil |
| 60 min | nil | nil | nil | nil |
| 90 min | nil | nil | nil | nil |
| 120 min | nil | nil | nil | nil |
| 150 min | nil | nil | nil | nil |
| 180 min | nil | nil | nil | nil |

## Conclusion

It can be concluded that proper selection of BF composition employed during membrane fabrication had provides a big different for the performance of membrane contactor system in removing the FFA in CPO. Different BF composition employed during membrane fabrication had prominently changed the internal membrane structure of 14PPSU membrane with slightly changed in membrane wettability and membrane pore size. The combination of distilled water/NMP in BF composition had changed the internal layer of 14PPSU membrane from tiny finger-liked morphology with larger macrovoid structure to more interconnected double-layers finger-liked morphology. For CPO deacidification process, 100% distilled water was the most suitable BF composition in producing 14PPSU-HF membrane due to its promising results with the highest FFA removal of 16.54% recorded without soap formation. For future work in this research area, it is recommended to investigate on the effect of dope extrusion rate (DER) during spinning process in order to understand the rheological influence of phase inversion in membrane production and separation performance of HF membrane contactor system.

**Abstract**

The oil and gas industry has been a constant developing industry as it is of importance to the maintenance of industrial civilization in its current configuration and play vital roles in many other industries. Some oil and gas industry operations have been accountable of water contamination through by-results of refining and oil slicks. One of the biggest by-products that have raised a critical environment concern is oilfield produced water. Oilfield produced water (OPW) is coproduced aqua liquid phase which originate from well alongside oil phases in normal production process. The content of OPW consists of different type of organic and inorganic mix. Discarding this kind of wastewater can lead to surface pollution especially on water sources as well as soil. Hence, to meet environmental regulations as well as reuse and recycling of produced water, many researchers have focused on treating oily saline produced water. Conventional technologies used to treat produced water consist of clarifiers, dissolved air flotation, hydro cyclones, and disposable filters/absorbers. Typically, additional chemicals for coagulation or settling are needed which are expensive and are incapable of achieving recently required standards of cleanliness. Therefore, researchers have swung to membrane filtration plans because of their capability to minimize extra expenses and surpass issues connected with current advances. Thus, the purpose of this review is to highlight the current and developed membrane technology used in treating the oilfield produced wastewater and its current progress.

**Keywords**: oilfield produced water, membrane filtration, mixed matrix membrane, oily wastewater

**Abstrak**

Industri minyak dan gas telah menjadi industri membangun berterusan kerana ia adalah penting untuk mengekalkan tamadun perindustrian dalam konfigurasi semasa dan memainkan peranan penting dalam banyak industri lain. Sesetengah operasi industri minyak dan gas telah dipertanggungjawabkan ke atas pencemaran air melalui tindakan penapisan dan minyak tumpahan. Salah satu yang produk sampingan yang terbesar yang telah menimbulkan kebimbangan persekitaran kritikal adalah air yang dihasilkan medan minyak. Air yang dihasilkan dari medan minyak (OPW) adalah dihasilkan bersama fasa cecair dan fasa minyak yang berasal dari telaga minyak dalam proses pengeluaran normal. Kandungan OPW terdiri daripada pelbagai jenis campuran organik dan bukan organik. Pembuangan jenis air sisa ini boleh membawa kepada pencemaran permukaan terutamanya kepada sumber air dan tanah. Oleh itu, untuk memenuhi peraturan-peraturan alam sekitar serta penggunaan semula dan kitar semula air yang dihasilkan, ramai penyelidik telah memberi tumpuan kepada merawat air masin yang dihasilkan dari medan minyak ini. Teknologi konvensional yang digunakan untuk merawat air yang dihasilkan terdiri daripada clarifiers, pengapungan udara terlarut, siklon hidro dan penapis boleh guna/penyerap. Biasanya, bahan kimia tambahan untuk pembekuan

atau pemendakan yang diperlukan yang agak mahal dan tidak mampu mencapai piawaian semasa kebersihan air. Oleh itu, penyelidik telah beralih kepada teknologi membran pemisahan kerana keupayaannya untuk mengurangkan perbelanjaan tambahan dan mengatasi isu-isu yang berkaitan dengan kemajuan semasa. Oleh itu, tujuan ulasan ini adalah untuk mengetengahkan teknologi membran semasa dan maju yang digunakan dalam merawat air sisa medan minyak yang dihasilkan dan kemajuan semasa teknologi ini.

**Kata kunci:** sisa medan minyak, penapisan membran, membran matriks campuran, air sisa berminyak

## Introduction

The fast growth of oil and gas industry is usually closely related to its vital role in the maintenance of industrial civilization in its current configuration. Virtually almost all economic sectors depend intensely on oil and gas. This ever-emerging industry has raised concern for many nations, mainly because its processes generate large volume of liquid waste [1].

Some oil and gas industry operations have overseen water contamination through by-results of refining and oil slicks. The oil and gas industry the biggest industrial source of discharges of volatile organic compounds (VOCs) which is a gathering of chemicals that add to the arrangement of ground-level ozone and this has raised many concern over the century. One of the biggest by-products that have raised a critical environment concern is oilfield produced water. Produced water is the aqueous liquid phase that is co- produced from a producing well along with oil phases during normal production process. Oilfield produced water contains different types of organic and inorganic contents. Discharging produced water can pollute surface and underground water and soil [1].

In recent years, it is found that universally produced water production is evaluated at around 250 million barrels each day. Since universally produced water production is more than production of oil, water cut has risen to 70%. Because of expanding volume of this waste everywhere throughout the world, the destiny and impact of releasing created water on natural has as of late turned into a noteworthy issue of ecological [2]. Figure 1 shows the estimation of onshore and offshore produced water production since 1990 until 2015. Ferro and Smith [3] forecasted that the production of oilfield produced water will be increased ultimately by years and this has been proven as the oil and gas industry has become a major industry since the early 2000s. The increasing demand in oil and gas industry has increased the production of wastewater which has in turned raised concern in terms of environmental safety.

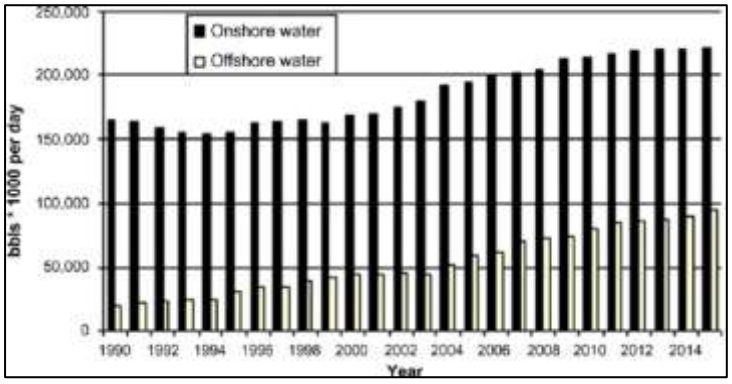

Figure 1. The estimation of produced water since 1990 until 2015 [3]

Historically, produced water was discarded in vast evaporation ponds. In any case, this has turned into an undeniably inadmissible disposal technique from both ecological and social viewpoints. Generally, produced water is often viewed as an industrial waste and coal seam gas (CSG) producers which are currently required to employ

any type of useful re-utilization for it. Currently, more-exacting environmental standards have led to greater efforts being made to treat produced water. Per Malaysia's Environmental Law, Environmental Quality Act, 1974, the Malaysia Environmental Quality (Sewage and Industrial Effluents) Regulations, 1979, 1999, 2000, the limit for oil and grease disposal in the water is 10 mg/L whereby the COD limit is 100 mg/L.

Hence, to meet environmental regulations as well as reuse and recycling of produced water, many researchers have focused on treating oily saline produced water [1]. There are several main contaminants of concern in the produced water which include high level of total dissolved solids (TDS), oil and grease (O&G), suspended solids (SS), dispersed oil, dissolved and volatile organic compounds, heavy metals, radionuclides, dissolved gases, and bacteria.

Generally, treatment of produced water from oilfield involved several stages that include pre-treatment to remove the bulk oil and gas as well as other coarse particle, main treatment that remove small droplets and particles, polishing treatment to remove ultra-small particles and finally optional tertiary treatment to removed dissolved matters and gases. There are different types of treatment that can be employed to achieve those treatments. The treatment of produced water is conventionally expensive and time consuming as capital cost of physical methods and cost of chemicals for chemical treatment of hazardous sludge is high [1]. The main aim in treatment of oilfield produced water is to remove hydrocarbon components. Table 1 shows the summary of type of treatment used in stages involved in treatment of produced water in a simple water treatment plant.

In produced water technologies, there are a few requirements that needed to be addressed to achieve high performance and separation. High recovery is desirable to decrease waste volume and disposal. Besides that, high rejections of contaminants are favored to meeting the stringent discharge requirements. In addition to that, a dynamic treatment should be very robust and comprises of low maintenance to reduce labor and supervision requirement. The treatment should also be flexible whereas it can handle high variation in water quality and quantity. Furthermore, in modular aspect, the technology should have small footprint as well as minimal disturbance.

Table 1. General overview of stages of oily wastewater treatment

| **Stages** | **Treatment** |
|---|---|
| Primary | Physicochemical |
| Secondary | Biological combined with physicochemical |
| Tertiary | Treating the sample for reuse |
| Finishing | Sludge treatment (natural/mechanical) |

Thus, with environmental regulations in concern and in effort to reduce cost, more researchers are focusing in coming up with novel technique in treating the oily wastewater which aims to reduce the cost as much as possible [4]. Domestic and foreign research institutions have tirelessly studied the matter in-depth and discussed on oily wastewater treatment methods, and the goal is both include of removal of a large amount of oil, considering the removal of dissolved organic matter, suspended solids, soaps, pH, sulfide, ammonia, etc. [5]. Customary physical-chemical strategies utilized for the treatment of oilfield produced water are frequently inadmissible since they are centered around the division of the dispersed oil or the expulsion of disintegrated organic pollutants from the aqueous stage with no synthetic change [6]. Although the produced water is a complex mixture of different contaminations, but, by using suitable and effective technologies it can be treated for various reclamation and re-use alternative options [7].

The environmental concerns regarding oilfield produced water usually due to the polluting impact which caused by numerous aliphatic and aromatic hydrocarbons, polycyclic aromatic hydrocarbons, phenols, and other chemical products. Current technologies used to treat produced water consist of clarifiers, dissolved air flotation, hydrocyclones and disposable filters/absorbers. Typically, without using the technologies, additional expensive

chemicals for coagulation or settling, these technologies are not capable of achieving recently required standards of cleanliness. Thus, operating expenses that enhanced and increased volumes of hazardous waste are produced. Even after a primary process of separation from the oil, the water still contains drops of oil in emulsion in concentrations as high as 2000 mg/L, necessitating further treatment before it may be discharge [8].

**Conventional treatment methods of oilfield produced water**

There are several conventional methods used to treat oily produced water that has been employed since decades before. The methods include flotation, coagulation, and biological treatment. Both flotation and coagulation are physicochemical method whereas biological treatments make use of anaerobic and aerobic method to reduced COD and BOD levels in the wastewater. However, the conventional treatment methods mentioned are not efficient enough especially when the sample involved has oil droplets that dispersed finely and low in concentration. The conventional way of produced water purification before was primarily involve the separation of oil and water physically by making use of gravity and the effluent was subsequently dump to the environment [9].

Due to different content in oily wastewater, the traditional methods are often failed in obtaining high separation result [10]. Besides that, most of the conventional techniques are only suitable for pretreatment of wastewater for in-situ reuse. It is not as versatile and dynamic hence there's a need for greater and more reliable treatments methods. The refractory nature of oily wastewater has made it difficult for the traditional technique to fully treat it and high success rate is often impossible.

**Flotation**

Flotation is a process of separating small particles of various materials by treatment with chemicals in water to make some particles adhere to air bubbles and rise to the surface for removal while others remain in water. The conventional dissolved gas flotation system is as depicted in figure 2. Flotation has shorter retention time and higher loading rate. This method has better separation efficiency in removing smaller and lighter particles [11].

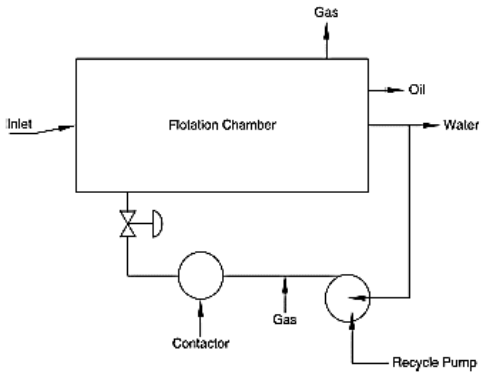

Figure 2. Conventional dissolved gas flotation systems [12]

However, for wastewater containing emulsified oil it is difficult to separate small bubble. There are several factors that is sensitive to the process and can affect the effectiveness of the process which includes pH, pressure, and feed rate. To improve the performance of floatation process, the process parameters and conditions or characteristics of floatable particles need to be determined properly [13]. This made the method more tedious, time consuming and multiple use of instruments and mechanism will increase the cost greatly.

**Coagulation**

Coagulation is a method which makes use of coagulants which destabilized the colloids by neutralizing the forces that keep them apart as depicted in Figure 3. This method usually coupled with flocculation which aims to agglomerate the fine particles and colloids into larger particles to reduce turbidity. The process comprised of two

stages which involve rapid mixing of dispersed coagulant into water and followed by flocculation for agglomeration of small particles into well define flocs via gentle agitation. This method has simple design, low energy consumption, easy operation and quite versatile as it can be used in different stages of wastewater treatment [14]. This method employed the usage of coagulants and the most extensively used coagulants in wastewater treatment include aluminium sulphate and polyaluminium chloride. Table 2 shows the most widely used coagulants in treatment of oily wastewater. Its mechanism is determined greatly on coagulant selection, dosage, wastewater characteristics and treatment technique.

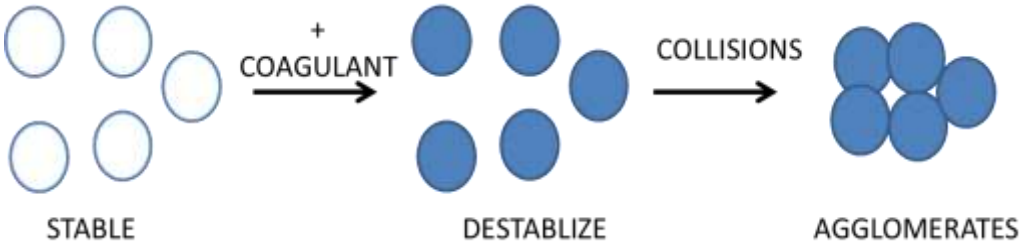

Figure 3. Basic mechanism of coagulation [15]

Table 2. Commonly used coagulant for treatment of oilfield produced water

| **Coagulant** | **Properties** |
|---|---|
| Aluminium sulfate | Inorganic salt, water soluble and act as medium strong acid which reacts with alkalis and attacks many metals in presence of water |
| Ferric chloride | Inorganic salt, water soluble, $FeCl_3$ in slightly basic water reacts with the hydroxide ion to form a floc of iron(III) hydroxide, or more precisely formulated as $FeO(OH)^-$, that can remove suspended materials |
| Polyaluminum chloride | polymeric structure, totally soluble in water, work extremely well at low raw water temperatures |

Dosage plays large roles in effectiveness of this method as overdosing the coagulant can cause the particles to restabilized. The use of chemical coagulant can rise another concern in terms of toxicity of alum and polymeric based coagulant whereby it has posed hazard to health. Overdosing of alum in wastewater treatment may lead to high residual of aluminium concentration [16].

Zhang Jin et al. [17] has employed coagulant utilization in treatment of oily wastewater and found that the coagulant has affected the filtration flux in their combined experimental methods. They found that by using coagulant, the filtration flux improved which mainly due to coalescence between the droplets taken together and the consequent the size of emulsion. However, the excess dosage of coagulant has also found to be the reason behind flux decrement.

**Biological treatment**

Biological treatments make use of microbial metabolism so that the water was dissolved colloidal organic pollutants into harmless substances. The use of anaerobic and facultative digestion has been employed to overcome the oily effluent pollution. Activated sludge process has been the mainstay of wastewater treatment however it is a very energy consuming process. Biological conversion of organic wastes which includes oily wastewater involves four fundamental phenomena which are hydrolysis, fermentation, acefogenesis and methanogenesis [18].

Biological treatments are usually considered as secondary treatment whereby it involves aerobic and anaerobic processes. The employment of mixed bacterial culture has demonstrated to be more advantageous in comparison with pure culture due to synergistic interactions among members of the associations [19]. Due to characteristics of poor nutrients of nitrogen and phosphorus, low BOD/COD ratio, high toxicity, oilfield produced water is difficult to be treated by a simple biological treatment [20].

Lu et al. [21] has developed a field pilot treatment system that employed hydrolysis acidification/bio-contact oxidation system (HA/BCO) as shown in Figure 4 at which air used to produce oxygen-saturated conditions was supplied to the two aerobic tanks through air diffusers, located at the bottom of the tanks, to supply sufficient oxygen to the biomass and to stir the liquid as well as to exfoliate the aged biofilm. The system can achieve the ratio of $BOD_5$ to COD of 0.24 which is around 65% COD removal efficiency and showed an overall hydrocarbon waste removal efficiency of 68%. Their study proved that biological treatment can be a cheap alternative however yet to prove its efficiency in overall treatment of oilfield produced water.

**Membrane technologies in oilfield produced water treatment**

Precise investigations of membrane marvels can be followed to the eighteenth century rationalist researchers. Through the nineteenth to mid twentieth hundreds of years, membranes had no modern or business utilizes, however were utilized as research center instruments to create physical/synthetic speculations [26].

Preparatory tests utilizing membrane innovation included isolating certain gasses and were at first led in 1950 [22]. The success of these membrane applications prompted the improvement and use of 219 membrane units in refineries around the globe until roughly 1993 [33], after which extra applications have been produced and utilized. Table 3 shows the advancements of membrane technologies utilization in treatment of OPW. For oilfield produced water treatments, there are many studies that have been conducted showing promising results via application of membrane technology which further details and examples are discussed in next sections.

**Type of membrane filtration process**

Researchers have swung to membrane filtration plans because of their capability to minimize extra expenses and transfer issues connected with current advances. Polymeric and ceramic membranes are found to be effective in separating the oils, emulsions, and silts from the produced water [8]. The membrane pressure driven procedure depends on the pore size of the layer to isolate the sample segments as indicated by their pore sizes [24]. membrane based operations tested so far include microfiltration (MF), ultrafiltration (UF), nanofiltration (NF) and reverse osmosis (RO). Also, the coalition of membrane based procedures has been examined as an effective device to treat the produced water to meet the quality benchmarks of environmental standards [25].

Table 3. Advancement in membrane utilizations for OPW purification

| Reference | Study | Inference |
|---|---|---|
| White et al. [27] | Polyimide membrane for separation of solvents from lube oil | Separate small molecules of methyl ethyl ketone solvent from lube oil |
| Buffle et al. [28] | A generalized description of aquatic colloidal interactions: The three-colloidal component approach | Utilization of UF Membrane for the development of filtration process that led to the upgrade visbroken residual products by UF during thermal cracking |
| Yu et al. [29] | Treatment of oily wastewater by organic–inorganic composite tubular ultrafiltration (UF) membranes | After UF treatment, there's significant decrement of oil and suspended solid content |
| Zhang et al. [30] | Development of a sulfated Y-doped nonstoichiometric zirconia/polysulfone composite membrane for treatment of wastewater containing oil | Oil retention is 99.16% and oil concentration in the permeation is 0.67 mg/L |
| Salahi et al. [31] | Nano-porous membrane process for oily wastewater treatment: Optimization using response surface methodology | Nano-porous membrane is efficient for the treatment of petroleum refinery waste water |
| Huang et al. [32] | Treatment of oily waste water by PVP grafted PVDF ultrafiltration membranes | Ultrafiltration performance of oil wastewater was improved greatly and flux recovery of PVDF–PVP membranes cleaned using NaOH solution exceeded 90%. |

**Microfiltration**

Microfiltration (MF) is a kind of physical filtration process where a polluted liquid is gone through an exceptional pore-sized layer to partitioned microorganisms and suspended particles from procedure fluid. It has significant applications in simple dead-end filtration for water, sterile fruit juices and wine, and aseptic pharmaceuticals [33]. However, not all applications that benefit from MF operate successfully in the dead-end mode. Recent innovation in microfiltration has mainly concerned the development of cross-flow filtration technology and membranes [26]. Thus, MF need to be coupled to other methods to achieved successful result.

There are numbers of research done in investigating the effectiveness of MF membrane on treatment of oily wastewater. Studies done by Kiss et al. [34] found that the oil emulsion can be separated with MF PTFE membrane however the retention has been decreased in presence of emulsifier due to arrest of oil coalescence.

A study done by Nandi et al. [60] confirmed that the MF membrane can be used for treatment of oil water emulsion to yield permeate containing oil concentration less than 10 mg/L. Some other research focused on the flux decline of the membrane to evaluate the effectiveness of MF membranes. Modeling of permeation flux decline during MF of oily wastewater in membrane with experimental results is important in evaluating membrane fouling [35].

Besides that, research done by Wang et al. [36] observed that for the treatment of factory emulsified oily wastewater, MF membrane could not be fully regenerated by using conventional cleaning method and combination of filtration with interval aeration would enhance the performance of the membrane. Hence, the use of MF operations would most likely result in better separation performance if coupled with other operations.

**Ultrafiltration**

Ultrafiltration uses a finely porous membrane to separate water and micro solutes from macromolecules and colloids. The average pore diameter of the membrane is in the 10 – 1000 ˚A range. Compared to conventional method, the use of ultrafiltration method is more energy saving and have consistent product quality. Typical filtration processes for emulsified oily wastewater can reach an oil rejection rate of 80 – 99% [37]. The application of ultrafiltration (UF) to the separation of oil emulsions (O/W) from oily wastewater streams has been extensively examined and it is observed that the ability of UF membranes in separating oil in water emulsions with high TOC rejection [39]. There are few researches has recorded successful application of UF membrane in treating wastewater.

Recently Abdullah et al. [40] has successfully synthesized a new type of adsorptive microporous UF membranes that were composed of an organic polysulfone (PSf) and inorganic HFO nanomaterial and has helped in removal of lead in the wastewater. Meanwhile Luo et al. [41] has employed ultrafiltration of oil-water separation using triangle-shape tri-bore hollow fibre membrane from sulfonated PSf and the result has shown that the water permeates after filtration are very clear with low turbidity. These researches show the promising ability of UF in oil-water separation and there are different opportunities in enhancing its ability even further.

**Nanofiltration**

Nanofiltration is a membrane filtration-based strategy that utilizes nanometer estimated barrel shaped through-pores that go through the membrane at 90°. Nanofiltration membrane has pore sizes ranging from 1 – 10 nanometers, smaller than that used in microfiltration and ultrafiltration, but just larger than that in reverse osmosis (RO). NF generally focused to expel just divalent and bigger particles. Monovalent particles, for example, sodium and chloride will go through a nanofiltration film, in this way a considerable lot of its uses include de-salting of the procedure stream.

This promising procedure has pulled in expanding consideration over late years because of the advancement of new applications in the few regions, for example, material industry (expulsion of color from waste wash water), paper, plating industry (constraining of consumption of clean water by reusing waste water similarly as the release waters don't contain too high measures of monovalent particles), drinking water generation and so forth.

**Reverse osmosis**

Reverse Osmosis (RO) utilizes a semipermeable film to evacuate particles, atoms, and bigger particles from drinking water. In reverse osmosis, a connected weight is utilized to overcome osmotic weight, a colligative property, that is driven by substance potential contrasts of the dissolvable, a thermodynamic parameter. The utilization of RO innovation in wastewater treatment has been accounted for since the 1970s. RO is the finest partition membrane process accessible, with pore sizes range from 0.0001 µm to 0.001 µm. RO can hold generally all atoms aside from water and because of the measure of the pores, the required osmotic weight is essentially more prominent than that for MF. Figure 5 depicts the commonly employed RO membrane used for water treatment. Due to both RO and NF small size pores, they are not preferable in treatment of oily wastewater.

Al-Jeshi et al. [42] has conducted an experiment to test the ability of RO membranes to treat water containing up to 50% (by volume) of oil and to evaluate the effect of oil contamination on membrane performance whereby it is found that the RO membrane employed can only treat wastewater with up to 50% oil contamination. Besides having questionable ability in separation of oil in water emulsion, the high-pressure pump supplies the pressure needed to push water through the membrane, even as the membrane rejects the passage of salt through it which makes the process make use of more energy compared to other separation methods.

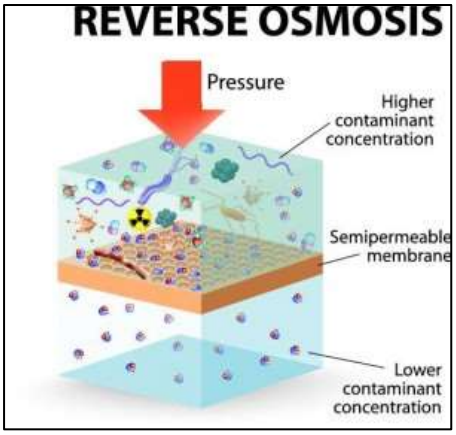

Figure 5. Mechanism of RO [42]

**Type of membrane for oilfield produced water treatment: Polymeric membrane**

Polymeric membrane is usually classified as synthetic membrane and is the most widely used in oil-in-water separation. Polymeric membranes, many organic polymers including crystalline and amorphous, glassy, and rubbery, are suitable membrane fabrication that targets oil-in-water separation. The preparation methods involve phase inversion, interfacial reaction, coating, stretching and etcetera [43]. Synthetic membranes such as polymeric membranes are the most commercially utilized membrane in oily wastewater separation with estimated sales of $2 billion in 2003 worldwide. Utilization of synthetic membranes in purification of oily wastewater such as produced water has better performance compared to the organic membranes. As compared to its biological or organic counterparts, polymeric membrane possesses variety of advantages especially in industrial application such as oil-in-water separation. Due to its wide variability of barrier structures and properties, polymeric membrane has ultimately been the first choice in development of oily wastewater treatment technologies. Its robustness has given the possibility to control the density, size, size distribution, shape and vertical alignment of membrane pores making it easier to be customized to suit the need of any certain application.

The ability of the polymeric membranes to be designed accordingly and with wide rooms for customization has given it upper hand in competing with its organic counterparts. Currently, there are two commercially designs used using polymeric membrane. Membrane filters are usually manufactured as flat sheet stock or as hollow fibers and then formed into one of several different types of membrane modules [44]. Polymeric membranes are generally classified by the nature of the materials, the membrane morphology, geometry, preparation method, separation regime and processes.

The polymeric membrane possessed three significant structural magnitudes namely thermocular, microcrystalline and colloidal. Thermocular level of the membrane is like the chemical nature of the polymer and it is responsible for the membrane's microcrystalline nature. The microcrystalline is the level at which play an important part for both the transport and mechanical properties of the membrane; and finally, the colloidal that involved macromolecules aggregation and affect the pores properties such as pore size, size distribution, density, and void volume [45]. The utilization of polymeric membrane in purification of oilfield produced water is still limited and only few literatures have been done using it as sample feed. There are a few researches that have been done in applying polymeric membranes and integrating it into the treatment technologies of oilfield produced water.

Xu and Drewes [45] in their report has tested thin-film composite polyamide membranes at which was applied in two standard laboratory cross-flow membrane filtration units to purify the water sample collected at a natural gas production facility in Eastern Montana. Their research was focused on salt rejection, iodide recovery and operating performance at which they employed bench-scale filtration tests and in situ characterization techniques to examine the viability of the selected membrane in multi-beneficial use of produced water. The research has concluded that

the studied polymeric membranes having high salt rejection and permeability, provide a viable technique for produced water treatment and beneficial reuse.

Besides that, Mondal et al. [46] have employed three layers' membrane distillation system which consists of polyester, polysulfone and polyamide to purify produced water that was obtained from three different sources. The membranes have different surface roughness and rejection behavior for the oily feeds. In their study, they had determined the variation of permeate flux with time during dead end filtration. Their results conclude that the usage of different polymeric membranes have given positive output at which all three successfully displayed minimum reduction of flux after tested with produced water. They have also concluded that membrane filtration could be a viable process for produced water treatment.

Besides tested on its own, the polymeric membrane has also been integrated to different technologies to further improve the system's performance. Qiao et al. [47] has developed a pilot-scale plant involving aeration tank, air floatation, sand filter and UF has been designed and performance characteristics of the hybrid process have been studied for treatment of oilfield produced water. The UF membrane used was a PVC alloy hollow fiber membrane. Their research resulted in the SS and oil removal in the UF unit of about 70% and 90%, respectively, and their respective contents in the effluent of UF are less than 0.5 mg/L and 1.0 mg/L meet the required standard for discharging or injection water.

A. Fakhru'l-Razi et al. [7] had employed two different polymeric membranes namely polyethersulfone (PES) and polyvinylidene fluoride (PVDF) in their membrane sequencing batch reactor which their coupled with utilization of isolated tropical halophilic microorganisms. It was found that the isolated microorganisms played an important role in the biodegradation of the pollutants and membrane separation was required for ensuring a stable permeate quality. They research has proven that it is possible to employ polymeric membrane in treatment of produced water.

**Ceramic membrane**

Ceramic membrane has reputable ability in treatment oily wastewater especially in oilfield produced water. It has excellent membrane reliability and stability which contribute to its high operation safety. Commonly, ceramic membrane has an asymmetrical structure with a viable top layer framed by coating or casting. Figure 2 shows the theoretical portrayals of ceramic membrane which are usually asymmetrical [48]. Sol-gel process usually produces typical ceramic membranes. In this process, particle dispersions are forced to agglomerate. To produce continuous and porous layers, particles of decreasing size are deposited and the membrane is sintered at extreme temperature. This resulted in asymmetric structure of the membrane. Pore size and characteristics of the selective layers of the membrane may be customized by using grain size and type of particles as basis.

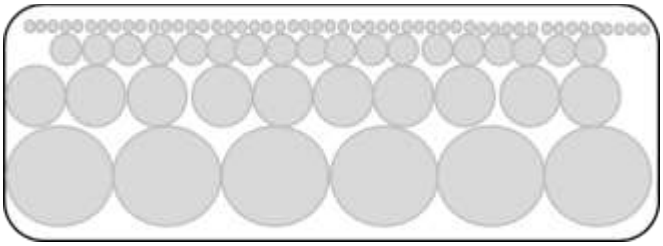

Figure 6. Theoretical portrayals of asymmetrical ceramic membrane

Lately, there is a developing enthusiasm for utilizing ceramic membrane for oily wastewater treatment since organic membranes affected by polar solvents, chlorinated solvents, and high oil fraction. Weschenfelder et al. [49] in their research have evaluated the commercialized Zirconium ($ZiO_2$) performance in treating oilfield wastewater using synthetic oil effluent. The membrane performance was tested in laboratory and results shows that the membrane could generate a permeate stream with an oil and grease content lower than 5 mg/L, which enables the reuse of

water. The research also shows that the cost estimation of using the ceramic membrane and it is found that there's increase of cost in using the membrane.

On the other hand, M. Ebrahimi et al. [8] has done characterization of five different ceramic membranes for oilfield produced water treatment which include MF and UF $Al_2O_3$ and MF and UF $TiO_2$ membranes and concluded that the tested membrane has been proven to be cost efficient for oil removal from oilfield produced water. However, the membranes have failed to reach an acceptable level of removed TOC. Their research has also highlighted the obstacles in treatment of produced water using membrane technologies which include membrane fouling, reduced trans-membrane flux and membrane cleaning.

Abadi et al. [50] have also employed tubular ceramic MF membrane using ($\alpha$-$Al_2O_3$) in treatment of refinery oily wastewater. Their research has resulted in 95% TOC removal efficiency which abides to the National Discharge Standard. They proposed the system to replace the conventional methods as it has higher efficiency rate as well as better separation for oil in water emulsions.

Li and Lee [48] in their research have also utilized ceramic membrane in purification of produced water. Their research investigates the micro- and mesoporous inorganic membranes, specifically clay membranes and zeolite membranes, on desalination of produced water. The study utilizes few ceramic membranes from different materials such as macroporous a-alumina (pore size ¼ 0.2 mm, Pall), disk-shaped stainless steel (0.5 mm, Mott), and Zr-coated stainless steel (pore size ¼ 0.1 mm, Pall), MFI-type zeolite membranes on porous a-alumina supports and laboratory fabricated clay membranes. The research concluded that microporous ceramic membranes are very effective for reducing concentrations of oil and suspended solids from produced water whereby clay and zeolite are microporous materials that show promising application in novel membrane fabrications that have potential for use in produced water deionization. MFI-type zeolite membranes formed on commercial tubular substrates give over 99% ion rejection at a water flux of approximately 10 $kg/m^2h$.

Besides using ceramic membrane on its own, there's also interest in coupling the ceramic membrane with other operation. Rahman et al. [51] has developed cross flow membrane bioreactor which utilizes hollow tubular alumina membranes in refining oily wastewater from refinery. They set up a laboratory-scale bioreactor comprised mainly of tubular ceramic membranes, aeration tank, and circulation pump. Their investigations resulted in COD removal efficiency of more than 93% and performance of the unit when operated with MLSS of 3000 mg/L was impressive with changing the influent mass loading from 30 to 65 g/day.

Different points of interest of ceramic membranes are identified with the capacity to treat slick waters without extra chemicals and its resistance against mechanical, thermal, and chemical stress, permitting a superior recovery of the layer with harsh chemical cleanings [49]. The essential preferred standpoint of utilizing ceramic membrane is the capacity to achieve the current regulatory treatment goals with no chemical pretreatment [8]. Besides that, benefits of ceramic membranes include bigger pore and enhanced hydrophilic surface which leads to higher fluxes, compared to organic membranes. The mechanical, thermal, and chemical resistance of the ceramic membrane has helps in increasing performance membrane and enhances the recovery.

Their ability to stand in harsh environment has open the way for ceramic membranes to be used in produced water purification [37]. For example, the zeolite membranes have high tolerance of organic solutions, excellent corrosion resistance, and very reliable under harsh operating conditions, i.e., high temperatures, high surface shear rates, or the presence of oxidative solvents [48].

However, utilization of ceramic membrane has its own challenges. There's always need to curb the problems regarding sealing which often caused by the thermal expansion of ceramic membrane and module housing. Besides that, its mechanical built which naturally more brittle makes it more sensitive and require a more tedious and careful handling. This diminishes its ability to be fully automated when integrated into other operation.

Notwithstanding that, the significant obstruction including ceramic film is flux misfortunes. Focused polarization frames close to the film surface amid the partition procedure which is administered by liquid science, membrane

properties and hydrodynamics [48]. Furthermore, conventionally the commercialized ceramic membranes (such as $Al_2O_3$, $SiO_2$, $ZrO_2$, and $TiO_2$) are too expensive for oil in water emulsion treatment [52].

**Advantages of membrane technologies and current challenge in treatment of oilfield produced water**

The usage of membrane filtration technologies such as UF, MF and NF has posed several advantages in treatment of oilfield produced water. Firstly, the technology is more widely applicable across a range of industries such as off shore and on shore oil exploration. The operation is practically easy to handle and require minimal supervision. In addition to that it can be fully automated to eliminate labor and human error. Besides that, operators have turned to membrane filtration schemes due to their potential to minimize additional costs and disposal issues [8]. The transport selectivity of the membrane is a unique characteristic that draws attention for its utilization in OPW purification.

Membrane systems can dominate over more complex treatment systems in terms of treating oily wastewater that is high in oil content, small particle size with flow rates more than 150 $m^3$/h. This is much preferable especially for medium and large offshore platforms. Besides that, utilization of membrane technologies has eliminated the usage of chemical additives and coagulant making it more environmental friendly and cost effective [1].

Membranes are favored over other technologies for water treatment, such as disinfection, distillation, or media filtration because, in principle, they require no chemical additives, thermal inputs, or require regeneration of spent media [53]. In addition to that, due to simple operation and mechanism, the utilization of membrane technology has also opened the opportunities to the building of small and compact treatment plant. These possibilities are even more favorable especially in offshore facilities which often have limited space. Membrane equipment has also smaller footprints which contribute to its environmental friendly properties.

Besides having simple operational mechanism, membrane has high reusability properties which allow recycling of selected waste streams. This reduces operational cost as well as increased the sustainability in terms of resources and energy. The use of membrane operation can be independent without pre- or post-treatment which eliminates extra costs and making it more economically feasible.
