In addition to that, there's vast opportunity of mixing the membrane with other technologies to further improve its performance. Its robustness allows rooms for further improvement and integration in development of better performing treatment technology. Being a versatile technology, employment of membrane can open more doors towards enhanced and excellent purification of wastewater especially produced water. Their reliability can be exploited to be adopted in the petroleum industry to satisfy the industry requirement for discharge and reuse standards [33]. Table 4 depicted the advantages of membrane technology over conventional method.

Despite its robust and versatile characteristics, membrane technology has stumbled across various challenges that hinder its performance in purification of oilfield produced water. One of the major hindrances of membrane technology is fouling. Fouling is caused by buildup of materials which can take up different form such as adsorption, pore blockage, deposition, and gel formation [55].

Fouling caused severe decline of flux which deter the membrane performance. It also contributes to the difficulties in membrane cleaning which add up extra steps in the treatment operation. Based on the sample to be treated, causes of fouling may vary. For oilfield produced water treatment, contaminants such as alumina, ammonia, organic matter, scale compounds, boron and silica can be the ones that contribute to membrane fouling during the treatment process [23].

These chemicals can lead to scaling at which concentration will increase and change the ph. This will lead precipitation of salt and hydroxide which are the main factors for scaling. Other than that, the accumulation of small molecules might tend to have strong interactions with some polymeric membranes. For instance, anti-foaming agents such as polypropylene glycols have tendency to strongly adhere to certain polymeric membrane and thus promotes pore blocking [56].

Table 4. Comparison between conventional method and membrane technology

| **Conventional Method** | **Membrane Technology** |
|---|---|
| Conventional techniques are only suitable for pre-treatment of wastewater for in-situ reuse [54] | Less complex & preferable for medium and large offshore platforms. [58] |
| Large amount of energy and chemical additives required, economically unfit and lower size molecules difficult to settle down [54] | No chemical additives, thermal inputs, or regeneration of spent media [54] |
| Very slow and complex process and required more place [58] | Simple operational mechanism [59] |
| Often involved spent chemical that in return add on to the chemical pollutants [59] | High reusability properties which allow recycling of selected waste streams [54] |
| Limited room for improvement as most of the technique are rigid and exacting [59] | Robust, allows rooms for further improvement and integration in development of better performing treatment technology [60] |

Besides fouling, another drawback that membrane technology possessed is sludge formation. This challenge often emerges in membrane bioreactor (MBR) which involved activated sludge removal. MBRs can be broadly defined as systems integrating biological degradation of waste products with membrane filtration [58]. This system has been integrated broadly in treatment of refinery wastewater as well as in upstream processing in oil and gas industry. The sludge form will eventually be released to the sea which in turns contribute to the severe sea pollution and pose harm to the surrounding ecosystem.

Drawbacks such as fouling and sludge formation can affect the performance of the membrane operations as it deters the transmembrane pressure as well as membrane flux. Pore blocking will also cause the membrane to function poorly after a few usages. In addition to that, there's need to add in membrane cleaning stage for the membrane to be reused. The cleaning stage might involve chemicals and additives which in turns will add on the pollutants in the final effluent from the technology.

## Conclusion

Oilfield produced water has delicate and complex content and may vary depends on different factors. Each location has their own complex content making it difficult to develop technologies that can suit each one of the produced water. This has made it one of the toughest wastewater to be treated. However, with its extended versatility and vast opportunities its offer has made membrane filtration as one of the most suitable technology to be employed in purification of produced water. The readiness of membrane technology to be customized and integrated into other existing technologies making it possible to treat the complex oilfield produced water. Despite being simple in terms of operation, employment of membrane technology has greatly improved the separation of different components in oilfield produced water. It has been the greatest contender in terms of purification performance compared to other conventional and existing technologies. It has enabled the utilization of single treating unit with little to no need of pre or post treatment stage. Being highly customized, the membrane technologies offer different rooms for the development of better and enhanced purification system for reusing and filtration of oilfield produced water. It is a highly potential technology that should be explored more in future.

**Abstract**

A new polymeric membrane blended from sulfonated polyetherimide (SPEI) and poly(eugenol sulfonate) (PES) was prepared as proton exchange membrane (PEM) for direct methanol fuel cell (DMFC). The membrane was characterized by Fourier Transform Infrared Spectroscopy (FTIR), thermogravimetric analysis (TGA) and Scanning Electronic Microscopy (SEM). Ion exchange capacity (IEC), proton conductivity, methanol barrier, water uptake, water contact angle and mechanical strength of the membrane was also being determined. The new PES/SPEI membrane with 3 wt.% PES and 20 wt.% SPEI show higher IEC, water uptake, proton conductivity and methanol barrier properties as compared to Nafion 117 membrane. As a conclusion, the results indicate that the SPEI/PES membrane has potential to be employed as PEM for DMFC application.

**Keywords**: sulfonated polyetherimide, poly(eugenol sulfonate), blend membrane, direct methanol fuel cell

**Abstrak**

Membran polimer baru diperbuat daripada campuran polieterimida sulfonat (SPEI) dan poli(eugenol sulfonat) (PES) telah disediakan sebagai membran pertukaran proton (PEM) untuk sel bahan api metanol langsung (DMFC). Membran ini telah dianalisis menggunakan Spektroskopi Inframerah Transformasi Fourier (FTIR), analisis termogravimetri (TGA) dan Mikroskop Imbasan Elektron (SEM). Sifat membran seperti kapasiti pertukaran ion (IEC), kekonduksian proton, halangan metanol, penyerapan air, sudut sentuhan air dan kekuatan mekanikal juga telah ditentukan. Membran baru PES/SPEI dengan 3 wt.% PES dan 20 wt.% SPEI telah menunjukkan nilai IEC, pengambilan air, kekonduksian proton dan halangan metanol yang lebih tinggi berbanding membran Nafion 117. Sebagai kesimpulan, hasil kajian menunjukkan bahawa membran SPEI/PES mempunyai potensi untuk digunapakai sebagai PEM untuk aplikasi DMFC.

**Kata kunci:** polieterimida sulfonat, poli(eugenol sulfonat), membran campuran, sel bahan api metanol langsung

## Introduction

The Direct Methanol Fuel Cell (DMFC) is one of the attractive fuel cell type for mobile application which is clean technology to the environment, having high efficiency, portable, and can be operated at relatively low temperatures

[1]. The key component in DMFC is proton exchange membrane, with respect to development of cell performance via an increase conductivity and a reduction of methanol permeability [2 – 5]. Perfluorosulfonic acid (PFSA) membrane, under Nafion commercial brand is a type (Proton Exchange Membrane) PEM that has been used widely with high proton conductivity, low dimensional change in water, and excellent cell performance in various environments [6 – 8]. However, Nafion membranes are expensive and lose their proton conductivity and durable properties at high temperature (>80 $^{o}$C) [5 – 11]. Therefore, many researchers have endeavored to develop inexpensive membranes for higher operation temperature and lower methanol permeability such as a variety of polymer blends.

The use of polymer blends means to combine two different characteristics then improving the comprehensive properties and modification of a matrix [5, 9 – 13]. Among many types of blend membranes, the sulfonated polymer organic blend membranes show many attractive properties. Polymer blend membranes described as organic materials are new class of interesting materials that exhibit improved proton conductivity and reduced methanol permeability when applied in DMFC. Many researchers have investigated the alternative cheap materials with new hydrocarbon polymers synthesized, or blended with a methanol hating material [11, 13, 16]. The improvement progress in the membrane for DMFC has been gradually made by physical and chemical changes of polymer materials, such as rigidity of main chains, length of side chains, equivalent weight of proton donors and concentration of introduced hydrophilic groups like sulfonic and phosphoric acids in the membranes [12]. The increase of concentration of those groups in the membranes produces more water clusters, which would be able to repair the controlled proton transport, water and methanol crossovers.

In previous study [7, 15], the preparation and characterization of a new type of proton exchange membrane based on SPEI, which was obtained by directly synthesis from sulfonated monomer, have been described. The conductivity values for the SPEI copolymers at ion exchange capacity around 0.553 meq/g were 0.0014 S/cm at 25 °C, indicating that they are promising candidates for PEM materials [7].

In this study, we have reported a new blend membranes material from sulfonated polyetherimide and poly(eugenol sulfonate) who has never done. Poly(eugenol sulfonate) have been aromatic phenol units provide high performance properties such as considerable mechanical strength, thermal stability and chemical resistance, while the flexible sulfonate linkages provide good processability [14].

## Materials and Methods

### Materials

All the membranes characterized were prepared in the laboratory with polyetherimide and methyl-2-pyrrolidone (NMP) supplied by Sigma–Aldrich, Eugenol supplied by Merck, and Nafion 117 membrane was purchased from DuPont Co.

### Synthesis of poly(eugenol sulfonate)

Poly(eugenol sulfonate) was synthesized from eugenol according to a previous study. Poly(eugenol sulfonate) (PES) is made from a mixture of concentrated sulphuric acid, eugenol and $PbSO_4$ in a steam bath at a temperature of 90 °C. The results are analysed with an infrared spectrophotometer [14].

### Sulfonation of polyetherimide

The synthesis sulfonated polyetherimide **(**SPEI) was carried out by the previous procedure. First, 10 g of PEI was dissolved in dichloroethane (50 mL) at 60 °C for 5 hours. The solution was kept at room temperature for 1 hour. Chlorosulfonic acid (2.06 mL) in dichloroethane (35 mL) was added drop-wise to the polymer solution under vigorous stirring for 45 minutes. The product was dissolved in DMAc after 2 hours, and the polymer solution was precipitated in isopropanol. The product was filtered and washed with isopropanol three times to remove impurities, and dried in an oven at 50 °C for 48 hours. The results were characterized with an infrared spectrophotometer [7, 15, 17].

**Preparation of membrane**
The polymer blended membranes were prepared with three different mass ratios of SPEI (15%, 20%, 25%) and three different mass ratio of SPEI: PES blend (15: 3, 20: 3, 25: 3)%. PES and SPEI were simultaneously dissolved in NMP to form 15 wt.% solutions with stirring at 60 °C for 12 hours. After cooled to room temperature, the resulting polymer solutions were cast on glass plates and dried in a room temperature for 12 hours. Then immersed to sulfic acid for 12 hours.

**Characterization of blend membranes**
FTIR spectra of the membranes were measured by in the range of 4000 – 400 $cm^{-1}$. The samples were dried at 80 °C for 1 hour before measurement. The surface and cross-section morphology of the blend membranes were examined with a Zeuss field emission scanning electron microscope. All the samples for cross-sectional view were fracture in liquid nitrogen. The mechanical properties of the blend membranes were measured by a tensile machine (Instron 5567, TA Instruments Co.) at room temperature. The samples were tested at elongation with rate of 5.0 mm $min^{-1}$. All membranes were tested five times to obtain an average value.

The contact angle (CA), of the membrane surface was measured using a Optima Surface Analysis System (AST Products Inc., Billerica, MA). Sample coupons with an area of about 5 cm x 1.5 cm were prepared by cutting to pieces at random locations within the membrane sheet. The sample was placed on a glass plate and fixed with a tape. A drop of distilled water was then placed on the sample surface using a microsyringe (Hamilton Company, Reno, NV). The CA was measured within a 30 s period after the water drop was placed. The CA was measured at 10 different spots on each membrane sample coupon and the values averaged.

Thermal stability of the samples was characterized using thermogravimetric analysis (TGA). Dry sample was ground into fine powder and the sample was placed in a platinum pan. The analysis was carried out at a heating rate of 10 °C $min^{-1}$ over 30 – 700 °C temperature range under air atmosphere. The sample powder was prepared in the pin stub holder and coated with gold for analysis.

**Water uptake and swelling ratio**
The membranes were dried at 80 $^{o}$C under vacuum for 24 hours and the dry weights of the samples were weighed. Subsequently, the membranes were immersed in deionized water for 24 hours at room temperature. After quickly wiping off the water adhered to the surface of the membranes, the weight and dimension of wet membranes were measured. The water uptake and swelling ratio could be determined according to the following equation 1 and 2 [18] :

$$\text{Water uptake} = \frac{W_{wet}-W_{dry}}{W_{dry}} \times 100\% \quad (1)$$

where $W_{wet}$ and $W_{dry}$ are the weight of membranes in wet and dry state, respectively.

$$\text{Swelling ratio} = \frac{L_{wet}-L_{dry}}{L_{dry}} \times 100\% \quad (2)$$

where $L_{wet}$ and $L_{dry}$ are the length of membranes in wet and dry condition, respectively [19].

**Ion exchange capacity**
The ion exchange capacity (IEC) of membranes was obtained by titration method. The dry membranes were immersed in the 1 mol $L^{-1}$ NaCl solution for 24 hours. This solution was titrated by 0.01 mol $L^{-1}$ NaOH with phenolphthalein as the indicator. The IEC of the samples was calculated by following equation 3:

$$IEC = \frac{V_{NaOH}-C_{NaOH}}{W_d} \times 100\% \quad (3)$$

where $V_{NaOH}$ is the volume of consumed NaOH solution, $C_{NaOH}$ is the concentration of NaOH solution and $W_d$ is the weight of the dry membrane [17].

**Methanol permeability and proton conductivity**

Methanol permeability was determined using a two-compartment diffusion cell. Compartment A was filled with 1 M methanol solution and compartment B was filled with deionized water. The membrane was placed between compartment A and B. Samples from compartment B were taken out every 30 minutes for 6 hours to determine its methanol concentration using high-performance liquid chromatography (HPLC). The methanol permeability values were determined by using equation 4 [18].

$$P = \left(\frac{\Delta C_B}{\Delta t}\right)\left(\frac{LV_B}{AC_A}\right) \quad (4)$$

P is methanol permeability of the membrane ($cm^2.s^{-1}$), $\Delta C_B/\Delta t$ is the slope variation of methanol concentration in compartment B as a function of time (mol $L^{-1}.s^{-1}$), $L$ is the thickness of the membrane (cm), $V_B$ is the volume of the water at compartment A ($cm^3$), $A$ is the membrane surface area ($cm^2$), and $C_A$ is the concentration of methanol in the cell A (mol $L^{-1}$). The proton conductivity of the membrane was measured using electrochemical impedance spectroscopy (EIS), at a frequency of 1-$10^6$ Hz. The proton conductivity values were calculated using equation 5;

$$\sigma = \frac{L}{R \times A} \quad (5)$$

where $\sigma$ is the proton conductivity of the membrane (S $cm^{-1}$), $L$ is the membrane (cm), $A$ is the membrane surface area ($cm^2$), and $R$ is the membrane resistance (Ω) [18].

## Results and Discussion

**Fourier transform infrared spectroscopy**

Fourier transform infrared spectroscopy (FTIR) spectra of PES+SPEI polymer blend membranes are shown in Figure 1. As for the SPEI, PES, and PES+PEI membranes, the bands at 708 $cm^{-1}$, 1071 $cm^{-1}$, 1279 $cm^{-1}$ are assigned to the stretching vibration of $–SO_3H$ groups [7, 9]. Furthermore, the broad band in the SPEI, PES and SPEI+PES spectra around 3600 $cm^{-1}$ was assigned to O–H vibration associated with the interaction between sulfonic acid groups and water molecules. This is confirmed that the sulfonic acid groups are successfully introduced to the resulting polymer. The hydrophilic clusters formed by the sulfonic acid groups could broaden the proton transfer channels. The bands for the stretching vibration of the C-N groups of SPEI can be observed at 1467 $cm^{-1}$ and the stretching vibration of the C=O groups of SPEI and PES can be seen at 1650 $cm^{-1}$.

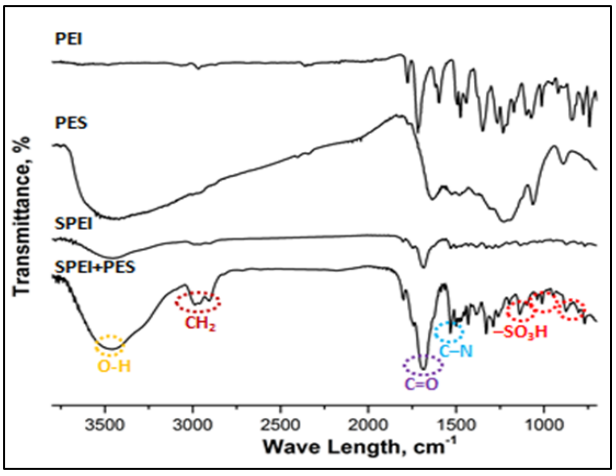

Figure 1. FTIR spectra of membranes

**Mechanical properties**

The mechanical strength of the blend membranes is significant for DMFC application to assure its stability as the electrolyte passes across the membrane. The mechanical strength of SPEI membrane and the blend membranes (SPEI-PES) were measured at room temperature.

As shown in Figure 2, the blend membranes show higher tensile strength along with the decrease of SPEI. The tensile strength rises from 13.9 to 30.7 MPa with the content of SPEI decrease from 25 to 15%. The tensile strength decrease from 31 to 13 MPa with the content of SPEI increase from 15 to 25% with added 3% PES. Such enhancement in tensile strength is due to the ionic crosslinking and close packed molecules in sulfonated blend membranes. However, the ionic crosslinking also reduces molecular flexibility, hence the blend membranes become more fragile and the elongation at break is decreased [9].

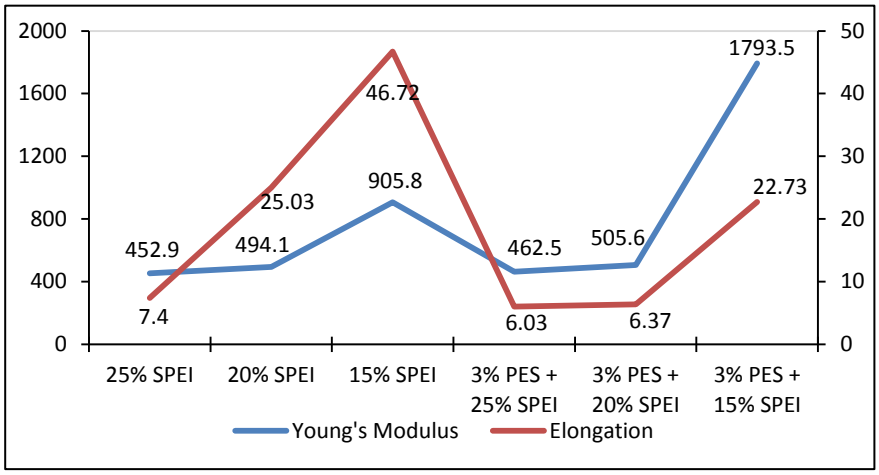

Figure 2. The mechanical properties of membranes

**Physically properties**

The water uptake, methanol uptake, swelling ratio, IEC and contact angle are important parameters for a membrane to be characterized. These properties of polymer blend membranes are presented in Figure 3. Many significant properties of the membrane, such as proton conductivity and water uptake, are related to IEC [9]. Ionic exchange capacity (IEC) is defined as the fixed milli equivalents of exchangeable group per gram of polymer, which is usually considered to correspond to the amount of sites for proton transfer and has great relation to the proton conductivity [5]. IEC depends on the content of free sulfonic acid groups in the membrane [9]. It can be seen that the IEC of the blend membranes increase with increase amount of the SPEI and also addition PES. One reason is due to the content of SPEI increase with the increase of sulfuric acid group of added PES.

Water uptake is another important parameter for ion exchange membrane. It has a great influence on the proton conductivity and dimensional stability of the membrane [9]. High water uptake can improve the proton conductivity [9]. As expected, hydrophilic side groups in SPEI and PES improve the amount of free sulfonic acid groups by polymer blend interactions. High content of SPEI leads water uptake increase, indicating the increase of hydrophilicity within the blend membranes. Moreover, the formation of cross-linked network structure increase free volume in blend membranes for water molecules which leads to water uptake increase. The swelling ratio reflects dimensional stability, and the lower swelling ratio is required for keeping membrane dimensional stable for a long time. Similar to the water uptake, all blend membranes show develop swelling ratio with increase of the SPEI and PES added [5, 9]. Therefore, it needs optimization composition of polymer. 20% (% weight ratio) SPEI/ 3% PES are the best compositions.

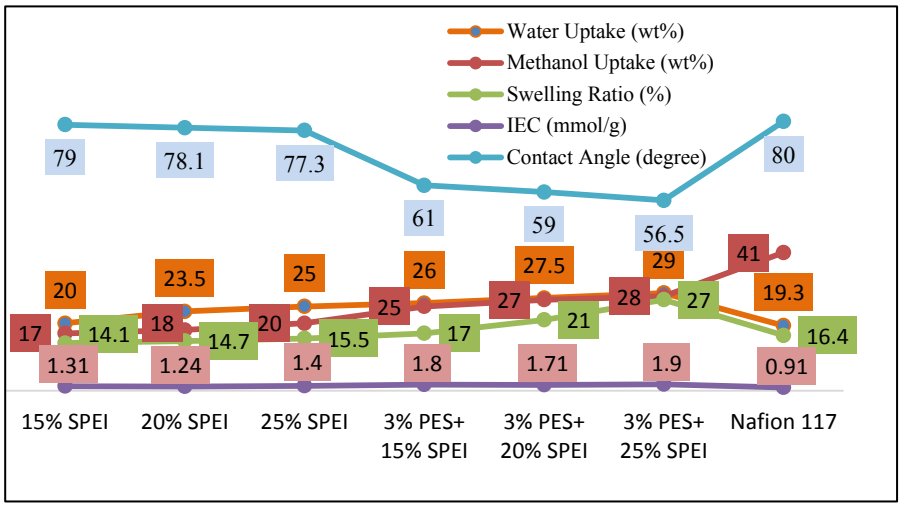

Figure 3. The physical properties of membranes

Permeability of methanol is a crucial parameter for DMFC, which represents the ability to prevent the crossover of positive and negative electrolytes [9]. Since DMFC uses methanol as fuel, low methanol permeability PEM would contribute to high efficiency fuel usage and low fuel loss [18]. Diffusion of methanol across the membrane will lead to self-discharge of the cell [9]. In this study, the methanol permeability of blend membranes and Nafion 117 membrane was measured. The calculated methanol permeability and proton conductivity are illustrated in Table 1.

Table 1. Methanol permeability and proton conductivity of pure PEI and PEI-PES membranes

| **Membranes** | **Proton Conductivity ($S.cm^{-1}$)** | **Methanol Permeability ($\times 10^{-7} cm^2.s^{-1}$)** |
|---|---|---|
| PES 20% | 0.0010 | 5.75 |
| SPEI 15% | 0.0018 | 11 |
| SPEI 20% | 0.0078 | 10 |
| SPEI 25% | 0.0069 | 13 |
| SPEI 20%-PES 3% | 0.0080 | 15 |
| Nafion® 117 | 0.0900 | 25 |

According to Table 1, all the blend membranes have lower methanol permeability than Nafion 117 membrane. However, methanol permeability can be improved by increasing hydrophilic polymer from sulfonic group addition. It caused the free volume of polymers will be bigger, which will result higher in their permeability's [9, 20].

In general, the smaller of contact angle indicates increasing hydrophilicity of the samples. Figure 3 illustrates the contact angles of the SPEI, PES, SPEI+PES significantly decrease because the presence of hydroxyl and sulfonic groups. Moreover, another important reason is the SPEI and PES possesses a high degree of sulfonic and hydrophilicity. This finding confirms the result of the water absorption of the membranes. This following Figure 4, provides information of the interactions between SPEI and PES membrane.

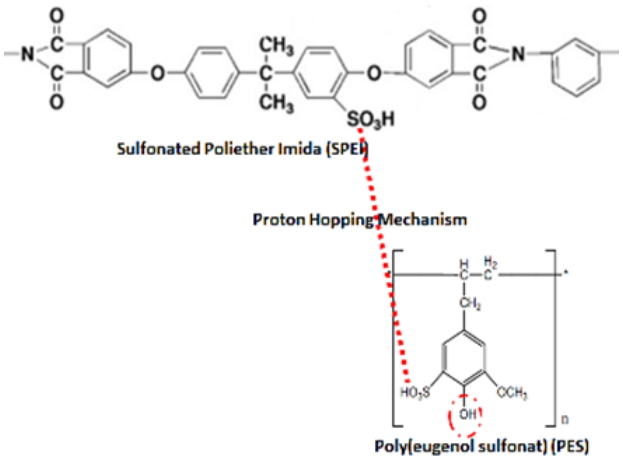

Figure 4. The interactions between SPEI and PES

Protons are largely transferred through the PEMs either as water-solvated species or by passing from one water molecule to another; hence, the ability of PEMs to imbibe large amounts of water molecules enhances the proton conductivity in the most cases. This effect is related to sufficient number of ionic sites and polar functional groups and also better formation and connection of proton-conducting channels in PEMs containing acid-bearing functionalities as well as higher dissociation degree of the ionic groups as the proton-conducting sites [21]. This statement is consistent as the Figure 4 contained polar functional groups such as $–SO_3H$ and –OH. With the sulfonate group will occur stepping proton from the one sulfonate group to another or called as proton hopping mechanism [21].

**Thermo gravimetric analysis**

Figure 5 illustrates the Thermo gravimetric analysis (TGA) curves of the membranes that under went both the dry method (slide casting and then vacuum), and wet method (spin coating and then waterbath), respectively. The changes in the sample weight with different temperatures under nitrogen flow using a standard temperature program with two steps were used for the TGA obtained at 550, 600, and 650 $^oC$ at a heating rate of 1 $^oC$ /min.

In Figure 5, it can be observed that the SPEI begins weight loss at around 200 $^oC$, followed by a final decomposition that began slowly around 450 $^oC$ after heating. The thermal decomposition of organic polymers is characterized by the breaking of the main chains [9] and different thermal degradation routes of SPEI. The decomposition of PES and PES+SPEI membranes weight significantly decreases after the temperature reaches approximately 550 $^oC$.This result may be due to the evaluation of a cleavage of the benzene ring of the SPEI and PES precursor. Consequently, the PEI-PES membrane can be expected to possess higher thermal stability characteristics compared to pure PEI membrane. Therefore, the resultant blend membrane is stable at desired operating temperatures (<100 $^oC$) for DMFC application.

**Morphology of the membranes**

Figure 6 shows the SEM images of SPEI and SPEI-PES particles. It appears that before the blending process, the 20% SPEI particles surfaces were less smooth and corrugated because casting solution is not perfect as shown in Figure 6 (a). After being blended with 3% PES (see Figure 6 (b)), the PES particles were dispersed and smooth its surface. These images prove that the PES has been successfully incorporated and dispersed into the SPEI. Also Figure 6 (c) and (d), with the elemental composition is given in Table 2, show the incorporation and dispersion of $–SO_3H$ groups on SPEI+PES. Oxygen, nitrogen, sulfuric elements present are important for bonding formation with organic polymer, enhancing the mechanical strength of its blending membrane, and developing the pathway for protons, thus consequently increase the membrane proton conductivity [18].

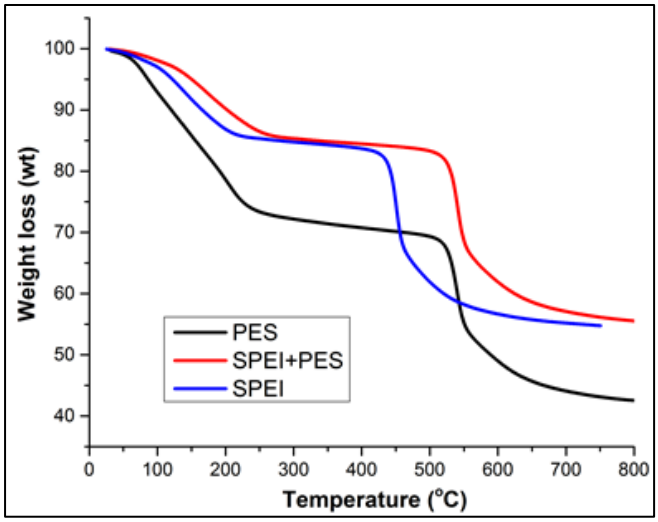

Figure 5. TGA curves SPEI, PES and SPEI+PES

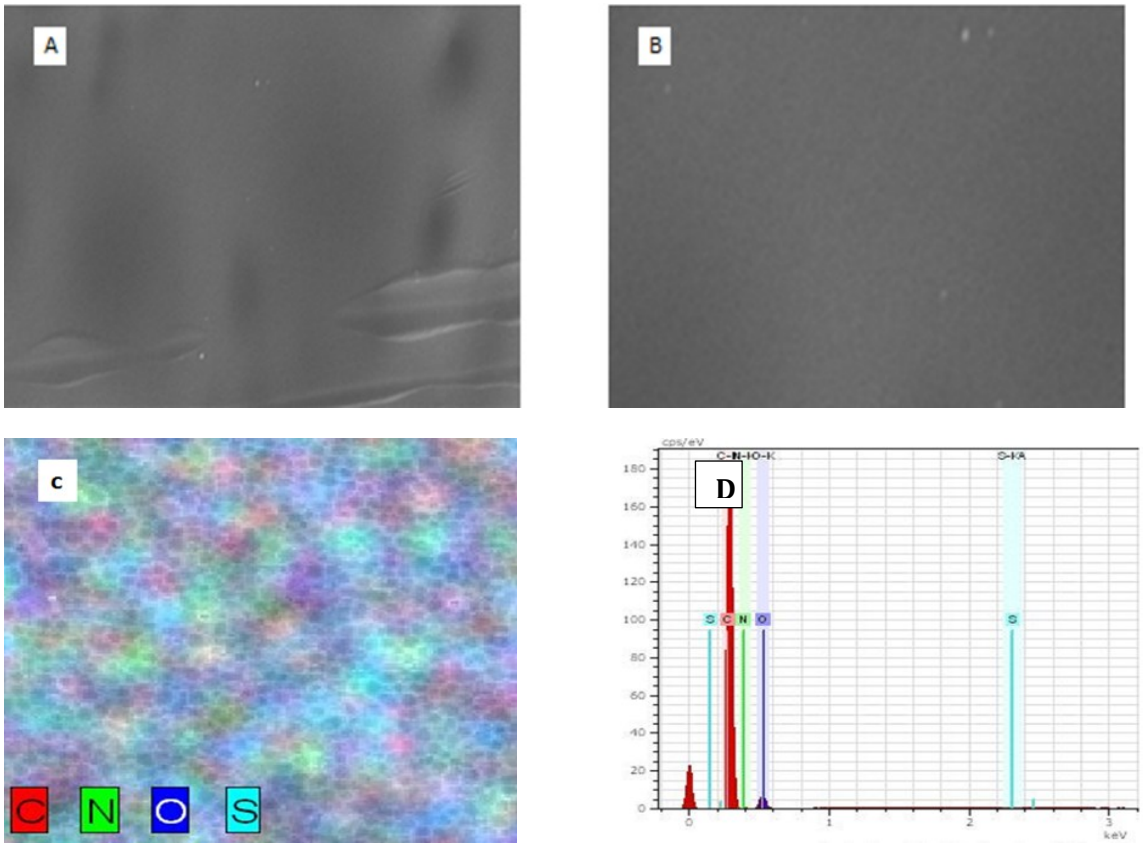

Figure 6. SEM images of (a) 20%SPEI, (b) 20%SPEI+3%PES, (c) Elements map and (d) EDX spectra of 20%SPEI+PES3%

Table 2. Elemental composition of 20%SPEI+PES3%

| E1 | AN | Series | Unn. C (wt.%) | Norm. C (wt.%) | Atom. C (at.%) | Error (%) |
|---|---|---|---|---|---|---|
| C | 6 | K-series | 70.84 | 70.84 | 76.11 | 21.5 |
| N | 7 | K-series | 4.01 | 4.01 | 3.70 | 1.6 |
| O | 8 | K-series | 24.92 | 24.92 | 20.10 | 7.9 |
| S | 16 | K-series | 0.23 | 0.23 | 0.09 | 0.0 |

## Conclusion

The blended membrane of SPEI and PES was successfully prepared using solution casting method. SEM images showed the evidence of PES incorporation and disperse into the PEI polymer matrix. The water uptake for SPEI-PES membranes increase as the increasing of SPEI concentration. The DMFC with blended membranes shows higher proton conductivity 0.008 $S.cm^{-1}$ and low methanol permeability $15 \times 10^{-7}$ $cm^2.s^{-1}$, which is better than the costly Nafion 117 membrane. Based on the obtained results, it can be concluded that PEI membrane blending with PES can be potentially used as promising polymer electrolyte membrane for DMFC applications.

**Abstract**

Microbial fuel cell (MFC) is a developed technology to utilize microbial degradation ability and turned the degradation products to electricity. One of the limiting factor that contributes to the performance level of MFC is the microorganism used in the MFC. In the present research, *Bacilli E1* has been tested for its ability to utilize glucose and converted it to electricity in dual chamber MFC. The MFC operated using E1 produced a maximum average of open circuit voltage (OCV) of 0.8 V. Meanwhile, by inserting a 1000 Ω resistance in the MFC circuit, produced a stable voltage of 0.1 V and calculated current and power were 0.2 ± 0.017 mA and 0.1 $Wm^{-2}$ Comparison of glucose based voltage production between individual and mixed culture shows similar pattern of voltage profile and since individual CC did not show any significant increase of OCV, it was concluded that *Bacilli E1* plays major role in the present MFC for power production.

**Keywords**: microbial fuel cell, *bacilli*, glucose

**Abstrak**

Sel bahan api berasaskan mikrob (MFC) adalah satu teknologi terbangun yang menggunakan keupayaan mikroorganisma mendegradasi dan menukarkan produk degradasi kepada elektrik. Antara yang menjadi faktor penghad yang menyumbangkan kepada tingkat prestasi MFC adalah mikroorganisma yang digunakan di dalam MFC. Dalam kajian ini, *Bacilli E1* telah diuji keupayaannya untuk menggunakan glukosa dan menukarkannya kepada elektrik dalam dwikebuk MFC. MFC yang dijalankan dengan menggunakan E1, telah menghasilkan voltan litar terbuka (OCV) sebanyak 0.8 V. Manakala, dengan memasukkan rintangan sebanyak 1000 Ohm dalam litar MFC menghasilkan voltan yang stabil berjumlah 0.1 V serta jumlah arus dan kuasa yang dikira adalah masing-masing 0.2 ± 0.017 mA dan 0.1 $Wm^{-2}$. Perbandingan antara penghasilan voltan daripada glukosa menggunakan individu dan kultur campuran adalah hampir serupa dan memandangkan CC secara individu tidak menunjukkan sebarang kenaikan dalam OCV, maka kesimpulan dibuat bahawa *Bacilli E1* memainkan peranan besar dalam MFC yang dijalankan untuk penghasilan kuasa..

**Kata kunci:** sel bahan api berasaskan mikrob, *bacilli*, glukosa

## Introduction

Microorganism(s) which has the ability to oxidize organic compounds to carbon dioxide, protons and electrons which the electrons are then been transferred to electrodes is called 'electricigens' [1, 2]. Electricigens are known to

convert organic waste into protons and electrons directly from the waste itself or with help of different alternative mechanism(s). However, in the advances in microbiology and biotechnology, some of the microorganisms have been identified as 'super bug' that mainly referred as unique microbes that can perform electron transfer directly with the aid of appendages equipped on the microorganisms or some natural surface proteins on the microbes. For example, *Geobacter* sp. [3] has been reported to possess appendage-like accessory called nanowire that can attach to electrodes and directly transferred electrons without any aid of other chemical substance or physical means. Recently, *Geobacter sulfurreducens* KN400 mutants were discovered to produce high current densities in pure cultures [4]. The addition of *Shewanella* sp. and *Pseudomonas* sp. diversified the types of unique microorganisms that each of one of them possesses different capacity of power generating mechanism(s).

Naturally, microorganism(s) competes to use substrate available in order to survive in their micro-environment and this may be a challenge in bioreactor like an MFC. However, there were reports of more than two microbes present in an MFC and able to produce way better or more or less similar power value to individual microbes [5, 6]. Previously, it was conducted by our research team on immobilized cells which were individual microbes been immobilized separately and then mixed in a single chamber MFC and produced comparable power to other MFC trials to date [7].

In the present research, a bacilli species has been isolated from anaerobic digester of a local waste water treatment plant (designated as E1) and been tested for its ability to initiate electricity production in a MFC. In addition, the *Bacilli E1* was mixed with another microorganisms which is known not able to conduct any voltage production as a control. The data will be presented on its open circuit and closed-circuit condition using a structurally designed MFC which was based on the principle of a dual chamber reactor separated by a proton-exchange membrane.

## Materials and Methods

### Microorganism characterization

*Bacilli E1* was isolated from an anaerobic digester of wastewater treatment system in a local palm oil mill in Pasir Gudang, Johor. Briefly, wastewater samples were diluted several times with sterile distilled water and dilutions were plated onto nutrient agar and incubated in an anaerobic jar (Thermo scientific Oxoid) supplemented with a commercially available Anaerogen sachet (Oxoid) which provides anaerobic conditions. Emerging microbes were then re-isolated in the same conditions and selected for MFC trials. Meanwhile, *Clostridium cellulolyticum* ATCC35319 (designated as CC) a strictly anaerobic microorganism has been purchased from American Type Culture Collection (ATCC).

Both microbes were subjected to standard simple staining and gram staining. Briefly, for simple staining, the microbes were heat-fixed onto a glass slide and one drop of methylene blue stain (Merck) was added to the glass slide for staining. Meanwhile, gram staining was conducted by fixing individual microbes onto a glass side and stained with sequential steps of different solutions (crystal violet, iodine, and safranin) which was purchased as kit from Merck Milipore.

### MFC preparation

Stock *Bacilli E1* and *CC* cell suspensions were maintained in -80 $^{\circ}$C previously and thawed prior to use. An amount 12.5 mL each of the cell suspension were transferred into a freshly prepared MFC containing 10% glucose in 0.1 M Potassium phosphate (Kpi) buffer with a pH of 7. All chemicals were analytical grade and sterilized through autoclaving prior to use.

### MFC operation

An acrylic dual chamber MFC was designed with a total volume of 250 mL for each chamber. In addition, anodic chamber was filled with 0.1 M Kpi, pH 7.0 mixed with cell suspension *Bacilli E1* and glucose as described previously or otherwise mixed of *E1* and *CC* for comparison. As for the cathodic chamber, 0.005 M of potassium permanganate in 0.1 M Kpi, pH 7, was added. Both chamber was equipped with rectangular shaped reticulated carbon cloth with a surface area of 20 $cm^2$. Meanwhile, a Nafion membrane (117) was pre-treated and set in between the chambers to separate them. The MFC was operated for three days to analyze the MFC performance in electrical production or voltage values with no resistant applied in between anode and cathode or indicated as open

circuit voltage (OCV). In addition, after OCV values were stable, different resistant values were applied in between the anode and cathode and voltage values were measured or indicated as closed-circuit voltage (CCV). Both OCV and CCV were monitored and recorded using an auto-logged multimeter.

**Closed-circuit voltage analysis**

CCV obtained was then calculated for power and current using the general equation (1 and 2) by Ohm's Law;

$$V = IR \quad (1)$$

$$P = V^2R \quad (2)$$

where V is the voltage obtained, I is the current calculated from V and resistant applied designated as R. P is the calculated power. All MFC trials were done in duplicates.

## Results and Discussion

**General characterization**

Simple and gram staining reveals that the microbe designated as E1 was bacilli in shape as shown in Figure 1. In addition, the gram staining shows that *Bacilli E1* was gram negative. In the group of 'electricigens' so far, there is no generalization that 'electricigens' are gram negative in nature but it is known from literature that generally in the MFC, these microbes tend to form electroactive biofilms on the anodic electrode [7, 8, 9] and it was also observed that after a period of time, biofilm formed on the anodic surface (data not shown). It was shown in several MFC trials that these electricigens within the attached biofilm on the anodic electrodes, capable of donating electrons or receiving electrons from electrodes, via extracellular electron transfer within the MFC environment [10]. However, it was difficult to explore how the electron transfer occurs in the vicinity of *Bacilli E1* without further dissections of the electron transfer process. In the next section, *Bacilli E1* capability in producing electricity will be discussed.

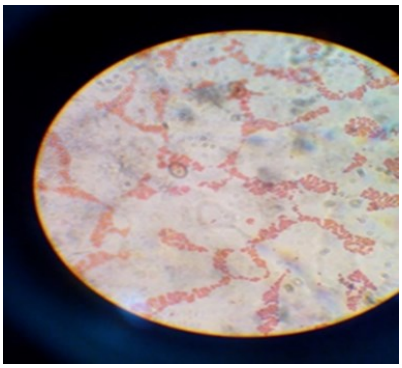

Figure 1. *Bacilli* E1 stained as gram negative

**Open circuit voltage**

Basically, OCV cannot be evaluated as indicator of the MFC performance but merely indicates of potential existence. Figure 2 (a) shows that a maximum average of 0.8 (V) was produced using *Bacilli E1* but *CC* did not show any changes in OCV values and produced less potential difference. Furthermore, similar maximum average of 0.8 (V) was observed for using a mixture of both microbes in the same MFC. This observation proved that the presence of E1 is needed to ensure the possibility of electrical activity initiated in the MFC. However, the OCV start-up seems to shift rapidly for mixed culture which an indication of possible fast degradation though there was no test done in access of the degradation products content. In addition, thermodynamically, the OCV value can be evaluated as the cell electron motive force ($E_{mf}$) which is a maximum achievable voltage without taking account on the losses due internal resistance in the system [11, 12]. From the present results, $E_{mf}$ = 0.8 V was achieved after 5

to 6 hours of operation and stabilized for almost 50 hours as shown Figure 2a. In contrast, as later shown, with current presents, the maximum voltage produced was much less than 0.8 V.

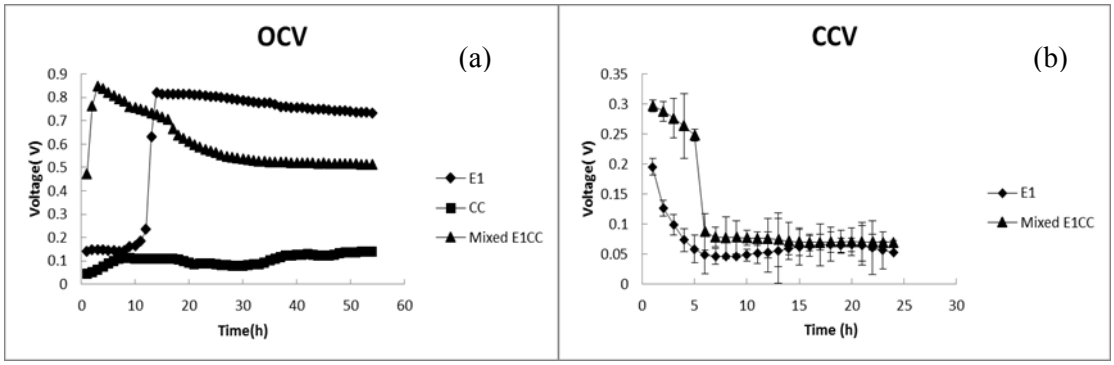

Figure 2. Voltage production in open and close circuit conditions (a) the open circuit voltage (OCV) profile and (b) shows the closed-circuit settings with 1000 Ohm as the resistant applied

**Closed circuit voltage**

The presence of load or resistant, at 1000 Ohm showed a rapid voltage drop (from 0.3 V to approximately 0.1 V) using the mixed culture which an indication of higher current densities produced (based on Ohm's Law) with maximum average calculated value of 0.2 ± 0.017 mA. In contrast, more stable voltage was activated after approximately 5 hours, mainly after large internal resistant and external resistant were equal [13]. It was reported previously more than 50% glucose carbon was discharged as carbon dioxide gas, acetate and various soluble products [14]. Meanwhile, it was also reported that the glucose metabolism within the fuel cell was a combination of both aerobic and anaerobic conditions which also means that the varieties of ionic components produced would probably lead to high internal resistance [12, 13, 14]. However, to synthesize the true source of high internal resistance that occurs in a particular MFC, further comparison in terms of type of membranes, electrolyte used and electrodes type should be conducted [15].

Meanwhile, Table 1 shows comparison of some established lab-scale MFC with the present tested MFC. Based on calculation, the presence dual chambered MFC for mixed culture used produced approximately 0.1 $Wm^{-2}$. The power density obtained was comparable to most sugar-based MFC but the differences in value are due to different materials of electrodes, the microbes used and independent design (anode surface area, volume, etc.) [16] which influence the performance of the MFC.

Table 1. Comparison of different studies of sugar-based MFC

| Type of MFC | Substrate or Fuel | Mode of Operation | Power ($Wm^{-2}$) | References |
|---|---|---|---|---|
| Dual chamber | Date syrup | Batch | 0.065 | [17] |
| Dual chamber | Date syrup | Batch | 0.052 | [18] |
| Dual chamber | Glucose | Fed-batch | 3.6 | [19] |
| Dual chamber | Glucose | Batch | 0.1 | Current work |

## Conclusion

It was revealed that *Bacilli E1* was able to be used for electricity production using microbial fuel cell (MFC). The highest OCV obtained by single microorganism *Bacilli E1* was 0.8 V and the CCV value with 1000 Ohm resistant produced a stable 0.1 V with calculated current of 0.2 ± 0.017 mA.

**Abstract**

Chitosan based inorganic hybrid membrane is a promising organic–inorganic hybrids for the development of high performance proton exchange membrane (PEM). The immobilization of modified montmorillonite (MMT) using GPTMS within chitosan matrix would possess superior physicochemical characteristics due to more hydrogen bonding formation introduced by GPTMS. Therefore, higher number hydrogen bond formation can be expected in Ch/MMT-GPTMS membrane rather than in pure Ch membrane. A fully hydrated membrane at elevated temperatures is desirable for efficient proton conduction in the membranes. It remains a critical challenge to maintain proper hydration of the membranes for the operation of the direct methanol fuel cell (DMFC). The microstructure obtained by SEM for composites showed that filler was successfully incorporated and relatively well dispersed in the chitosan polymer matrix. The role of surface modification of MMT filler by GPTMS have increase the functional group that can form hydrogen bonding which suitable for interaction with water. High water uptake is favourable for high performance PEM to facilitate great numbers of protons hopping and diffusion through the membrane. In addition, greater hydrogen bonding formation would lead to the tighter packing of composite membrane, resulting in higher bonding strength and higher thermal resistance. The Ch/MMT-GPTMS composite membrane with 5 wt% filler loading exhibited the best proton conductivity are 4.66 $mScm^{-1}$, with water contact angle value of 64.73°. A maximum power density of 0.24 $mWcm^{-2}$ was obtained with a 2M methanol feed. The relationship of water contact angle, water upake, membrane swelling, thermal stability, and proton conductivity shown suitable trend, it means that all quality of them are related to the hydrophilicity properties.

**Keywords:** chitosan, montmorillonite, (3-glycidoxypropyl) trimethoxysilane, direct methanol fuel cel

**Abstrak**

Kitosan berasaskan membran hibrid tak organik ialah kacukan organik-tak organik yang menjanjikan pembangunan pertukaran proton membran berprestasi tinggi (PEM). Montmorillonit (MMT) pegun diubahsuai menggunakan GPTMS dalam matriks

kitosan akan mempunyai ciri-ciri fiziko-kimia unggul kerana lebih pembentukan ikatan hidrogen yang diperkenalkan oleh GPTMS. Oleh itu, pembentukan jumlah ikatan hidrogen yang lebih tinggi boleh dijangka pada membran Ch/MMT-GPTMS bukannya pada membran Ch tulen. Setiap membran terhidrat sepenuhnya pada suhu tinggi adalah diperlukan untuk pengaliran proton cekap dalam membran. Ia kekal sebagai cabaran kritikal untuk mengekalkan penghidratan membran untuk operasi sel bahan api metanol langsung (DMFC). Mikrostruktur diperolehi melalui SEM untuk komposit menunjukkan bahawa pengisi telah berjaya digabungkan dan tersebar di dalam matriks polimer kitosan. Peranan pengubahsuaian permukaan MMT pengisi oleh GPTMS telah meningkatkan kumpulan berfungsi yang boleh membentuk ikatan hidrogen yang sesuai untuk berinteraksi dengan air. Pengambilan air yang tinggi adalah baik untuk PEM yang berprestasi tinggi bagi membantu proton bergerak dan penyebaran melalui membran. Di samping itu, pembentukan ikatan hidrogen yang lebih besar akan membawa kepada pembungkusan membran komposit yang lebih ketat, menyebabkan kekuatan ikatan dan rintangan haba yang lebih tinggi. Membran komposit Ch/MMT-GPTMS dengan 5% berat pengisi mewujudkan kekonduksian proton terbaik iaitu 4.66 $mScm^{-1}$, dengan nilai sudut sentuhan air ialah 64.73°. Ketumpatan kuasa maksimum ialah 0.24 $mWcm^{-2}$ telah diperolehi dengan suapan 2M metanol. Hubungan sudut sentuhan air, serapan air, pengembangan membran, kestabilan haba, dan kekonduksian proton menunjukkan corak yang sesuai, ia bermaksud semua kualiti yang terhasil adalah berkaitan sifat hidrofilik.

**Kata kunci:** kitosan, montmorillonit, (3-glisidoksipropil) trimetoksisilana, sel bahan api metanol langsung

## Introduction

Fuel cells are considered as green, reliable and highly efficient power generation technology in the current century. Among the different types of fuel cells, direct methanol fuel cell (DMFC) are promising candidates for portable devices or transportation applications in view of their high energy density, simplified system design, low emission, low temperature and pressure operation and high efficiency [1,2]. Polymer electrolyte membranes (PEM), a crucial component in the DMFC separating the cathode and anode, function as proton conductor as well as methanol separator between the cathode and anode [3]. In fact, the performance of DMFC is profoundly connected to PEM, wherein the electrochemically generated protons transport from anode to cathode electrodes. Perfluorosulfonic acid membranes (Nafion©) are widely used as PEM for DMFC applications, owing to good chemical and thermal resistance and high ionic conductivity [4,5]. However, these membranes suffer from drastic high methanol diffusion, high cost and rapid dehydration with decreasing proton conductivity at high temperatures. The high methanol diffusion causes loss of fuel, reduced fuel efficiency, reduced cathode voltage and excess thermal load in the cell [4,6,7].

Chitosan is considered to be the second most abundant polysaccharide in the world after cellulose which can be renewed and produced by utilizing marine waste such as shrimp, crab, lobster, and fish shells [8,9]. Chitosan can also be prepared from fungal cell walls via fermentation technology [10]. Chitosan is a polyaminosaccharide with good mechanical strength, biodegradable, and nontoxic properties [11,12]. Chitosan is not directly available in nature, however, it can be easily generated through the process of deacetylation of chitin by a strong alkali [8]. In the recent years, the comprehensive utilization of chitosan as bio-based polymer has drawn elevated attention for various functional hybrid materials with tremendous properties for various applications such as medicine, pharmaceutical, food industries, waste water treatment and energy [13–17].

It has been reported that the reinforcement of nanomaterial in bio-polymeric matrices has greatly improved the physicochemical, mechanical and thermal stability characteristic of resultants bio-polymer nanocomposites [18–20]. Recently, the incorporation of layered silicates and in particular montmorillonite (MMT) in chitosan has been extensively studied [21–24]. The use of MMT as a filler in bio-polymer is interesting due to its environmental and economic importance. MMT has several advantages including easy to obtain, having a large specific surface area, chemical resist, having strong absorption capability, and having good cation exchange capacity, and having good adhesive capability [25–28].

MMT as an inorganic material cannot collaborate perfectly with organic polymer, because the surface layer of montmorillonite cannot interact maximally with the organic portion of the polymer. Organophilization process is one of the promising methods to improve the interaction of MMT in polymer matrices [29,30]. Huang and co-workers prepared carboxymethyl chitosan/organically MMT with enhanced thermal stability and antimicrobial activity with complexation with copper ion [22]. Wang et al. developed an organic-inorganic composite using chitosan as the polymer matrix and zeolite as inorganic filler [31]. Their study indicated that by using (3-

glycidoxypropyl) trimethoxysilane (GPTMS) to modify the zeolite surface, the new developed composite membrane was able to achieve denser and high thermal stability.

In this study, we prepared chitosan/MMT-GPTMS composite membrane by utilizing dried shrimp shell powder as chitosan source and acetic acid as solvent. The surface modification process of MMT using (3-glycidoxypropyl) trimethoxysilane (GPTMS) would provide excellent compatibility with chitosan membrane.The immobilization of modified MMT using GPTMS within chitosan matrix would possess superior psychochemical characteristics due to more hydrogen bonding formation introduced by GPTMS. Therefore, higher number hydrogen bond formation can be expected in Ch/MMT-GPTMS membrane rather than in pure Ch membrane. A fully hydrated membrane at elevated temperatures is desirable for efficient proton conduction in the membranes. It remains a critical challenge to maintain proper hydration of the membranes for the operation of the DMFC. The aim of this study is to analyse a relationship between proton conductivity, hydrophilicity, and thermal stability of chitosan/montmorillonite composite membrane modified GPTMS as the electrolyte membrane for direct methanol fuel cell. The morphological structure and functional groups was analysed by SEM and FTIR. The thermal stability TGA/DTG and The hydrophilicity properties was investigated by water contact angle, water uptake (WU) and membrane swelling (MS). The proton conductivity, methanol permeability, DMFC single cell are carried out to determine the overall membrane performance for DMFC applications.

## Materials and Methods

### Materials

Shrimp shell waste of *Penaeusmonodon* was used the chitosan source. Montmorillonite (MMT K-10, S.A 220 – 270 $m^2/g$) powder, (3-glycidoxypropyl) trimethoxysilane (GPTMS)and phosphotungstic acid (PTA, $H_3PW_{12}O_{40}$. $xH_2O$, MW: 2880.05) were purchased from Sigma-Aldrich. Sodium hydroxide (NaOH), hydrochloric acid (HCl), methanol (MeOH), acetic acid, in pure analytical grade were purchased from Merck. The distilled water was used throughout the study.

### Extraction of chitosan matrix and MMT modification

Chitosan was extracted according to the approach reported in the literature [32], with four step process includes preparation, deproteination, demineralization and deacetylation. First step, shrimp shell waste was driedat 60 $^oC$ and then it was grinded until it became dried shrimp shell powder. Second step, dried shrimp powder was added into 3.5% NaOH solution with a ratio of 1:10 (w/v) under continuous stirring for 2 hours at 65 $^oC$. Then, the mixture was filtered and the outcome was washed until pH 7 and dried at 105 $^oC$. Third step, the dried powder was then demineralized using 1 M HCl, stirred for 30 minutes at 65 $^oC$ with a ratio of 1 : 15 (w/v), washed, and dried. The results of demineralization process is dry powder form, called chitin. The chitin powder obtained was then run through the deacetylation process in last process, using 50% NaOH solution, stirred for four hours at 120 $^oC$ with a ratio of 1:10 (w/v), washed, and dried until it became dried powder called chitosan.

The modification of MMT sample was performed using the surface hydroxyl groups of MMT by dehydration process and condensation with GPTMS. MMT powder, GPTMS and toluene were mixed in a reactor with weight ratio 1:2:20. The reaction was carried out at refluxing temperature of toluene (110 °C) and stirred for 24 hours. After being washed with ethanol for three times, the sample was soaked in a solution of 0.1 M HCl for 24 hours at room temperature. The precipitate then was filtered and washed with demineralized water until neutral. Finally, the precipitate was dried in the oven at 100 °C for four hours. The surface-modified MMT was designated as MMT-GPTMS.

### Membrane fabrication

Chitosan powder was dissolved in 25 mL of 2% acetic acid, and stirred at 80 °C and 400 rpm. Another 25 mL of 2% acetic acid was used to dilute MMT-GPTMS powder and ultrasonic treatment for 30 minutes. Then, both mixtures were mixed together and stirred for 30 minutes at 80 °C. After that, the mixture was given an ultrasonic treatment for 30 minutes, stopped for 30 minutes, and then, an ultrasonic treatment was carried out again for 30 minutes. After degasification, the mixture was then caston glass panel and dried at room temperature for 48 hours. The detached membrane was then immersed in 1 M NaOH for 15 minutes before being washed with distilled water until neutral pH was achieved.The membrane then immersing in 2% w/v of PTA solution for 24 hours, and then washed

repeatedly with distilled water to remove the remaining PTA acid before being dried at room temperature for 24 hours[33,34]. The pristine chitosan membranes and MMT unmodified was synthesized by the same process.

**Membrane characterization**

Fourier Transform Infrared Spectroscopy (FTIR) was used to analyse the structure and functional group. The disk containing 0.1 – 0.2 g sample and 0.5 – 1.0 g of fine grade KBr was mixed and crushed into powder, and pellets were formed with a hydraulic press. All measurements were scanned within the waverange of 650 – 4000 $cm^{-1}$. The morphological structural of the resultant material was analysed by means of Scanning Electron Microscopy (SEM) Bruker analysis. The sample powder was prepared in a pin stub holder and coated with gold before the analysis. Thermo gravimetric analysis (TGA) was carried out using a Mettler Toledo 851e TGA/DTG thermogravimetric analyser at a heating rate of 10 $^{o}C\ min^{-1}$ under air flow of 30 mL $min^{-1}$ from room temperature to 800 $^{o}C$.

Water uptake (WU) were conducted by measuring the weights of membranes under fully hydrated and completely dried conditions. A detail procedure was reported previously [31]. Water uptake was calculated using equation (1).

$$WU(\%) = \frac{W_{wet} - W_{dry}}{W_{dry}} \times 100 \quad (1)$$

where $W_{dry}$ and $W_{wet}$are the membrane weight before and after immersion in gram, respectively. The membrane swelling (MS) was defined as follows (equation 2):

$$MS(\%) = \frac{L_{wet} - L_{dry}}{L_{dry}} \times 100 \quad (2)$$

where $L_{wet}$ and $L_{dry}$ are the thickness of wet and dry membranes, respectively.

The hydrophilicity property of membrane studied based on water contact angle (WCA) measurement. The water contact angle was determined by using a contact angle goniometer (OCA15Pro, Data Physics), equipped with image-processing software. This instrument was used to evaluate the degree of membrane hydrophilicity via sessile drop technique. The proton conductivity of the membrane was measured using electrochemical impedance spectroscopy (EIS), at a frequency of 1-$10^6$ Hz. The proton conductivity values were calculated by using equation (3)[34].

$$\sigma = \frac{L}{R \times A} \quad (3)$$

where $\sigma$ is proton conductivity of the membrane (S $cm^{-1}$), $L$ is the membrane (cm), $A$ is the membrane surface area ($cm^2$), and $R$ is the membrane resistance (Ω).

Methanol permeability was determined by using a two-compartment diffusion cell. Compartment A was filled with 1 M MeOH solution and compartment B was filled with deionized water. The membrane was placed between compartment A and B. Samples from compartment B were taken out every 30 minutes for 3 hours, to determine its methanol concentration using High Performance Liquid Chromatography (HPLC). The methanol permeability values were determined by using equation (4) [34].

$$P = \left(\frac{\Delta C_B}{\Delta t}\right)\left(\frac{LV_B}{AC_A}\right) \quad (4)$$

$P$ is methanol permeability of the membrane ($cm^2.s^{-1}$), $\Delta C_B/\Delta t$ is the slope variation of methanol concentration in compartment B as a function of time ($mol.L^{-1}.s^{-1}$), $L$is the thickness of the membrane (cm), $V_B$ is the volume of the water at compartmentB ($cm^3$), $A$ is the membrane surface area ($cm^2$), and $C_A$ is the concentration of methanol in the cell A ($mol.L^{-1}$).

To evaluate the cell performance of the DMFC, a membrane electrode assembly (MEA) was made by catalyst-coated membranes were sandwiched within gas diffusion layers, inside the test single cell. The Pt-Ru/C with 40 wt.% Pt + 20 wt% Ru/C and the Pt/C catalyst with 20 wt.% Pt were used as the anodic and cathodic catalyst,

respectively. The active area of the cells was 2.5 cm x 2.5 cm. The MEA was hot-pressed at 105 $^{o}$C and 5 MPa for 1 min. The performance of the single cell was measured at room temperature with a Fuel Cell Test Autolab instrument. 2 M MeOH solution with a flow rate of 20 mLmin$^{-1}$ and oxygen with a flow rate of 0.5 Lmin$^{-1}$ were used [35].

## Results and Discussion

### Biopolymer extraction and modification process

Figure 1 shows the FTIR spectra of chitin and chitosan. The peak at 3514 cm$^{-1}$ described of stretching vibration -OH group and as seen as the characteristic peaks of the chitin which is at 3298, 3155, 1579 cm$^{-1}$ derived from stretching vibration group NH (-NHCOCH$_3$) and at 2970 cm$^{-1}$ for absorption of a methyl group (-CH$_3$), but lost in the spectra of chitosan, however presence overlapping of stretching vibration –OH and –NH group at 3508 cm$^{-1}$. The characteristic of chitosan shown the reduce of the peak at 1670 and 1622 cm$^{-1}$ attributed from stretching vibration of C=O group on the cluster NHCOCH$_3$ chitin, shown that the removal of the acetyl group into the amine group due to the process of deacetylation. This phenomenon was supported by the loss of a methyl group (-CH$_3$) from the amide (-NHCOCH$_3$) which are known from the absorption loss at 2970 cm$^{-1}$. The typical characteristic of chitosan is visible at 1662 cm$^{-1}$ shows the bending vibration of NH amine (-NH$_2$) [36]. The peaks at 2945, 1429 and 929 cm$^{-1}$ in chitosan spectra assigned to stretching vibration of methylene -CH$_2$-, C-N stretching vibration, and buckling vibration –C-O-C- showed glucopyranose ring, respectively, similar peak also presence in chitin spectra.

The functional group analysis of MMT before and after modification using FTIR sre presented in Figure 1. Two peaks at 3440 and 1640 cm$^{-1}$ corresponded to the –OH stretching and bending vibrations of H–O–H on the MMT surface, respectively. The GPTMS modification has reduced the intensity of -OH stretching bond vibration of pure MMT, as a result of the consumption of the MMT hydroxyl groups by condensing with the silanol groups, and meanwhile the surface of the MMT occurred decreasing of the water adsorption [33]. The characteristic peaks at 2940 cm$^{-1}$ is corresponded to C–H valence vibration for epoxy ring from GPTMS structure.

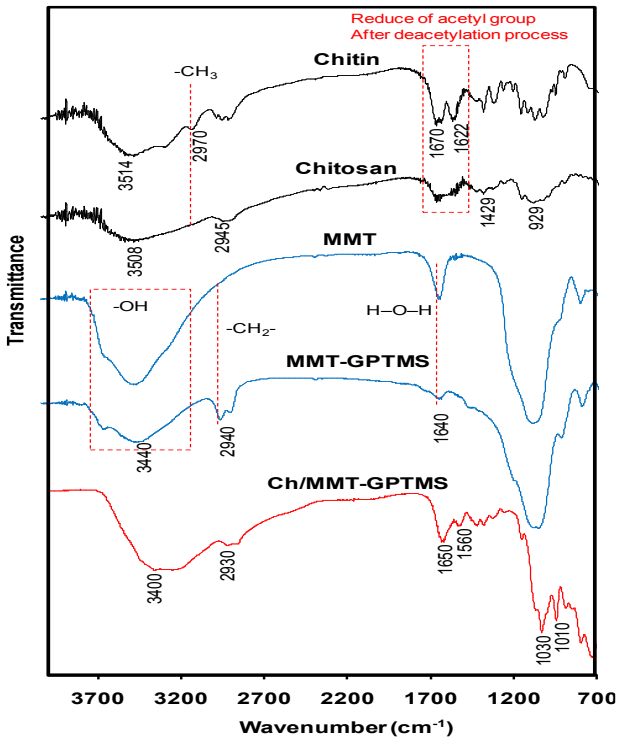

Figure 1. FTIR spectra of MMT, MMT-GPTMS, Chitin, Chitosan and Ch/MMT-GPTMS composite membrane

The filler modification process is illustrated in Figure 2(a). The modification process starts with hydrolysis of the three labile metoxy groups attached to silicon atom. The –OH group for the hydrolysis process was contributed by water present on the MMT surface. Then, a reactive silanol group is formed, which can bind together with other silanol groups to be oligomers at condensation step. The third step is to attach the oligomers via hydrogen bonding with –OH groups on MMT surface. Finally, termination reaction of epoxy groups with HCl acid solution catalytic, resulting in hydroxyl group formation at the end side of GPTMS[37,38].

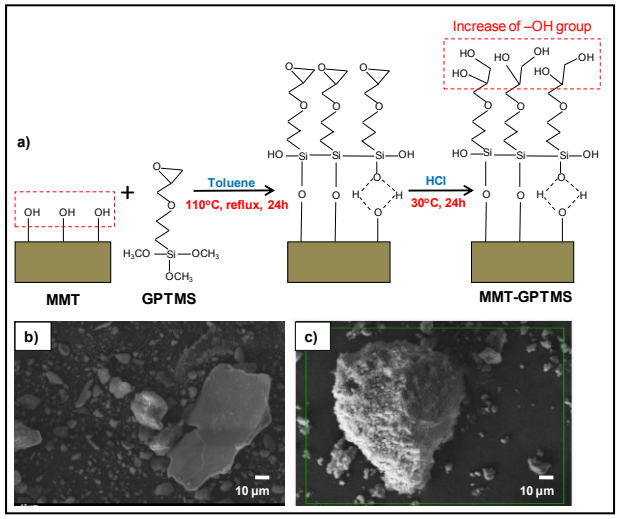

Figure 2. Illustration scheme of MMT modification process by GPTMS (a) and SEM image (b) MMT and (c) MMT-GPTMS

Figure 2 (b, c) shows the SEM images for MMT and MMT-GPTMS surface. The MMT surfaces are smooth and flat, but after the modification process, the MMT-GPTMS surface becomes rough and overgrown soft granules are spread almost evenly on the MMT-GPTMS surface (Figure 2b). This indicates that GPTMS has been successfully incorporated on the surface of MMT, showing good interlocking interaction. SEM and FTIR results confirmed that the MMT particles were successfully modified using GPTMS to form MMT-GPTMS filler.

**Physicochemical and thermal stability of membrane**

The FTIR spectra of Ch/MMT-GPTMS composite membrane presented in Figure 1. Two peaks at 3400 $cm^{-1}$ and 1650 $cm^{-1}$ which are attributed to hydroxyl group and amide groups, indicating that the characteristics of chitosan still exist as a matrix in composite membrane. The peaks at 2930 $cm^{-1}$ were assigned to $–CH_2$ stretching, and the two bands at 1030 $cm^{-1}$ and 1010 $cm^{-1}$ for chitosan matrix were merged and shifted towards 1030 $cm^{-1}$ in MMT-GPTMS filled composite membranes due to the overlapping of Si–O band with the C–O stretching band [16].The SEM images for pure chitosan membrane, Ch/MMT and Ch/MMT-GPTMS composite membrane are presented in Figure 3.

As can be seen in Figure 3(a), the pure chitosan membrane shows a void free dense structure. Meanwhile, Figure 3(b) shows the MMT agglomeration between the chitosan polymer matrix, which is due to the incompatibility between inorganic and organic material. Better interfacial morphology was able to be achieved after the MMT modification using GPTMS, thus improving the compatibility between chitosan organic polymer and MMT-GPTMS inorganic filler, and reducing the MMT-GPTMS agglomeration, as shown in Figure 3(c) [33,38]. The incompatibility between chitosan organic polymer and MMT inorganic filler has caused the phase separation in Ch/MMT 5 membrane, thus the agglomeration of MMT particles are formed (Figure 3(e)). However, the cross-section image of Ch/MMT-GPTMS 5 shows that the MMT-GPTMS filler was well dispersed inside the chitosan

polymer matrices with no visible agglomeration occurred (Figure 3(f)). This proves that the addition of GPTMS on the surface of MMT filler was able to increase the compatibility between the chitosan matrix and MMT-GPTMS filler.

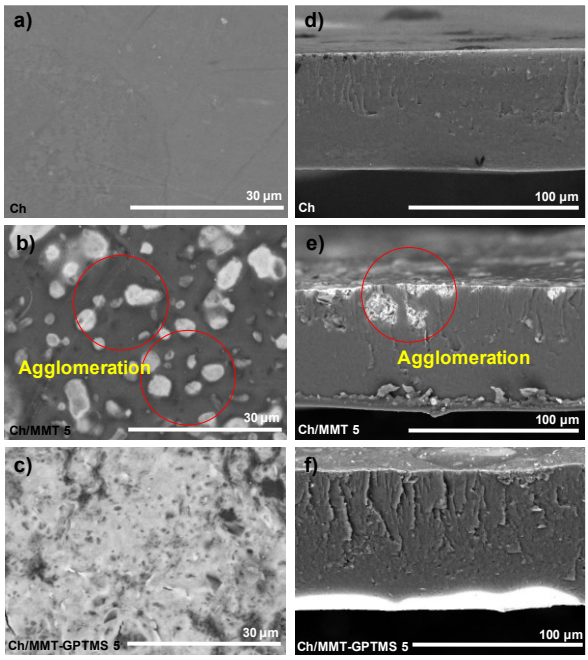

Figure 3. SEM images of (a) pristine Ch, (b) Ch/MMT, and (c) Ch/MMT-GPTMS membrane, (d), (e), and (f) showed the cross section of chitosan, Ch/MMT and Ch/MMT-GPTMS membrane, respectively

The TGA analysis was carried out to evaluate the thermal stability of the pure chitosan, Ch/MMT and Ch/MMT-GPTMS. The TGA and DTG curves in Figure4 show that all membranes followed almost identical degradation mechanism since there were miniscule difference in $T_{10\%}$, $T_{30\%}$, $T_{50\%}$, and $T_{max}$, as shown in Table 1. As shown in the Figure 4 all membranes show three stages of weight loss, the first stage that happens below 175 $^{o}$C which was attributed to the evaporation of absorbed water[14,39]. The second stage happens at 175 – 400 $^{o}$C interval because of the chitosan polymer chain degradation, and the last stage happens after 400 $^{o}$C due to the decomposition of residual organic group [31]. It has been reported that the decomposition of montmorillonite clay is not complete until 800 $^{o}$C [39]. Therefore, it is believed that the incorporation of inorganic filler might fill the gaps between the chitosan polymer matrixes, thus making the chain becomes tighter and increases the strength of the chitosan polymer chain. This occurrence might attribute to the increasing of thermal stability characteristics of Ch/MMT and Ch/MMT-GPTMS membrane compared to its parent chitosan membrane as shown in Figure 4. As can be seen in Table 1, the neat chitosan exhibited the lowest in residual percent, while the Ch/MMT-GPTMS exhibited the higest. The incorporation of GPTMS has improved the interaction of MMT with chitosan by introducing more functional groups, so increasing of thermal stability of Ch/MMT-GPTMS composite membrane. These results are in good agreement with previously reported values for chitosan composites [14].

Furthermore, Figure 4 suggested that the Ch/MMT-GPTMS membrane has lower weight loss percentage compared to the Ch/MMT membrane. The greater hydrogen bond formation was expected in Ch/MMT-GPTMS membrane rather than in Ch/MMT membrane (As can be illustrated in Figure 5(a) and (b)). Thus, the greater hydrogen bonding formation would improve the interaction of MMT filler within chitosan polymer matrices. Consequently, the

Ch/MMT-GPTMS membrane becomes tighter and stronger than Ch/MMT membrane, thus giving the Ch/MMT-GPTMS membrane higher thermal stability characteristics compared to Ch/MMT membrane.

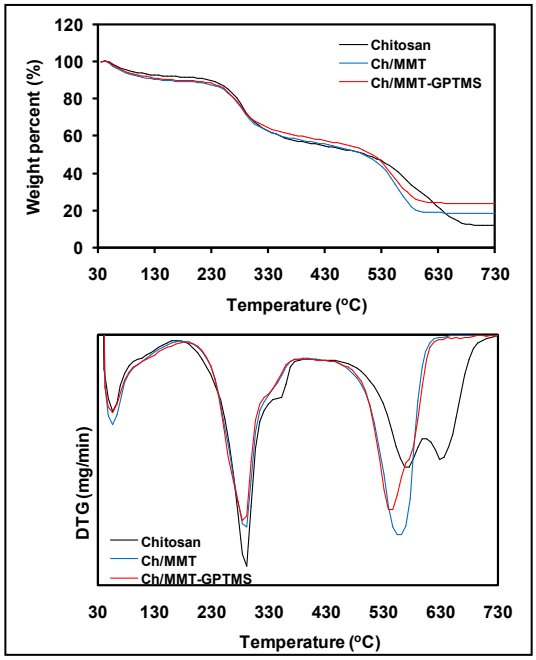

Figure 4. TGA and DTG curves for pristine chitosan, Ch/MMT, and Ch/MMT-GPTMS membrane.

Tabel 1. Thermal Stability Data of Ch, Ch/MMT, and Ch/MMT-GPTMS composite membrane

| Sample | $T_{10}$% (°C) | $T_{30}$% (°C) | $T_{50}$% (°C) | DTG peak, $T_{max}$ (°C) | | | Residu at 730 °C (%) |
|---|---|---|---|---|---|---|---|
| | | | | $T_{max}^{1}$ | $T_{max}^{2}$ | $T_{max}^{3}$ | |
| Chitosan | 220.9 | 298.4 | 500.9 | 56.4 | 290.6 | 575.7 | 12.1 |
| Ch/MMT | 122.2 | 290.3 | 498.5 | 56.3 | 290.3 | 561.7 | 18.9 |
| Ch/MMT-GPTMS | 144.6 | 298.1 | 514.5 | 56.4 | 290.3 | 546.3 | 23.8 |

Similar observations also have been reported by Wang and co-worker with CS/Zeolite and CS/Zeolite-GPTMS composite membrane [31]. In their study, the CS/Beta-GPTMS membrane showed a little higher thermal stability than the CS/Beta membrane. It has been suggested that the organic chains and –OH groups on the surface of the GPTMS-modified zeolite beta particles can enhance the interactions between the zeolite beta and chitosan molecules, which decelerate the decomposition of the chitosan main chain. Wang and co-workers had reported the strong interaction of MMT filler in the CS matrix to form flocculated structure in Ch/MMT composite. Since one chitosan unit possesses one amino and two hydroxyl functional groups, these functional groups can form hydrogen bonds with the silicate hydroxylated edge groups from montmorillonite filler, which lead to the strong interaction between matrix and MMT layers [40]. The same phenomenon of interaction polymer clay composite has been reported [41], the layer of biopolymer is adsorbed by means of a hydrogen bonding mechanism, since the hydroxyl functional groups in surface of the MMT has been already balanced by functional groups of the chitosan layer as a matrix.

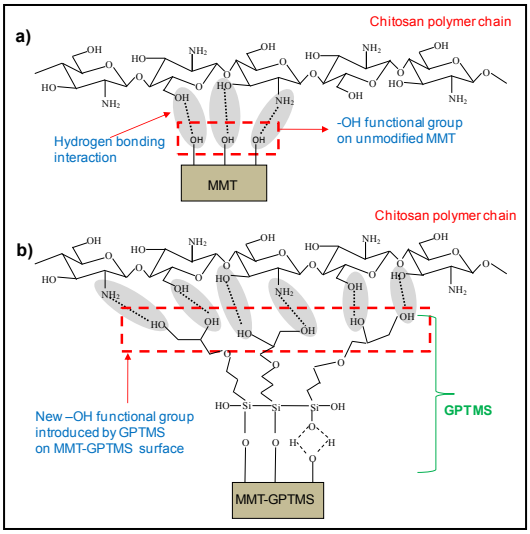

Figure 5. Plausible schematic diagram illustrates the bonding formation between chitosan parent polymer and its filler for (a) Ch/MMT and(b) Ch/MMT-GPTMS composite membranes

**Water uptake, membrane swelling and hydrophilic properties**

The hydrophilic property of membrane was studied based on water contact angle (WCA), water uptake (WU) and membrane swelling (MS). The water uptake has a profound effect on proton transport and dimensional stability of proton conducting membranes. The high water uptake is favorable for high performance PEM to facilitate great numbers of protons hopping and diffusion through the membrane. The water uptake and membrane swelling for chitosan, Ch/MMT and Ch/MMT-GPTMS is shown in Table 2. The water uptake for pure chitosan membrane is 72.9%, after the incorporated of inorganic filler the water uptake decreased at 54.5% and 62.1% for Ch/MMT and Ch/MMT-GPTMS, respectively. The similar trend has been reported in previous study, the water uptake for Ch/Zeolite composite membrane showed a decrease as the zeolite filler load increased [31]. In addition, Madaeni and co-worker reported in previous study where the water uptake for PVA composite membrane decreased by incorporated filler [42].

Table 2. Water uptake and membrane swelling for chitosan, Ch/MMT and Ch/MMT-GPTMS

| Membrane | Water Uptake (%) | Membrane Swelling (%) |
|---|---|---|
| Chitosan | 72.9 | 23.7 |
| Ch/MMT 5 | 54.5 | 18.5 |
| Ch/MMT-GPTMS 5 | 62.1 | 19.7 |
| Ch/MMT-GPTMS 10 | 53.9 | 18.1 |
| Ch/MMT-GPTMS 15 | 49.2 | 17.9 |

The high water uptake of chitosan membrane showing better hydrophilic trend, compared to Ch/MMT composite membrane which presence decreased the water uptake. This phenomenon suggested to the dynamic water contact angle of pristine chitosan and Ch/MMT 5 composite membrane are plotted in Figure 6. It was found that the initial contact angle of pristine chitosan showed a better hydrophilicity than Ch/MMT 5 (35.9$^{o}$ compared to 82.8$^{o}$). This results established that lower contact angle showed a better hydrophilicity, thus notably indicating that hybrid

membrane presented an enhanced hydrophilicity or decrease of hydrophilicity depends to addition inorganic filler [31, 42, 43].

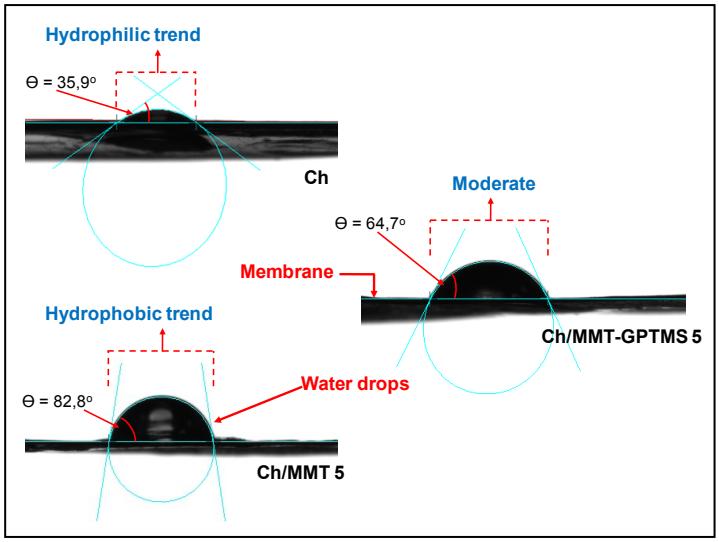

Figure 6. Water contact angle Ch, Ch/MMT and Ch/MMT-GPTMS

In another part, for direct methanol fuel cell application, membrane with high hydrophilic properties are very crucial to be able to hold existence of water because the proton will be transported along the water channel created in the membrane composite, however the hydrophobic properties also crucial to reduce methanol permeation rate which causes decrease of membrane efficiency. Therefore the moderate membrane is very suitable for this application, for get high proton conductivity and low methanol permability as previous study [31, 38]. Thus, in this study, we were able to prepare composite membrane with moderate properties, Ch/MMT-GPTMS 5 with water uptake at 62%, suggested to the equilibrium water contact angle, at 64.7$^{o}$ (Figure 6).

As seen as Table 2, shows the water uptake as a function of the membrane swelling of the chitosan, Ch/MMT and Ch/MMT-GPTMS membranes. As compared to pristine chitosan, high water uptake values were characterized for Ch/MMT and Ch/MMT-GPTMS composite membranes, but all of them showed low membrane swelling. The targeted membranes should be modest water uptake values and low membrane swelling ratios. These results revealed that the role of surface modification by GPTMS in Ch/MMT-GPTMS composite can be expected to possess higher thermal stability characteristics and lower membrane swelling, compared to pure Ch and Ch/MMT membrane. Therefore, the resultant composite membrane is stable at desired operating temperatures (<100 $^{o}$C) for DMFCs application.

**Proton conductivity, methanol permeability and DMFC performance**

Proton conductivity is one of the most essential requirement to enable membranes to be applicable in DMFC. The efficiency of the proton transfer within the PEM is therefore related either as water solvated species or the number of ionic sites, polymer functional groups and microstructure formation in the PEM through the interconnection between proton-conductive channels/species in the membranes [44]. The proton conductivity for chitosan and composite membranes are listed in Table 3. As seen as Table 3, the proton conductivity of hydrated plain chitosan membrane was 2.4 mS cm$^{-1}$ and increase with incorporated of MMT loading 5% in composite membrane, at 2.7 mScm$^{-1}$. The composite membrane Ch/MMT-GPTMS 5 is able to achieve maximum proton conductivity of 4.7 mScm$^{-1}$, an increase from 2.7 mScm$^{-1}$ exhibited by the Ch/MMT 5. The phenomenon can be explained that, the surface modification of MMT using GPTMS make an increase of hydroxy group, thus it can improve interaction

between the –OH group of MMT-GPTMS filler with hydroxy group and amine group of biopolymer chitosan via hydrogen bonding. High interaction in membrane structure provides additional conduction site for proton to be transported, thus increases the proton conductivity of the membrane.

Table 3. Proton conductivity and methanol permeability for chitosan, Ch/MMT and Ch/MMT-GPTMS

| **Membrane** | **Proton Conductivity ($mScm^{-1}$)** | **Methanol Permeability ($x\ 10^{-7}\ cm^2\ s^{-1}$)** |
|---|---|---|
| Chitosan | 2.4 | 4.9 |
| Ch/MMT 5 | 2.7 | 4.7 |
| Ch/MMT-GPTMS 5 | 4.7 | 3.0 |
| Ch/MMT-GPTMS 10 | 4.3 | 3.2 |
| Ch/MMT-GPTMS 15 | 4.1 | 7.6 |

Ch, MMT and GPTMS are able to establish channels of hydrophilic or water bulk phase which allows the protons to be transported via vehicle mechanism in the form of hydronium ions [44–46]. It has been suggested that, electrostatic interaction in the membranes which contain the abbundance hydroxy group and presence of $–NH_3^+$ allows the proton transferred along the ionic bonds and hydrogen bonds by "jumping" from one functional group to another. The incorporation of modified MMT (MMT-GPTMS) within the chitosan matrix has given chance for more protons to transport in Ch/MMT-GPTMS membrane, so that the proton conductivity of the membrane is higher than the Ch/MMT membrane. However, higher filler load had led to agglomerations problem in composite membrane, hence reduce of both water content and effectiveness of filler to provide conduction site for proton at the same time, thus decrease the proton conductivity of the membrane. The proton conductivity decrease after 10% loading filler at 4.3 $mScm^{-1}$ and 4.1 $mScm^{-1}$ for Ch/MMT-GPTMS 10 and Ch/MMT-GPTMS 15, respectively (Table 3). This results established that a better hydrophilicity and high thermal stability are important characteristics to be able to hold water and reduce of hidration phenomenon. The proton will be transported along the water channel created in the membrane composite by hydronium ions. The existence of water has a profound effect on proton transport and dimensional stability of proton conducting membranes.

The methanol permeability of the chitosan and composite membranes at room temperature is shown in Table 3. The role of GPTMS for MMT modification process in composite membranes exhibited low methanol permeability until 3.0 x $10^{-7}cm^2s^{-1}$ for Ch/MMT-GPTMS 5. This results lower than that of pristine chitosan (4.9 x $10^{-7}cm^2s^{-1}$) and Ch/MMT (4.7 x $10^{-7}cm^2s^{-1}$). It is suggested that, existense of GPTMS attributed hydrophobic characterstic in morphology membrane structure, shown incline hydrophobicity with increasing of initial contac angle (Figure 6), and in the other hand the MMT-GPTMS structure that has a quite wide and long ratio which creates longer diffusion path for methanol permeate [47]. The methanol permeability of Ch/MMT-GPTMS is obtained the lowest with the MMT-GPTMS filler loading at 5%, but increased slightly with 10% filler load, then an increase in the permeability of methanol is significant when the filler loading was increased to 15%. This phenomenon can be explained that, the matrix and filler need good collaboration with a specific composition, especially with addition of GPTMS included in the layer structure of the membrane can support the interaction between the inorganic filler and biopolymer matrix. Therefore, the precise composition of composite membrane will have a good structure, more dense and has the ability to reduce of methanol diffusion. The increase of the methanol permeability of Ch/MMT-GPTMS 15 more than a double of Ch/MMT-GPTMS 10 is due to the excess of filler load showing a low interaction distribution in membrane structure, therefore it caused agglomeration. This phenomenon led to the presence of pin hole in the composite membrane, which provide greater opportunities for methanol to diffuse into the membrane structure, thus the methanol permeability is significanly increased. The similar trend also can be found in previous study [31].

The DMFC responses of Ch/MMT-GPTMS composite membrane compared with Ch/MMT at room temperature with 2M methanol consentrations and oxygen flow at the 2 mL/min is represented in Figure 7. The cell performance

based on Ch/MMT composite membrane in terms of power density was 5.01 x $10^{-2}$ mW/cm$^2$, and increase of the cell performance for Ch/MMT-GPTMS until 24.87 x $10^{-2}$ mW/cm$^2$. Clearly, the higher cell performance based on Ch/MMT-GPTMS membrane was attributed to the fact that more hydrogen bonding and water content to achieve proton conductivity comparable to Ch/MMT-GPTMS because the hydrophilic characteristics. In the Ch/MMT-GPTMS composite membrane, the proton transport can occur from $H_3O^+$ as proton donor to $H_2O$ as acceptor on the membrane structure. Uniform distribution and optimum water content within the composite membrane is critical for the continuous proton transfer pathway with minimum resistance.

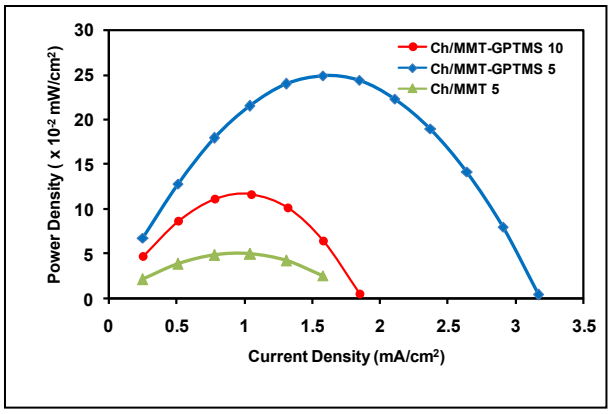

Figure 7. DMFC performance of composite membrane

## Conclusion

A composite membrane was obtained through using solution casting method, and GPTMS was introduced into the system to increase of matrix and filler interaction. The properties of the composite membranes, such as thermal stability, hydrophilicity and proton conductivity were significantly improved. The Ch/MMT-GPTMS showed excellent proton conductivities varying from 4.1 to 4.7 mS cm$^{-1}$ at 25 °C, which are higher compared to pristine chitosan and Ch/MMT. The Ch/MMT-GPTMS composite membrane with 5 wt% filler load exhibited the best proton conductivity are 4.7 mScm$^{-1}$, with water contact angle value of 64.7$^o$ and shown maximum power density of 0.24 mWcm$^{-2}$ was obtained with a 2M methanol feed. In this study it was known that water contact angle, membrane swelling, thermal stability, and proton conductivity show suitable trend, it means that all quality of them are related to the hydrophilicity properties.

**Abstract**

A new method of extraction by using a microwave has been widely used in the extracting of bioactive compound from plants. In this research**,** the pineapple (*Ananas comosus L., Merr*) wastes (namely skin) has been chosen as it contains a very high phenolic compound and provide a good source of antioxidant to human's health. The three parameters varied were the microwave power, the types of solvent extraction and the extraction temperature. Each of the samples was evaluated for the Total Phenolic Compound (TPC) and Antioxidant Activity (AA). The aims of this study are to obtain the optimum operating condition of Microwave-Assisted Extraction (MAE) in the extraction of phenolic compound from pineapple skins and to compare the extraction yield between MAE and Soxhlet Extraction (SE) method. From the results, it was found that the optimum condition was at 750 W microwave power, 60 °C operating temperature and with the solvent ratio of ethanol: water (50-50) by volume**.** At this optimum condition, the TPC observed was 207.72 mg GAE/g dw, whereas for the $EC_{50}$, DPPH value obtained was the lowest, 13.2 mg/mL. MAE has proven that this method is comparable to SE, with the TPC obtained was 28.78 mg GAE/g dw and $EC_{50}$ of 2.78 mg/L, respectively.

**Keywords**: pineapple skin, microwave-assisted extraction, microwave power, total phenolic compound, antioxidant activity

**Abstrak**

Satu kaedah baru pengekstrakan dengan menggunakan gelombang mikro telah digunakan secara meluas di dalam pengekstrakan sebatian bioaktif daripada tumbuhan. Di dalam kajian ini, sisa (kulit) nenas (*Ananas comosus L., Merr*) telah dipilih kerana ia mengandungi sebatian fenolik yang tinggi dan menyediakan sumber antioksidan yang baik kepada kesihatan manusia. Tiga parameter boleh ubah iaitu kuasa gelombang mikro, jenis pelarut pengekstrakan dan suhu pengekstrakan. Setiap sampel telah dinilai untuk jumlah sebatian fenolik (TPC) dan aktiviti antioksidan (AA). Tujuan kajian ini adalah untuk mendapatkan keadaan pengendalian optimum oleh bantuan gelombang mikro (MAE) di dalam pengekstrakan sebatian fenolik daripada sisa nenas dan membandingkan hasil pengekstrakan di antara MAE dan pengekstrakan Soxhlet (SE). Daripada keputusan, telah didapati bahawa keadaan optimum adalah pada kuasa gelombang mikro 750 W, pengendalian suhu 60 °C dan nisbah pelarut etanol: air (50-50) mengikut isipadu. Pada keadaan optimum ini, TPC yang dicerap adalah 207.72 mg GAE/g dw, manakala untuk $EC_{50}$, DPPH telah didapati pada nilai yang paling rendah, iaitu 13.2 mg/mL. MAE telah membuktikan bahawa kaedah ini setanding dengan SE, dengan TPC diperoleh adalah masing – masing 28.78 mg GAE/g dw dengan $EC_{50}$ 2.78 mg/L.

**Kata kunci:** kulit nenas, gelombang mikro terbantu, kuasa gelombang mikro, jumlah sebatian berfenol, aktiviti antioksidan

## Introduction

Phytochemicals are the major bioactive compounds which usually available in fruits and vegetables. Usually, the plants phenolics are found in both edible and non-edible parts of the plants and was reported to have multiple biological effects, including antioxidant activity [1]. In the recent years, the phenolics compound, or known as polyphenolics have become one of the interest due to their ability to act as a powerful antioxidant [2]. An antioxidant is a group of compounds which are able to delay or inhibit the oxidation lipids or other biomolecules and hence could prevent or repair the damaged body cells that is oxidized by the oxygen [3,4] and it has beneficial effects on metabolism.

The source of antioxidants can be synthetic or natural based. Due to the adverse effect of the synthetic antioxidant, there is an increasing attention to develop a new approach by using natural antioxidant, which is mostly, comes from fruits and vegetables [5,6]. Studies have revealed that daily intake of natural antioxidant will help to reduce the risk of those common diseases such as cancer, cardio and cerebro-vascular diseases [7].

In industry, normally the processing fruits will leave behind a large amount of fruits residue, such as peels, seeds, pulp, bean, rind and skin. The disposal of these fruit wastes can create the pollution problem to the environment [8]. In order to overcome this problem, the recovery of the fruit residues is one of the best alternatives. This is because the output from this recovery could be used in pharmaceutical industry, food and cosmetic [9]. In the past few years, the research on the phenolic compounds and antioxidant activity in fruits residues has been conducted on guava leaves [4], mango seed kernel [10], cantaloupe residue (leaf, stem, skin, seed and flesh) [11], bean [12], peanut skins [13], peels of mangosteen, rambutan and pomegranate [14] and citrus mandarin peels [15] and the residue of Kinnow (seed and peel), Litchi (seed and pericarp), grape seed and banana peel [8].

The pineapple, also known as *Ananas comosus L., Merr*, by-products is not exempted because it consists of peels, stem, pulp and leaves as it's residual. As one of the most important fruits in the world, the pineapple is the leading edible member of the *Bromeliacea*'s family [16]. It contains a good nutrient which gives benefit to human's health. This is because the pineapple contains a very high amount of phenolics compound [6, 16 – 20]. Several studies have been conducted in the extracting of phenolic compound from pineapple with different methods such as by using Soxhlet extraction unit [8, 21], magnetic stirrer [6, 19, 22] and orbital shaker (incubator shaker) [20].

In the recent technology of extraction, the microwave-assisted extraction (MAE) has been introduced. As compared to the conventional method, namely Soxhlet extraction unit, the MAE has a lot of advantages in the extraction process such as higher extraction rate, less extraction time, less solvent needed and can produce better product with lower cost [23]. This extraction method has been done on *Berberis asiatica* leaves [24], chokeberries (*Aronia melanocarpa*) [25], bark extracts [26], asparagus, cauliflower, celery, and chicory wastes [27], longan peel [28], bean [29], citrus mandarin peel [30], peanut skin [31] and many more.

This research is the extension research which has been done before where the pineapple wastes (namely skin) has been extracted for the analysis of phenolic compounds and antioxidant activity [17]. In this preliminary research, the parameters varied were only the temperature of extraction and the type of solvent used in the extraction, whereas the microwave power has been fixed at 250 W. From this research, it was found that the optimum condition at 250 W of microwave power was at 30 °C by using the deionized water as the extraction solvent, with the optimum value of phenolic compound and antioxidant activity ($EC_{50}$) were 206.46 mg GAE/g dw and 13.65 mg/mL, respectively. It indicated that the higher the phenolic value, the lower the $EC_{50}$, the better the antioxidant property. Thus, it was proven that the pineapple could serve as the potential candidate in becoming one of the best natural antioxidant [17]. However, based on the previous study the microwave power was just fixed at one value only, which was at 250 W. Thus, the effect of the variation in the usage microwave power has not been studied. Therefore, in this research, the microwave power will be varied, as well as the extraction temperature and the types of solvent used. The outcome of this result should reveal the optimum condition of MAE in the extracting of pineapple wastes and the results will be compared with the Soxhlet Extraction Method.

## Materials and Methods

### Material

The skin of the pineapple (waste) was peeled for the sample preparation [17].

### Sample preparation

The samples (skin) obtained were washed, frozen, dried and grounded. Each sample was weight at 5 g each before the extraction process [17].

### Microwave-assisted extraction

The extraction process was conducted at three different parameters, namely, the microwave power (500 W, 750 W and 1000 W), temperature (30 °C, 60 °C and 90 °C) and the type of solvent used (100% ethanol, 50% ethanol in deionized water and 100% deionized water). About 1 mL of sample was mixed with 50 mL of solvent. The extraction time was 20 minutes. The extract obtained was then analyzed for total phenolic compound and antioxidant activity [17].

### Total phenolic compound

The total phenolic compound was measured using the Folin-Ciocalteu method [32]. The results were expressed in milligram of Gallic Acid Equivalent (GAE)/gram of dry weight sample of pineapple (mg GAE/g dw). All samples were analyzed in duplicates [17].

### Scavenging activity on DPPH radical

The scavenging activity or antioxidant activity of the extract was analyzed by 2,2'-diphenyl-1-picrylhydrazyl radical (DPPH) [33,34,35]. All tests were performed in duplicates [17].

### Sample statistical analysis

All the experiments were conducted in duplicates and the mean was calculated using MS Excel [17].

### Soxhlet extraction

A total volume of solvent 250 mL (50 mL of ethanol in 200 mL of deionized water) was used in the Soxhlet experiment. The solvent was mixed with 5 g of sample and refluxed for 5 hours at 78 °C. After the extraction process, the supernatant was separated from the solvent by using the rotary evaporator for 15 minutes. The supernatant was then tested for total phenolic content and scavenging activity on DPPH radical analysis.

## Results and Discussion

### Effect of microwave power

The MAE is the process whereby the polar solvent which in contact with the solid samples is heated by using microwave energy [36], thus reducing the extraction time and amount of solvent consumed. The mechanism of MAE in the extracting of phenolic compound can be explained by a phenomenon. In the extraction process, the dried plant used normally will contain small traces of moisture. When the microwave energy is absorbed, this energy will be change to heat and thus the moisture starting to evaporate. This evaporated water will cause the pressure to increase inside the cell wall and lead to the rupture of the cell in the sample. Eventually, the active compound will be released from the rupture cell into the surrounding solvent and increasing the extraction yield [37].

In this research, there were three effects that have been studied. The first effect or parameter was the microwave power used in the extraction. The values were ranged from 250 W to 1000 W. For each of the microwave power value, the total phenolic compound and antioxidant activity of the pineapple waste were evaluated. Based on the previous research, a standard calibration curve was prepared to get the value of phenolic compound. The graph showed a linear relationship, whereby the gallic acid were ranged from 50 – 500 mg/L, with a correlation coefficient ($R^2$) of 0.97 [17].

From the preliminary study, the optimum condition at 250 W microwave power had been obtained at 30 °C operating temperature by using deionized water as solvent. The study has proven that at 120 °C operating

temperature, both phenolic compound and $EC_{50}$ (defined as the concentration of antioxidant required for 50% scavenging of DPPH radicals, is a parameter widely used to measure antioxidant activity value from antioxidant activity) marked a deteriorated value [17]. Therefore, in this study the temperatures were varied from 30 °C to 90 °C only.

Table 1 showed the extraction condition at 500 W microwave power. At 30 °C operating temperature by using ethanol as the solvent, the phenolic compound was 165 mg GAE/g dw, whereas the antioxidant value, which reported as $EC_{50}$, the value was 21.68 mg/mL. Meanwhile, by using the deionized water at 30 °C operating temperature, the phenolic compound increased to 177.24 mg GAE/g dw. The $EC_{50}$ value at this condition was 15.07 mg/mL. As the temperature increased to 60 °C, there was a remarkable increase for the phenolic compound, 200.63 mg GAE/g dw and a sharply decrease for $EC_{50}$ value, 14.59 mg/mL. The solvent used was ethanol in deionized water (50-50). At the highest operating temperature, which was at 90 °C the phenolic compound and $EC_{50}$ recorded were 184.56 mg GAE/g dw and 14.84 mg/mL, respectively. The trends showed that as the temperature increase, the phenolic compound increased until 60 °C but then decrease at 90 °C. This was contradicting with the trends in $EC_{50}$, whereby as the temperature increase, the $EC_{50}$ dropped at 60 °C but then inclined to 90 °C. From 500 W microwave power, the optimum value was obtained at 60 °C by using ethanol in deionized water (50-50). The phenolic compound and $EC_{50}$ value recorded at this condition were 200.63 mg GAE/g dw and 14.59 mg/mL, respectively. $EC_{50}$ value is a parameter to measure the antioxidant activity. It is also known as the concentration of antioxidant required for 50% scavenging of DPPH radicals. The smaller value of $EC_{50}$, the higher antioxidant activity of the plant extracts [38]. Therefore, the higher the phenolic compound, the lower the $EC_{50}$ value, the better the antioxidant property of the pineapple skins.

Table 1. Total phenolic compound and DPPH radical scavenging of the extract at the microwave power of 500 W with different temperatures and solvents

| **Temperature (°C)** | **Types of Solvent** | **Phenolic compound (mg GAE/g dw)** | **$EC_{50}$ (mg/mL)** |
|---|---|---|---|
| 30 | Ethanol | 165.23 | 21.68 |
| 30 | Water | 177.24 | 15.07 |
| 60 | Ethanol-Water (50-50) | 200.63 | 14.59 |
| 90 | Ethanol-Water (50-50) | 184.56 | 14.84 |

The extraction at 750 W microwave power was shown in Table 2. As compared to the operating microwave power at 500 W, generally the readings of phenolic compound at 750 W were much higher. The phenolic compound recorded at 30 °C using ethanol as solvent was 186.25 mg GAE/g dw and the $EC_{50}$ value obtained was 16.51 mg/mL. Similar trends go to the operating temperature of 30 °C using deionized water, the phenolic compound was higher compared to the solvent with pure ethanol. In general, the phenolic compound at 30 °C operating temperature using deionized water was higher both in 250 W and 500 W microwave power. Meanwhile, by using the ethanol in deionized water as a solvent, the phenolic compound at 60 °C and 90 °C were 207.72 mg GAE/g dw and 182.34 mg GAE/g dw, respectively. The value of $EC_{50}$ was recorded at 13.2 mg/mL for 60 °C operating temperature. At 90 °C, the $EC_{50}$ was a slightly higher at 14.38 mg/mL. Thus, the optimum condition at 750 W was at 60 °C by using ethanol in deionized water.

On the other hand, Table 3 showed the total phenolic compound and $EC_{50}$ value at 1000 W microwave power of extraction. Overall, the readings of phenolic compound at 1000 W microwave power were slightly decreased as compared to 750 W. At 30 °C operating temperature, the phenolic compound and $EC_{50}$ value were recorded at 165.54 mg GAE/g dw and 84.03 mg/mL, respectively. Those values were analysed by using ethanol as the solvent. Meanwhile, at 60 °C operating temperature by using deionized water as the solvent, there was a small inclined in the phenolic compound reading, 187.74 mg GAE/g dw. The $EC_{50}$ value for the antioxidant activity was recorded at 16.41 mg/mL. There were a tremendous decreased in the phenolic compound value for both at 60 °C and 90 °C

operating temperature, which recorded at 163.32 mg GAE/g dw and 79.8 mg GAE/g dw, respectively. The same pattern of depreciation could be observed in the $EC_{50}$ value which depicted at 22.15 mg/mL and 65.96 mg/mL for 60 °C and 90 °C operating temperature, respectively. The optimum value at 1000 W microwave power was obtained at 30 °C operating temperature by using deionized water as solvent.

Table 2. Total phenolic compound and DPPH radical scavenging of the extract at the microwave power of 750 W with different temperatures and solvents

| Temperature (°C) | Types of Solvent | Phenolic compound (mg GAE/g dw) | $EC_{50}$ (mg/mL) |
|---|---|---|---|
| 30 | Ethanol | 186.25 | 16.51 |
| 30 | Water | 195.68 | 15.02 |
| 60 | Ethanol-Water (50-50) | 207.72 | 13.20 |
| 90 | Ethanol-Water (50-50) | 182.34 | 14.38 |

Table 3. Total phenolic compound and DPPH radical scavenging of the extract at the microwave power of 1000 W with different temperatures and solvents

| Temperature (°C) | Types of Solvent | Phenolic Compound (mg GAE/g dw) | $EC_{50}$ (mg/mL) |
|---|---|---|---|
| 30 | Ethanol | 165.54 | 84.03 |
| 30 | Water | 187.74 | 16.41 |
| 60 | Ethanol-Water (50-50) | 163.32 | 22.15 |
| 90 | Ethanol-Water (50-50) | 79.80 | 65.96 |

In any plant extraction, the extraction yield might be reduced if the high microwave power is applied. This is due to the degradation or decomposes of thermal sensible compound. Generally, as the microwave power increase, the extraction yield will be increase linearly, up to a certain limit, before it starts to decrease or become insignificant [39 – 42]. Microwave power supplies the heating directly to the sample and will assist the MAE to break down the plant cell so that the active compound (analyte) could diffuse from the plant and dissolve in the solvent [43].

From the four-optimized microwave power that have been discussed above based on the reading of phenolic compound and $EC_{50}$ value, the most optimum microwave power was determined at 750 W. The operating temperature was at 60 °C and ethanol in deionized water was used as the solvent. At this optimum condition, the highest value of phenolic compound was recorded at 207.72 mg GAE/g dw, wheareas the antioxidant activity, $EC_{50}$ value was obtained at the lowest value of 13.20 mg/mL.

**Effect of operating temperature**

The second effect observed in this study was the effect of the extraction temperature. The value of temperature was ranged from 30 °C up to 90 °C for all the samples. The temperature and microwave power are interconnected. This is because as the temperature increases, the solvent power will be increases as well due to the decreasing in viscosity and surface tension [37]. However, there will be always a limit of the operating temperature for all the plants and fruits tested before the phenolic compound starts to degrade. A report has claimed that at a very high microwave power such as 1000 W, the extraction yield of the flavonoids from Radix astragali roots has been decreased if the extraction temperature was higher than 110 °C [40]. Another investigation found that the phenolic compound extracted from Oolong tea has been increased with the increasing extraction temperature and the optimum temperature was obtained at 170 °C [44].

According to our preliminary research, the reading of the phenolic compound was increased with the increasing temperature, but slightly decreased at 90 °C and declined sharply at 120 °C due to the thermal degradation [17, 43]. Since the extraction at 120 °C has proven to be the worst among all the temperatures tested, therefore in this research the focus of temperatures was between 30 °C to 90 °C. In general, the trends in operating temperature were the same for all the microwave power tested. This is proved by the result from Table 1, 2 and 3. Nevertheless, out of all the operating temperature, the value of the antioxidant activity, $EC_{50}$ showed the highest value at 30 °C by using ethanol as the extraction solvent for all microwave power. This showed that the condition was not suitable to extract the phenolic compound from the pineapple skins. Therefore, the most suitable temperature to extract the phenolic compounds from the pineapple wastes was at 60 °C at 750 W microwave power.

**Effect of solvent extraction**

Among the most commonly used solvent for the extraction of phenolics compound from fresh fruits or plants at different concentration in water are such as ethanol, methanol, ethyl acetate, propanol, acetone and dimethylformamide [45,46]. The percentage of polyphenolic yield produced from plant materials is depending on the solubility of the phenolic compounds in the solvent used for the extraction. In other words, the solvent types used in the extraction process is very important as well as its polarity [22]. For example, in the extraction of phenolic compounds from grape skin and seed, methanol has been used as the solvent and it has been proven that the yield of polyphenolic was higher as compared to ethanol, but the latter extract had stronger antioxidant properties [47]. Generally, ethanol is the most common solvent used and acts as a good microwave absorber to extract the bioactive compounds from plants [48]. Based on the result, by referring to the all powers and temperatures shown in Table 1, 2 and 3, the highest yield of phenolic compounds was obtained by using ethanol in deionized water as the solvent, at 750W microwave power and 60 °C of operating temperature. The $EC_{50}$ value recorded was also the lowest at this condition. A study has been reported that by addition of water to the solvent has increased the yield [49]. Several organic solvents should be prepared in the aqueous solution form before it is used as a solvent extraction. This is because with the presence of water in the organic solvent, it can improve the penetration of the solvent into the plant cell and hence, could increase the heating efficiency [50].

**Comparison between microwave-assisted extraction method and the soxhlet extraction method**

From the study of the three effects that have been discussed, the optimum condition for microwave power, operating temperature and solvent extraction were 750 W, 60 °C and ethanol in deionized water, respectively. This condition was then compared with the conventional method, namely Soxhlet extraction, by using the ethanol in deionized water as a solvent. The time taken for the Soxhlet extraction was 2 hours [51], whereas for the MAE needed only 20 minutes of extraction time.

Based on Figure 1, there was a significant different in phenolic compound value by using Soxhlet extraction, which was recorded at 28.78 mg GAE/g dw as compared to the MAE [51]. The results of phenolic compound are comparable since the value obtained by using the MAE was much higher at 207.72 mg GAE/g dw. On the other hand, Figure 2 shows that the value for $EC_{50}$ for Soxhlet extraction was lower, 2.78 mg/mL compared to 13.20 mg/mL by using MAE. As discussed in the previous section, the lower the $EC_{50}$, the greater the antioxidant activity. Even though the $EC_{50}$ value of Soxhlet extraction is lower compared to MAE, but based on the value of phenolic compound obtained, it has proven that MAE is an effective method compared to Soxhlet extraction. This is in line with the advantages of MAE which only consumed less solvent and has shorter extraction time [52]. Higher extraction rate in fruits, vegetables, foods and beans have been reported in several studies by using MAE compared to the Soxhlet extraction [53,54,55]. Lower yield, high amount of solvent used and continuous operation time of 6 or 12 hours make the Soxhlet is not the best extraction method. The long operating hours will lead to the increasing of the operational cost [56].

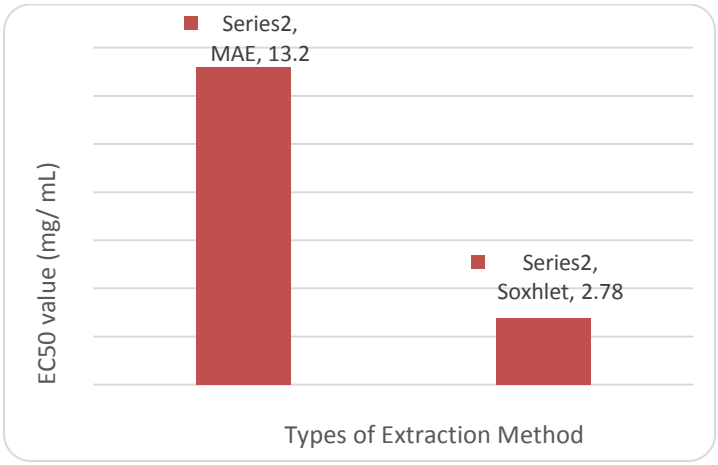

Figure 2. Comparison of DPPH radical scavenging value using microwave-assisted extraction and soxhlet method

## Conclusion

Microwave-assisted extraction (MAE) is an alternative technique of extraction which provides higher yield, shorter time and less solvent used. In this research, three parameters were varied, namely, the microwave power, extraction temperature and solvent type. Based on the results, the optimum condition has been achieved at 750 W of microwave power, 60 °C of operating temperature and ethanol in deionized water was used as the solvent. At this optimum condition, the phenolic compound was obtained at the highest yield, which was 207.72 mg GAE/g dw, whereas the antioxidant activity or $EC_{50}$ value was at the lowest, 13.2 mg/mL. The higher the phenolic compound, the lower the $EC_{50}$ value, the better the antioxidant properties of the fruits or plants. Thus, the pineapple skins could become one of the good sources of antioxidant, which are renewable and environmental friendly compared to the commercial antioxidant. As compared to the Soxhlet extraction method, MAE exhibits more efficient method with a higher extraction of phenolic compound value.

**Abstract**

In this study, Aurum (Au) was used as the second metal in palladium catalyst (Pd) and carbon nanofiber (CNF) as catalyst support for glycerol oxidation. Second metal and catalyst support will help to improve catalytic activity and decrease adsorbed oxidation intermediates species. Carbon nanofiber supported PdAu nanoparticles was synthesized by using trisodium citrate as stabilizing agent and sodium borohydride as reducing agent. Physicochemical characterizations of the catalyst were performed by X-ray Diffraction (XRD), Transmission Electron Microscope (TEM), Field Emission Scanning Electron Microscope (FESEM) and Brunauer-Emmett-Teller (BET) to study the nature of the catalysts. The electrochemical activity for oxidation of glycerol on PdAu/CNF was evaluated in half cell under alkaline media by cyclic voltammetry potentiostat. The densities and mass activity obtained from half-cell analysis were 73.81 mA $cm^{-2}$ @ 492.04 mA $mg^{-1}$, 63.82 mA $cm^{-2}$ @ 425.44 mA $mg^{-1}$ and 55.73 mA $cm^{-2}$ @ 371.54 mA $mg^{-1}$ for PdAu/CNF, Pd/CNF and Au/CNF, respectively in 1 M KOH + 0.5 M glycerol electrolyte. The electrochemical study, exhibited the superior performance of bimetallic PdAu/CNF catalyst as compared to monometallic Pd/CNF. This indicate that the electronic coupling between Pd and Au can promote the electrocatalytic activity for glycerol oxidation.

**Keywords:** PdAu, carbon nanofiber, glycerol oxidation, alkaline media

**Abstrak**

Dalam kajian ini, Au telah digunakan sebagai logam kedua dalam pemangkin paladium dan gentian nano karbon sebagai sokongan pemangkin kepada pengoksidaan gliserol. Logam kedua dan sokongan pemangkin akan membantu meningkatkan aktiviti pemangkin dan mengurangkan perjerapan spesis pertengahan pengoksidaan. PdAu dengan disokong oleh gentian nano karbon telah disintesis dengan menggunakan trisodium sitrat sebagai ejen penstabil dan natrium borohidrat sebagai agen penurunan. Pencirian fizikal-kimia pemangkin telah dijalankan oleh pembelauan sinar-X (XRD), Mikroskop Elektron Penghantaran (TEM), Mikroskop Imbasan Elektron (FESEM) dan Brunauer-Emmett-Teller (BET) untuk mengkaji sifat pemangkin. Aktiviti elektrokimia untuk pengoksidaan gliserol pada PdAu/CNF dinilai dalam sel separuh di bawah media beralkali dengan menggunakan kitaran voltammetri potentionstat. Ketumpatan arus dan berat aktiviti yang diperolehi daripada analisis sel separuh adalah 73.81 mA $cm^{-2}$ @ 492.04 mA $mg^{-1}$, 63.82 mA $cm^{-2}$ @ 425.44 mA $mg^{-1}$ dan 55.73 mA $cm^{-2}$ @ 371.54 mA $mg^{-1}$ masing-masing untuk PdAu/CNF, Pd/CNF dan Au/CNF, dalam 1 M KOH + 0.5 m gliserol elektrolit. Kajian elektrokimia, mempamerkan

prestasi unggul pemangkin PdAu/CNF berbanding dengan Pd/CNF and Au/CNF. Ini menunjukkan bahawa gandingan elektronik antara Pd dan Au boleh menggalakkan aktiviti elektrokatalitik untuk pengoksidaan gliserol.

**Kata kunci:** PdAu, gentian nano karbon, oksidasi gliserol, media beralkali

## Introduction

Fuel Cell is one of the alternative energy use to generate electricity without any combustion. Direct Alcohol Fuel Cell in which use methanol and ethanol can be applied in small electronic appliances like hand phone, laptop, camera and lamp. The use of methanol in the fuel cell can be absolutely no doubt, while the use of ethanol has increasing attention among researchers. However, properties of methanol that has high toxicity[1-2] and high volatility of ethanol [3] make both fuels unsuitable as a fuel for the commercialization of fuel cell [4]. One alternative proposed currently is glycerol, to replace methanol in fuel cell application. The growing biodiesel market in Malaysia as Malaysia is the world's largest producer of palm oil will lead to surpass the capacities of glycerol as a by-product. Fuels such as glycerol have drawn an attention because they are renewable from biomass production, less harmful, have high energy density, low vapor pressure, low cost, and easy storage and transportation needs [5-6].

Glycerol is feed at the anode side of fuel cell where the oxidation reaction of glycerol occurs to produce carbon dioxide, electrons and protons. To complete the full reaction in fuel cell, the electrons are pass through the electronic circuit while the proton are permeated through membrane both to cathode side. At the cathode is where the oxygen reduction reaction occurs to complete the cell and produce electricity. However, the oxidation of glycerol quite complicated in which the partial oxidation will produce unwanted products such as glyceraldehyde, 1,3-dihydroxyacetone, glyceric acid, hydroxypyruvic acid, tartronic acid, mesoxalic acid, formic acid, ocilic acid and glycolic acid [7, 9 -11]. All these partial oxidation products are not desirable as these products will reduce the performance single fuel cell. Thus, the catalyst selection for the glycerol oxidation is important to increase overall performance fuel cell. The main problem with glycerol oxidation is the potential of generation intermediates species during anodic oxidation of glycerol which might be poison the catalyst surface [12]. Due to this, selection of catalyst is the critical issue in order to increase the activity of glycerol oxidation in anode side and at the same time minimize the cost of the fuel cell itself. Up until now, there are several catalysts use to study the oxidation of glycerol such as platinum. The use of platinum has brought stability issue as another intermediate product of carbon monoxide poisoning the platinum surface by adsorbing too strong on the platinum surface.

Bimetallic electrocatalysts have been used as catalysts in this study, which the purpose is related to the decreased load of the noble metal and combine with secondary metals (normally transition metal). This combination will enhance the electrocatalytic activity of bimetallic mixtures in terms of electrocatalytic activity of bimetallic mixtures in terms of current density and tolerance to the carbon monoxide poisoning effect [13,14]. Several previous literatures, reported the effectiveness PdAu bimetallic as the electrocatalyst. Bimetallic containing gold show higher activity and selectivity in helping to oxidize CO resulting from the reaction intermediate with more efficient even below room temperature in oxidation of ethanol [15,16,17]. Therefore, bimetallic palladium-Aurum (PdAu) is used to study the activity of oxidation reaction of glycerol. The Pd-Au is supported to the carbon nanofiber (CNF) so that the catalyst can evenly distributed and to reduce the usage of metal for glycerol oxidation reaction but at the same time have higher catalyst activity. This study will focus on PdAu supported with carbon nanofiber, which believed can give high durability and stability to the catalyst as this bimetallic catalyst has high a tendency to agglomerate. This paper reports the synthesis, physicochemical and electrochemical characterization analysis of Pd/CNF, Au/CNF and PdAu/CNF for glycerol oxidation in half cell.

## Materials and Methods

### Materials

To carry out this research all precursor metal salts and chemicals such as tetrachloroauric acid ($HAuCl_4 \cdot 4H_2O$), palladium chloride ($PdCl_2$), trisodium citrate ($Na_3Ct$), sodium borohydride ($NaBH_4$), carbon nanofiber, sodium hydroxide and glycerine has been purchased from Sigma-Aldrich (USA).

**Preparation of catalysts using reduction method**

In brief, the synthesized catalyst was modified from the previous study [17], where 0.05 M $PdCl_2$ (Sigma-Aldrich) (in 0.1 M HCl) was mixed together with 0.05 M of $AuCl_3 \cdot HCl \cdot 4H_2O$ (Sigma- Aldrich) bring a total solution of 15 mL. The mixed solution was added to some amount of trisodium citrate in drop wise manner. Subsequently, the above solution was added drop-wise to a stirred CNF slurry (isopropanol and deionized water) and stirred for 2 hours. Next, the reduction of the metal precursors is carried out using an appropriate amount of freshly prepared ice-cold sodium borohydride ($NaBH_4$) and the solution was stirred overnight at 10 ºC. Longer reaction time is needed to allow the sodium borohydride as it has strong reducing abilities to react with metal precursors to form product. The molar ratio of $NaBH_4$ to metal ions was taken as 5:1. The solid was filtered and washed with deionized water several times and dried at 80 ºC overnight.

**X-ray diffraction analysis**

XRD is a powerful method used to give the crystallinity of the metal synthesis. The samples data were collected at 2θ from 20° to 90°. While FESEM and TEM provide the information about size, size distribution, dispersion and the morphology of various shapes of particles. The morphology of the synthesized catalysts was observed by using FESEM model Zeiss/SUPRA 55VP. The electron microscope specimens have been prepared by dispersing the small amount of catalyst in ethanol and casting it by dropping the solution onto the copper-grids. BET analysis provides on determination the precise specific area evaluation of materials by nitrogen multilayer adsorption measured as a function of relative pressure using a fully automated analyzer. The technique encompasses external area and pore area evaluation to determine the total specific area evaluation to determine the total specific area in $m^2/g$ yielding important information in studying the effects of surface porosity and particle size in many applications.

**Cyclic voltammetry analysis**

Cyclic voltammetry is a type of potential dynamic electrochemical measurement. All apparatus for cyclic voltammetry measurement was performed by using Autolab (PGSTAT101) electrochemical workstation under room temperature. The catalyst ink solution was carefully transferred onto the glassy carbon electrode by using micropipette and then leave dried under room temperature. The electrochemical characterization of three types of catalysts was studied by a cyclic voltammetry (CV) test in the potential range -0.7 to 0.4 V in 50 $mVs^{-1}$ in 1 M KOH and at scan rate 50 $mVs^{-1}$ in 0.5 M glycerol/1 M KOH solution. Both solution was de-oxygenated by bubbling with $N_2$ at 200 mL $min^{-1}$ for 30 minutes before taking any measurement of glycerol oxidation reaction.

## Results and Discussion

Phase analysis by X-ray diffraction (XRD) goes beyond elemental composition to characterize the crystalline forms present and understand the alloy structure of bimetallic nanoparticles. Figure 1 showed the XRD patterns of the catalyst samples. The XRD patterns confirmed the presence of target metal in catalyst samples of Pd/CNF, Au/CNF and PdAu/CNF and fit well their characteristic of face centered cubic (fcc) patterns. The $2\theta$ angle of the diffraction meter was stepped from 20° to 90° [18]. The first strong peak for all catalyst samples with value 25.83° referred to the carbon (002) facet of the carbon nanofiber support. The diffraction peaks in catalyst sample Pd/CNF exhibited the characteristic face-centred cubic crystalline structure of Pd-based material with $2\theta$ values of 39.84°, 46.53°, 67.53°, and 81.61°correspond to the (111), (200), (220) and (311) of the metallic palladium face respectively. The diffraction peaks of Au/CNF are 38.08°, 44.21°, 77.80°, 65.01° correspond to the (111), (200), (220) and (311) facets of Au crystals respectively. Meanwhile, for catalyst sample of PdAu/CNF shows that the both metal has form metal alloyed particles since there is only a single peak. The diffraction peak positions for PdAu/CNF, move which located between two wavelengths at each monometallic nanoparticle for Pd and Au. This indicates that, Au has entered Pd lattice and form a homogeneous substitution alloy [19].

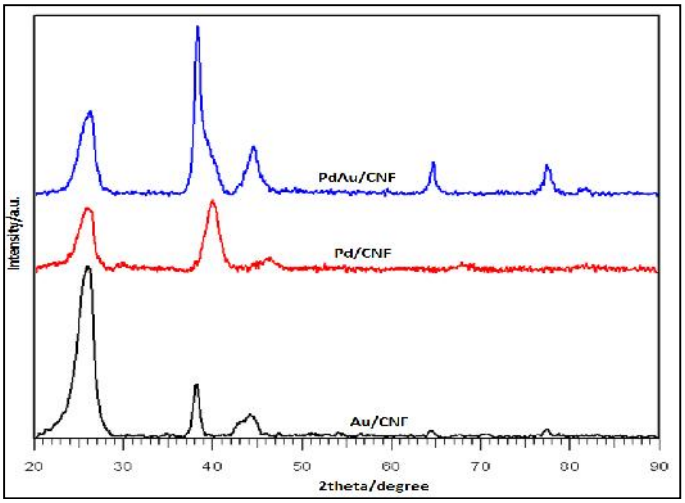

Figure 1. XRD patterns of PdAu/CNF, Au/CNF and Pd/CNF catalysts

BET analysis has been conducted to evaluate the specific area of the catalyst support to ensure the pore of the support has been filled in the catalyst. Specific surface area for CNF before catalyst deposition is 370$m^2$/g. Table 1 shows the BET analysis of surface areas for all catalyst samples. From the Table 1 shown that the value of BET has decrease after deposition of catalysts on CNF surface. The metal catalyst has been successfully deposited onto the surface of CNF support. This is due to metal catalyst reduced onto the support and blocks some microspores which leads to a decreased BET surface area.

Table 1. Crystal size, particles size and surface area of the Pd/C, Au/C and PdAu/CNF based on XRD, TEM and BET analysis

| **Catalyst** | **XRD** | **TEM** | **BET Surface Area ($m^2$/g)** |
|---|---|---|---|
| | **Crystallite Size (nm)** | **Particle Size (nm)** | |
| Pd/CNF | 6.0 | 5.7 | 24 |
| Au/CNF | 8.7 | 7.5 | 20 |
| PdAu/CNF | 4.4 | 4.8 | 26 |

Figure 2a-c shows the FESEM image of porous structure of the prepared Pd, Au and PdAu supported with carbon nanofiber. The images reveal a three-dimensional image of the catalysts surface and shows the equilibrium forms of small metal crystallites on the dispersed on the support. Meanwhile Figure 3d-f shows the TEM images of Pd/CNF, Au/CNF and PdAu/CNF catalyst samples. From TEM images clearly shown that there is no large agglomeration of metal catalysts and supported in CNF. The shape catalysts shown here have ununiformed particle size but still in dimension of nanometre. The determination of activity catalyst not only size dependence as the catalyst size become small so as the surface area for active site become large but the distribution of catalyst on CNF also important. The CNF as catalyst support help increase in catalyst distribution so that the active site for reaction happen also increase.

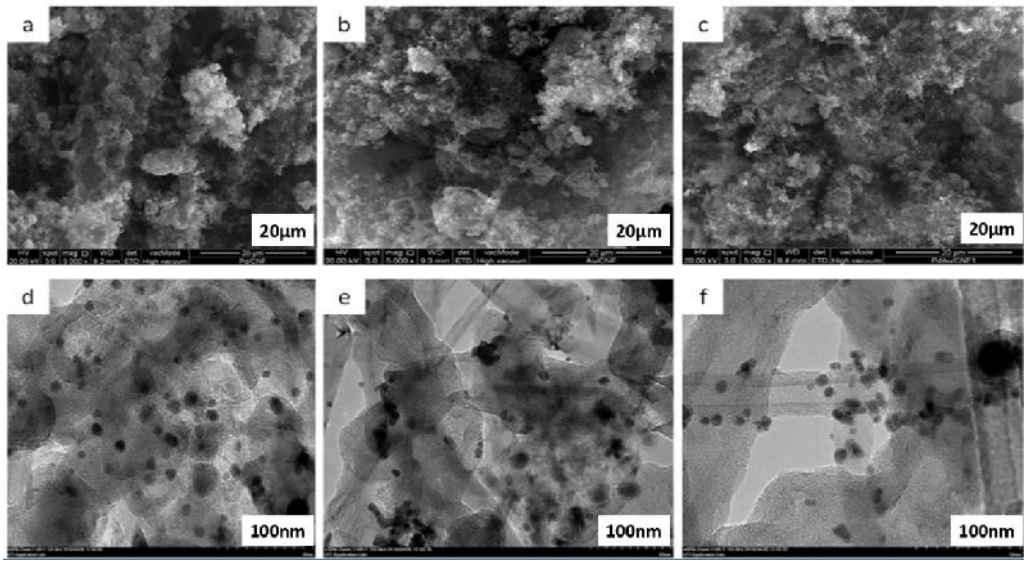

Figure 2. FESEM images of catalysts a) Pd/CNF b) Au/CNF and c) PdAu/CNF. TEM images of d) Pd/CNF, e) Au/CNF and f) PdAu/CNF catalyst

**Electrochemical analysis of cyclic voltammetry**

The performance of catalysts in glycerol oxidation reaction (GOR) was evaluated in terms of two aspects: (1) onset potential ($E_{on}$); indicative of the catalytic activity over glycerol oxidation reactions, (2) forward anodic specific peak current density ($I_f$); showing the catalyst maximum performance. To get acquiring qualitative information for catalysts activity in alkaline media, CV experiment is carried out in 1.0 M NaOH. The CV behaviour of Pd-based catalyst was preliminarily investigated in 1.0 M KOH without the presence of glycerol as shown in Figure 3. As this analysis is conducted under alkaline environment it can be found that the onset of the oxide formation and the peak potential of the oxide reduction for PdAu/CNF shifted to more negative potentials which exhibit the chemisorption of OH on the Pd at a negative potential. Glycerol is a complex molecule, due to this the oxidation of glycerol in alkaline medium can form numbers of possible oxide/hydrous or oxide/hydroxyl surface molecules. This is having been described in reduction wave [20]. Based on the previous study the major electrooxidation of glycerol by using Pd catalyst in alkaline media can be described as equation 1 – 3 follow [3];

$$Pd + OH^- \leftrightarrow Pd - (OH)_{ads} + e^- \quad (1)$$

$$Pd + C_2H_3\ OH\ _2 - CH_2\ OH\ + 3OH^- \leftrightarrow Pd - (C_2H_3(OH)_2 - CO)_{ads} + 3H_2O + 3e^- \quad (2)$$

$$Pd{-}(OH)_{ads} + Pd - (C_2H_3(OH)_2 - CO)_{ads} \rightarrow C_2H_3(OH)_2 - COOH + 2Pd \quad (3)$$

$$C_2H_3(OH)_2 - COOH + OH^- \rightarrow C_2H_3(OH)_2 - COO^- + H_2O \quad (4)$$

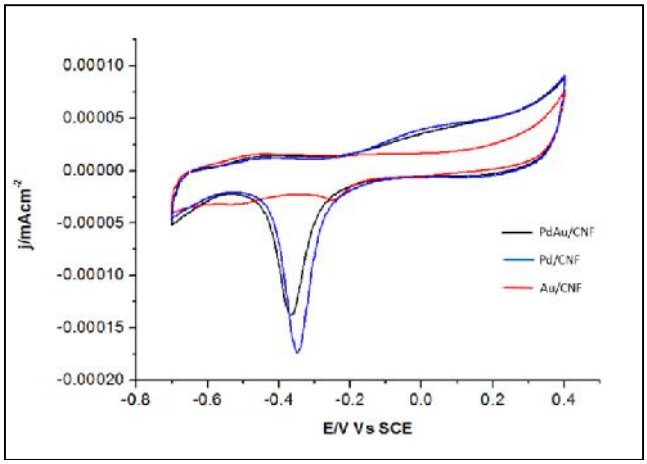

Figure 3. Cyclic voltammogram of PdAu/CNF in 1 M KOH solution at room temperature with the scan rate of 50 mV/s

Figures 4 shows the CV scans for Pd/CNF, Au/CNF and PdAu/CNF catalyst for glycerol oxidation in 1.0 M KOH solution containing 0.5 M glycerol in the potential range -0.7V to 0.4V. In these CV scans, a peak is an indication of surface interaction or reaction between some species and catalyst. In the positive-going (forward scan), is attributed to the electrooxidation of glycerol on the catalysts. Meanwhile, during the reverse scan there is a secondary oxidation peak which associated with incomplete oxidation of carbonaceous residues from the glycerol in forward scan. Between three synthesized catalysts, the bimetallic catalyst which is PdAu/CNF shows the best performance towards glycerol oxidation in alkaline media compare with Pd/CNF and Au/CNF in terms of onset potential and current density. The onset potential ($E_{on}$) is -0.45 for Pd/CNF, -0.46 for Au/CNF and -0.48 for PdAu/CNF, while the peak current density ($I_f$) for PdAu/CNF is 73.81mA $cm^{-2}$ which is highest compare to Pd/CNF and Au/CNF. The results in forward scan shows that the addition of Au in Pd form bimetallic catalyst can significantly improve the catalytic activity of Pd for glycerol oxidation in alkaline media.

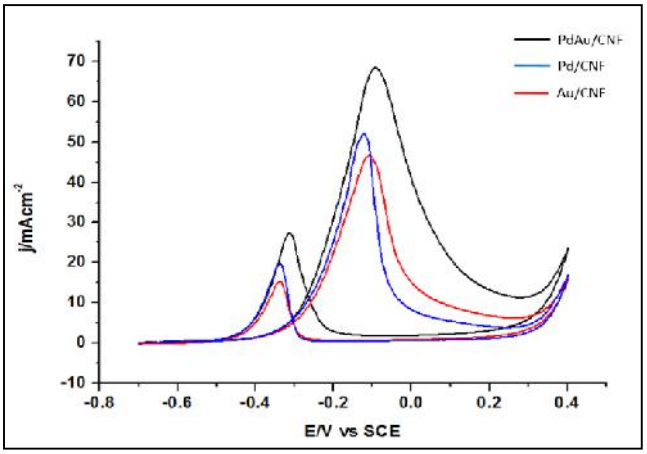

Figure 4. Cyclic voltammograms of Pd/CNF and PdAu/CNF for the electrooxidation of 0.5 M glycerol using 1.0 M KOH as an electrolyte scan rate of 50 mV/s

The actual performance glycerol oxidation in alkaline media has been summarized in Table 2. Based on Table 2, the onset potential ($E_{on}$) of glycerol oxidation with PdAu/CNF catalyst reveal more negative value compared to Pd/CNF and Au/CNF. This indicates, the significant enhancement oxidation kinetic activity for glycerol by addition of Au. With the addition of Au making the adsorption of oxygen species such as OH occurs at much lower potential than on monometallic Pd and Au surface to oxidize CO or adsorbed CO-like carbonaceous species on Pd sites. The addition of Au as second metal in PdAu/CNF also contribute to sufficient oxygen containing species such as OH to remove the adsorbed carbonaceous species and in other way it will beneficial in oxidation of glycerol [19]. Meanwhile the catalyst poisoning against the carbonaceous species can be traced from the forward scan to backward ($I_f/I_r$) scan peak current density ratio as shown in Table 2. The ratio of PdAu/CNF catalyst show higher value compare to Pd/CNF and Au/CNF. Therefore PdAu/CNF show better oxidation of methanol to carbon dioxide during anodic scan and less accumulation of carbonaceous species on the catalyst surface compare to Pd/CNF and Au/CNF [21].

Table 2. Electrocatalytic properties Pd/CNF and PdAu /CNF catalysts for glycerol oxidation

| **Catalyst Types** | **$E_{on}$ V vs SCE** | **$E_p$ V vs SCE** | **Ip (mA cm$^{-2}$)** | **$E_r$ V vs SCE** | **Ir (mA cm$^{-2}$)** | **j (mA mg$^{-1}$)** | **$I_f/I_B$** |
|---|---|---|---|---|---|---|---|
| Au/CNF | -0.46 | -0.071 | 55.73 | -0.29 | 23.14 | 371.54 | 2.40 |
| Pd/CNF | -0.45 | -0.044 | 63.82 | -0.27 | 40.58 | 425.44 | 1.57 |
| PdAu/CNF | -0.48 | -0.091 | 73.81 | -0.32 | 27.94 | 492.04 | 2.64 |

**Chronoamperometric study**

Chronoamperometric study has been employed for 3600s, where the considerable stability and tolerance to poisoning by intermediates species can be tested. Figure 5 shows the chronoamperometry obtained at room temperature in solutions 1.0 M NaOH and 0.5 M glycerol for 3600s. For all three catalysts, we can observe a decay of current value in the time interval measured for the studied electrocatalysts. However, after the initial drops the performance become stable for all the catalyst tested. From Figure 6 shows that the PdAu/CNF demonstrates better stability compared to Pd/CNF and Au/CNF alone, indicating that the present of Au could improve the stability of the catalyst by give a balance adsorption between OH species from Au and species from glycerol adsorption on Pd [22].

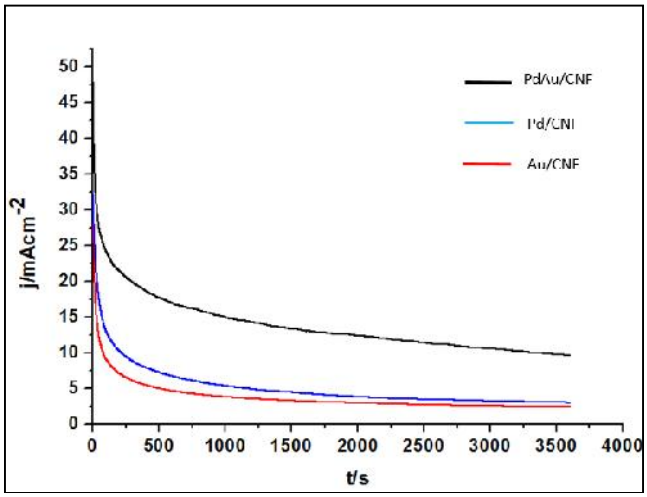

Figure 5. Cyclic voltammograms of Pd/CNF and PdAu/CNF for the electrooxidation of 0.5 M glycerol using 1.0 M KOH as an electrolyte

## Conclusion

In summary, the three types of catalysts namely as Pd/CNF, Au/CNF and PdAu/CNF have successfully synthesize by a facile method. XRD data clearly show the presence of Pd, Au and bimetallic PdAu. The FESEM and TEM image shown that the catalysts distributed on supported catalysts of CNF. The CV results exhibited, PdAu/CNF shows excellent catalytic activities and high stability for glycerol oxidation compared to Pd/CNF and Au/CNF. The onset potential of glycerol oxidation for PdAu/CNF more negative than Pd/CNF and Au/CNF which was attributed to the electronic effect. As well as the current density peak for PdAu/CNF is higher compared to monometallic catalyst. In addition, the $I_f/I_r$ ratio which reflect poisoning species for the oxidation of glycerol shows that bimetallic PdAu/CNF again is higher ratio value which means bimetallic catalyst has higher tolerance to the poisoning species.

**Abstract**

Heterogeneous catalytic cracking is currently one of the most effective ways for both reducing tar content and enhancing hydrogen ($H_2$) content in syngas at relatively low temperature, besides being environmental friendly. Sonochemical treatment has also been shown to lower reaction times with enhanced reaction rate and enables production of particles with high surface area. Two different types of metal oxides, which are Nickel Oxide (NiO) and Zirconium Oxide ($ZrO_2$) at combinations of 1:1, 1:2 and 2:1 ratios with Zeolite NaY as the supporter were synthesized via sonochemical treatment. The catalysts were then characterized using X-Ray Diffraction (XRD), Temperature Programmed Reduction in $H_2$/Argon (TPR-$H_2$), Brunauer-Emmett-Teller surface measurement (BET), Scanning Electron Microscopy (SEM) and Transmission Electron Microscopy (TEM). From SEM and TEM analysis, nickel tends to agglomerate and form globular shapes, zirconium forms coral-like branching structure and Zeolite NaY forms stacks of cubic clumps. The most promising NiO to $ZrO_2$ ratio for syngas production is 1:1 because it removes the most reactive oxygen during hydrogen reduction at 0.83 $x10^{21}$ atoms/g, has small crystallite size at 56.90 nm and has the highest surface area for maximum contact with the reactants at 506.52 $m^2$/g. Generally, sonochemical treatment also reduces the catalysts crystallite size (54.83 nm) and increases the catalysts surface area (506.52 $m^2$/g) and oxygen removal (0.83 $x10^{21}$ atoms/g) as well as lowers the reduction temperature (637 K) which is favourable in term of production cost.

**Keywords**: heterogeneous catalysts, nickel oxide, zirconium oxide, zeolite, syngas

**Abstrak**

Perekahan pemangkin heterogen adalah salah satu cara terkini yang paling efektif untuk mengurangkan kandungan tar dan juga meningkatkan kandungan hidrogen ($H_2$) di dalam singas pada suhu rendah, di samping mesra alam sekitar. Rawatan sonokimia juga telah dibuktikan dapat mengurangkan masa tindak balas di samping meningkatkan kadar tindak balas dan membolehkan penghasilan partikel dengan luas permukaan yang tinggi. Dua jenis besi oksida berbeza, iaitu Nikel Oksida (NiO) dan Zirkonium Oksida ($ZrO_2$) dalam kombinasi nisbah 1:1, 1:2 dan 2:1 dan Zeolit NaY sebagai penyokong dihasilkan melalui rawatan sonokimia. Katalis – katalis tersebut kemudian dianalis menggunakan pembelauan sinar-X (XRD), Penurunan Suhu Berprogram (TPR-$H_2$), pengukuran permukaan Brunauer-Emmett-Teller (BET), Mikroskop Imbasan Elekron (SEM) dan Mikroskop Elektron Transmisi (TEM). Daripada analisis SEM dan TEM, nikel cenderung untuk bergumpal dan membentuk glob besar, zirkonium membentuk struktur seperti karang bercabang dan Zeolit NaY membentuk lapisan kubik. Nisbah NiO kepada $ZrO_2$ yang paling

berpotensi adalah 1:1 kerana ia menyingkirkan banyak oksigen yang reaktif semasa reduksi hidrogen pada kadar 0.83 $x10^{21}$ atom/g, mempunyai saiz kristal yang kecil iaitu 56.90 nm dan mempunyai luas permukaan yang paling tinggi pada 506.52 $m^2/g$ untuk kontak maksimum dengan bahan tindak balas. Umumnya rawatan sonokimia juga mengurangkan saiz kristal katalis (54.83 nm) dan meningkatkan luas permukaan pemangkin (506.52 $m^2/g$) dan juga penyingkiran oksigen (0.83 $x10^{21}$ atom/g) di samping mengurangkan suhu penurunan (637K) di mana ia adalah baik untuk penjimatan kos pengeluaran.

**Kata kunci:** pemangkin heterogen, nikel oksida, zirkonium oksida, zeolit, singas

## Introduction

The depletion of world petroleum reserves and increased environmental concerns has stimulated the search for the alternative renewable fuels that are capable of fulfilling an increasing energy demand. The biomass fuels represent an abundantly available and renewable energy resource with $CO_2$ neutral impact. It is the only sustainable source of energy and organic carbon for industrial society [1]. Among different processes for their utilization, the biomass gasification is one of the best options in order to optimize the conversion of the chemical energy of the fuel. Instead of using edible biomass (sugars, starches, and vegetable oils) for large scale production of fuels, the development of nonedible biomass (lignocellulosic biomass) permits sustainable and cheaper production of fuels and chemicals without affecting food supplies [1]. Biomass gasification is one of the most promising options for converting lignocellulosic biomass to synthesis gas (syngas), a mixture of CO and $H_2$, which can be used either as a fuel to produce heat and power or as an intermediate in the production of liquid fuels (e.g. diesel fuel, dimethyl ether) and chemicals (e.g. methanol).

Tar is a complex mixture of condensable organic compounds, which includes single ring to 5-ring aromatic compounds along with other oxygen-containing hydrocarbons and complex polycyclic aromatic hydrocarbons (PAHs), which can foul the equipment and cover the surface of catalysts to slow or stop the reaction [2]. Tars present a number of process challenges, including coking of catalysts and condensation on downstream piping, filters, and other equipment. The tar removal cost is as expensive as the overall process to produce syngas [3]. Tars cause severe operational problems associated with their condensation and polymerization. Tar removal is a critical issue in the development of biomass gasification, especially in the Fischer–Tropsch (F–T) synthesis where those impurities can lower the F-T activity in the bio-syngas catalytic conversion [2]. Moreover, a high $H_2$/CO ratio in the gas stream is desirable for F-T synthesis.

Catalytic cracking/reforming is currently one of the most effective ways for both reducing tar content and enhancing $H_2$ content in syngas at relatively low temperature. Recently, conventional homogeneous base catalysts are expected to be replaced in the near future by environmentally friendly heterogeneous base catalysts mainly because of environmental constraints and simplifications in the existing processes. Heterogeneous catalytic is considered as a technology with the highest potential to contribute to the solution of tar decomposition. In addition, the use of a catalyst can enhance the gas yield and promote the reforming reactions of residual hydrocarbons. In heterogeneous reaction, the interaction of methane with metals results in $H_2$ evolution where at temperature above 400K, dehydrogenation of $CH_x$ species becomes fast and the elemental carbon is more stable forming stronger bonds with the metal surface [4].

Several catalytic materials have been studied as additives in fluidized-bed reactor in order to achieve in situ catalytic conditioning of the product gas inside the gasifier reactor. Many works on in-bed catalysts consider dolomite [2,5,6], olivine [3,6], nickel [2,3,5-8] and noble metal (NM) based catalysts [4]. A tar conversion rate of 99% has been achieved by using dolomite and Ni-based catalysts [2]. The catalytic performance of dolomite in tar cracking is directly proportional to the number of surface base sites [3].

Although NMs, such as Ru, Rh, Pd, Pt, and Ir, have been studied extensively for dry reforming reaction, their high cost and limited availability limits their industrial applications [9]. Nickel-based catalyst has been considered as the most suitable due to its fast turnover rates, long-term stability and lower cost [4]. However, the major challenge in many processes involving Ni-based catalyst is deactivation by carbon deposition [2]. Therefore, an effective catalyst that minimizes coke deposition should be developed. Zirconium has been tested as a base catalyst to reform gas containing tarry impurities. Zirconium catalyst works efficiently in decomposing tars, especially heavier

hydrocarbons. In several tests done by Simell and Kurkela [10], zirconium catalysts provided a tar conversion of 60 to 80% at a temperature of about $600^0$C. Zirconium has also been used as support for Ni-based catalyst for syngas production by dry reforming reaction, which enables direct conversion of natural gas into liquid fuels at remote extraction sites [4].

Metal oxides are constituents of the Earth crust and have been catalyzing different important reactions in chemical evolution. They are good adsorbents and efficient catalysts [11]. They consist of dispersed surface metal oxide species and catalytic active sites supported on high surface area oxides [12]. Mixed metal oxide catalysts are used in heterogeneous catalysis for chemical processes and being further developed for their catalytic performance and durability [13]. Supported metal oxide catalysts have been extensively investigated since 1950s. According to Lee and Wachs [14], the surface metal oxide species of supported metal oxide catalysts control the overall catalytic performance such as activity and selectivity. Zirconium oxide ($ZrO_2$) has high thermal stability as a catalyst support. It is proved to be a very good promoter for cobalt catalyst where it enhanced CO conversion rate and C5+ selectivity [2]. A study comparing $Ni/CeO_2$, $Ni/ZrO_2$, and $Ni/CeO_2$-$ZrO_2$ mixed oxide catalysts for methane partial oxidation at 700 °C showed higher activity and coke resistance on the composite supports as compared to the individual metal oxides [6]. Another study using combination of Ni-Ce-$ZrO_2$ catalyst showed high conversions of reactants (97%) and provide high resistance to catalyst deactivation, but still requires a high temperature [4].

Catalytic performances are expected to be improved by the optimization of the catalytic filter system and the use of more active in-bed catalysts. In this study, the catalysts used are two different types of metal oxides, which are Nickel Oxide (NiO) and Zirconium Oxide ($ZrO_2$) with Zeolite supporter. Zeolites have been added to the conventional F-T system in many studies. They have a shape-selective property that restrains the formation of products that are larger than the size of the zeolite channels and result in lighter hydrocarbons. Zeolites acid site can help with cracking, isomerization and aromatization reactions for F-T products [2]. They are also widely used in heterogeneous catalysis because of their well-defined pore structures and capabilities of extremely high surface area and surface acidity [6].

The catalysts used for this study were synthesized via sonochemical treatment. Sonochemically assisted reactions showed lower reaction times with enhanced reaction rate. It enables production of small and high uniform particles sizes with high surface area, metal dispersion and defects that have been shown to play a crucial role in catalysis [15-20]. The utilization of sonochemical treatment in the synthesis of the catalysts was proven to show significant increase in the catalytic activity, stability and selectivity of catalysts [20].

## Materials and Methods

### Preparation of mixed nickel oxide and zirconium oxide catalysts

Mixture of NiO and $ZrO_2$ catalysts was synthesized by conventional impregnation /co-precipitation method by mixing NiO (from Hmbg) and $ZrO_2$ (from Acros Organics) at three different NiO to $ZrO_2$ ratios of 1:1, 1:2 and 2:1 in 100 mL distilled water. The solutions were then sonicated separately for 30 minutes with 2 cm diameter Ti-horn, 20 kHz, 500W probe. The temperature was kept constant at 80 °C. The samples were then cooled to room temperature. The resultant solid (mixture of NiO and $ZrO_2$) was then recovered using centrifuge for 5 minutes at 2000 rpm [21]. It was then subsequently washed with distilled water followed by washing with acetone to remove the by-products [22] before oven dried overnight at 105 °C for 12 hours according to Tao et al. [23].

### Preparation of Zeolite NaY supporter

The supporter used was Zeolite Y sodium (Zeolite NaY), procured from Alfa Aesar. Table 1 showed its mole ratio and surface area.

Zeolite NaY was first treated with sonochemical treatment and the resultant solid was recovered using centrifuge before oven dried overnight at 105 °C. The synthesized mixture of NiO and $ZrO_2$ were then added with Zeolite at a loading of 10g equally, in 100 mL distilled water. The mixture was then stirred on a hot plate with a magnetic stirrer for one hour. The solid was again recovered using centrifuge technique and subsequently washed with distilled water followed with acetone then oven dried overnight at 105 °C for 12 hours [23]. The catalysts mixtures were then calcined in air at 500 °C for 4 hours, yielding a homogeneous catalyst powder, according to Klimova et al. [24]

and Maciel et al. [25]. Calcining the synthesized catalysts powders also removes structure directing agents and other organic substances present in them [26].

Table 1. Mole ratio and surface area of Zeolite NaY

| Zeolite NaY Characterization | $SiO_2$ | $Al_2O_3$ |
|---|---|---|
| Mole ratio | 5.1 | 1 |
| Surface area ($m^2/g$) | 900 | 900 |

**Catalyst characterization**

The catalysts were then characterized through a series of analysis as follows. X-ray diffraction (XRD) analysis was carried out using Shimadzu diffractometer model XRD 6000 at range 2Θ from 5° to 80° in continuous scanning at 2° per minute and sampling pitch of 0.02°. Hydrogen temperature programmed reduction analysis ($H_2$-TPR) was performed using Thermo Fisher Scientific TPDRO 1100 apparatus that was equipped with a thermal conductivity detector (TCD). The total surface areas of the catalysts were then measured using Thermo Electron Sorptomatic 1990 and Quantachrome AS1Win$^{TM}$ Automated Gas Sorption Data Acquisition and Reduction utilizing Brunauer-Emmett-Teller (BET) method. The catalyst samples were degassed at 300 °C for 12 hours. Electron microscopy technique was used to obtain the information on the morphology and size of the catalyst samples by using LEO 1455 Variable Pressure scanning electron microscope (SEM). The particle sizes of the samples were examined using Hitachi H-7100 energy filter transmission electron microscope (TEM).

## Results and Discussion

**X-Ray diffraction analysis**

X'Pert HighScore software from PANalytical B. V. was used to analyze the XRD data. From the XRD data of all samples, the presence of NiO phase appeared consistently at $2\Theta$ = 37.3°, 43.4°, 62.8° and 75.4° (JCPDS File No. 00-022-1189) but the peak intensities are very low. This might be due to high metal dispersion of NiO on the surface of Zeolite NaY due to the effect of sonochemical treatment in improving particles size distribution The presence of $ZrO_2$ phase appeared at multiple degrees = 24°, 24.3°, 28.4°, 31.7°, 34.4°, 35.6°, 40.9°, 49.4°, 50.3°, 50.8°, 54.2°, 55.5°, 58.6° and 62.2° (JCPDS File No. 00-013-0307). While Zeolite NaY showed multiple peaks at 2Θ = 6.4°, 10.5°, 12.2°, 15.9°, 19.0°, 20.6°, 23.0°, 24.0°, 27.3°, 29.9°, 31.1°, 31.7°, 34.4°, 40.9°, 49.4° and 54.2° (JCPDS File No. 00-038-0239). Some of the peaks of $ZrO_2$ and Zeolite NaY seem to overlap with each other and it is quite difficult to distinguish the peaks between the two.

Based from the peak intensities shown in Figure 1, the sonochemically treated catalysts with NiO: $ZrO_2$ ratio of 1:1 shows the lowest peak intensities followed by catalysts ratio 2:1 and 1:2. It seems that equal amount of NiO and $ZrO_2$ contributes to higher dispersion of metal oxides on Zeolite's surface compared to the unequal amounts of NiO and $ZrO_2$. Catalysts ratio 1:2 shows the highest peak intensities where $ZrO_2$ is double the amount of NiO. Since the peaks of $ZrO_2$ are more prominent than NiO, it can be said that $ZrO_2$ is not as well dispersed as NiO on the surface of Zeolite NaY supporter.

Zeolite NaY generally has the highest crystallinity and more defined structures compared to NiO and $ZrO_2$. It is identified to possess cubic crystal system. Its particle size is also the largest compared to NiO and $ZrO_2$ (average of 201 to 493 nm). The size of crystallite can be estimated from the XRD data as shown in Table 2, using Scherrer equation in equation 1 [27],

$$L = K\lambda/\beta.\cos\Theta \quad (1)$$

where L = average crystallite size, K = constant which is normally taken as 0.9, λ = X-ray wavelength, β = peak width of the diffraction profile at half maximum height and Θ can be either in degrees or radians.

Based from Table 2, catalyst ratio 2:1 showed the smallest crystallite size average of 54.83 nm compared to other catalysts with different ratios. This is to be expected since the TEM analysis images also show that Ni has the smallest particle size (average of 6 to 12 nm) and that the high amount of NiO means it is well dispersed on the surface of the catalyst, thus contributing to smaller crystallite size. However, the crystallite size of catalyst 2:1 is not significantly different than catalyst ratio 1:1. While catalyst ratio 1:2 shows the biggest crystallite size due to higher amount of $ZrO_2$.

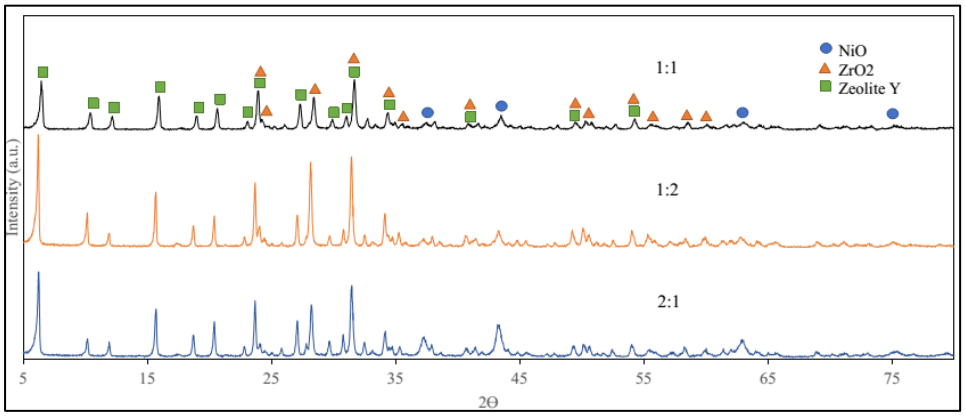

Figure 1. XRD patterns of NiO:$ZrO_2$ catalysts ratio of 1:1, 1:2 and 2:1 treated with sonochemical treatment for 30 minutes

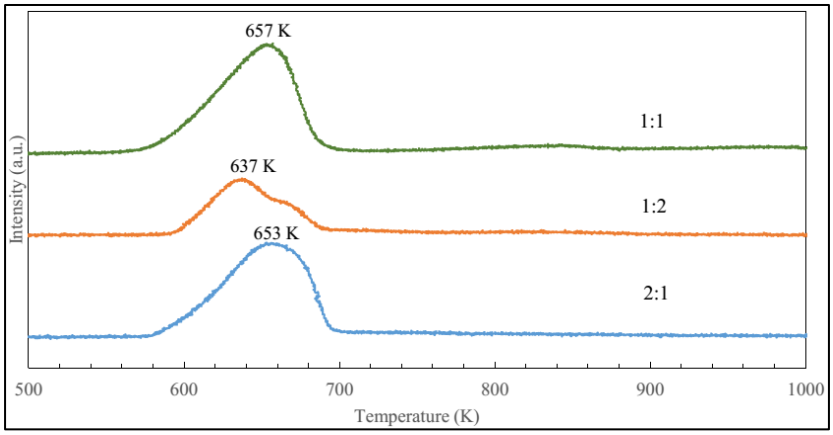
Table 2. Crystallite size average from XRD data (nm)

| **Catalyst** | **Crystallite Size Average (nm)** |
|---|---|
| 1:1 | 56.90 |
| 1:2 | 62.51 |
| 2:1 | 54.83 |

**Temperature programmed reduction (TPR in $H_2$/Ar)**
All catalyst samples produced a single reduction peak at temperature ranging from 637 K to 657 K as shown in Figure 2 and Table 3.

As can be seen in Table 3, catalyst ratio 1:1 removed the highest amount of oxygen at 0.83 $x10^{21}$ atoms/g followed by catalysts ratio 2:1 and 1:2. From the data, it is shown that catalyst ratio 1:1 is the most efficient reactive oxygen removal while catalyst ratio 1:2 is the least efficient with reactive oxygen removal at 0.48 $x10^{21}$ atoms/g. This is also in agreement with the XRD data discussed earlier where catalyst ratio 1:1 with equal distribution of NiO and $ZrO_2$ is well dispersed with small crystallite size. However, catalyst ratio 1:2 and 2:1 have lower $T_{max}$ at 637K and 653K respectively compared to catalyst ratio 1:1 at 657K. Despite the 20K $T_{max}$ difference between catalysts ratio 1:1 and 1:2, catalyst ratio 1:1 has almost double the amount of reactive oxygen removed compared to catalyst ratio 1:2.



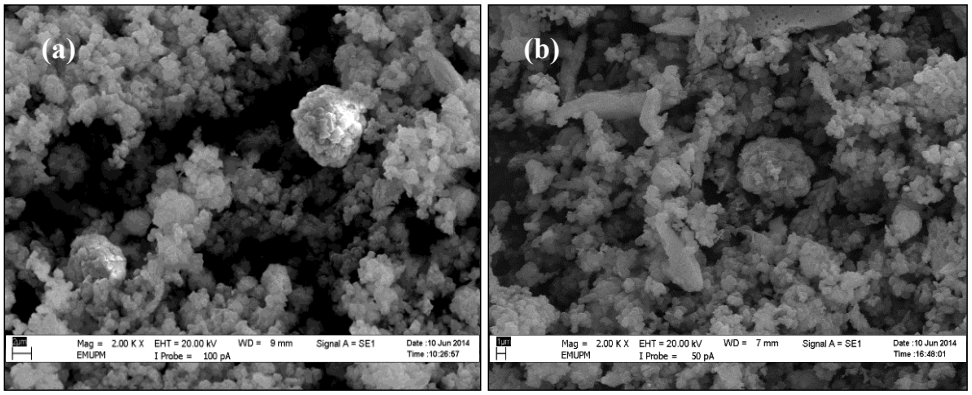


Figure 2. Temperature programmed reduction profiles for NiO: $ZrO_2$ ratio 1:1, 1:2 and 2:1

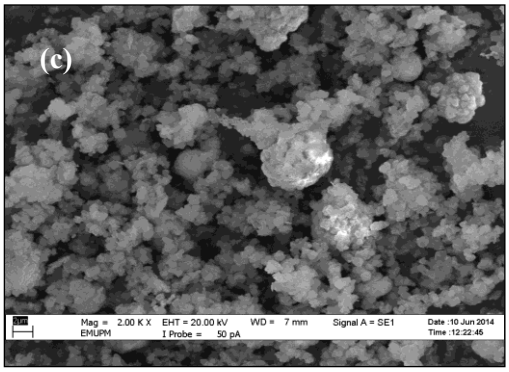
Table 3. Total amount of oxygen removed from the catalysts by reduction in $H_2$/Ar

| Catalyst | $T_{max}$ (K) | $H_2$ gas adsorbed ($x10^{-3}$ mol/g) | Total $O_2$ removed ($x10^{21}$ atoms/g) |
|---|---|---|---|
| 1:1 | 657 | 1.37 | 0.83 |
| 1:2 | 637 | 0.79 | 0.48 |
| 2:1 | 653 | 1.21 | 0.73 |

**Scanning electron microscope**

In all samples, NiO tends to agglomerate into large globular shape while Zeolite NaY forms stacks of cubic shaped clumps and mostly spread out trough out the entire sample. Generally $ZrO_2$ forms the smallest structures among the other two catalysts. It was seen to be in cylindrical form in coral-like branching structure distributed throughout the sample. Figure 3 shows large globular clumps of NiO surrounded by Zeolite NaY and some smaller coral-like $ZrO_2$ clumps can be seen around it.



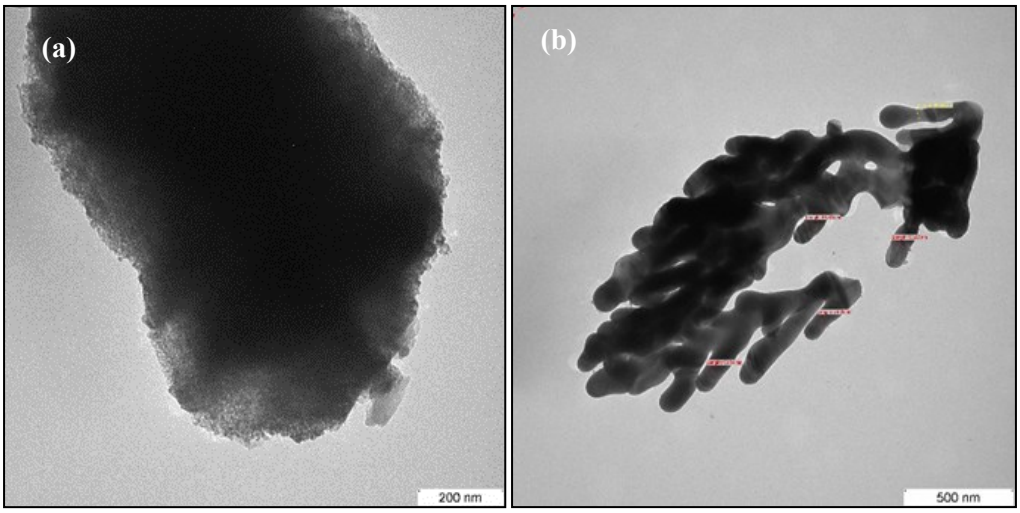


Figure 3. SEM micrograph of sample (a) 1:1, (b) 1:2, and (c) 2:1 at magnification 2000x

Catalyst ratio 1:1 shows NiO agglomerated globular clumps with $ZrO_2$ smaller structures are equally distributed on the surface of Zeolite NaY while catalyst ratio 1:2 shows more and bigger structures of $ZrO_2$ on the surface of the catalyst. Globular clumps of NiO are more apparent in catalyst ratio 2:1, as can be seen in Figure 3.

**Transmission electron microscope**

Figure 4 shows agglomerated NiO particles with sizes ranging from 6 to 12 nm in catalyst ratio 1:1. From the same sample, $ZrO_2$ forms coral-like branching structures with diameters ranging from 74 to 94 nm while crystal-like Zeolite NaY stacks up on each other with diameters ranging from 201 to 493 nm. TEM images shows that $ZrO_2$ average particle size is larger than NiO and this is in agreement with XRD results where catalysts ratio 1:2 also has the highest peak intensities where $ZrO_2$ is double the amount of NiO. Since the peaks of $ZrO_2$ are more prominent than NiO, it can be said that $ZrO_2$ is not as well dispersed as NiO on the surface of Zeolite NaY supporter due to its larger particle size and its branching structures.

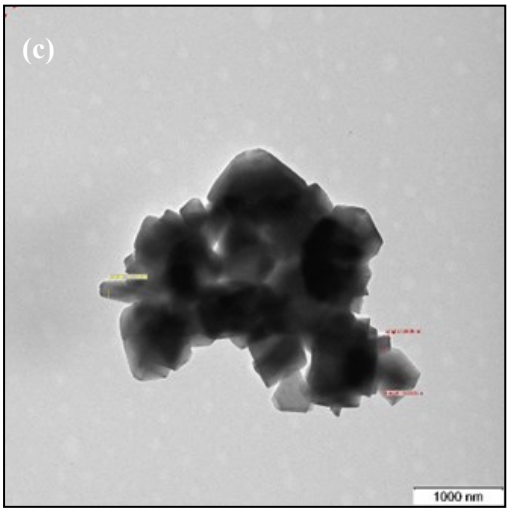

Figure 4. TEM micrograph of catalyst ratio 1:1 of (a) NiO at magnification 100 000x, (b) $ZrO_2$ at magnification 50 000x, and (c) Zeolite at magnification 20 000x

**BET surface area measurement**

Based from Table 4, catalyst with the highest surface area is catalyst ratio 1:1 with surface area of 506.52 $m^2/g$ and the lowest surface area is catalyst ratio 1:2 with surface area of 399.88 $m^2/g$. This is in agreement with the XRD and TPR-$H_2$ data where catalyst ratio 1:1 has well dispersed metal oxides with average crystallite size of 56.90 nm and the highest reactive oxygen removal at 0.83 $x10^{21}$ atoms/g compared to catalysts ratio 1:2 and 2:1.
While catalyst ratio 1:2, with its higher amount of $ZrO_2$ on the surface of Zeolite NaY has reduced the surface area of the catalyst (399.88 $m^2/g$) as well as reduced contact with the active sites thus contributing to low removal of reactive oxygen as presented in previous TPR-$H_2$ section discussion.

The presence of Zeolite NaY supporter and $ZrO_2$ in catalysts was reported by Derekaya and Yasar [28] to give higher surface area compared to the catalysts without their presence. Zeolite NaY also has high surface area (900 $m^2/g$) and well dispersed pore structure. $ZrO_2$ was also implied to act as a surface area agent. However, higher ratio of $ZrO_2$ to NiO is proven to significantly reduce the surface area of the catalysts.

There is also a huge discrepancy between pure Zeolite NaY surface area (900 $m^2/g$) and treated Zeolite NaY surface area. The drying and calcination of catalyst could also possibly affect the total surface area. This also means that both NiO and $ZrO_2$ loading on Zeolite NaY significantly reduced the surface area of Zeolite NaY. This might be due to the effects of sonication treatment which caused the agglomeration of active metal Ni on the surface of Zeolite NaY where it could lead to blockage of pores and reduces the overall surface area of Zeolite NaY [17].

Table 4. Specific BET surface area of NiO: $ZrO_2$ catalysts

| Catalyst | Surface Area ($m^2/g$) |
|---|---|
| 1:1 | 506.52 |
| 1:2 | 399.88 |
| 2:1 | 436.37 |

A summary of comparisons between catalysts ratio 1:1, 1:2 and 2:1 is shown in Table 5.

Table 5. Comparisons of properties between catalysts with different ratio

| Catalyst | Average Crystallite Size (nm) | $T_{max}$ (K) | $H_2$ Gas Adsorbed ($x10^{-3}$ mol/g) | Total $O_2$ Removed ($x10^{21}$ atoms/g) | Surface area ($m^2/g$) |
|---|---|---|---|---|---|
| 1:1 | 56.90 | 657 | 1.37 | 0.83 | 506.52 |
| 1:2 | 62.51 | 637 | 0.79 | 0.48 | 399.88 |
| 2:1 | 54.83 | 653 | 1.21 | 0.73 | 436.37 |

## Conclusion

The catalysts studied, which are NiO and $ZrO_2$ with Zeolite NaY as supporter will help in the study of catalytic cracking/ reforming mechanisms in good quality and cleaner syngas production. However the results are not conclusive yet since syngas evaluation using Temperature Programmed Gasification (TPG) has not been done yet. The results from TPG analysis will determine the performance of the catalysts and will relate with the catalysts characterization data. For now, it can be said that the most promising NiO to $ZrO_2$ catalyst ratio is ratio 1:1 because of the well dispersion of mixed metal oxides on the catalyst surface with small average crystallite size of 56.90 nm, removal of reactive oxygen at the highest rate at 0.83 $x10^{21}$ atoms/g as well as possessing the highest surface area at 506.52 $m^2/g$. Equal distribution of mixed metal oxides on the surface of Zeolite NaY supporter produces favourable characteristics for the production of quality syngas. Higher amount of $ZrO_2$ however causes blockage of the pores, thus reduces the catalyst surface area because of its tendencies to agglomerate and form large branching structures, which produces catalyst of poorer profile compared to catalysts ratio 1:1 and 2:1. From SEM and TEM analysis, NiO tends to agglomerate and form sizable globular shapes, $ZrO_2$ forms coral-like branching structure and Zeolite NaY forms stacks of cubic clumps. From the catalysts characterization data and analysis obtained, catalysts with NiO: $ZrO_2$ ratio of 1:1 seems to be a promising catalyst for producing rich syngas with higher catalytic activity and reaction.

**Abstract**

The combustion of coal for energy had created severe environmental issues mainly due to the release of particulate matter and flue gases containing sulphur dioxide ($SO_2$) during the processing. At present limestone based adsorbent is used to desulphurize flue gas. Egg shell is a type of food waste and it contains high amount of calcium carbonate which is similar to limestone. In this study, the potential of egg shell as a substitute material to replace commercial limestone based calcium oxide was investigated. Waste egg shell and commercial calcium carbonate (limestone)(CCC) were calcined at various temperatures (750 – 950 ºC) and holding time (2 and 4 hours). The calcined samples were tested for $SO_2$ adsorption using a gas reactor at room temperature with a flow rate of 300 mL/min. The initial concentration of $SO_2$ is 200 ppm. Characterization of the adsorbents will be done using Fourier Transform Infrared (FTIR), Brunauer-Emmett-Teller (BET) and X-ray Diffraction (XRD) to understand the sorption behavior. Calcined egg shell and calcined CCC takes about 110 min and 180 min for saturation. It is noted that calcined egg shell could remove $SO_2$ alike calcined CCC. However, the adsorption capacity of egg shell is lower compared to CCC and this could be due to impurities.

**Keywords**: sulphur dioxide, adsorption, egg shell, calcium carbonate

**Abstrak**

Pembakaran arang batu untuk sumber tenaga telah mewujudkan isu-isu alam sekitar yang teruk disebabkan oleh pembebasan habuk tertentu dan gas serombong yang mengandungi sulfur dioksida ($SO_2$) semasa pemprosesan. Pada masa ini, batu kapur berasaskan serapan digunakan untuk menyingkirkan gas serombong. Kulit telur adalah sejenis sisa makanan dan ia mengandungi jumlah kalsium karbonat yang tinggi dan sama seperti batu kapur. Dalam kajian ini, potensi kulit telur sebagai bahan pengganti untuk menggantikan kalsium oksida daripada batu kapur komersial telah dikaji. Sisa kulit telur dan kalsium karbonat komersial (batu kapur) (CCC) telah dibakar pada pelbagai suhu (750 – 950 ºC) dan masa induk (2 and 4 jam). Sampel yang telah dibakar kemudian diuji untuk penyerapan $SO_2$ menggunakan reaktor gas pada suhu bilik dengan kadar aliran 300 mL/min. Kepekatan awal $SO_2$ adalah 200 ppm. Pencirian serapan dilakukan dengan menggunakan Infra merah Transformasi Fourier (FTIR), Brunauer-Emmett-Teller (BET) dan pembelauan Sinar-X (XRD) untuk memahami keadaan penyerapan itu. Kalsin kulit telur and kalsin CCC masing-masing memerlukan tempoh selama 110 min and 180 min untuk mencapai ketepuan. Ternyata bahawa kalsin kulit telur boleh menyingkirkan $SO_2$ seperti kalsin CCC. Walau bagaimanapun, kapasiti penyerapan kalsin kulit telur lebih rendah berbanding dengan kalsin CCC yang mungkin disebabkan oleh berhadas.

**Kata kunci:** sulfur dioksida, penyerapan, kulit telur, kalsium karbonat

## Introduction

Combustion of the sulphur containing fuel, such as coal and oil, results in the formation of sulphur dioxide ($SO_2$). Flue gas from coal processing is one of the major contributors of $SO_2$ to the environment. It has been reported that a typical coal-fired plant generates about 10,000 tons of $SO_2$ [1]. The releasing of $SO_2$ into the air will bring adverse effects to the human health and environment. Several technologies had been invented to treat $SO_2$ from flue gas before it is being released to the atmosphere. Flue gas desulphurization (FGD) is one of the methods that removes the $SO_2$ content in the flue gas from solid, liquid or gases [2]. Wet desulphurization method using limestone as adsorbent had been used widely due to the high removal efficiency (higher than 90 %) of the $SO_2$ [3]. However, the usage of limestone a depleting natural source for cleaning purpose is not economically viable. Besides using limestone as an adsorbent for FGD, many other types of adsorbents such as activated carbon, activated coke, fly ash have been reported in the literature to remove $SO_2$ [4-6].

Egg shell (ES) is an emerging abundant solid waste from the sources such as poultry, homes, restaurants, and food manufacturing industries [7]. In Malaysia about 642,600 tonnes of egg is produced every year and from this total about 70,686 tons of ES waste is expected to be generated every year [8]. Furthermore, recently in Malaysia egg cracking industries is growing rapidly giving largest chuck of ES. ES usually are disposed to landfills without prior treatment and this indirectly creates negative effect to the environment and human health [9-10]. Many investigations have been conducted to explore usefulness of ES such as ES based fertilizer, cement additive, heavy metal adsorbent, catalyst and collagen [11-13]. However, none have been tested for pollutant gas adsorption.

In present study, waste egg shells were tested as a new material to treat $SO_2$ from flue gases. Egg shells are calcined to calcium oxide (CaO). Calcined ccommercial calcium carbonate ($CaCO_3$) was also used to compare the performance of egg shell waste to commercially available adsorbent.

## Materials and Methods

### Eggshell preparation

ES was collected from the university campus canteen. About 1 kg of waste ES was collected in a day throughout the campus. The collected ES was thoroughly washed to remove any white or yellow egg residue and egg membrane. It is then dried at 105 °C till a constant weight is obtained. Prior to storage, ES powder was sieved to a particle size of 63 µm. This size was chosen to standardize the adsorbent size and preliminary study shows smaller size has better adsorption capacity due large surface area. In order to test the potential ES for $SO_2$ removal, it was further processed to form CaO. The calcination processes were done by varying the calcination temperature (750 – 950 °C) and time (2 and 4 hours). The temperature and time range was chosen based on a preliminary study and literature [8]. Similarly, was done for the commercial calcium carbonate (CCC) (lab grade, 99% purity) purchased from Merck.

### Sulphur dioxide removal

Desulfurization experiments were performed in a laboratory scale of adsorption system with a fixed bed adsorber. Figure 1 shows the illustration of the experimental rig. The height and inner diameter of the reactor are 180 mm and 9 mm. The concentration of $SO_2$ gas was measured using a gas analyzer (Vario Plus Industrial Gas Analyzer, V: 1.78-000). About 0.5 g of adsorbent was placed in the reactor. 200 ppm $SO_2$ and $N_2$ as the balance was passed through the reactor at room temperature. The feed flow through the reactor was controlled at 300 ml/min. The amount of $SO_2$ adsorbed by the prepared adsorbent was expressed in breakthrough curves. Three sets of $SO_2$ adsorption study was done for each sample and the average data was used to plot the breakthrough curves.

The adsorption capacity was calculated based on the breakthrough curve data. The time equivalent to the total or stoichiometric capacity of $SO_2$ was calculated numerically by integrating the following equation 1;

$$t_t = \int_0^{\infty} 1 - \frac{C}{Co}\, dt \qquad (1)$$

Where $t_t$ is the time equivalent to the total or stoichiometric capacity, $t$ is the time, $C$ is the concentration of $SO_2$ at time, $t$ and $Co$ is the feed concentration of $SO_2$. With $t_t$ determined, the amount of adsorbed by adsorbent (the adsorption capacity) was calculated at STP condition from the following equation 2 and 3 [14];

$$q = \frac{Q_f t_t y_f}{m_c} \tag{2}$$

$$q = 1 - \frac{C}{Co} \frac{Q_f t_t y_f}{m_c} \tag{3}$$

where $q$ is the adsorbent sorption capacity, $q_t$ is the breakthrough sorption capacity at 5% from initial concentration, $y_f$ is the mole fraction of $SO_2$ in the feed, $Q_f$ is the volumetric feed flow rate at STP and $m_c$ is the mass of adsorbent used in the bed.

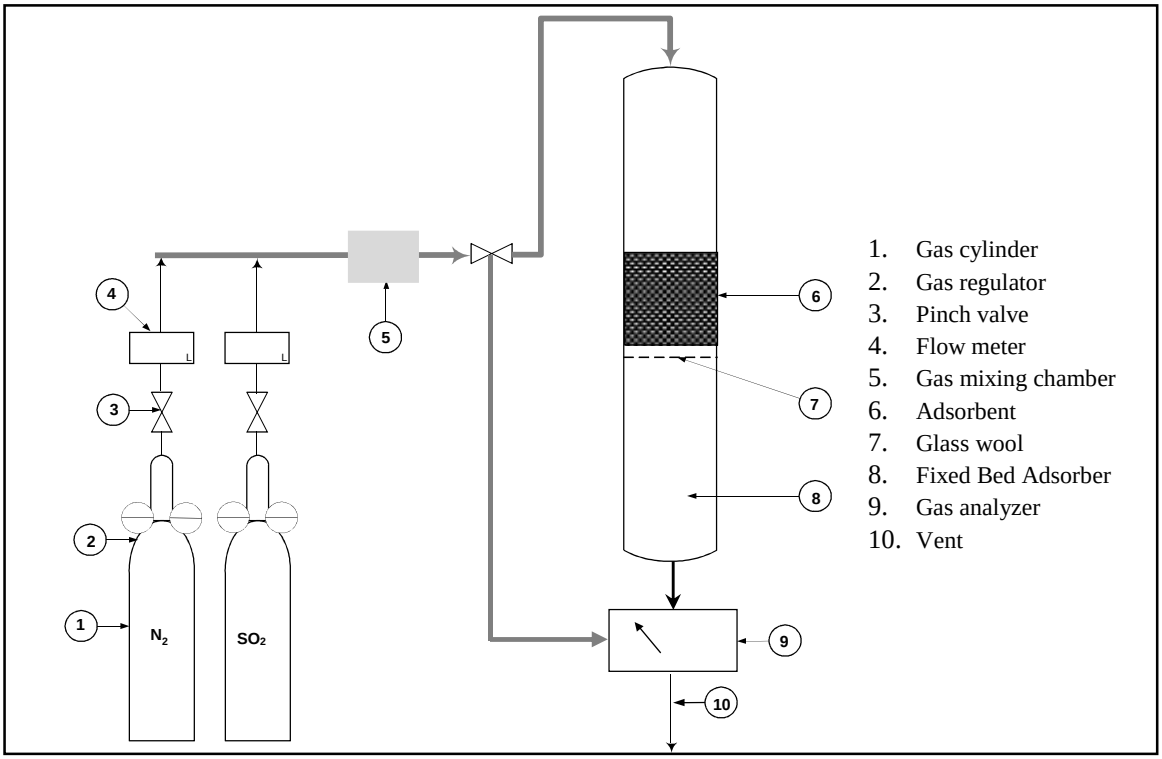

Figure 1. Experimental rig for desulphurization

**Characterization**

In this study, the prepared adsorbent will be characterized to determine their physical and chemical properties. The Fourier Transform Infrared (FTIR) was used to qualitatively identify the functional groups on the surface of ES and CCC using PerkinElmer FT-IR 2000. The spectra were obtained in the range of 400 – 4000 $cm^{-1}$ with a resolution of 4 $cm^{-1}$. The sample preparation consisted of mixing fine powder of each sample with KBr powder. The Brunauer-Emmett-Teller (BET) surface area analysis was done using $N_2$ adsorption and desorption isotherms measured at 77 K using Micromeritics (ASAP 2020 V4.02) volumetric gas adsorption instrument. Prior to measurements, the samples were degassed at 105 °C for 24 hours. The X-ray diffraction patterns of the samples were recorded by XRD-6000, Shimadzu using Cu-Ka radiation. The measurements were made at temperature range of 15 – 70 °C on $2\theta$ with a step size of 0.02°. The diffraction patterns were analyzed using the Joint Committee on Powder Diffraction Standards (JCPDS). CaO crystallite size was calculated using Scherrer equation from the most intense CaO peak at $2\theta$ of 37.6°.

## Results and Discussion

The $SO_2$ adsorption performance by calcined ES and CCC at different temperature and time are shown in Figure 2(a) and 2(b) and Figure 3(a) and 3(b) respectively. The data was plot based on average of three replicates and the difference of each set was less than 4%. The longest time (180 minutes) taken for saturation by CCC was at temperature 900 °C with 2 hours of calcination. The adsorption capacity of this sample was calculated as 3.95 mg/g. It was noticed that as the temperature was increased from 750 to 900 °C the saturation time for CCC increased rapidly. However, at temperature 950 °C the adsorption curve was narrower and almost similar to 900 °C. Further increase in temperature did not show significant changes in the removal efficiency. This is because the maximum conversion of $CaCO_3$ to CaO happens at 900 °C [15]. Thus, any sample prepared at lower temperature is expected to give less adsorption capacity due to incomplete process of $CaCO_3$ calcination.

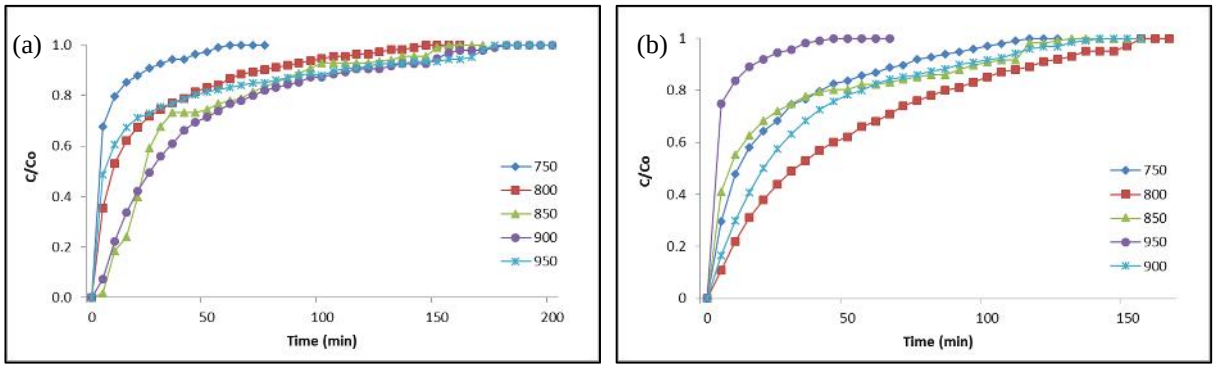

Figure 2. $SO_2$ breakthrough curve at different temperature for CCC at (a) 2 hours and (b) 4 hours of calcination

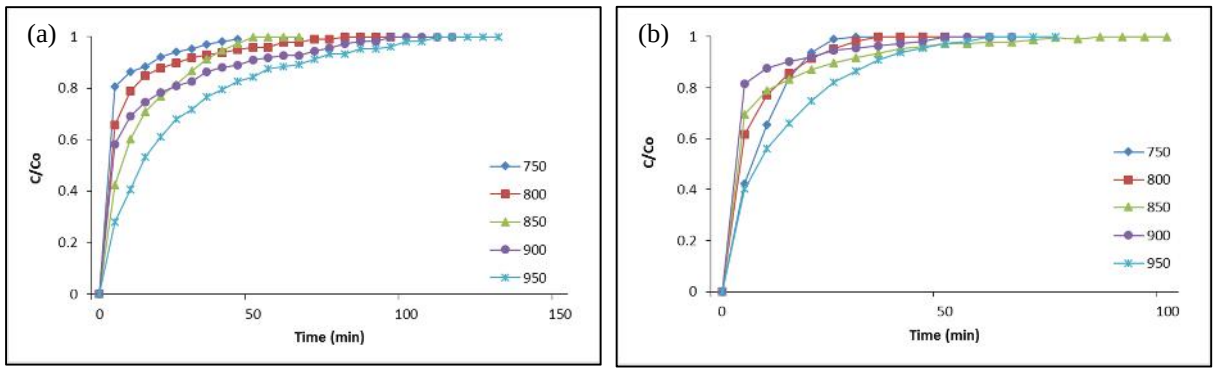

Figure 3. $SO_2$ breakthrough curve at different temperature for egg shell at (a) 2 hours and (b) 4 hours of calcination

Furthermore, it was noticed that further increase in time as shown in Figure 2(b), decreased the removal efficiency and saturation time. This could be due to overheating of the sample. Hu et al. reported that sintering of limestone particle could be the main reason. Limestone particles lost partly their reactivity after a heat treatment at 1123 K. The loss of the reactivity was also dependent on the duration of heat treatment, whereby a longer heat treatment will cause a greater loss of reactivity [16]. Sintering effect can be proven using the surface area data in Table 1. It is clearly seen that the surface area of calcined CCC at higher temperature was lower compared to the best removal sample. The best sample for 4 h of calcination was found to be at 800 °C for CCC. This further proves that increase in time and temperature at certain condition discourages $SO_2$ adsorption by CCC due to the reasons given above.

Table 1. Surface area of CCC, calcined ES and calcined CCC

| Sample | BET Surface Area ($m^2/g$) | CaO Crystallite Size (nm) | Adsorption Capacity (mg/g) |
|---|---|---|---|
| CCC | 1.12 | - | - |
| Eggshell | 0.56 | - | - |
| Calcined CCC – 900-2h | 9.51 | 3.29 | 3.95 |
| Calcined ES – 950-2h | 6.54 | 2.95 | 2.15 |
| Calcined CCC – 900-4h | 7.98 | 3.56 | 3.16 |
| Calcined ES - 950-4h | 4.25 | 3.07 | 1.19 |

A similar trend was observed for calcined ES. It was noticed that the longest saturation time (110 minutes) was achieved at temperature 950 °C and 2 hours of calcination for ES. The adsorption capacity of this sample was calculated as 2.15 mg/g. Overall, it was observed that 4 h of ES calcination, did not improve the saturation time for $SO_2$ removal. Moreover, all adsorbents were not capable of removing 100% $SO_2$, as after a few seconds the $SO_2$ concentration started to increase immediately. The figures did not show any significant breakthrough point. These results most likely reflect the fact that the specific surface area of the adsorbents was low. This can be further proven from the surface area data shown in Table 1. All adsorbents have surface area of less than 10 $m^2/g$. It was reported in the literature that most calcium-based materials have low sorption capacity due to low surface area [17-18].

Figure 4 shows XRD patterns of the best calcined CCC (a) and calcined ES (b). X-ray diffraction pattern of ES and CCC shows 2θ values of CaO at 32.4 and 37.6 when the eggshell was calcined at 950 °C for 2 hours (Figure 4b) and CCC was calcined at 900 °C for 2 hours (Figure 4a) which was indexed to JCPDS 82-1690. Similar peaks were also observed by Piker et al. and Joshi et al. [15,19]. XRD pattern of the calcined CCC (Figure 4a) appeared at almost at the same $2\theta$ angles as that of the calcined ES. However, the peaks intensities of the calcined CCC were higher than those of the ES, suggesting that the CaO crystalline size of CCC was larger than that of the calcined ES. The CaO crystallite size calculated by using Scherrer equation is listed in Table 1. It was denoted that the best sample of calcined CCC generated CaO with a crystalline size of 3.29 nm while ES showed a much lower degree of crystallinity with the size of 2.95 nm for the its best performed sample. This could be also another reason for the poor performance of calcined ES compared to calcined CCC. It had been reported that the commercially available CaO has a larger crystalline size compared to calcined eggshell by other researchers as well [17].

FTIR spectra of the best calcined adsorbent prepared by ES and CCC were analyzed to identify chemical constituents in a compound. Figure 5 shows the functional group peaks of the samples and it was observed that both samples have similar peaks. Two well-defined infrared bands were noticed at about 1424 and 875 $cm^{-1}$. They are characteristics of the C–O stretching and bending modes of calcium carbonate, respectively [17]. Gergely et al. suggested that the OH stretching vibration band at 3639 $cm^{-1}$ is probably related to Ca–O bonds [20]. Furthermore, Joshi et al. suggested that normally stretching vibration associated to water molecule in uncalcined ES is a broad band around 3432 $cm^{-1}$. However, for calcined ES a sharp absorption band appeared at 3640 $cm^{-1}$ suggesting reaction of CaO with OH [15].

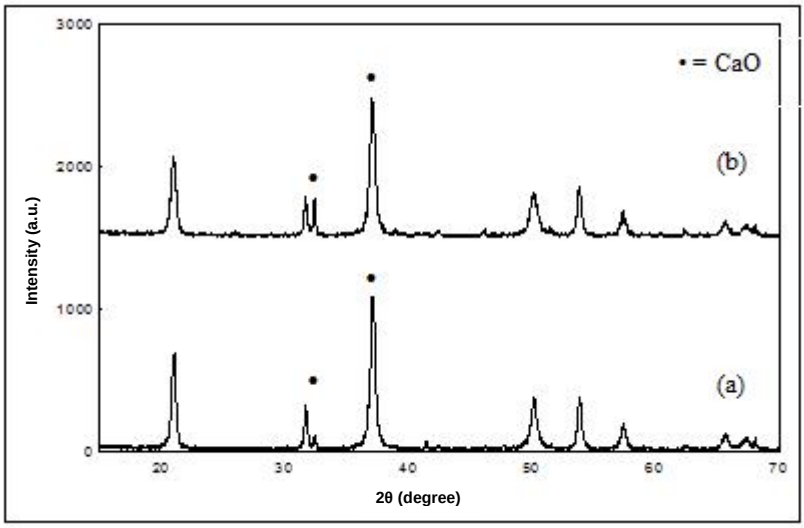

Figure 4. XRD patterns of (a) calcined CCC (900 - 2h) and (b) calcined ES (950 – 2h)

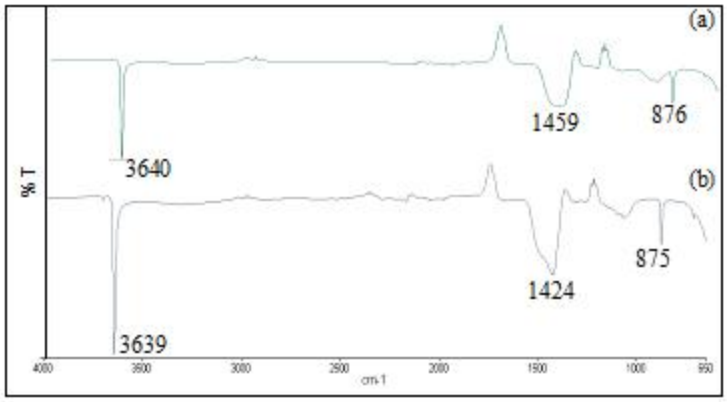

Figure 5. FTIR spectra of (a) calcined CCC (900 - 2h) and (b) calcined ES (950 – 2h)

Joshi et al. reported that peaks at 1424 $cm^{-1}$ and 1459 $cm^{-1}$ were broad and weak identifying reduced mass of the group $CO_3^{2-}$ upon calcination at 900 °C. The trend is identical for this study, suggesting the samples have been transformed to CaO [15]. However, samples were not fully calcined. In order to further understand the main reason for the poorer adsorption capacity by ES comparatively to CCC even though the composition and level of calcination is alike, a detailed study on using XRF and EDX should be done. Impurities may exist in ES which causes a poorer adsorption.

## Conclusion

The purpose of this study is to reutilize waste eggshell into an economic valuable product. The feasibility of ES to substitute limestone a depleting natural resource in flue gas desulphurization was tested. Results proved that ES can be used as a substitute of limestone for $SO_2$ removal. However, the capacity of removal was not as good as CCC. Even though the removal capacity was lower, the potential of ES to remove $SO_2$ was encouraging. The structure, surface area and functional groups of ES were also found to be like CCC. The most efficient calcined ES was found at 950°C for 2h. The adsorption capacity of the best calcined ES was 2.15mg/g. The surface area and crystallinity of the ES plays the major role in the adsorption of $SO_2$. This finding indicates that the CaO derived from the waste ES

is attractive for the use as $SO_2$ sorbent due to its low cost (derived from waste), environmentally friendly and high removal capacity of $SO_2$.

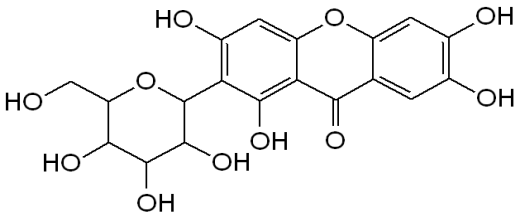
**Abstract**

*Mahkota Dewa* (*Phaleria macrocarpa)* is a popular herbal plant that is indigenous to Indonesia and Malaysia. The bioactive ingredients in the plant contain antihistamine, antioxidant, and anti-cancer compound. In this work, experimental study was performed using subcritical water extraction (SWE) method to extract bioactive compound namely mangiferin from *Mahkota Dewa* fruits. A sequential screening strategy using one-factor-at-a-time (OFAT) was carried out at different solid to solvent ratios (30 – 70 g/L), temperatures (50 – 150 °C) and extraction times (3 – 7 hours). The yield of mangiferin extracted was measured using high performance liquid chromatography (HPLC). The results show that the solid to solvent ratio, extraction temperature and time cause significant effect on the mangiferin yield. The best operating conditions for extracting *Mahkota Dewa* fruit with subcritical method is 60 g/L solid to solvent ratio and 100°C extraction temperature for 5 hours with mangiferin yield of 3.202% w/w.

**Keywords**: *Mahkota Dewa*, subcritical water extraction, mangiferin, one factor at a time

**Abstrak**

*Mahkota Dewa* (*Phaleria macrocarpa*) adalah tumbuhan herba yang popular berasal dari Indonesia dan Malaysia. Bahan bioaktif yang boleh didapati dalam ekstrak tumbuhan ini adalah seperti antihistamin, antioksidan, dan juga anti-kanser. Dalam kerja penyelidikan ini, satu eksperimen telah dijalankan dengan menggunakan proses pengekstrakan air subgenting (SWE), untuk mengekstrak bahan bioaktif daripada buah *Mahkota Dewa* iaitu mangiferin. Proses saringan secara berturutan dengan menggunakan kaedah satu-faktor-pada-satu-masa (OFAT) telah dijalankan pada pelbagai nisbah pepejal kepada pelarut (30 – 70 g/L), suhu (50 – 150 °C) dan masa pengekstrakan (3 – 7 jam). Hasil ekstrak mangiferin dianalisis dengan menggunakan kaedah kromatografi cecair berprestasi tinggi (HPLC). Hasil analisa menunjukkan bahawa nisbah pepejal kepada pelarut, suhu pengekstrakan dan masa memberi kesan yang besar ke atas hasil ekstrak mangiferin itu. Parameter eksperimen yang terbaik untuk mengekstrak buah *Mahkota Dewa* dengan menggunakan kaedah subgenting adalah pada nisbah pepejal kepada pelarut 60 g/L dan suhu ekstrak pada 100 °C selama 5 jam dengan hasil ekstrak mangiferin sebanyak 3.202% w/w.



**Kata kunci:** *Mahkota Dewa*, pengekstrakan air subgenting, mangiferin, satu faktor pada satu masa

## Introduction

In Malaysia, more than 2000 plant species exist possess healing properties and extensive potential to be commercialized. *Phaleria macropcarpa* or else known as *Mahkota Dewa* is one of typical herbal plants that are highly in demand nowadays. *Mahkota Dewa* is an Indonesia plant of *Thymelaceae* family that grow in the topical areas of Papua Island [1,2]. Though originated from Indonesia, due to the resemblance of climate, *Mahkota Dewa* can be easily cultivated and discovered in Malaysia. *Mahkota Dewa* as illustrated in Figure 1(a) is a complete tree with stem, leaves, flowers, and also fruits. Normal height for *Mahkota Dewa* tree ranges from 1 to 6 m with productive age ranges from 10 to 20 years [1,3,4]. Its leaves are green and elongated with the length and width ranging from 7 to 10 cm and 3 to 5 cm, respectively. Fruits of *Mahkota Dewa*, as illustrated in Figure 1 (a), are green when unripe and turn to red once ripening. It's brown and anatropous seed exist as 1 to 2 seed per fruit [3]. *Mahkota Dewa* fruits contain ranges of chemical constituents include saponin, flavoid, polyphenol, alkaloid and mangiferin [3,5].

(a)

(b)

Figure 1. (a) *Mahkota Dewa* (*Phaleria macrocarpa*) fruits and (b) molecular structure of Mangiferin

Among the bioactive compounds, mangiferin as illustrated in Figure 1(b), has an extensive range of pharmacological effects including anti-inflammation, antioxidant, anti-diabetic, anti-tumor and also anticancer activity [5–7]. Mangiferin ($C_{19}H_{18}O_{11}$) is reported as a heat stable molecule and it's natural pharmacological active compound has been proven to have various biological benefits [8]. Despite its beneficial bioactive effect, only few researches [5,9] reported the extraction of bioactive compounds from *Mahkota Dewa* using conventional extraction method. Considering the benefits of the plant extraction, it is necessary to explore other alternative method to extract the bioactive compounds.

Extraction method can be further divided into two, which is a conventional and non-conventional method. Conventional techniques is a classical existing techniques based on the extracting power of different solvents in use and also the application of heat and/or mixing towards the target plant [10]. It can be further classified into hydrodistillation, maceration and soxhlet extraction. This technique are still being practiced as a comparison technique to non-conventional methods [10,11]. Non-conventional such as microwave assisted extraction (MAE), ultrasound-assisted extraction (UAE) and subcritical water extraction (SWE) methods are reported to have more advantages compared to the conventional techniques [10,12,13]. These includes environmental friendly and cost efficient due to less usage of synthetic and organic chemical, short operational time, higher yield and good extract quality [10,12–14].

Previous work demonstrates the usage of organic solvent like methanol and ethanol as extraction solvent [15, 16]. Due to long extraction time, low extraction yield, and residual toxic problem, the urge to develop new non-organic solvent-based extraction methods with higher extraction efficiency is needed. Subcritical water extraction (SWE) implements use of green solvent such as water and it is well known as environmental-friendly and non-toxic solvent. Water demonstrates exceptional properties as it has high boiling point for its mass, high polarity and high

dielectric constant [17,18]. SWE promote shorter extraction time, higher quality of extract and lower extraction cost at temperature between 100 °C to 374 °C. By increasing the temperature at moderate pressure, it reduces the surface tension and viscosity, and increasing its diffusion rate causes SWE is comparable to organic solvents [17,19].

Recently, it has been reported that extraction efficiency of triterpenes from dry loquat leaves using SWE method produced yield of 1.7 times higher than those obtained using traditional methods which was soxhlet extraction (SE) [18]. The aim of this research work was to demonstrate the extraction of mangiferin from *Mahkota Dewa* using subcritical water extraction approach. The effect of solid to solvent ratio, temperature, and time on extraction yields of mangiferin was investigated. The results obtained would be useful as alternative experimental design to extract and analysis plant material, for further analysis in form of making the process more efficient and to increase the process economy.

## Materials and Methods

### Materials

Dried *Mahkota Dewa (Phaleria macrocarpa)* fruits were supplied by Ethno Resources Malaysia Sdn. Bhd. (Petaling jaya, Malaysia). *Mahkota Dewa* provided were planted in Selangor, Malaysia. The dried *Mahkota Dewa* was ground with Ultra Centrifugal Mill ZM 200 (Haan, German) to an average size of 500 µm. HPLC grade methanol (99.9% purity) and ortho-phosphoric acid (85% purity) purchased from Permula Chemicals Sdn. Bhd (Kuantan, Malaysia). Mangiferin (1S-1,5-Anhydro-1-(1,3,6,7-tetrahydroxy-9-oxo-9H-xanthen-2-yl)-D-glucitol) standard and 2,2-diphenyl-1-picrylhydrazyl (DPPH) were purchased from Merck (Selangor, Malaysia). All chemicals were used without further purification. Deionized water was prepared using a Milli-Q, Ultrapure Water Purification System (Massachusetts, USA) with a 0.22 mm filter. The 0.2 µm nylon membrane filter and 0.45 µm nylon syringe filter used in sample preparation prior to HPLC analysis were supplied by MHY Energy Resources (Kuantan, Malaysia).

### Subcritical water extraction

A classical approach one-factor-at-a-time (OFAT) was used to determine the optimum range of the selected process parameters during the SWE process. Through this technique, one level of the factor to be investigated was changed over the desired range and at the same time keeping the level of other factors constant [20]. SWE experiments were performed in a 10 cm (W) x 20 cm (H) stainless steel batch Buchiglasuster Kiloclave laboratory pressure vessel reactor system (Uster, Switzerland) as illustrated in Figure 2. The vessel can be operated within temperature range of -20 °C to 250 °C and can hold up sample up to 2 L. This multipurpose pressure reactor is made up from stainless steel and designed for the use of large steel pressure vessel.

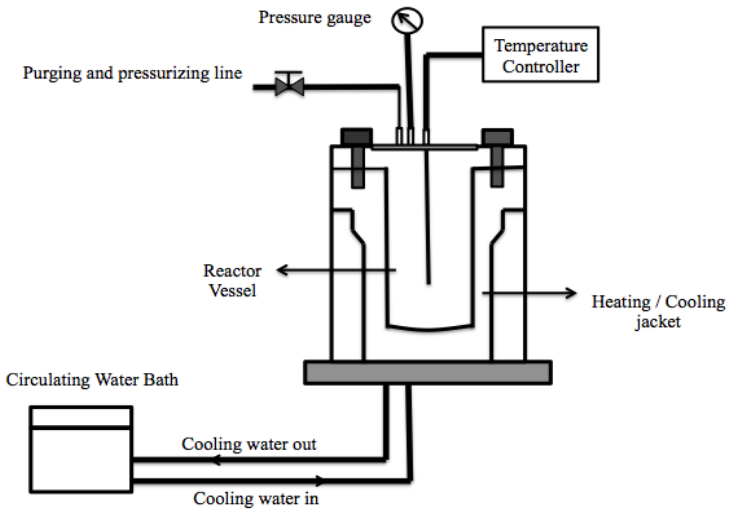


Figure 2. Schematic diagram of Buchiglasuster Kiloclave laboratory reactor system

Process parameters studied were solid to solvent ratio, temperature and extraction time. Summaries of the parameters investigated at different levels are tabulated in Table 1. Dry ground *Mahkota Dewa* fruit sample weighed and placed into the extraction vessel. Exact volume of deionized water (1 L) was added as extraction solvents and mixed thoroughly. Reactor was tightly closed and secured with bolts and nuts. Temperature and time were set at desired value. Once extraction was completed, vessel was allowed to cool to room temperature, 24 °C. Cooling water was supplied using Stuart recirculating cooler RE300RC (Staffordshire, UK). Extract was collected by loosing the nut and bolt of the reactor and then poured into a sample bottle. About 40 mL of the extract was then poured into the centrifuge tube and centrifuged for 30 min at 5000 rpm and the rest of the extract stored in -20 °C refrigerator. Extract supernatant isolated from precipitate and sonicated for 10 minutes to evenly disperse the particle in water. During the sonication, 10 ml of sonicated extract collected then diluted with 20 mL of methanol by using syringes. Mixtures filtered using 0.45 μm nylon syringe filter into Agilent MS analyzed vial kits (California, USA) and analysed using HPLC. All the experiments performed in triplicates.

Table 1. Summary of process parameters for OFAT

| Parameters | Experimental Conditions | Fixed Parameters |
|---|---|---|
| Solid to solvent ratio (g/L) | 30, 40, 50, 60 and 70 | Temperature - 100 °C<br>Time - 5 h |
| Temperature (°C) | 50, 75, 100, 125 and 150 | Solid to solvent ratio - 6:100 g/L<br>Time - 5 h |
| Time (h) | 3, 4, 5, 6 and 7 | Solid to solvent ratio - 6:100 g/L<br>Temperature - 100 °C |

**High performance liquid chromatography analysis**

Chemical compound in *Mahkota Dewa* was determined using HPLC (Agilent Technologies 1100, California, USA). Column used was Zorbax Eclipse Plus C18, Analytical 4.6 X 250 mm, 5 Micron (Agilent Technologies, California, USA). Detection was performed using a diode array detector (DAD). The chromatographic separation was performed at a wavelength of 258 nm. Mobile phase comprises of HPLC grade methanol and 0.1% aqueous phosphoric acid with a ratio of 31:69 and filtered with 0.2 μm nylon membrane filter prior to analysis. Mobile phase flow rate was set at 1.0 mL/min with amount of sample injection of 10 μL. HPLC unit was calibrated with mangiferin standard solution prepared prior to each analysis at different concentrations. Standard solution was prepared by diluting 5.0 mg of mangiferin standard with 10 mL methanol to produced 500 ppm of concentration [5]. This mixture was then diluted into several concentrations (5 to 60 ppm) and was used to construct a calibration curve. HPLC chromatogram of mangiferin standard and *Mahkota Dewa* extract are shown in Figure 3. The relationship between peak area, $x$ and concentration of mangiferin, $y$ can be represented by a linear equation as follows:

$$y = 15.806x \ (R^2 = 0.99482) \quad (1)$$

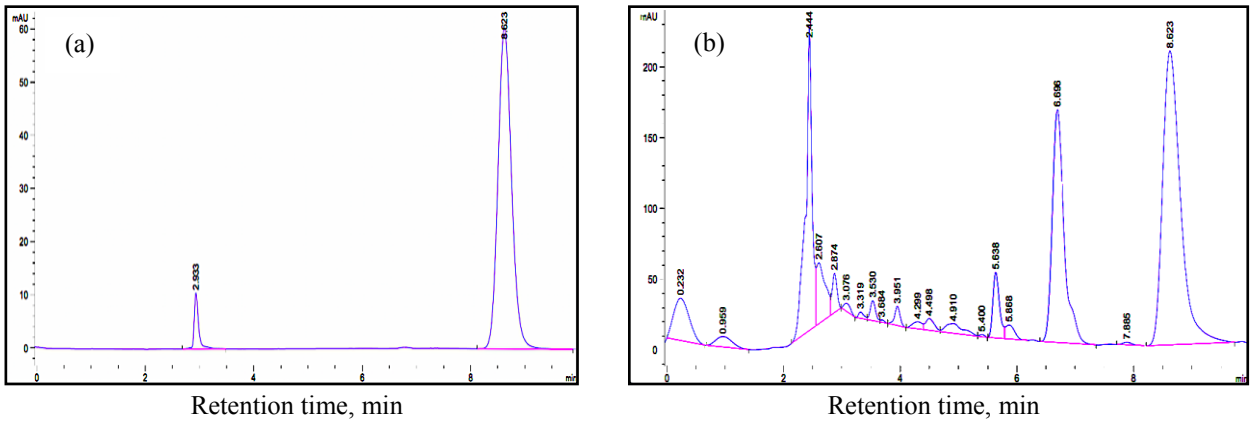

Figure 3. HPLC chromatogram of (a) mangiferin standard and (b) *Mahkota Dewa* extract. The peak at retention time of of 8.623 min was used to estimate the mangiferin yield

## Results and Discussion

### The effect of solid to solvent ratio

The results show that among solid to solvent ratio tested, 60 g/L was most effective. Figure 4 shows the effect of solid to solvent ratio on the mangiferin yield. Mangiferin yield was increased from 0.962% w/w to 1.8718% w/w at solid to solvent ratio of 30 to 60 g/L. However, the mangiferin yield was reduced to 1.524% w/w at the solid to solvent ratio of 70 g/L. The removal of solute require a lot of energy using water as solvent, consequently if more water used in an extraction, it may lead to higher energy consumption [21]. In general, the higher the amount of solid in a solvent would reflect the higher amount extraction yield. This statement is in agreement with the mass transfer principle, where its driving force depends on the concentration gradient between solute and the solvent [22,23]. High solid to solvent ratio produce high concentration gradient, thus cause an increase of diffusion rate, which allows greater extraction of solute by solvent [11,12]. The decrease of mangiferin yield beyond solid to solvent ratio of 60 g/L is probably due to low extraction efficiency, where the solvent was not sufficient enough to dissolve the solute and the equilibrium of solute and solvent was achieved [11]. Equilibrium of solute and solvent defined as a condition where no further changes in either phase will occur for the solid and solvent phases [17,24–26]. Smaller volumes of solvent can lead to incomplete target extraction while larger volumes can make the extraction procedure becomes complex and wasteful. This findings is in agreement with Zhang et al. [27] which stated that the chance of bioactive components come into contact with the extracting solvent is increase with the increase amount of solute and will not continue to increase once equilibrium is reached.

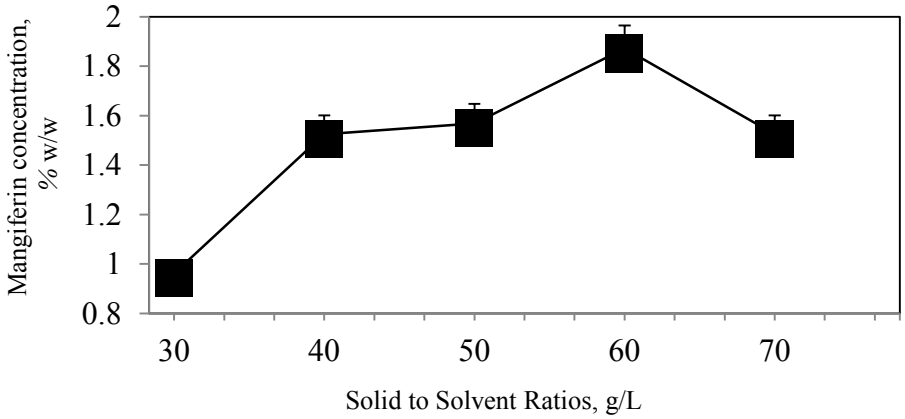

Figure 4. Effects of different solid to solvent ratio on mangiferin yield. The extraction temperature and time were fixed at 100 °C and 5 hours, respectively. Values are mean ± standard deviations

**The effect of temperature**

Figure 5 illustrates the effect of extraction temperatures on the mangiferin yield. It can be seen that the yield of mangiferin increase with the increase of temperature from 50 °C up to 100 °C. The highest mangiferin yield (2.405% w/w) was obtained at extraction temperature of 100 °C. At temperature of 125 °C and 150 °C, a slight decreased of mangiferin yield was observed with the yield of 1.827% w/w and 1.435% w/w, respectively. Both the equilibrium (solubility) and mass transfer rate (diffusion coefficient) can affect the extraction temperature and high temperature is often associated with the increase rate of diffusivity and solubilization of solute but decrease in the viscosity and surface tension of solvent. In theory, the penetrability and solubility of the solvents increased with the increase of the temperature, thus resulting in an increased of extraction efficiency and speed. Increase in yield with respect to increasing temperature is attributed to thermal kinetics of mass transfer and the thermodynamic effect of temperature on solubilization [21]. Therefore, extraction process that performed at high temperature often shows an increment in yield. According to Gbashi et al. [19], it is recommended to extract at the high permitted temperature since low temperature result in low diffusivity and consequently low extraction yield [18–20]. Consistent with previous works yield decreases as operating temperature exceeds 100 °C [21, 30]. The main disadvantage of applying higher temperature is the increase of the solvent boil off and reducing effective contact area between solid and liquid phases. As a result, lower yield of the final extracts [21]. This extraction process aiming to extract mangiferin compound and water temperature does not necessarily have to be high as possible, all of the parameter should be optimized and carefully controlled [31]. It is suggested that the best operational temperature that yield highest amount of mangiferin was at 100 °C with extraction yield of 2.405% w/w.

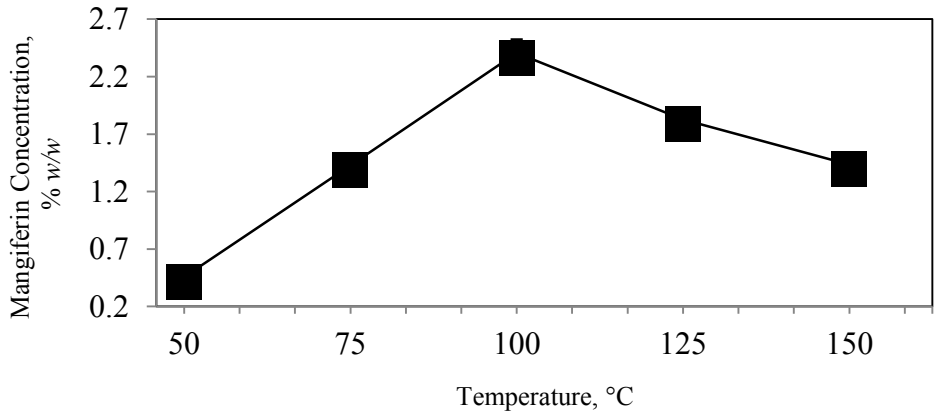

Figure 5. Effects of different temperature on mangiferin yield. The extraction solid to solvent ratio and time were fixed at 60 g/L and 5 h, respectively. Values are mean ± standard deviations

**The effect of time**

The extraction process was carried out at different times with fixed solid to solvent ratio of 60 g/L and temperature of 100 °C. The results illustrated in Figure 6 show a significant increment of extraction yield from extraction time of 3 hours (2.506% w/w) to extraction time of 5 hours (3.202% w/w). Further increase of the extraction time, which is from 6 to 7 hours reduced the mangiferin yield to 2.631% w/w. It is essential to determine the duration of the extraction process required to extract most of the desired bioactive compounds. Under static extraction, equilibrium among the sample components was still bound to the matrix and the water phase, in which the components are already solubilized, might be reached [28,29]. By using this information, suitable duration can be selected and operating cost for the process can be reduced [21]. Based on the result, the efficiency of the extraction time was not increase within 5 hours of extraction and since most bioactive compounds are sensitive to elevated temperature, keeping them for a longer period would lead to the thermal decomposition of the bioactive compounds. For this reason, best extraction time for subcritical water extraction of *Mahkota Dewa* is 5 hours with yield of 3.202% w/w

of mangiferin. This results as further support the finding reported by Tunchaiyaphum et al. [29] and Kim et al. [5] who found that the degradation of extracted compound at prolonged extraction time.

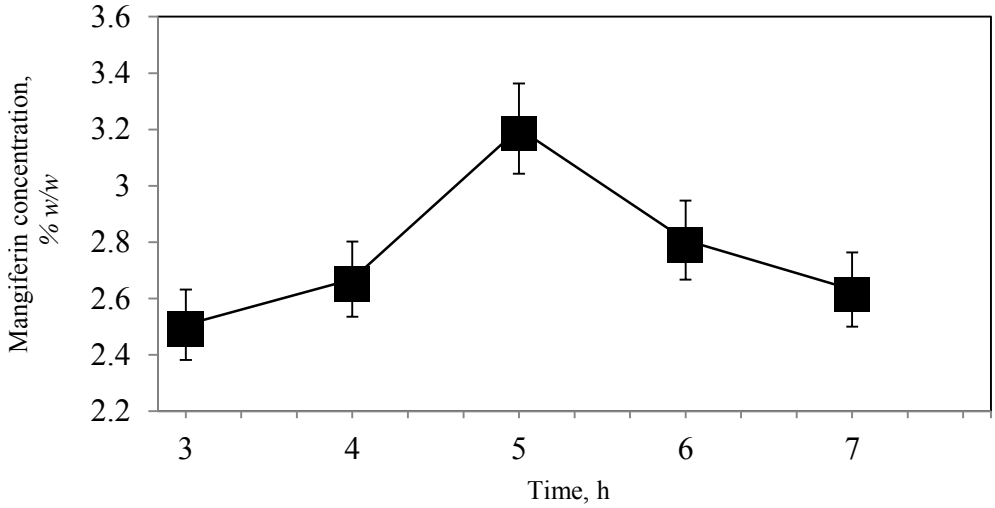

Figure 6. Effects of different time on mangiferin yield. The extraction solid to solvent ratio and temperature were fixed at 60 g/L and 100 °C, respectively. Values are mean ± standard deviations

## Conclusion

The effect of process parameters in extracting mangiferin from *Mahkota Dewa* fruits, i.e., solid to solvent ratio, extraction temperature, and time on a subcritical water extraction (SWE) batch extraction of have been investigated. In general, solid to solvent ratio, extraction temperature, and extraction time was found to show significant effect on the amount of mangiferin extracted from *Mahkota Dewa* fruits. The increased of the solid to solvent ratio, extraction temperature, and extraction time up to certain extent, increased the mangiferin yield. The best operating parameters that produced the highest mangiferin yield of 3.202% w/w) were at 60 g/L of solid to solvent ratios, extraction temperature of 100 °C and extraction time of 5 hours.

**Abstract**

This research aims to investigate the optimum condition of oil extraction method to extract maximum oil yield from freshwater microalgae *Chlorella vulgaris*. The modified soxhlet extraction method was used to identify the best solvent systems which are heptane, heptane: methanol (1:1), heptane: methanol (1:2), heptane: ethanol (1:1) and heptane: ethanol (1:2) for extracting the microalgae oil. The effect of different mixing rate (rpm), temperature ($^oC$) and extraction time (hours) were carried out using the optimized solvent system to evaluate the optimum condition of oil extraction. Based on the yield of oil extraction, heptane alone become the best solvent to extract the oil with the yield of 57.5%, followed by heptane: methanol (1:2), heptane: ethanol (1:1), heptane: ethanol (1:2) and heptane: methanol (1:1) with the yield of 47.5%, 44.8%, 43.2% and 41.4%, respectively. Maximum oil quantity of 61.27% was obtained after extracted the *Chlorella vulgaris* biomass using heptane as a solvent at the following optimal conditions: mixing rate of 600 rpm, temperature of 65 °C and extraction time of 5 hours. This study confirmed that an increasing temperature resulted in the increased of oil yield, but at higher temperature (greater than 65 °C), the oil yield was decreasing. Too high of temperature in oil extraction may cause partial decomposition of the microalgae cells and thus lowering the yield of oil extracted.

**Abstrak**

Kajian ini bertujuan untuk mengkaji keadaan optimum bagi kaedah pengekstrakan minyak dalam usaha untuk mendapatkan hasil minyak maksimum daripada mikroalga air tawar *Chlorella vulgaris*. Kaedah pengekstrakan soxhlet yang diubah suai digunakan untuk mengenal pasti sistem pelarut yang terbaik iaitu heptana, heptana: metanol (1:1), heptana: metanol (1:2), heptana: etanol (1:1) dan heptana: etanol (1:2) untuk mengekstrak minyak mikroalga. Kesan daripada kadar pencampuran yang berbeza (rpm), suhu ($^oC$) dan masa pengekstrakan (jam) telah dijalankan dengan menggunakan sistem pelarut yang telah dioptimumkan untuk menilai keadaan optimum pengekstrakan minyak. Berdasarkan hasil pengeluaran minyak, heptana bersendirian menjadi pelarut terbaik untuk mengeluarkan minyak dengan hasil sebanyak 57.5%, diikuti oleh heptana: metanol (1:2), heptana: etanol (1:1), heptana: etanol (1:2) dan heptana: metanol (1:1) dengan hasil masing – masing 47.5%, 44.8%, 43.2% dan 41.4%. Kuantiti minyak maksimum 61.27% telah diperolehi selepas biojisim *Chlorella vulgaris* diekstrak menggunakan heptana sebagai pelarut pada keadaan optimum berikut: kadar percampuran 600 rpm, suhu 65 $^oC$ dan 5 jam masa pengekstrakan. Kajian ini mengesahkan bahawa suhu meningkat menyebabkan peningkatan hasil minyak, tetapi pada suhu yang lebih tinggi (lebih daripada 65 $^oC$), hasil minyak telah berkurangan. Suhu yang terlalu tinggi dalam pengekstrakan minyak boleh menyebabkan penguraian sebahagian daripada sel-sel alga dan seterusnya mengurangkan hasil minyak yang dikeluarkan.

**Kata kunci:** pengekstrakan soxhlet, pengekstrakan minyak, mikroalga air tawar, *Chlorella vulgaris*, sistem pelarut

## Introduction

Limitations of fossil fuels have brought the studies of microalgae as the promising raw materials to produce biodiesel. Microalgae appear to be the source of biodiesel production because of the high growth rate without competing for arable land which makes algae an exciting raw material to the sustainable fuel portfolio [1]. Besides, it has the potential to produce more oil as compared to the other raw materials [2] such as rapeseed, soybean, sunflower and palm. Moreover, microalgae biodiesel are non-toxic, highly bio-degradable; contain no sulphur and the left over materials after extracting the oil can be used for ethanol production or as soil fertilizer [3]. In addition, renewable biodiesel produce from microalgae is capable of meeting the global demand for transport fuels and oil productivity of microalgae greatly exceeds the oil productivity of the best producing oil crops such as corns.

Chisti [4] reported that *Chlorella* sp., *Spirulina* sp. and *Nitzschia* sp. are the main microalgae sources that are usually used to produce biodiesel. It is because these three microalgae species produce the highest oil content (% dry weight) among the other species with 28-32% oil content produced by *Chlorella* sp., *Spirulina* sp. produce 50 – 77% oil content and *Nitzschia* sp. produce about 45 – 47% oil content. According to Islam et al. [5], microalgae have received much attention as a new source of renewable energy in the form of biodiesel. However, they are not yet commercially viable because of the high cost of the production process and also limited information available on the parameters affecting extraction of microalgae oil for commercial biodiesel production. For this reason, a vigorous quantification of the extraction parameters is critical to optimize and consequently increase the feasibility of the process.

Oil extraction from algae is a hotly debated topic currently because this process is one of the more costly processes which can determine sustainability of algae-based biodiesel. Various methods to extract the oil from microalgae are available such as expeller/press, solvent extraction and supercritical fluid extraction [2]. Expeller pressing is the method of extracting oil with a mechanical press rather than utilizing a chemical extraction process and this method provides yields of only 65 – 70% of the oil [6] while extraction using supercritical fluid gives very high purity and good product concentration but the operating and investment cost is high [7].

Solvent extraction method is a common and efficient technique for producing oil for biodiesel production since it is recovers almost all the oil and leaves behind only 0.5% to 0.7% residual oil in the raw material [8] and it is also involves the transfer of a soluble fraction from a solid material to a liquid solvent. In addition, this method has a relatively low operating cost compared with supercritical fluid extraction [9]. However, there are certain disadvantages for solvent extraction method such as poor extraction of polar lipids, long time required for extraction and hazards of boiling solvents [10].

In order to obtain maximum amount of oil extraction by using solvent extraction method, the optimum condition of extraction process for all parameters used in this study must be optimized. Therefore, the following objectives should be achieved in this investigation which are i) to investigate the oil extraction of microalgae biomass using five different solvent systems and ii) to assess the efficiency of solvent extraction method with the use of three different parameters such as mixing rate, temperature and extraction time to obtain maximum oil extraction.

## Materials and Methods

### Microalgae

The microalgae *Chlorella vulgaris* was used in this research. A microalgal strain *C. vulgaris* was obtained from Culture Collection of Algae and protozoa (CCAP). *C. vulgaris* appears to be the best choice and the most suitable algae species for producing biodiesel [11]. It is one of the most attractive microalgae species for oil extraction owing to its fast growth and easy cultivation [12]. Besides, the strain became the most favored by researchers [13] since it have a high lipids content and easily growth in the laboratory.

### Media preparation

The unicellular microalgae *C. vulgaris* were actually cultured in Bold's Basal Medium with 3-fold nitrogen and vitamins (BBM) by adding 20 mL of (BBM) (I), 12 mL of BBM (II), and 2 mL each of BBM (III) and BBM (IV) to 2000 mL sterilized distilled water (DW). BBM (I) contain the following compounds per 1 L of DW: 75.0 g of $NaNO_3$, 2.5 g of $CaCl_2.2H_2O$, 7.5 g of $MgSO_4.7H_2O$, 7.5 g of $K_2HPO_4.3H_2O$, 17.5 g of $KH_2PO_4$ and 2.5 g of NaCl,

BBM (II) contained the following compounds per litre of DW: 97.0 mg of $FeCl_3.6H_2O$, 41.0 mg of $MnCl_2.4H_2O$, 5.0 mg of $ZnCl_2$, 2.0 mg of $CoCl_2.6H_2O$ and 4.0 mg of $Na_2MoO_4.2H_2O$, BBM (III) contains 0.12 g of vitamin $B_1$ (Thiaminhydrochloride) per 100 mL DW and BBM (IV) consists of 0.1 g of vitamin $B_{12}$ (Cyanocobalamin) per 100 mL DW.

**Preparation of *Chlorella vulgaris* culture**
The process had been done by using aseptic technique to avoid any contamination towards microalgae and media. The medium and flasks were sterilized in an autoclave, HV-85 (HIRAYAMA, Japan) for 15 minutes at 121$^{o}$C. Approximately, 5 mL of microalgae stock culture was seeded into 2 L Schott bottle filled with 2 L of sterilized DW that contained BBM (I-IV) at 25 $^{0}$C. Two fluorescent lamps were used for continuous lighting and was cultured with continuously aerated for 12 days by bubbling air through it at a constant pressure [13].

**Microalgae harvesting**
The *C. vulgaris* cells were harvested using centrifuge model 5810 R (Eppendorf, Malaysia) at 8000 rpm for 10 minutes. After centrifugation, the clear solution had been discarded and the resulting *C. vulgaris* biomass was rinsed once with de-ionized water to remove residual nutrients [14].

**Microalgae freeze drying**
The extraction was performed on the dry biomass. Therefore, freeze dryer was used to dry the microalgae biomass before the oil extraction was took over. The biomass was dried overnight by using freeze dryer, RP2 V (SGD Serail Argenteuil, France) to measure the cell dry weight [15].

**Destruction of microalgae cells**
Freeze-dried samples of 0.05 g of *C. vulgaris* biomass along with 16.6 mL DW were placed into 250 mL of round bottom flask and then sonicated for 5 minutes to lyse the cells [15].

**Oil extraction**
Solvent extraction method by using modified Soxhlet extraction (SE) was used in the oil extraction process. Modified Soxhlet extraction set up mainly consist of the following apparatus: condenser, retort stand, hot plate stirrer, 1L beaker, tube and 250 mL round bottom flask. Approximately 27.2 mL of solvent systems was used for each 0.05 g of the freeze-dried microalgae biomass in extraction step. Five different solvent systems were used to extract the oil from the *C. vulgaris* biomass which are heptane, heptane: methanol (1:1), heptane: methanol (1:2), heptane: ethanol (1:1) and heptane: ethanol (1:2). The extraction took place about 5 hours to extract oil from microalgae. Magnetic stirrer was used to mix up the biomass with the solvent at mixing rate of 600 rpm and temperature of 65 $^{o}$C. After 5 hours of extraction, the mixture was then centrifuged at 4000 rpm for 2 minutes and resulted in separation into three layers [15]. The upper layer contains only water, while middle layer was biomass and lowest layer was oil-solvent mixture. The lowest layer was collected and evaporated using rotary evaporator model BUCHI Rotavapor R-200 to obtain the microalgae oil. After that, the extraction was executed in different parameters such as mixing rate, temperature and extraction time to enhance the oil yield from *C. vulgaris* biomass using the best solvent from previous result. The details of the experiment are summarized in Table 1.

Table 1. Manipulated and constant variables used in each extraction step

**Determination of oil extraction yield**

After extract the oil, the amount of oil extracted using different solvent systems and parameters was determined by using the following equation 1 [16]:

$$\text{oil extraction yield (\%)} = \frac{\text{weight of oil extraction (g)}}{\text{weight of microalgae biomass (g)}} \text{ x } 100\% \quad (1)$$

## Results and Discussion

**Effect of solvent systems on oil extraction**

The effect of solvent systems on microalgae oil extraction yield is shown in Table 2. The solvents used for the extraction of microalgae biomass showed the different yields. The highest oil extraction yield of 57.5% was achieved from *Chlorella vulgaris* biomass was heptane. Approximately 47.5% of oil extraction yield was achieved using heptane: methanol (1:2). Whereas the yield 44.8% was obtained using heptane: ethanol (1:1). The oil extraction yield for heptane: methanol (1:1) and heptane: ethanol (1:2) was found to be 41.4% and 43.2%, respectively.

Table 2. Effect of various solvent systems on oil extraction yield (%)

| Solvent/Solvent Mixture | Ratio | Oil Extraction (%) |
|---|---|---|
| Heptane | - | 57.5 ± 0.5 |
| Heptane: Methanol | 1 : 1 | 41.4 ± 0.5 |
| Heptane: Methanol | 1 : 2 | 47.5 ± 1.0 |
| Heptane: Ethanol | 1 : 1 | 44.8 ± 0.6 |
| Heptane: Ethanol | 1 : 2 | 43.2 ± 1.0 |

Figure 1 shows the percentage of oil yield obtained for different solvent systems. The extraction yield increase in the following order: H:M (1:1) < H:E (1:2) < H:E (1:1) < H:M (1:2) < H. Oil extraction by heptane alone is found to

be most effective than combination of solvent systems. This observation might be due to the other solvent's physical characteristic distracting the ability of heptane to extract the oil. Therefore, the combination of solvent system between heptane and alcohol are less effective to extract the oil compared to heptane alone.

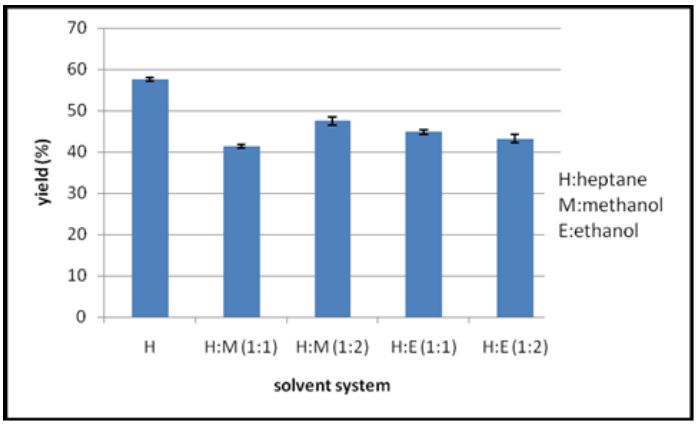

Figure 1. Oil extraction yield with different solvent systems

The selection of the solvent system for oil extraction is an important factor in order to produce the highest yield of oil. Basically, solvent system should have a higher solubility with oil to degrade the cell walls of the microalgae and also to dissolve the oil to enhance the oil yield. However, efficiency of oil extraction yield depends on polarity of the compound and solvent viscosity [17].

The selected solvents were come from two polarity-based classes: polar protic and non-polar. Polar protic solvents usually used to dissolve salt. Generally, these solvents have high dielectric constant and high polarity. The common characteristic of polar protic solvents is hydrogen bond containing hydroxyl group [17] for example water, low molecular weight alcohol such as methanol and ethanol, and the solution that have low molecular-weight carboxylic acid. While, non-polar solvents contain bonds between atoms with similar electronegativities [17] such as carbon and hydrogen. Similar electronegativities mean that small difference between atoms causing less polar bond, thus easier to extract the oil. Alkanes like hexane and heptane are example for this non-polar solvent [18].

Besides, solvent viscosity becomes one of the physical properties that affect the extractability of oil from microalgae. Low-viscosity solvents have a high diffusivity that allows them to easily diffuse into the microalgae biomass to leach out the oil [19].

Based on the research done by Conkerton et al. [20], heptane is the best alternative solvent to replace hexane since the physical properties of heptane is quite similar to hexane which is high stability, low greasy residual and low corrosiveness. Heptane also has a low viscosity and low polarity since it is non-polar group compared to the other solvents. Low viscosity and polarity gave a result of higher yield compare to the other solvent systems.

However, when the heptane is combine with other solvent to extract the oil, the yield of oil extraction become low. This observation is in contrast to the study of Ryckebosch et al. [21] which state that solvent mixture containing a polar and a non-polar solvent could extract a great amount of oil such as a combination of chloroform (non-polar) and methanol (polar). In addition, the result studied by Li et al. [22] also showed a significant difference in extraction efficiency between single and mixture solvent. The oil extraction yield in the mixture was nearly three times higher than when using single solvent.

Despite of these contradict results with Ryckebosch et al. [21] and Li et al. [22], experimental result obtained is similar with Shen et al, [23] where oil recovery was higher in the single solvent. A possible cause for the lower oil

recovery efficiency in mixture solvent may be that small quantities of oils are took over by polar solvent that cannot be extracted by heptane. Besides, the physical properties of solvent systems such as viscosity and polarity might be change due to the mechanism formed by two different solvents with microalgae cells. The combination of solvents may changes the polarity and viscosity of heptane that have an ability to extract the oil, thus may not help to extract the oil as much as heptane alone can extract. However, the combination of solvent systems between heptane and alcohol still can be used as long as it is implied at appropriate proportions of polar and non-polar solvents in order to achieve high oil extraction yields.

**Effect of mixing rate on oil extraction**

The effect of mixing rate on oil extraction is shown in Figure 2. The oil extraction yield in the range of 500 to 700 rpm was evaluated with constant temperature of 4 $^0$C and extraction time of 4 hours. The result obtained shows that the oil yield was increasing with the increase in the mixing rate. The oil extraction yield increased from 54.74% at 500 rpm to 57.86% at 600 rpm. However, at 700 rpm, there was no significant increase in the oil yield where 57.94% of oil can be extracted from *C. vulgaris*.

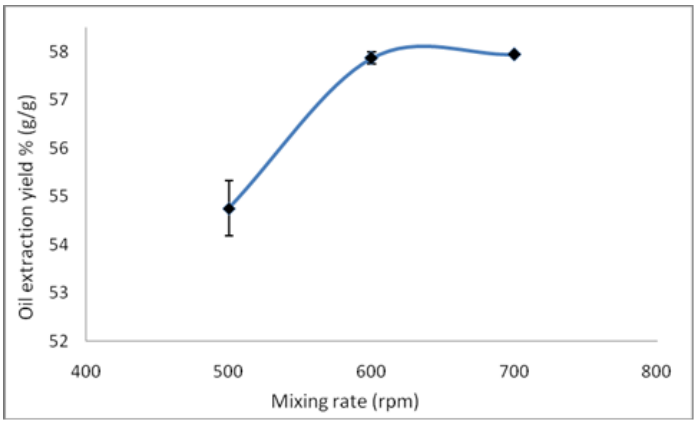

Figure 2. The effect of mixing rate on the oil extraction yield

Mixing rate of the extraction will affects the oil yield of *C. vulgaris*and it is proving by result obtained in Figure 2. Increasing mixing rate will increases the eddy diffusion and the transfer of oil from the slurry form of the microalgae biomass to the solvent mixture [24]. The increasing oil yield shows that the mass transfer plays major role during the extraction process. However, at 700 rpm, the oil yield becomes constant because the extraction has gone completion at 600 rpm and no further increase in oil extraction yield was observed. Thus, it can be concluded that the maximum oil yield was obtained at 600 rpm which is 57.86%.

Similar phenomenon was also found by Suganya and Renganathan [24] that studied the effect of mixing rate on oil extraction from *U. lactuca* using hexane as a solvent and solvent-to-ratio of 5:1. They have extracted oil from 7.81% to 9.36% with the use of mixing rate varying from 200 to 800 rpm. Maximum oil yield was achieved at 500 rpm which is 9.36%. Another research by Kadi and Fellag [25] indicated that the oil extraction from olive foot cake using hexane as a solvent have extracted oil from 6.9% to 7.7% with the use of mixing rate varying from 600 to 1000 rpm and the maximum yield was obtained at 800 rpm which is 7.7%. Even though the optimum mixing rate for both cases were achieved in the range of 500 to 800 rpm, the oil yield obtained from the previous researches is smaller which is between 7.7 to 9.36% compared to the current study (57.86%). The major differences in the oil yield obtained from previous studies and current study is due to the different extraction time used to extract oil from *U. lactuca*, olive foot cake and *C. vulgaris*. Oil yield obtained from *U. lactuca* and olive foot cake were studied for 120 minutes and 10 minutes only, while the extraction time used to obtain the oil yield from *C. vulgaris* is 4 hours which is longer than the extraction time used in previous studies and eventually more oil is extracted in longer extraction time.

**Effect of temperature on oil extraction**

The effect of temperature on the microalgae oil extraction was investigated over the range of 55 to 75 $^0$C from *C. vulgaris* biomass (Figure 3). The increase in temperature from 55 to 65 $^0$C leads to increase in the oil extraction yield from 47.29% to 56.92% while increasing the temperature from 65 $^0$C to 75 $^0$C resulted in decreasing the oil yield from 56.92% to 52.26%.

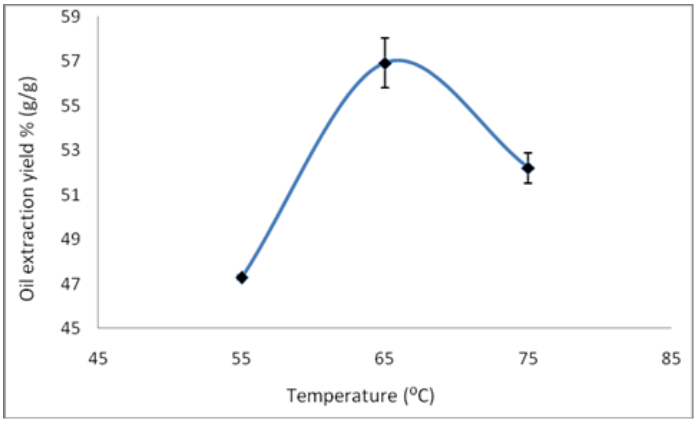

Figure 3. The effect of extraction temperature on the oil extraction yield

At the lower temperature (smaller than 65 $^0$C), the oil extraction yield was found to be increased with an increase in the temperature (Figure 2). This result is due to the enhanced in the dissolution capacity of the solvent system [24]. Moderate increase in temperature can lead to a large decrease in fluid density, with a consequent reduction in solute solubility and volatility which resulted in the increase of oil yield [26]. In addition, the increase in temperature will also accelerate the mass transfer and improve the oil extraction yield [27]. However, the result in Figure 3 shows a decrease in oil yield from temperature of 65 to 75$^0$C. High temperature will affect the solubility of interfering substances in the sample, resulting in lower selectivity of the extracts. Moreover, too high of an extraction temperature may cause partial decomposition of the extracted substances and thus disturb the result of the extracted lipids [28]. From the result obtained in Figure 3, it can be concluded that the maximum oil extraction yield was obtained at temperature of 65 $^0$C which is 56.92%. This result was also found in the study of the effect of temperature on the extraction yield of spearmint (*M. spicata L.*) leaves at 3 different temperature level of 40, 50 and 60 $^0$C [29]. The extraction yield of spearmint leaves increased with temperature and the highest extraction yield (60.57 mg/g) was obtained at 60 $^0$C.

**Effect of extraction time on oil extraction**

In this research, the effect of extraction time on the oil extraction yield of *C. vulgaris* was examined with different time intervals varying from 4 to 8 hours. The result obtained in Figure 4 shows that the oil extraction yield enhanced with the increase of extraction time. The extraction was settled at the optimum mixing rate and temperature from the previous experiment which is 600 rpm and 65 $^o$C, respectively. The oil yield was observed to be increased from 56.09% to 61.27% from 4 hours to 6 hours. However, at 8 hours, the oil yield did not show any significant changes in the extraction where 61.26% of oil can be extracted at that time. Hence, 6 hours was found to be an optimum extraction time for the oil extraction of *C. vulgaris* where the oil obtained is in the maximum yield (61.27%).

It is crucial to determine the optimum extraction time required for the extraction process. As the extraction time increases, the oil yield also increases. The increase in the oil yield is due to the increase of mass transfer of oil [24]. However, at 8 hours, the oil yield becomes constant because the extraction has gone completion at 6hours and no

further increase in oil extraction yield was observed. Thus, it can be concluded that the maximum oil yield was obtained at 6 hours which is 61.27%.

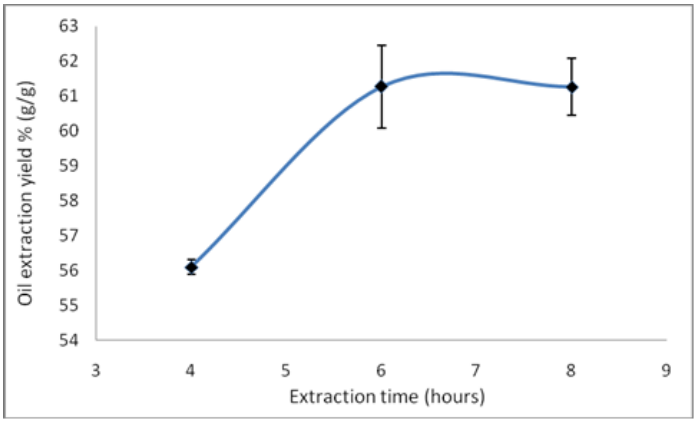

Figure 4. The effect of extraction time on the oil extraction yield

A similar pattern of oil yield produce also was made by McConnel and Farag [30] which studied the extraction of *C. vulgaris* using solvent to dry algae ratio of 30:1 at different time interval varying from 5 to 100 minutes. The optimum time was found to be 60 minutes for maximum production of oil at 2.60 g lipid extracted per 100 g of dry algae. At the extraction longer than 60 minutes, the oil yield obtained is constant. Another research by Suganya and Renganathan [24] was studied the effect of extraction time on the oil yield of *U. lactuca* at different time intervals varying from 20 to 160 min shows that at 140 minutes, the oil was found at the maximum yield which is 10.59% and at extraction time above 140 min did not show any further significant improvement in the extraction.

## Conclusion

The extraction of oil from *Chlorella vulgaris* biomass using heptane showed the highest result compared to the other solvent systems with the yield of 57.5%. By using heptane as solvent system, the maximum oil extraction yield of 61.27% was obtained with optimum conditions of mixing rate of 600 rpm, temperature of 65 $^{0}$C and 5 hours of extraction time from *C. vulgaris*. The result shows that the oil extraction yield increasing with the increase of mixing rate, temperature and extraction time. When the operating condition of the extraction process passes the optimum condition, the oil yield of *C. vulgaris* show no significant increases. The constant oil yield extracted is because the extraction has gone completion at that point. Extraction process should not be done at higher temperature to avoid the decomposition of the microalgae which will affect the result of oil yield obtained.

**Abstract**

In this research, the decolourisation performance of Reactive Red 120 (RR120) in aqueous solution using $O_3/S_2O_8^{2-}$ was evaluated. RR120 was selected due to high solubility in the aquatic environment. Ozonation ($O_3$) experiments were conducted as a control, to compare the treatment performance after addition of sodium persulphate. The aim of this research is to identify the effect of operational parameters of $O_3/S_2O_8^{2-}$ treatment on colour and COD removal. All experiments were carried out under continuous operation in a bubble column reactor. Operational parameters, namely initial dye concentration, $S_2O_8^{2-}$ dosage, initial pH, and contact time, were manipulated to optimize the performance of $O_3/S_2O_8^{2-}$. The effect of parameters on decolourisation performance was identified based on colour and COD removal. The performance of colour and COD removal in the $O_3$ was also compared with $O_3/S_2O_8^{2-}$ treatment processes. The intermediates were characterized based on its spectra evolution via UV-Vis spectrophotometer. The findings showed on increases in $S_2O_8^{2-}$ dosage that leads to an increase in the decolourisation efficiency. In addition, when the initial concentration increased to 300 mg/L, the decolourisation efficiency decreases as high concentration of azo bond cause the deficiency of the oxidation process. The $O_3/S_2O_8^{2-}$ performance also improved in alkaline pH, in the presence of hydroxyl radical. By comparing these two treatments, $O_3/S_2O_8^{2-}$ obtained better removal efficiency in colour than $O_3$.

**Keywords**: $O_3/S_2O_8^{2-}$, ozonation, decolourisation, Reactive Red 120, persulphate

**Abstrak**

Dalam kajian ini, prestasi penyingkiran warna $O_3/S_2O_8^{2-}$ dinilai terhadap Reactive Red 120 (RR120) dalam larutan akues. RR120 telah dipilih kerana keterlarutan tinggi dalam persekitaran akuatik. Eksperimen pengozonan ($O_3$) telah dijalankan sebagai kawalan, untuk membandingkan prestasi rawatan selepas penambahan natrium persulfat. Tujuan kajian ini adalah untuk mengenal pasti kesan parameter operasi rawatan $O_3/S_2O_8^{2-}$ terhadap penyingkiran warna dan COD. Eksperimen ini telah dijalankan di bawah operasi yang berterusan dalam reaktor turus panjang. Parameter operasi, iaitu kepekatan awal pewarna, dos $S_2O_8^{2-}$, pH awal, dan masa sentuhan, telah dimanipulasikan untuk mengoptimumkan prestasi $O_3/S_2O_8^{2-}$. Kesan parameter terhadap prestasi penyingkiran telah dikenal pasti berdasarkan penyingkiran warna dan COD. Prestasi penyingkiran warna dan COD dalam $O_3$ juga telah dibandingkan dengan proses rawatan $O_3/S_2O_8^{2-}$. Perantaraan daripada RR120 telah dicirikan berdasarkan perubahan spektrum menerusi spektrofotometer UV-Vis. Hasil kajian menunjukkan peningkatan dos $O_3/S_2O_8^{2-}$ membawa kepada peningkatan kecekapan penyingkiran warna. Di samping itu, apabila kepekatan awal RR120 meningkat kepada 300 mg/L, kecekapan peyingkiran warna turut berkurangan, kerana kepekatan ikatan azo meningkat menyebabkan proses pengoksidaan berkurangan. Prestasi $O_3/S_2O_8^{2-}$ juga bertambah baik pada pH alkali, dengan kehadiran radikal hidroksil. Dengan membandingkan kedua-dua perawatan, didapati $O_3/S_2O_8^{2-}$ mempunyai kecekapan penyingkiran warna yang lebih baik daripada $O_3$.

**Kata kunci:** $O_3/S_2O_8^{2-}$, pengozonan, penyingkiran warna, Reactive Red 120, persulfat

## Introduction

Textile industry is one of the largest industries in the world in terms of its production and employment [1]. Dyes are widely used in the textile industries due to favourable characteristics, such as intense colour, water fastness, and uncomplicated application techniques. In the industries, the azo are among the most common synthetic dyes both in terms of the number and amount produced with azo bond groups [2]. Besides, azo dyes account for approximately 60 – 70% of all dyes used in food and textile manufacture [3]. Normally industrial effluent is not treated completely before discharging it into the water bodies such as rivers or lakes. There are many industries come out with their own wastewater treatment plant. But the discharge effluents still do not follow the standard that can discharge to water bodies. Dye wastewater is mainly generated from the wet-processing originates from washing and bleaching in textile industry [4,5]. Dye is a colorant used to dye textile fibres; in other words, it has an affinity to the material to which it is applied to. The colour of dyes is due to the presence of chromophore group, which is also known as auxochoromes and conjugated bond [6]. Azo dye wastewater is comprised of high biological oxygen demand (BOD) and chemical oxygen demand (COD) content, which has the impact on visible colour; obstruct light penetration and oxygen transfer into water bodies. The common methods used in dye wastewater treatment are carbon adsorptions and flocculation processes. Though other parameters can be treated by conventional chemical, physical or biological method, colour remained after treatment. Therefore, the colour problem caused by residual dyes requires more effort and time to study and investigate [2].

Advanced oxidation processes (AOPs) have high efficiency in treating dye wastewater in terms of decolourisation and degradation of refractory pollutants compared to other methods. Over years, ozonation and AOPs involving ozone in combination with hydrogen peroxide ($O_3/H_2O_2$), photolytic $H_2O_2$ oxidation (UV radiation with $H_2O_2$) and advanced fenton became the new technology to treat dyes textile and dyestuff industrial effluent. Now, ozone-based concept treatment has extended to the oxidation processes with sulphate radicals ($SO_4^{\bullet-}$), namely ozone persulphate ($O_3/S_2O_8^{2-}$). This treatment has operational advantages over conventional processes such as suitable for wide pH range, low cost of oxidant precursors, no post treatment steps and complete mineralization of pollutants into harmless products [7]. Lastly, the present research is very significant for the development of the efficient and economical treatment for the mineralization of the industrial dye wastewater. Thus, this current study will investigate the efficiency of $O_3$ and $O_3/S_2O_8^{2-}$ on industrial dye wastewater treatment.

## Materials and Methods

### Materials

The analytical grade diazo RR120 was selected as model due to its common application in industries obtained from Sigma-Aldrich. Its molecular weight and molecular formula is 1,469.98g and $C_{44}H_{24}Cl_2N_{14}O_{20}S_6Na_6$, respectively. The appropriate weight of dye will be dissolve to ultrapure water for the preparation of stock solution. Figure 1 present the chemical structure of the studied dye.

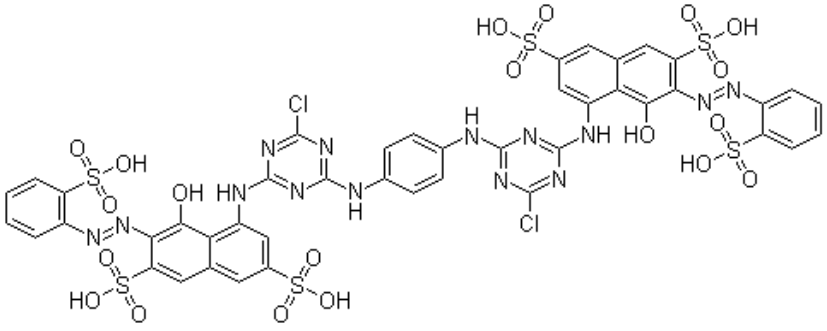

Figure 1. Chemical Structure of RR120 [8]

### Experimental set-up

$O_3$ gas was generated in laboratory and supplied to a 2 L of cylindrical glass reactor connected to 2% of potassium iodide trap which act as $O_3$ destructor. The $O_3$ gas was generated using A2Z (model Z-3G) Ozone Generator which

continuously supplied with purified $O_2$. During experiments, $O_3$ gas constantly flow through a diffuser to produce fine bubbles into 2 L dye sample. For the $O_3/S_2O_8^{2-}$, predetermined $S_2O_8^{2-}$ dosage was added to the dye sample before $O_3$ entered the reactor.

2 L/min $O_2$ flow rate was applied to generate $O_3$ throughout the experiments. Different dosage of 1, 3, and 5 g $S_2O_8^{2-}$ /g dye at pH 7. The $O_3$ and optimum $S_2O_8^{2-}$ dosage were applied to the study of the effects of pH (3, 5, 7, 9, 11), together with the initial concentration of 100 and 300 mg/L. The experiments were conducted at room temperature with different contact time of 0, 1, 2, 3, 4, 5, 10, 15, and 20 minutes. Finally, the samples were withdrawn at definite intervals for analyses.

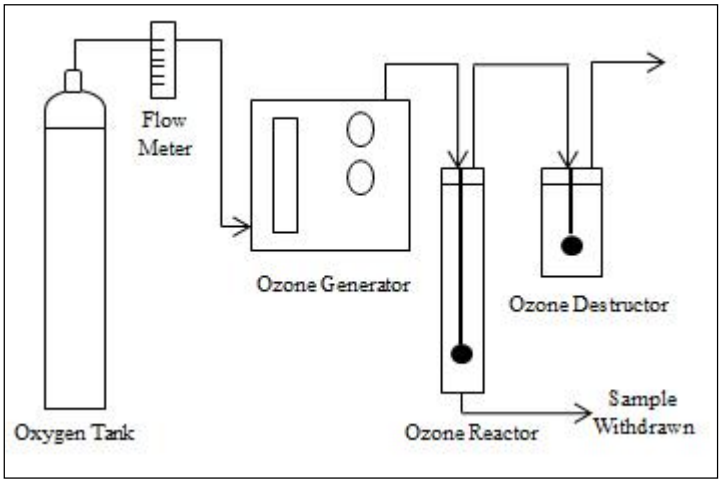

Figure 2. Schematic diagram of experimental set-up for $O_3$ and $O_3/S_2O_8^{2-}$

**Analytical method**

The potassium iodide titration will use to determine the $O_3$ flow rate dye samples. UV-Vis spectrophotometer will be used to analyse the absorbance colour change and dye concentration of the dye samples. The pH value before and after the treatment will be tested by using pH meter (Hannah Instruments H1223). The value of COD will be tested before and after treatment by $O_3/S_2O_8^{2-}$ oxidation with the standard APHA method. HACH DR200 COD reactor and DR2800 spectrophotometer will be used to react and take the COD reading in terms of mg/L, respectively [9]. The COD analysis will repeat for 3 times and the average is calculate. The removal efficiency of COD and colour was determined using Eq. 1.

$$\text{Removal (\%)} = [\ C_i - C_f/C_i\ ] \times\ 100 \quad (1)$$

where $C_i$ and $C_f$ were respectively refer to the initial and final colour and COD concentration.

## Results and Discussion

The comparison of colour and COD removal of RR120 for both treatment methods are based on the optimum operating parameter, where the most favourable condition to achieve highest removal efficiency are at pH 7, 100 mg/L of initial dye concentration and dosage of 5 g $S_2O_8^{2-}$/g dye for $O_3/S_2O_8^{2-}$system. In addition, ozone flow rate was maintained at 2 L/min.

**Effect of initial pH**

The effect of initial pH on the UV-Vis spectra obtained is given in the Figure 3. The visible region reduces rapidly in alkaline condition, might be due to the dissociation of the N=N bonds. The decreasing of the visible region means that there is cleavage of chromophore, which is azo bond that give colour to RR120.

The pH value was known as the important parameters that affect the colour and COD removal. For the initial concentration of 100 mg/L and initial dosage of 5 g $S_2O_8$/g dye, the dye has completely decolourize after 5 minutes of treatments as shown in Figure 4. Various studies showed that solution of pH is directly effect the decomposition of ozone [10]. The ozone molecular remain as the main oxidant at low pH values, while at high pH hydroxyl radicals are formed from ozone decomposition [11]. Since the decolourization of dye can be at different pH in colour effluents, the effects of pH value in the pH range 3 to 11 was studied. The solution of dyes were adjusted by addition of $H_2SO_4$ or NaOH in order to get desired pH. The complete decolourization was observed from pH 3 to 5 and the further to 11. This condition may be explained by the radical way reactions predominated at higher pH values which is efficient in colour removal by equal cleavage of two electron bond [12].

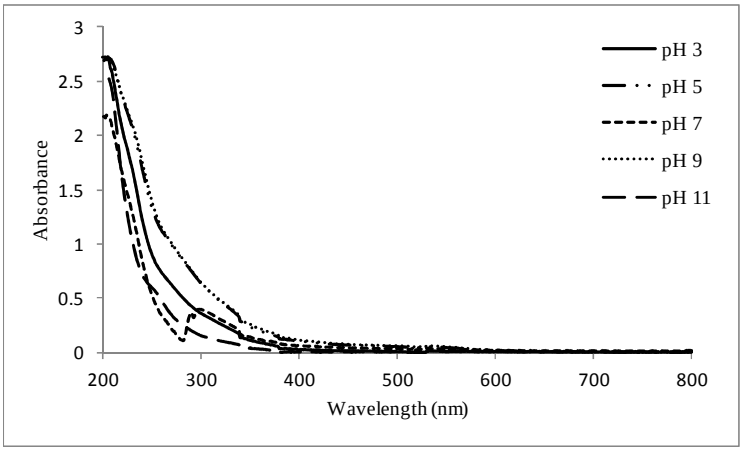

Figure 3. Effect of pH on the UV-Vis spectra

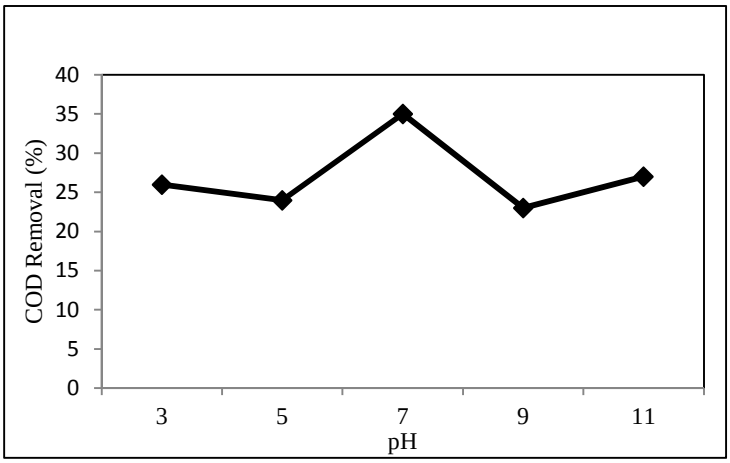

Figure 4. Effect of pH on the COD removal

Figure 4 also presented the COD results obtained for the COD analysis of dye solution after the $O_3/S_2O_8^{2-}$ treatment. COD removal was decreased from pH 3 to 5 and sharply rose to 7. This can explained by reaction between molecular ozone and organic polltant is the predominat mechanism at low pH and took over by hydroxyl radicals at high pH [13]. Therefore, the COD concentration is decreased as pH value increase due to stronger oxidizing power of hydroxyl radicals.

**Effect of initial dosage**

The changes of UV-Vis spectra obtained from the different intial $S_2O_8^{2-}$ dosage are presented in Figure 5. Figure below represented two different trends of wavelength spectrum; the first is before the treatment and the second is after the treatment. After 20 minutes treatment, the peaks of absorbance in the visible region gradually declined resulting the decolourization. Therefore, the decrease of visible region indicate that azo bonds cleavage, while in UV region indicates aromatic such as benzene and naphthalene cleavage.

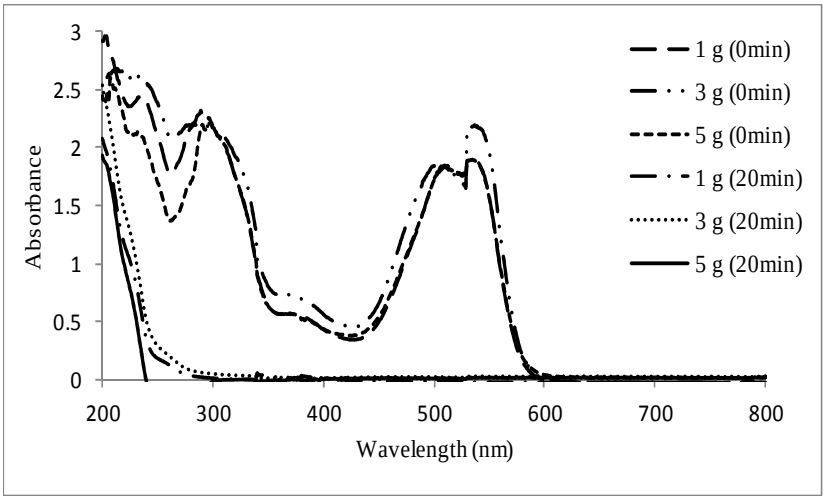

Figure 5. Effect of $S_2O_8^{2-}$ dosage on the UV-Vis spectra

Figure 6 showed that at dosage 5 and 3 g $S_2O_8^{2-}$/g dye, the percentage of colour removal for RR120 almost similar. An amount 5 g $S_2O_8^{2-}$/g dye has 25% COD concentration at 10 min, and 3 g $S_2O_8^{2-}$/g dye achieved after 15 minutes, while dosage 1 g $S_2O_8^{2-}$/g dye only achieved after 20 min of reaction time. Hence, it is necessary to further increase the dosage to various levels in order to investigate the relationship of dosage with colour and COD removal. The initial $S_2O_8^{2-}$ dosage gives a very important effect in the generation of hydroxyl and sulphate radicals for the dye degradation. In general, higher hydroxyl radical concentrations produced from the higher initial dosage which able to decomposes more target compound such as dyes resulting colour and COD removal. In this research, the degradation of dye was evaluate for several initial $S_2O_8^{2-}$ dosage (1, 3, 5 g $S_2O_8^{2-}$/g dye) at constant initial dye concentration and pH. The results indicate that, higher dosage of $S_2O_8^{2-}$ produces higher colour and COD removal. Generally, when $S_2O_8^{2-}$ is added into the ozonation system, the decomposition of $O_3$ into hydroxyl radical accelerated the process and shift the process entirely to an AOPs [14]. Therefore, with the more number of hydroxyl radicals and the presence of sulphate radical, they can attack the azo bond faster than breaking down the sulphonate group and naphthalene ring in dye [15].

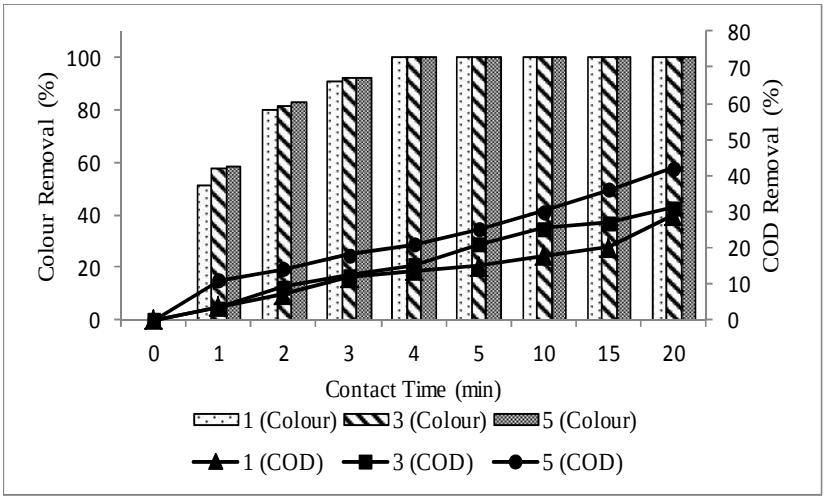

Figure 6. Effect of $S_2O_8^{2-}$ dosage on the colour and COD removal

**Effect of initial dye concentration**

Figure 7 shows the effect of initial dye concentration on the UV-Vis spectra during $O_3/S_2O_8^{2-}$. It can be seen that the intensity of absorbance was reduced sharply after 20 minutes of treatment time for $O_3/S_2O_8^{2-}$, which represents the cleavage of azo bond and resulting in decolourisation. On the other hand, the benzene and naphthalene ring are connected to the azo bond at 212 and 298 nm, respectively in the UV region also showed greatly reduced with $O_3/S_2O_8^{2-}$ treatment. Azo bond will be attacked first before the degradation on the benzene ring or naphthalene. This is because the absorption bands intensities for UV region is degraded more slowly than visible band. Therefore, the colour of RR120 has been disappeared first by breaking azo bond and the followed by oxidation of benzene ring and naphthalene that cannot been see by eyes, but only detected with UV-Vis [16].

In this study, the dye degradation was investigated for several initial concentrations of dye (100 and 300 mg/L) at a constant initial dosage of 5 g $S_2O_8^{2-}$/g dye. Figure 8 illustrated the effect of initial dye concentration on the colour and COD removal during $O_3/S_2O_8^{2-}$ at constant pH which is pH 7. The colour removal efficiency decrease as the concentration of dye increase due to less production of persistent intermediates [12]. The initial dye concentration of 100 mg/L achieved more that 80% of colour removal after 2 minutes, whereas 300 mg/L obtained after 10 minutes. On the other hand, completely decolourisation was presented after 4 and 15 minutes for 100 and 300 mg/L dye concentration, respectively. The initial dye concentration give an important role in the determination of economical use of ozone for decolourisation [10]. Therefore, longer reaction time is needed to completely decolourise higher concentration of dye. Various researches have obtained that the time required for decolourisation of the dye solution is dependent on the initial dye concentration [17]. The COD removal has the same result as colour reduction efficiency. It can be seen that 100 mg/L achieved better COD reduction compared to 300 mg/L dye concentration. The 100 mg/L dye concentration reduced 10% of the COD concentration after 1 min of treatment, whereas 300 mg/L concentration achieved after 3 minutes. In fact, increasing the dye concentration will decreased the pollutant ration of ozone molecules to dye molecules. Therefore, more oxidants needed to be consumed in order to completely degrade the refractory pollutants. The removal rate of COD will increase as the increasing of the treatment contact time. This condition can be explained by the amount of hydroxyl free radicals in dye solutions increase with the reaction time [18].

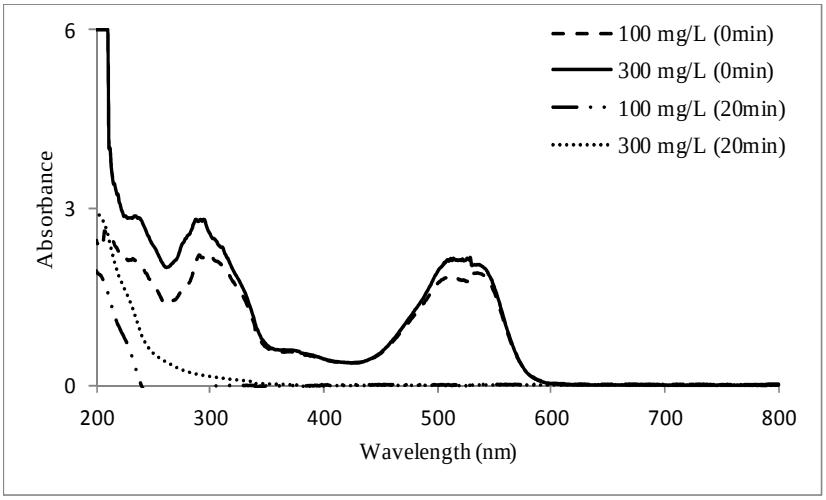

Figure 7. Effect of initial dye concentration on the UV-Vis spectra

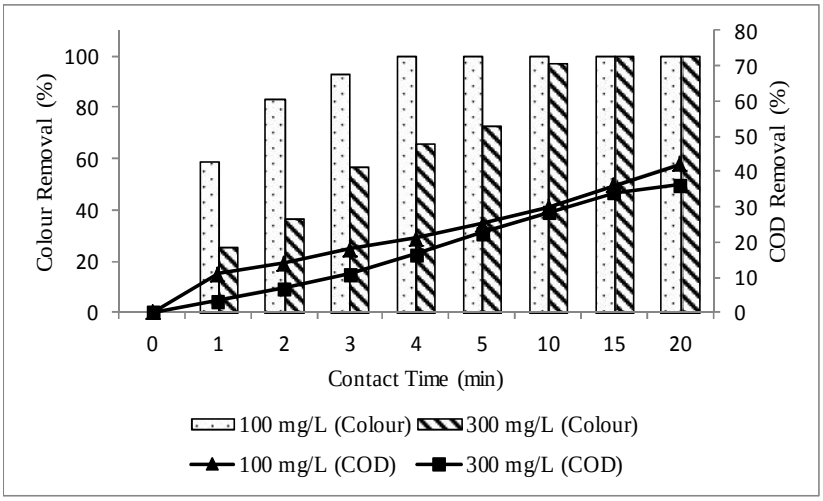

Figure 8. Effect of initial dye concentration on the colour and COD removal

**Comparison of $O_3$ and $O_3/S_2O_8^{2-}$**

Figure 9 showed the colour, and COD removal percentages of RR120 at initial dye concentration 100 mg/L for a different method which are $O_3$ and $O_3/S_2O_8^{2-}$. This graph indicates increasing in reaction time has caused in an increasing in colour and COD removal. The decolourisation of dye occurred faster than the COD removal. This situation may be explained that chromophore may destroyed during treatment and partially mineralized to a smaller fragments [19]. The $O_3/S_2O_8^{2-}$ oxidation achieved completely decolourisation after 4 min, while this condition happened to $O_3$ after 5 min. The results proved that $O_3/S_2O_8^{2-}$ more capability to breakdown the azo bond from the dye structure than the $O_3$ alone. This is because the $O_3/S_2O_8^{2-}$ is involving the generation of two type reactive free radicals, which are hydroxyl radicals and sulphate radical at neutral or basic pH. Both radicals played an important role in this processes in terms of decolourisation. On the other hand, $O_3$ is only able to produce the hydroxyl radicals through the process.

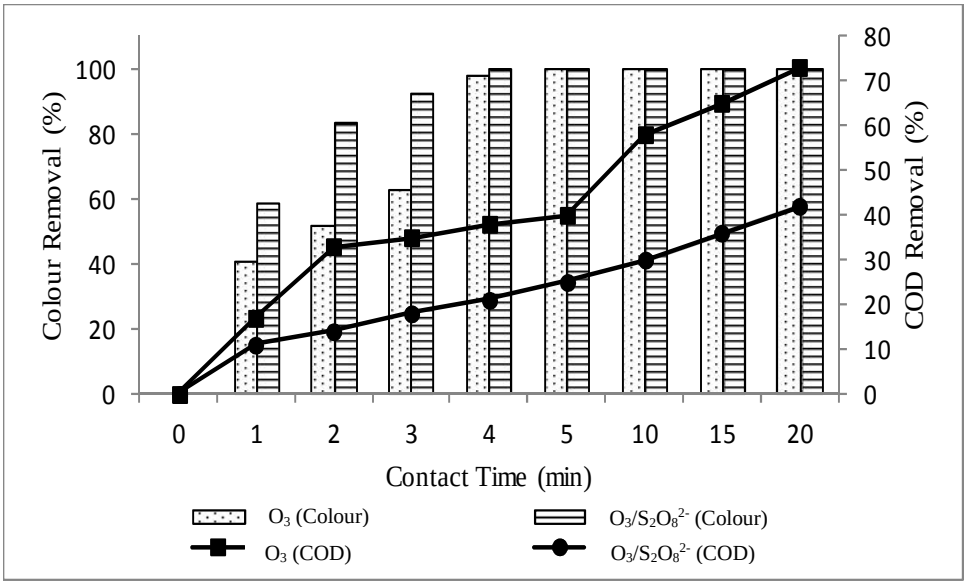

Figure 9. Effect of $O_3$ and $O_3/S_2O_8^{2-}$ on the colour and COD removal

## Conclusion

This study has found that generally, the $O_3/S_2O_8^{2-}$ advanced oxidation treatment provides good performances in the colour removal of the RR120 in water. The initial $S_2O_8^{2-}$ dosage, dye concentration and pH give a very important role in the generation of hydroxyl and sulphate radicals for the dye generations. The results of this investigation show that, the decolourisation was strongly depending on initial $S_2O_8^{2}$ dosage. The decolourisation efficiency increased with increasing $S_2O_8^{2-}$ dosage and reaction time. While, decolourisation efficiency decreased with raising the initial dye concentration.

**Abstract**

Melt compounding processing approach for incorporating cellulose nanocrystals (CNC) into thermoplastic polyurethane (TPU) has not well been explored. This is primarily due to the poor thermal stability and dispersibility of CNCs. As they are typically obtained from sulphuric acid hydrolysis, they give rise to degradation and discolouration of the extruded nanocomposites. The investigation of this research demonstrates sulphuric acid hydrolysis (CNC-S), phosphoric acid hydrolysis (CNC-P) and a novel non-hydrolytic high energy bead milling method (CNC-MC) into a polyether based thermoplastic polyurethane via melt compounding using twin screw extruder. The TPU film incorporated with CNC-S obviously shows the sign of CNC degradation where TPU film was changed to brown colour. The tensile strength of TPU reinforced with CNC-S, CNC-P and CNC-MC shows 18%, 16% and 14% of improvement at CNC loading of 0 to 1 wt.% upon host polymer. CNCs isolated via mild acid hydrolysis and mechanical milling methods, can be easily processed via large scale melt-processing techniques for reinforcing thermoplastic polyurethane without affecting their physical appearance and elastic properties.

**Keywords**: cellulose nanocrystals, thermoplastic polyurethane, nanocomposites

**Abstrak**

Kajian mengenai penggunaan nanokristal selulosa (CNC) di dalam termoplastik poliuritena (TPU) amat jarang diterokai. Ini adalah kerana CNC mempunyai ketahanan haba yang rendah. CNC yang dihasilkan melalui proses hidrolisis asid sulfurik mudah terdegradasi apabila digabungkan dengan polimer yang melalui proses meramu pencairan umumnya menggunakan suhu pemprosesan yang tinggi. Kajian ini menggunakan CNC yang dihasilkan daripada hidrolisis asid sulfurik (CNC-S), asid fosforik (CNC-P) dan kaedah novel pengisaran manik (CNC-MC) ke dalam poliuretana termoplastik berasaskan berasas polieter melalui proses meramu pencairan. Filem TPU yang digabungkan dengan CNC-S jelas menunjukkan tanda degradasi CNC apabila filem TPU bertukar warna kepada coklat. Kekuatan tegangan TPU diperkukuhkan dengan CNC-S, CNC-P dan CNC-MC menunjukkan 18%, 16% dan 14% peningkatan pada muatan CNC 0-1 wt.% di dalam komposit. CNC yang dihasilkan melalui hidrolisis asid berkekuatan sederhana dan melalui kaedah mekanikal boleh diproses melalui teknik meramu pencairan yang berskala besar dan mampu meningkatkan kekuatan poliuretana termoplastik tanpa menjejaskan penampilan fizikal mereka dan sifat elastiknya.

## Introduction

Thermoplastic polyurethane (TPU) is a versatile material which has both thermoplastic and elastomeric properties with unique attributes, for instance, melt-process ability, recyclability and easy to mould [1]. One of the methods to improve the properties of TPU is by using reinforcing filler. Recently nanoscale fillers such as clay, carbon nanotubes, metal and metal oxides have been demonstrated to remarkably enhance the thermal, physical and mechanical properties of TPU within very low loading [2-4]. Recently cellulose nanocrystal (CNC) has gained high attention as reinforcing filler due to its key attributes such as very high specific mechanical properties of individual nanocrystals and renewability. Moreover, CNC reinforced polymer nanocomposites can retain the transparency of the polymer matrix [5]. With polyurethanes and different types of nanocellulose particles, remarkable reinforcements have been demonstrated. Specifically at a low volume fraction of CNC, TPU nanocomposites has demonstrated an extraordinary increase in tensile strength without compromising the tensile strain and stiffness of the material [6]. However, their processing involves solvent based methods. Conventional method like solvent casting poses a challenge in terms of production speed and environmental issue due to the high solvent usage [7]. Thus, for TPU industrial scale production, classical melt-processing methods such as compounding, reactive extrusion and moulding are preferred. Melt compounding method which has been explored with other thermoplastics whose fusion temperatures are below 170°C such as poly lactic acid [8] and polyethylene [9], is however limited due to the poor thermal stability, dispersibility of CNCs and degradation in optical transparency of the host for most of the thermoplastics whose processing temperatures are above 170 °C.

Hence, this work focuses on the processing of TPU nanocomposites reinforced with three types of CNCs which were obtained via sulphuric acid hydrolysis (CNC-S), and phosphoric acid hydrolysis (CNC-P) and acid-free high energy bead milling (CNC-MC), via a classical melt compounding method using an intermediate scale twin screw extruder. Their processing and properties enhancement are compared with the nanocomposites processed by solvent casting method.

## Materials and Methods

### Materials

Cellulose source used was Whatman filter paper (Advantec) and commercial microcrystalline cellulose (Avicel PH-101). Sulphuric acid ($H_2SO_4$, 98%) and ortho-phosphoric acid ($H_3PO_4$, 85%) from Merck Australia was used in for acid the hydrolysis process. The TPU grade selected, Texin 990, was purchased from Bayer Materials Science. This grade was specifically selected because it represents one of the highest selling aromatic polyether grades and is employed in a multitude of applications. Dimethylformamide (DMF) was purchased from Merck and used for solvent casting.

### Isolation of cellulose nanocrystals: Acid hydrolysis method

The isolation process using sulphuric acid was adapted from Capadona et al. [10] with some modifications. The solid to liquid ratio for this isolation process was 1:75. Filter paper was blended with deionised water. The sulphuric acid was added slowly under vigorous mechanical stirring to the cooled filter paper until the final solution reached an acid concentration of 32%. Since the acid hydrolysis process is exothermic, while adding acid, ice bath is used to keep the temperature below 20 °C. After the acid addition is complete the reaction is set at 50 °C or higher for a stipulated time. The mixture was then heated to 50 °C for 3.5 hours. The cellulose suspension was cooled to room temperature and was subsequently centrifuged four to five times at 4750 rpm until it became turbid. The cellulose suspension was then dialyses against deionised water until the suspension reached the neutral state. Then the cellulose suspension was ultrasonicated using high intensity ultrasonication (QSonica ultrasonicator) for 30 minutes. Finally, the cellulose suspension was lyophilised using liquid nitrogen and was vacuum freeze dried. The CNC obtained was denoted as CNC-S. Meanwhile, acid hydrolysis of cellulose using $H_3PO_4$ was adapted from Camarero et al. [11], with slight modification, and generally the procedure is very similar to $H_2SO_4$ hydrolysis. This CNC is denoted as CNC-P.

### High energy bead milling method

Isolation of CNC via high energy bead milling (HEBM) was carried out based on the work of Amin et al. [12]. The cellulose source used in this process was microcrystalline cellulose (MCC). Various concentrations of MCC were dispersed in deionised water overnight. Then the dispersion was milled using a laboratory agitator bead mill

(Labstar, Netzsch, Germany). Using various milling times, 0.4 mm of zirconium beads were used to mill the cellulose dispersion at 1000 rpm in a batch process mode. Finally, the resulting suspensions obtained were freeze dried.

**Processing of nanocomposites**

In these nanocomposites, CNC loading levels were 0.5, 1, and 5 wt.% respectively. In melt compounding method, initially CNC and PU resin were mixed physically. TPU nanocomposites reinforced with three types of CNCs were processed by melt-compounding using a ThermoHaake PolyLab twin-screw extruder. The extrudates were pelletised and compression moulded.

In solvent casting process, TPU resin and CNC were individually dissolved in DMF. 0.5 wt.% of CNC in TPU was prepared by mixing the desired amounts of CNC and TPU solution in DMF. The mixture was stirred vigorously for 1 hour at room temperature. The mixture was then sonicated for 2 minutes at 20 kHz. Subsequently, further stirring was undertaken after the sonication process and immediately cast onto a Teflon petri dish. The films were dried under nitrogen purged for 24 hours and subsequently annealed in a vacuum condition at 80 °C for 12 hours. TPU nanocomposites prepared by solvent casting were denoted as SC-TPU/CNC *X* where *X* represents the volume fraction of CNC. TPU nanocomposites processed via the melt compounding process were denoted as MC-TPU/CNC *X*.

**Characterisation and mechanical testing**

The morphology and thermal stability of CNCs were characterised by transmission electron microscopy (TEM) and thermogravimetric analysis (TGA). TGA measurements were carried out on a Mettler Toledo DSC/TGA Star$^e$ system using aluminum crucible standard 40 µL. The samples were heated in a nitrogen atmosphere. The samples were first heated from room temperature to 110 °C, at a heating rate of 10 °C/min, isothermally held for 10 minutes and further heated to 500 °C at a heating rate 5 °C/min.

The mechanical properties of the composites were measured at room temperature on an Instron model 5543 universal testing machine equipped with a 500 N load cell. The tensile and hysteresis tests were cut into dumbbell shapes according to ASTM d-638-M-3. The tests were performed with a gauge length of 14 mm and crosshead speed of 50 mm/min and pneumatic grips were employed to prevent slippage.

## Results and Discussion

**Cellulose Nanocrystals (CNC)**

Figure 1 shows the transmission electron micrographs (a-b) and thermograms (d) of the CNCs obtained via hydrolysis using sulphuric acid (CNC-S), phosphoric acid (CNC-P) and mechanical method (CNC-MC). The dimensions of CNCs were measured from at least 10 particles using ImageJ analytical software. From Figure 1a-c, the 'rod-like' shape CNC can be seen clearly with an average aspect ratio of 13, 10 and 25, for CNC-S, CNC-P and CNC-MC respectively. The HEBM process is more environmentally friendly than the acid hydrolysis methods as it was produced without using any acids, as well as being a more economically viable and scalable approach to produce CNC.

The thermal stability of CNC was determined using TGA and the associated thermograms are shown in Figure 1 (d). It can be clearly seen that CNC-S have the lowest onset degradation temperature ($T_{onset}$) noted at 200 °C as presented in Table 1. In contrast, CNC-P and CNC-MC recorded $T_{onset}$ values of 255 °C and 258 °C, respectively. Despite the well-known advantages of CNC isolated via sulphuric acid hydrolysis in terms of stable aqueous colloidal stability, which is due to the negative sulphate group introduced into the surface of CNC, this method leads to poor thermal stability. The sulphate groups formed are known to promote dehydration reactions and act as flame retardants, but this characteristic also gives rise to a low nanocellulose thermal stability [13,14].

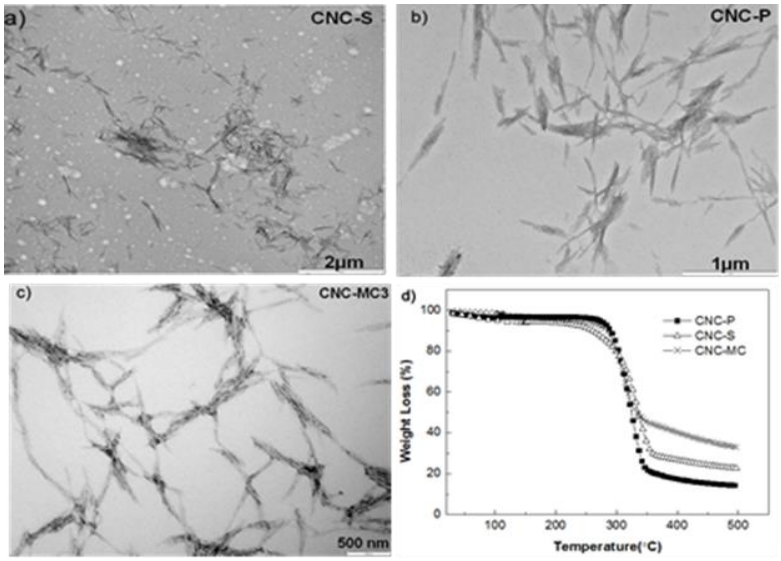

Figure 1. TEM images of CNCs produced from acid hydrolysis; a) CNC-S, b) CNC-P, c) HEBM method (CNC-MC) and d) their corresponding TGA thermograms

On the other hand, CNC-P and CNC-MC isolated from phosphoric acid hydrolysis and HEBM methods both clearly demonstrated a better thermal stability than CNC-S. Possibly phosphate group ($(PO_4)^{3-}$ ) attached on the surface of CNC-P is also able to assist with aqueous colloidal stability, but in this case without affecting the thermal behaviour of CNC [15]. The CNC-MC nanocellulose sample was successfully produced in a green and clean process (without the use of any acids or oxidising agents), and this approach also appears to have contributed to better thermal stability. Importantly, both of these strategies have shifted the onset degradation temperatures well above the typical melt compounding or reactive extrusion temperature window commonly employed for TPU processing with temperature of 180 – 230 °C, depending on the TPU grade and formulation.

Table 1. Dimensions and production yield of CNC isolated from the acid hydrolysis and HEBM methods

| Sample | Length (nm) | Diameter (nm) | Aspect Ratio | Yield (%) | Onset Degradation Temperature ($T_{onset}$)(°C) |
|---|---|---|---|---|---|
| CNC-S | 213 ± 50 | 16 ± 3 | 13 | 81 | 200 |
| CNC-P | 270 ± 135 | 26 ± 13 | 10 | 62 | 255 |
| CNC-MC | 424 ± 90 | 17 ± 4 | 25 | 76 | 258 |

**Physical appearance of TPU nanocomposites**

The influence of different thermal stabilities and surface chemistry of CNC on processing can be clearly observed in Figure 2 from the physical appearance of compression moulded nanocomposite films produced via melt compounding and solvent casting. The TPU/CNC nanocomposite films produced via solvent casting retained the transparency of the host TPU at low 0.5-1 wt.% loading levels for all types of CNCs, and at the higher 5 wt.% loading the nanocomposites with CNC-S and CNC-MC showed just some feint discolouration. The solvent cast nanocomposites with CNC-P were able to retain the transparency of the host TPU even at 5 wt.%. However, very obvious and commercially-unacceptable colour changes to darkening for nanocomposites obtained via melt-compounding can be seen from Figure 2, and the order of extent of discolouration is as follows: TPU control (MC-TPU Control) < Nanocomposites using phosphoric acid hydrolysed CNCs (MC-TPU/CNC-P) << Nanocomposites

using micronised CNCs (TPU/CNC-MC) < Nanocomposites using conventional sulphuric acid hydrolysed CNCs MC-TPU/CNC-S.

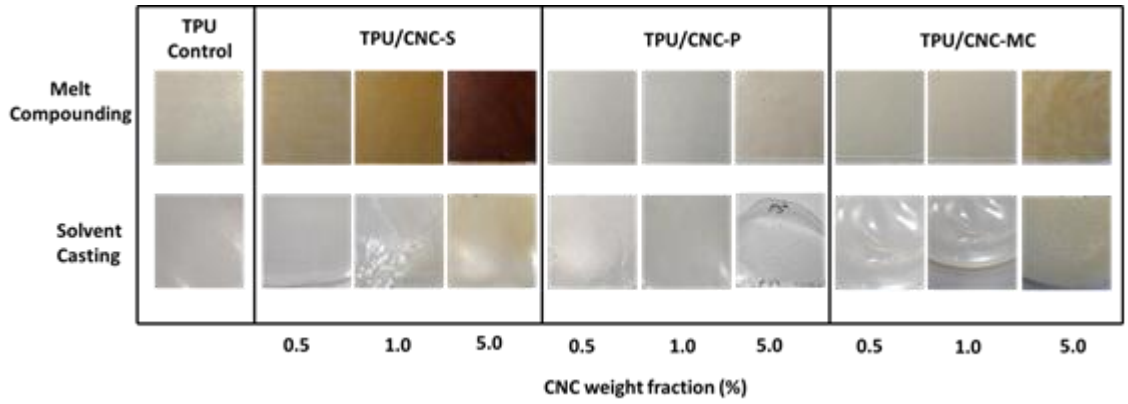

Figure 2. Photographs of TPU control and TPU/CNC nanocomposites processed via solvent casting (bottom) and melt compounding (top)

Even at 0.5 wt.% of CNC-S loading, the light brown colour of nanocomposite films was noticeable. As the processing temperature employed in the extruder was about 225 °C, the CNC isolated from sulphuric acid hydrolysis showed degradation behaviour and darkened. As reported previously, sulphate $(SO_4)^{2-}$ groups, which are present on the surface of CNC might promote the dehydration reactions [14,16,17]. The onset degradation temperature of CNC-P and CNC-MC are 255 and 258 °C, respectively. However, the dispersibility of CNC-P where phosphate groups assist in achieving superior colloidal suspension stability is better than CNC-MC, which also gives rise to the discolouration of nanocomposites incorporating CNC-MC. This strongly suggests that this discolouration in melt compounded TPU nanocomposites is due to relative CNC thermal stability and degradation, which in-turn leads to the aggregation of the less thermally stable nanocellulose.

**Mechanical properties**

The reinforcement effect of the CNCs was investigated by measuring the tensile properties of the TPU control and its nanocomposites, at room temperature. Figure 3 shows the stress-strain curves of TPU control and nanocomposites produced via both processes and the values determined are summarized in Table 2. Obviously, no significant changes in tensile strength upon 0 to 300% of tensile strain were observed for melt compounded material, whereas solvent cast nanocomposites show the increase difference immediately after 50% of strain. The solvent cast TPU control obtained higher tensile strength than melt compounded materials. The reduction mostly contributed by transurethanisation reaction occurred due to the harsh environment in the extrusion process.

The tensile strength of TPU reinforced with CNC-S, CNC-P and CNC-MC shows 18%, 16% and 14% of improvement respectively upon host polymer via melt compounding method. The increase was recorded at CNC loading of 0 to 1 wt.%, as it reached 5 wt.% mechanical properties of the composites was declined. Regarding percolation model related to volume fraction of filler, the percolation threshold for CNC previously has been determined at 1- 2 volume % [18,19] for CNC to form network with polymer matrix which most probably linked by the hydrogen bonding. Thus, in this work, CNC loading at 5 wt. % have been assumed ineffective as reinforcing element to the TPU matrix.

Moreover, elongation and stiffness at the optimum value of tensile strength were also unaffected indicating the soft-segment domain of TPU was not disrupted by the cellulose addition. Furthermore, the reinforcement of CNC was also can be seen from the improvement in toughness and tear strength of TPU nanocomposites. These results indicate that CNCs able to work as an efficient stress transfer medium without disrupting the original function of the TPU microstructure (hard segment and soft segment). Indeed preventing the undesired stiffening with soft domain

was able to maintain the elongation of the TPU composites. The strength of the material fabricated via melt compounding is competent by comparing it with solvent casting process. This also proved that cellulose (CNC-P and CNC-MC) able to be processed with high processing temperature method.

## Conclusion

Three types of CNCs isolated via sulphuric acid hydrolysis (CNC-S), phosphoric acid hydrolysis (CNC-P) and mechanical milling method (CNC-MC) were successfully incorporated into TPU via melt compounding method. These nanocomposites were compared with that processed via conventional solvent casting method. The thermally stable CNCs (CNC-P and CNC-MC) have demonstrated the melt process ability with polyether based thermoplastic polyurethane (TPU) without affecting the optical transparency, whereas, CNC-S has shown the degradation behavior. Remarkable reinforcement effect has been observed for nanocomposites with all the three CNCs, in terms of improvement in tensile strength and toughness without affecting elongation. It can be summarized that CNC isolated via mild acid hydrolysis and an optimized mechanical milling methods, can be easily processed via large scale melt-processing techniques for reinforcing thermoplastic polyurethanes at 0.5-1 wt. % without affecting their physical appearance and elastic properties.

# CHEMICAL SENSOR FOR HYDRAZINE DETECTION USING POLYANILINE THIN FILM

## (Sensor Kimia Untuk Mengesan Hidrazin Dengan Menggunakan Polyanilina Berbentuk Filem Nipis)

**Abstract**

Polyaniline (PANI) doped with dioctyl sodium sulfosuccinate (AOT) was prepared by chemical oxidative polymerization method. This PANI thin film was used as an effective chemical sensor at room temperature for different concentrations of hydrazine (10, 100, 1000 and 10000 ppm) detection. The PANI chemical sensor has shown a good recyclability up to 10 cycles with 2 minutes response time and immediate recovery time. The sensor response was proved by red-shift of the UV-Vis at 780 nm which indicates the transformation of emeraldine salt (ES, conducting state) to leucoemeraldine salt (LES, non-conducting state) of PANI. Besides that, the intensity ratio of $I_{Quinoid}/I_{Benzenoid}$ at FTIR spectroscopy can explicit the predominating benzenoid species that formed as a result of ES interaction with hydrazine. In this study, a very simple and inexpensive sensor setup has been successfully developed for hydrazine detection compare to the complicated traditional chemical sensors.

**Keywords**: polyaniline, hydrazine, dioctyl sodium sulfosuccinate, chemical sensor, conductivity

**Abstrak**

Polianilina (PANI) yang didopkan dengan natrium dioktil sulfosuksinat (AOT) telah disediakan melalui kaedah pempolimeran pengoksidaan kimia. Filem nipis PANI telah digunakan sebagai sensor kimia pada suhu bilik untuk mengesan hidrazin dengan kepekatan yang berbeza (10, 100, 1000 dan 10000 ppm). Sensor kimia PANI telah menunjukkan penggunaan semula sehingga 10 kali dengan masa 2 minit dengan masa pemulihan segera. Keputusan sensor telah dibuktikan dengan peralihan-merah UV-Vis pada 780 nm yang menunjukkan transformasi garam emeraldina (ES, konduktif) kepada garam leukoemeraldina (LES, tidak konduktif). Selain itu, nisbah keamatan $I_{Kuinoid}$ / $I_{Benzenoid}$ di FTIR spektroskopi telah menjelaskan spesies benzenoid lebih banyak sebagai hasil interaksi ES dengan hidrazin. Dalam kajian ini, penyediaan sensor yang sangat mudah dan murah telah berjaya diperkembangkan untuk mengesan hidrazin berbanding dengan sensor kimia tradisional yang rumit.

**Kata kunci:** polianilina, hidrazin, natrium dioktil sulfosuksinat, sensor kimia, konduktiviti

## Introduction

In recent years, there has been growing interest in conducting polymers due to their versatile applications in light emitting diodes, electronic devices, sensors, actuators, catalysis, corrosion protection coatings and microwave

absorption [1-5]. Among the conducting polymers, polyaniline (PANI) is the most promising semiconductor because of its ease of synthesis [6], high conductivity, low cost and good environmental stability [7, 8]. However, the great potential of PANI was masked by few disadvantages such as insolubility, infusibility and hence poor process ability. Attempts have been made to improve its solubility, of which the most widely used strategy is to dope PANI with suitable surfactants such as dodecylbenzene sulphonic acid (DBSA), camphor sulphonic acid (CSA) and etc. [9]. The PANI with improved solubility can be spin coated on an appropriate substrate to be used as a sensing material for toxic compounds such as ammonia, hydrogen peroxide, hydrazine and etc [10].

Hydrazine and its derivatives are commonly known for fuels in explosives, antioxidants, rocket propellants, blowing agents, photographic chemical, corrosion inhibitor, insecticides and plant growth regulators [11]. In spite of this, hydrazines are well known as neurotoxin, carcinogen, mutagen and hepatoxic [12]. Besides that, the exposure of high level of hydrazine can cause irritation to nose, eye, throat, dizziness, nausea, temporary blindness, pulmonary edema and coma, which will eventually endanger the liver, kidneys and central nervous system of humans [13].

Therefore, it has been realized that, effective and sensitive sensing methods need to be explored to detect the hydrazine. Presently, several efforts have been developed towards the rapid, sensitive and selective methods for the detection of hydrazine. The sensing properties of hydrazine have been extensively studied by various methods using different metal oxides, electrodes and semiconductors [14, 15]. Electroanalytical techniques were proven to be relatively direct and effective for the detection of hydrazine [16]. Unfortunately, hydrazine exhibits irreversible oxidation which required large overpotentials at bare carbon electrodes. Recently, various chemically modified electrodes (CMEs) have been prepared and applied in the detection of hydrazine [17-21], which can significantly lower the overpotentials and increase the oxidation current response. However, the tedious preparation method, expensive electrode modification techniques, control on pH of reactants have made these methods cumbersome and thus the door for a fast track, cheap and sensitive methodology is still opened. The preference for a conducting polymer especially PANI over a conventional metal as sensing material stems from several factors such as it can be operated at lower applied voltages and temperatures, unique acid-base chemistry and it interacts more favorably with both organic and inorganic compounds [10].

In this study, PANI was prepared by chemical oxidation method in the presence of dioctyl sodium sulfosuccinate (AOT) as a dopant to improve the solubility and enhance electrical conductivity. A very simple sensor set-up has been utilized and investigated by using UV-Vis, FTIR and conductivity studies to evaluate the response of PANI thin films against different concentrations of hydrazine such as 10, 100, 1000 and 10000 ppm.

## Materials and Methods

### Raw materials

All chemicals such as aniline (Ani) monomer, dioctyl sodium sulfosuccinate (AOT) and ammonium peroxydisulfate (APS) were purchased from Sigma Aldrich. Hydrochloric acid (HCl) 37% was purchased from Lab Scan Sdn. Bhd. Technical grade of toluene was used as a solvent for PANI thin film preparation. Distilled water was used throughout the research. Other reagents were used without purification unless noted.

### Synthesis of PANI

PANI was synthesized by chemical oxidation method at 0 – 5 ˚C. Firstly, 1 mmol of AOT was dissolved in 1 N of HCl followed by the dropwise addition of Ani (1 mmol). Then, 1 mmol of APS solution was added slowly into the solution mixture and the polymerization was preceded for 24 hours. After that, the PANI was washed by distilled water for three times and dispersed in toluene for film preparation by using spin coater.

### Characterizations

The characterizations of PANI films were investigated through ultraviolet-visible (UV-Vis) by using UV-1650 PC spectrometer in the wavelength range of 300 – 900 nm and Fourier transform infrared (FTIR) by using Perkin Elmer RX1 FTIR ATR spectrometer in the range of 4000 – 400 $cm^{-1}$.

**Sensor set-up**

In this study, a simple and cost-effective sensor set-up has been developed by using glass cuvettes. PANI film was immersed into the hydrazine solution in cuvette to determine the response of PANI against hydrazine. Measurements were taken before and after immersion into hydrazine solution using UV-Vis and FTIR spectroscopy and standard four point probe method (model Loresta HP) was used to study the normalized conductivity.

## Results and Discussion

**Characterizations**

UV-Vis spectrum of PANI was shown in Figure 1. The spectrum shows typical characteristic peaks of doped PANI such as π- π* conjugation at 350 nm, shoulder peak at 415 nm which showed enhanced polaronic character and a peak at 779 nm that resembles doped state of quinoid cations [22].

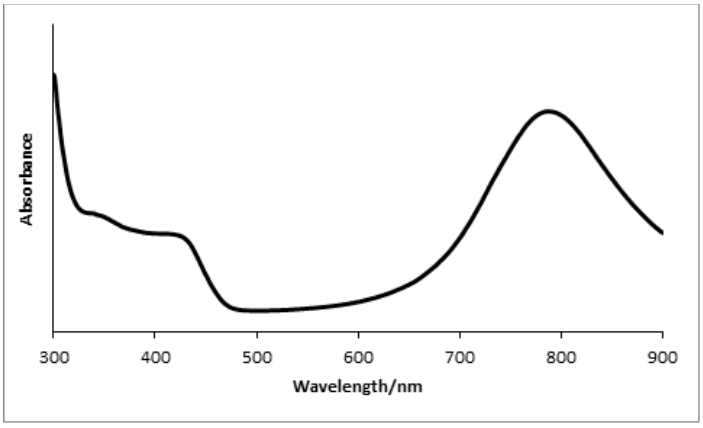

Figure 1. UV-Vis spectrum of doped PANI

The FTIR spectrum of PANI as shown in Figure 2 exhibited few significant peaks at 773 $cm^{-1}$ which corresponds to the C-H bending vibration out of the plane of benzene and 1140 $cm^{-1}$ which attributed to the $NH^{+}$ vibration mode. Meanwhile, 1183 $cm^{-1}$ peak shows the presence of S=O symmetric and 1284 $cm^{-1}$ peak shows asymmetric which arise from AOT dopant and C-N stretching peaks. The structure of PANI was confirmed by the appearance of main characteristic peaks at 1477 $cm^{-1}$ and 1578 $cm^{-1}$. These two peaks contributed to the stretching vibration mode of benzenoid ring and vibration mode of quinoid, respectively [23, 24]. Therefore, UV-Vis and FTIR spectra have confirmed the chemical structure of the resulted PANI.

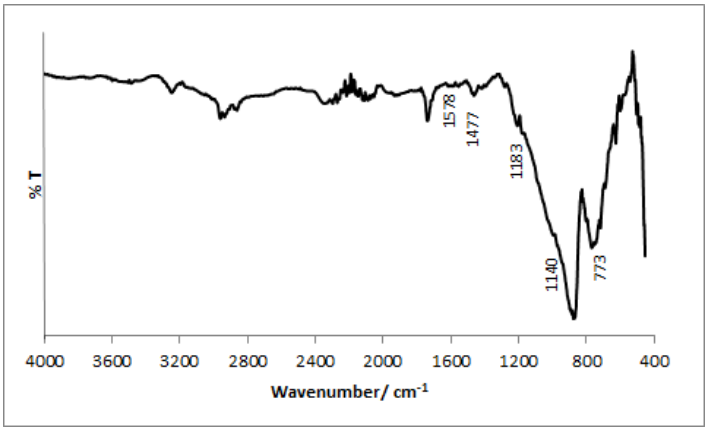

Figure 2. FTIR spectrum of doped PANI

**Sensor measurements**

First of all, the immersion time for PANI into hydrazine was optimized through conductivity study. Figure 3 shows the effect of immersion time for PANI chemical sensor against 100 ppm of hydrazine. The *y*-axis is the normalized conductivity ($\sigma_f/\sigma_i$), where $\sigma_i$ is the initial conductivity of the doped PANI (before immersion) and $\sigma_f$ is the time dependent conductivity of the film after exposed to hydrazine. The PANI thin film has recorded an initial conductivity of $4.883 \times 10^{-2}$ S/cm and it decreased with time after expose to 100 ppm of hydrazine. After 2 minutes of exposure time, the conductivity of PANI film decreased to $2.133 \times 10^{-2}$ S/cm. Besides that, the normalized conductivity decreased insignificantly from the 2nd minute to 5th minute. Therefore, 2 minute was chosen as optimum exposure time of PANI for 100 ppm of hydrazine. PANI exhibits decrease in overall conductivity upon exposure to hydrazine is due to the transformation of conducting state of PANI (emeraldine salt (ES)) to non-conducting state of PANI (leucoemeraldine salt (LES)) [25].

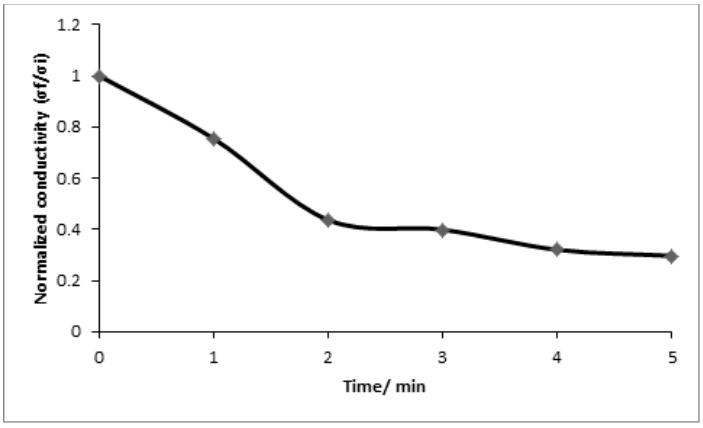

Figure 3. Normalized conductivity of PANI chemical sensor against 100 ppm of hydrazine with respect to time

Figure 4 shows the response of PANI chemical sensor in term of conductivity study against different concentrations of hydrazine such as 10, 100, 1000 and 10000 ppm. The PANI thin films have recorded 2 minutes of response time for 10 - 100 ppm of hydrazine while it showed an immediate response for 1000 - 10000 ppm of hydrazine concentrations. It revealed that the decrease in conductivity for higher concentration of hydrazine is much bigger with shorter response time compare to the lower concentration of hydrazine. It is because of higher concentration of hydrazine will possess higher hydrazinium ions which can dedope the PANI from ES to LES at much faster rate and thus decrease the conductivity of the ES within a shorter response time [18].

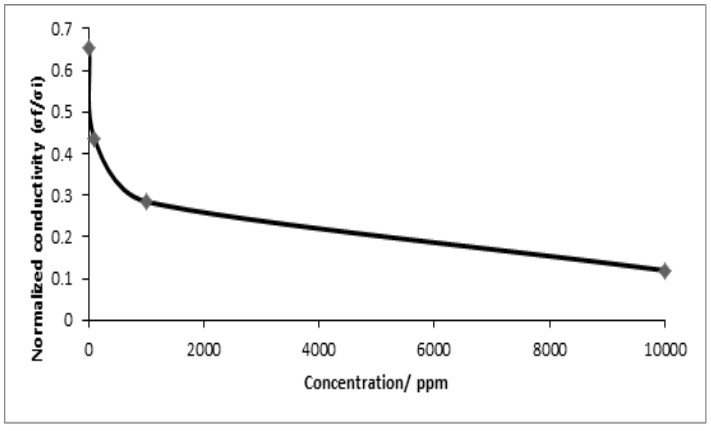

Figure 4. Normalized conductivity of PANI chemical sensor against different concentration of hydrazine

On the other hand, the recyclability of PANI chemical sensor has also been evaluated via conductivity study. According to the theory, conducting state of PANI ES will possess benzenoids and quinoids that can be dedoped by hydrazine to form LES which is an electrical insulator with predominating benzenoid units. Later, LES can be redoped back by an acid to produce ES. Thus, it is known as a reversible interaction between ES and LES with the help of a reducing agent (hydrazine) and acid. Figure 5 shows that the PANI chemical sensor can be recycled up to 10 cycles. The initial conductivity of this film was $3.899 \times 10^{-2}$ S/cm and the conductivity after the $10^{th}$ recycle was $6.167 \times 10^{-1}$ S/cm [26]. It is observed that, the normalized conductivity of PANI chemical sensor is about 15 times higher compare to the initial conductivity. It is due to the role played by the acids that used to redope PANI chemical sensor. Normally, inorganic acids will yield PANI with higher conductivity [26].

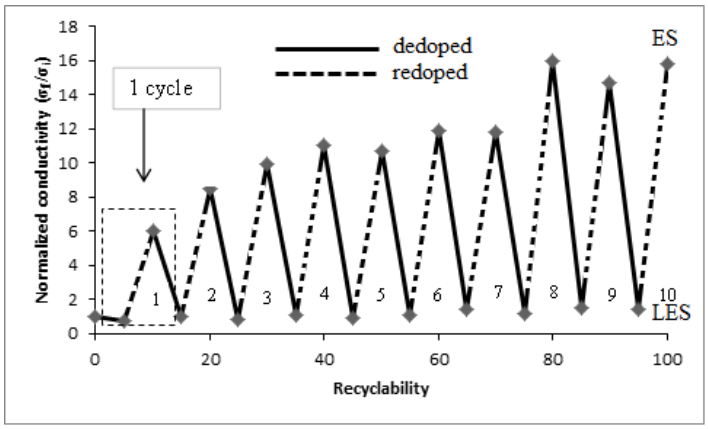

Figure 5. Recyclability of PANI for 100 ppm of hydrazine in terms of conductivity

In this study, for the first time, the UV-Vis and FTIR measurements as the supporting data were used for conductivity study of PANI chemical sensor for hydrazine detection. In the UV-Vis spectra, red-shift can be observed at ~780 nm due to the interaction of ES with hydrazine to form the LES. In general, ES will possess stretched polaron due to the quinoids as shown in the peak at 780 nm. Once the ES dedoped by hydrazine, the stretched polaron will diminish and shows a red shift which indicates the transformation of ES to LES. In Figure 6, low concentration of hydrazine (10 and 100 ppm) exhibited shorter wavelength shift while high concentration of hydrazine (1000 and 10000 ppm) exhibited longer wavelength shift from the initial wavelength of PANI films. This could be explained by the fact that higher concentration of hydrazine will possess higher amount of hydrazinium ions which can readily dedope ES to form the LES compare to the lower concentration of hydrazine which will require more time to interact with ES matrix.

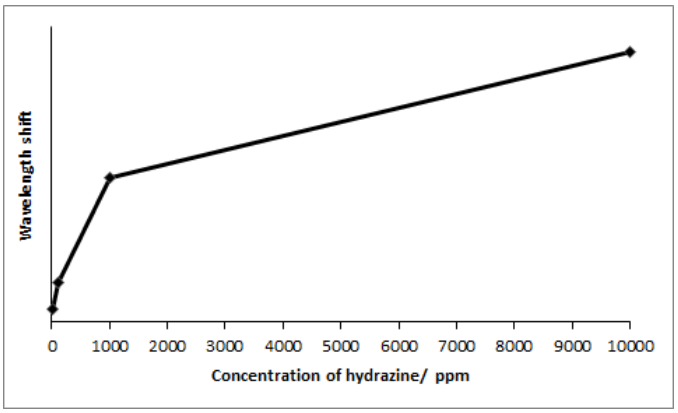

Figure 6. Wavelength shift observed for PANI for different concentration of hydrazine at 780 nm

Figure 7 illustrates the supportive data for recyclability of PANI against 100 ppm of hydrazine as explained by the conductivity data from Figure 3. ES exhibit red shift at polaron stretching around 780 nm upon dedoping by hydrazine which indicates the transformation of ES to LES while blue shift will be observed at polaron stretching when the redoping done by an acid which attributed to the conversion of LES to the conducting state of ES. Thus, Figure 7 clearly confirmed that PANI ES can be recycled up to 10 cycles. This is one of the most important characters of a chemical sensor to be used as a reusable sensor.

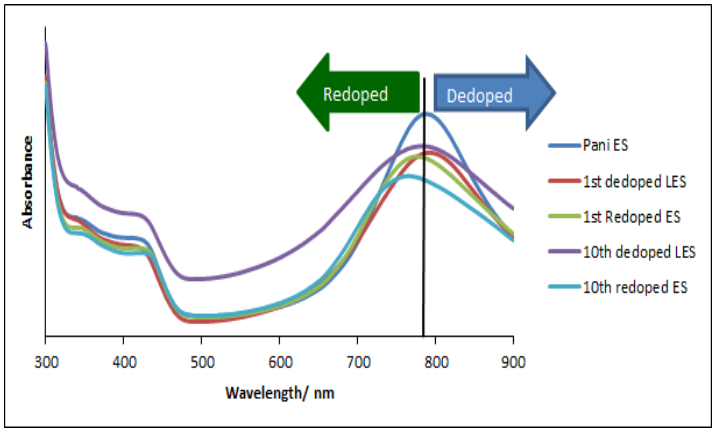

Figure 7. UV-Vis spectra of recyclability of PANI upon dedope by 100 ppm of hydrazine and redope by 1N HCl

Figure 8 shows the PANI sensing response against hydrazine by means of FTIR spectra. In general, PANI shows two significant characteristic peaks at 1477 and 1578 $cm^{-1}$ which corresponds to the benzenoid and quinoid ring stretching, respectively. Thus, the intensity ratio ($I_{1578}/I_{1477}$) of these bands could be used as an indicator for the degree of oxidation of PANI [27]. Table 1 shows the intensity ratio of ES and LES after exposure to different concentrations of hydrazine. It can be observed that, intensity ratio of LES is smaller than of ES for all hydrazine concentration; this shows that, the presence of benzenoid is predominating in the PANI chain which is an important structure of LES. So, these results further prove the changes of ES to LES upon dedope by hydrazine.

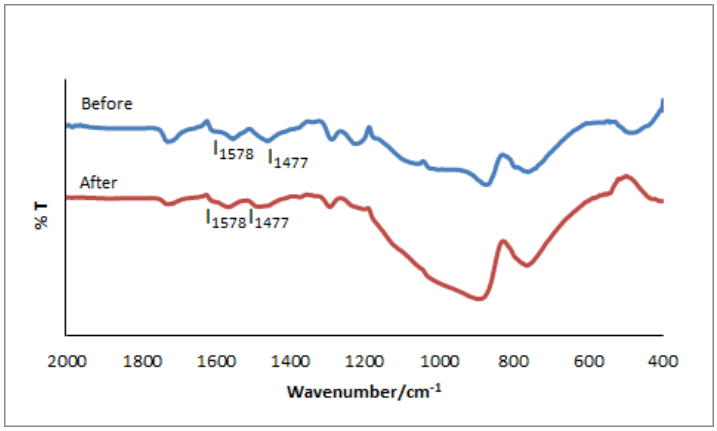

Figure 8. FTIR spectra of PANI before and after exposure with 100 ppm hydrazine

Table 1. FTIR intensity ratio of quinoid/benzenoid for different concentration of hydrazines

| **Concentration of Hydrazine (ppm)** | **ES ($I_{1578}/I_{1477}$)** | **LES ($I_{1578}/I_{1477}$)** |
|---|---|---|
| 10 | 1.00 | 0.99 |
| 100 | 1.00 | 0.99 |
| 1000 | 1.00 | 0.98 |
| 10000 | 1.00 | 0.92 |

## Conclusion

PANI was successfully synthesized and applied as an effective chemical sensor for hydrazine detection. The PANI can detect hydrazine with various concentrations such as 10, 100, 1000 and 10000 ppm with recyclability up to 10 cycles. Besides that, PANI sensor measurements were also shown in terms of UV-Vis wavelength shifts and the PANI ES and LES structural changes via FTIR spectra. In future prospect, the PANI sensor study can be carried out in a dynamic range of hydrazine concentration to determine the limit of detection and limit of quantitation. Besides, that incorporation of metal oxides into the PANI matrix would provide synergetic effects for PANI as a chemical sensor.

## Acknowledgement

The authors would like to show high gratitude for the financial support by UiTM Negeri Sembilan Branch, Kuala Pilah Campus to attend SKAM 29 and University of Malaya (UMRG: RP020A-16SUS) for research purposes.

**Abstract**

Isolation of chitin and chitosan from natural sources are widely known as they can be used in many applications. Extraction of chitin and chitosan are carried out in exoskeleton of flower crab, *Portunus pelagicus.* Chemical treatments such as demineralization and deproteinzation processes are used for chitin extraction, and followed by deacetylation process of chitin, which is to produce its derivatives that known as chitosan. Characterization of chitin and chitosan has been done using Fourier Transform Infrared (FTIR) Spectroscopy, X-ray diffraction (XRD), CHNS elemental analysis and Thermogravimetric analysis (TGA). Preliminary results of FTIR vibrations patterns showed stretching of hydroxyl (O-H), amine (N-H) and carbonyl (C-O) groups indicated the presence of chitin and chitosan. XRD analysis indicates the crystalline nature of chitin and chitosan. The degree of deacetylation of chitin was characterized using CHNS elemental analyzer. The extracted chitosan will be used as reducing agent for silver nanoparticles synthesis in the future studies.

**Abstrak**

Pengasingan kitin dan kitosan daripada sumber semulajadi telah dikenali secara meluas kerana dapat digunakan dalam banyak aplikasi. Pengekstrakan kitin dan kitosan dari exoskeleton ketam bunga, *Portunus pelagicus* telah dilakukan. Rawatan kimia seperti proses demineralisasi dan proses deprotenisasi telah digunakan untuk pengekstrakan kitin dan diikuti dengan proses deasetilasi daripada ktin untuk penghasilan terbitannya yang dikenali sebagai kitosan. Pencirian kitin dan kitosan telah dilakukan dengan menggunakan Spektoskopi Inframerah Transformasi Fourier (FTIR), pembelauan Sinar X (XRD), analisis unsur CHNS dan analisis termogravimetri (TGA). Dapatan awal getaran FTIR menunjukkan regangan bagi kumpulan hidroksil (O-H), amino (N-H) dan karbonil (C-O) menunjukan kehadiran sebatian kitin dan kitosan. Analisis XRD menunjukkan sifat kristal bagi kitin dan kitosan. Pencirian darjah deasetilasi kitin telah dilakukan menggunakan penganalisis unsur CHNS. Ekstrak kitosan akan digunakan sebagai agen penurun bagi sintesis nanopartikel perak untuk kajian masa hadapan.

**Kata kunci:** krustasea, invertebrata marin, bio-polimer, penurun semulajadi.

## Introduction

Polysaccharides have given many advantages in life science as their unique structure has shown some potential as natural bioactive component. Chitin is the second most abundant of polysaccharides on earth after cellulose that formed a linear chain of acetylglucosamine group. Chitin can be isolated from exoskeleton of crustacean for instance; shrimp shells [1], crab shells [2], fish scales [3], gastropod shell and operculum [4]. Chitin is available in three different forms, which are α, ß and γ forms. In addition, chitin has a compact structure and strong intra and inters molecular hydrogen bonds [5] that may causes the insolubility in most of the organic solvents, thus limit it in many applications, especially in clinical field. Due to this concern, chemical modification on chitin is performed,

which is to increase the solubility. Chitin can be deacetylated or partially deacetylated into chitosan that can be identified by calculating the percentage of degree of deacetylation (DD). Chitin and chitosan represent as white solid, non-toxic, odourless, biodegradable, biocompatible with living tissues and bio-absorbable with antibacterial, free from antigenic effect, polar in nature and can form stable complexes with heavy metals [6,7]. Chitosan has versatile properties that can be used in different fields such as biomedicals [8], tissue engineering [9], textiles [10,11], and food processing industries [12].

In general, three major steps are used in the isolation process. The processes include demineralization, deproteinization and deacetylation. Demineralization is a process of removing inorganic materials from the natural sources (i.e; exoskeleton of invertebrates), using dilute acidic solution. Then, the process is continued with deproteinization process that aided in the protein separation and followed by deacetylation process, which gives the final product of chitosan. Deacetylation process occurred at elevated temperature (in range 105 to 110 $^{o}$C) in concentrated bases solution (40% to 50%) [13 - 15]. Blue swimmer crab, *Portunus pelagicus* (*P. pelagicus*) is a major marine crab that distributed in the coastal water of western South China Sea. In the recent study, extraction of chitin and chitosan from blue swimmer crab, *P. pelagicus* (Figure 1) was conducted using this standard method and the obtained chitosan will be used as reducing agent to chelate metal ion in silver nanoparticles synthesis for upcoming research work.

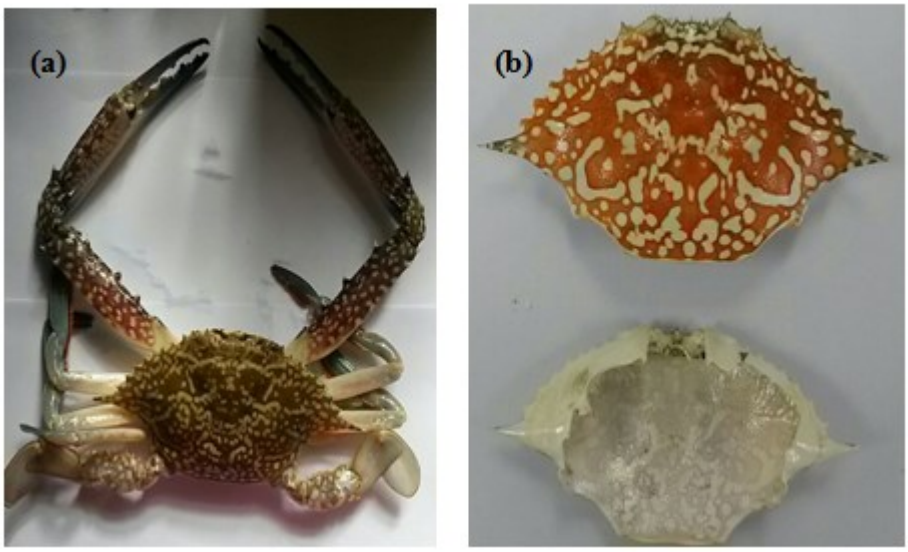

Figure 1. (a) Blue swimmer crab, *P. pelagicus* and (b) its carapace after drying process

## Materials and Methods

### Raw material preparations

Blue swimmer crab, *P. pelagicus* is bought from a local market in Kuala Terengganu, Malaysia. The carapace was scrapped free from any loose tissues, washed, dried and ground (Retsch PM 100) into fine powder with size average of 450 μm.

### Extraction procedures

Chitin was extracted from *P. pelagicus* carapace following method by Sagheer et al. [16] with some modifications. The demineralization process begins by treating the pulverized carapace in 1.0 N hydrochloric acid, HCl solution (1:15 solid-to-solvent ratio, w/v) with constant stirring for 1 hour. No thermal heating used in this process. The deproteinization process was performed by heating the demineralized powder under reflux in 1.0 N sodium hydroxide, NaOH solution (1:15 solid-to-solvent ratio, w/v) at 80 °C for 6 hours. Then, removal colour of the deproteinized powder was conducted in acetone (1:100 solid-to-solvent ratio, w/v) with constant stirring for 24

hours. The purified chitin was filtered, washed to neutrality and dried in oven at 60 °C. White powder of carapace shell was obtained after undergo the demineralization, deproteinization and decolourization processes.

**Chitin deacetylation**
Chitin was deacetylated using traditional thermal heating. The samples was mixed in 50% (w/v) of sodium hydroxide, NaOH at 1:20 solid-to-solvent ratio and stirred for 6 hours at 110 °C. After the deacetylation process, the sodium hydroxide, NaOH was drained off and the pure chitosan was washed with deionized water to neutrality and dried in oven at 60 °C.

**Characterization of chitin and chitosan: Fourier transform infrared spectroscopy**
The vibration of functional groups spectra of chitin and chitosan prepared were analyzed using FTIR spectroscopy. All samples were KBr supported, pressed to result homogenous sample/KBr disc and analyzed over the frequency of 4000 to 400 $cm^{-1}$ at resolution of 4 $cm^{-1}$ using Perkin Elmer Spectrum 100 FT-IR Spectrometer.

**X-ray powder diffractometry**
The XRD measurement of powder samples were carried out using a model of Rigaku MiniFlex II diffractometer equipped with Ni – filtered Cu Kα radiation (λ = 1.5406 Å) as the X-ray source. The diffractometer was set up at 1.25° diverging and receiving slits at 40 kV and 30 mA. Data was collected at a scan rate of 2°/min with the scan angle from 3° to 40°.

**Elemental analysis**
The average degree of deacetylation (DD) of chitosan samples was determined using CH-NS Elemental Analyzer (CHNS Microanalysis / EA1112 CHNS – O Analyzer). The DD% value of chitosan samples were calculated from the following formula:

$$DD\% = [(6.857 - C / N) / 1.7143] \times 100 \quad (1)$$

where C/N is the carbon to nitrogen ratio peak area measured from the elemental composition of the chitosan samples.

**Thermogravimetric analysis**
Thermogravimetric analysis (Perkin Elmer TGA analyzer) were carried out using approximately 20 mg of sample with temperature range of 30 to 600 °C, and with heating rate of 10 °C/min under (30 mL/min) nitrogen atmosphere.

## Results and Discussion

**Extraction of chitin and chitosan**
In this study, extraction of chitin and chitosan from the carapace of crab, *P. pelagicus* was initiated by treatment of crab shells in dilute acidic solution for the removal the inorganic content such as calcium carbonate, $CaCO_3$ from the shells. Bubbles were released after the penetration of the acid on the surface of crab shell indicates the emission of carbon dioxide, $CO_2$ gas. During this treatment, low concentration of acidic solution, which is 15 mL/g of 1.0 N HCl was used to prevent the hydrolysis of chitin structure [17]. Deacetylation process is a conducted, which is to remove the acetyl group in chitin, thus produce chitosan [5]. Bolat et al. [18] reported the chitin and chitosan content for freshwater crab were 6.83% and 4.56%, respectively. In this study, the dry weight of chitin and chitosan contents for the carapace of *P. pelagicus* were 20.24% and 13.56%, respectively and the result is consistent with the result reported by Das et al. [19].

**Characterization of chitin and chitosan: Fourier transform infrared analysis**
Fourier transform infrared (FTIR) spectroscopy is a technique that is used to determine the vibration of functional groups in chitin and chitosan. The FTIR spectra of chitin and chitosan of *P. pelagicus* were examined as shown in Figure 2. Chitin spectrum shows bands at 3447 $cm^{-1}$, 3103 $cm^{-1}$ and 1657 $cm^{-1}$ corresponds to the vibration of hydroxyl, the O–H stretching, aliphatic compound, the $CH_3$ stretching and amide I, the stretching of C=O group, respectively. These peaks are pivotal to observe because they are used to differentiate the formation between chitin and chitosan from the extracted sample. The vibration of Amide III was observed at peak 1314 $cm^{-1}$ due to the

presence of protein content in the chitin complexes. Vibration of N–H stretching that associated with O-H stretching was observed in chitosan FTIR spectrum at band 3447 $cm^{-1}$. The vibration of $-CH_3$ group in chitin spectrum was absence in the FTIR spectrum of chitosan after treating in concentrated NaOH for six hours, thus this finding proved that the acetyl group, $COCH_3$ in chitin backbone was removed during the deacetylation process, thus produced chitosan. Besides, there is no significant between the FTIR spectrum of prepared chitosan and commercial chitosan. Table 1 shows the spectral value of chitin, chitosan and commercial chitosan.

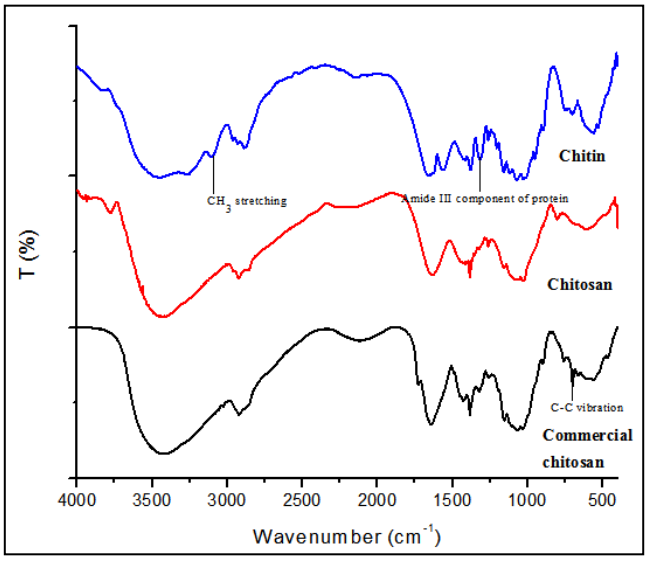

Figure 2. FTIR spectra of chitin, chitosan and commercial chitosan

Table 1. FTIR spectra value of chitin, chitosan and commercial chitosan

| **Assignment** | **Frequency ($cm^{-1}$)** | | |
|---|---|---|---|
| | **Chitin** | **Chitosan** | **Commercial Chitosan** |
| Hydroxyl, O-H stretch (H-bonded) | 3445 | - | - |
| Amine, $NH_2$ stretch and hydroxyl, O-H stretch | - | 3435 | 3429 |
| Amine, N-H stretch | 3264 | - | - |
| Aliphatic compound, $-CH_3$ stretch | 3102 | - | - |
| Aliphatic compound, $-CH_2$ stretch | - | 2924 | 2921 |
| Secondary amide, C=O stretch | 1657 | 1636 | 1643 |
| Amide, N-H bend | 1559 | - | - |
| Aliphatic compound, $-CH_2$ bend | 1417 – 1379 | 1412 - 1384 | 1430 - 1384 |
| Amide III, component of protein | 1314 | - | - |
| Complex vibration of NHCO group | - | 1261 | 1262 |

| Carbonyl, C-O stretch | - | 1023 | 1070 |
| Ring vibration (C-C) | - | - | 699 |

**X-ray powder diffractometry analysis**

X-ray diffraction analysis is applied to determine the crystallinity structure of extracted chitin and chitosan. In the crystallography study of the prepared samples (Figure 3), the XRD patterns of chitin shows three sharp peaks at 9.3°, 19.4°, 26.0° and a small peak at 13.0°. These peaks often used as reference peaks for α chitin [15, 20 - 21]. In addition, weak reflection of α chitin peak at 26° was observed in the chitosan of *P. pelagicus.* This condition is occurred may due to the partial deacetylation of chitin. Furthermore, strong reflection was observed at 9.3° and 19.2° belongs to chitosan and these peaks were almost similar to the peaks available in the commercial chitosan.

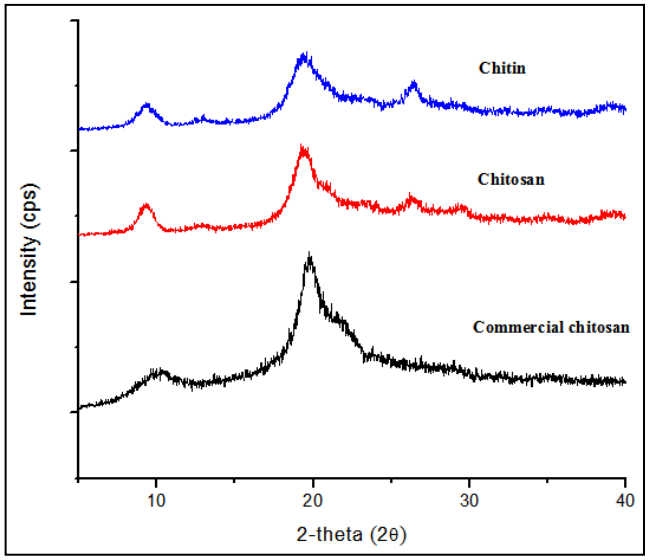

Figure 3. XRD patterns for chitin, chitosan and commercial chitosan

**Elemental analysis**

Table 2 shows the chemical composition of chitin and chitosan. The percentage for carbon, C in chitin and chitosan were 77.67% and 73.93%, respectively. The decreasing value of the C percentage is due to the removal of acetyl groups in the chitin structure. Kaya et al. [22] stated that the theoretical of N percentage for pure chitin is 6.9%. Hence, the N percentage in chitin and chitosan prepared were 9.62% and 12.00%, respectively, which are higher than 6.9% reported in literature. This is due to the present of protein residue in the both samples and supported by the results obtained from FTIR spectra. Furthermore, the two components (C and N) are important to determine the percentage of the DD of the chitosan sample followed by the formula given. The DD of the chitosan of *P. pelagicus* was 40.60% slightly lower than the suggested DD (approximately 50%). However, this might cause by partially deacetylation of chitin and the result is consistent with the crystallinity data obtained.

Table 2. The percentage composition of carbon, nitrogen and hydrogen in chitin and chitosan

| Samples | Carbon (%) | Nitrogen (%) | Hydrogen (%) | C/N |
|---|---|---|---|---|
| Chitin | 77.67 | 9.62 | 12.71 | 8.07 |
| Chitosan | 73.93 | 12.00 | 14.07 | 6.16 |

**Thermogravimetric analysis**

Thermogravimetric analysis (TGA) is conducted, which is to study on thermal degradation of chitin and chitosan. The TGA curves (Figure 4) was observed that chitin and chitosan have two degradation steps. The first stage of degradation chitin and chitosan occurred at temperature range 30 °C to 125 °C and 30 °C to 123 °C with 7% and 12% of weight loss, respectively. This degradation may attribute to the loss of water molecules because the chitin

and chitosan structures have strong affinity towards water and lead dehydration. The second stage of chitin and chitosan degradation begins around 152 °C to 398 °C and 148 °C to 392 °C with 61% and 48% of weight loss, respectively. The second degradation belongs to thermal decomposition of chitin and chitosan. Although the chitin and chitosan prepared shows a similar trend of thermal degradation curves, but chitin has larger decomposition rate as compared to chitosan [15].

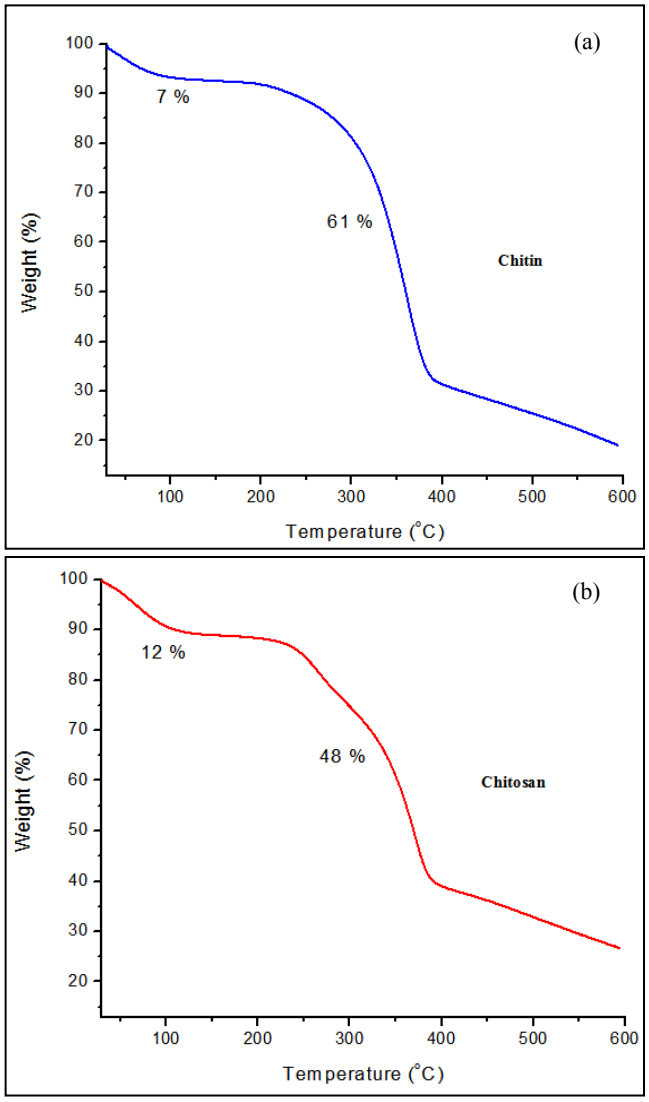

Figure 4. TGA analysis of (a) chitin and (b) chitosan

## Conclusion

Chitin and chitosan were successfully extracted from the carapace of blue swimmer crab, *P. pelagicus* with significant outcomes. Dry weight of chitin and chitosan content were 20.24% and 13.56%, respectively. FTIR analysis confirmed the structural change between chitin and chitosan. Crystallinity analysis revealed the formation of α chitin from the studied species. Partially deacetylation of chitin into chitosan was observed with 40.60% of DD. Additionally, the thermal degradation analysis proved that α chitin exists as a stable structure towards thermal

decomposition than chitosan. It is suggested that chitin and chitosan from the carapace of blue swimmer crab, *P. pelagicus* can be used as potential a reducing agent for synthesizing silver nanoparticles in future studies.

Received: 16 January 2017; Accepted: 14 June 2017

**Abstract**

The fine powders from young tubers of *Hydnophytum formicarum* were soaked and extracted by Soxhlet in methanol. Both methanol solutions were evaporated with rotary evaporator to yield cold and hot methanol extracts. Chromatographic separation on the extracts by vacuum liquid and radial chromatography gave two new compounds namely hydnophaldehyde [4,4′,10′,13′,14′-pentamethylgona-7′,9′(11′)-dien-17′-yl(6)-2,2-dimethylheptanal] (**1**) and 2-(2′-methoxyphenyl)ethyl palmitate (**2**). The structures of the above compounds were established by interpreting their spectral data of mass, 1-D Nuclear Magnetic Resonance (NMR), 2-D NMR, and Infrared (IR).

**Keywords**: Rubiaceae, *Hydnophytum formicarum*, hydnophaldehyde, 2-(2′-methoxyphenyl)ethyl palmitate

**Abstrak**

Serbuk halus bonjolan muda *Hydnophytum fomicarum* direndam dengan metanol dan diekstrak mengunakan kaedah Soxhlet. Kedua-dua larutan metanol disejat dengan penyejat berputar bagi menghasilkan ekstrak metanol sejuk dan panas. Pemisahan kromatografi terhadap ekstrak tersebut dengan kromatografi cecair vakum dan radial memberikan dua sebatian baru bernama hidnofaldehid [4,4′,10′,13′,14′-pentametilgona-7′,9′(11′)-dien-17′-il(6)-2,2-dimetilheptanal] (**1**) dan 2-(2′-metoksifenil)etil palmitat (**2**). Struktur sebatian di atas disahkan dengan mentafsirkan data spektrum bagi jisimnya, Resonans Magnetik Nuklear (RMN) 1-D, RMN 2-D dan Inframerah (IM).

**Kata kunci:** Rubiaceae, *Hydnophytum formicarum*, hidnofaldehid, 2-(2′-metoksifenil)etil palmitat

## Introduction

Ant-house plants of *Hydnophytum* genus are distributed in Southeast Asia, the Pacific region, and also extending into northern Australia state of Queensland. The plants grow on tree branches and on trunks by their epiphytic attaching tubers that look like the swollen succulent stems are having few woody branches with leaves. The genus comprises 55 species, of which 44 are found in New Guinea [1]. *Hydnophytum formicarum* Jack. (Rubiaceae) forms a symbiotic relationship with ants where its hollow as well as smooth-walled tunnels within the modified stems provide shelter for ant colonies, and in return they provide nutrients to the plants by leaving wastes within the tunnels. In Malaysia, the plant is known as Sarang Semut, Kepala Beruk, and Raja Satong. The tubers of *H. formicarum* have been used in Thai as well as in Malaysian traditional herbal medicine for cancer treatment. To date, only eight known compounds of β-sitosterol, stigmasterol (steroids), protocatechualdehyde, isoliquiritigenin, butein (phenolic compounds), butein [2, 3], sinapinic acid [4] and 7,3',5'-trihydroxyflavanone (flavonoids) [5] were isolated from *H. formicarum* tubers.

Previous study showed that ethanolic and phenolic-rich extracts of *H. formicarum* tubers possessed both antiproliferative activity as well as HDAC inhibitory activity in HeLa cells that are mediated by induction of apoptosis. On the other hand, methanol, methanol-water (1:1), and water extracts of *H. formicarum* showed selective activity against human tumor cell lines, HeLa, and A549. These results support the efficacy of *H. formicarum* tubers for the treatment of cervical cancer, colon cancer, and T-cell leukemia in an alternative medicine. Thanaset et al. stated that sinapinic acid that is isolated from *H. formicarum* tubers, inhibited the growth of HeLa and HT29 cells more effectively than sodium butyrate. However, it inhibited the growth of HCT116 and Jurkat cells less effectively than sodium butyrate. The non-cancer cell line (Vero cells) and breast cancer cell line (MCF-7 cells) appeared to be resistant to both sinapinic acid and sodium butyrate. The growth inhibitory effect of sinapinic acid in HeLa cells was mediated by induction of apoptosis. *Hydnophytum formicarum* tubers-derived 7,3',5'-trihydroxyflavanone could induce the apoptotic cell death of MCF-7 cells by increasing Bax expression level [6]. In view of the above, we embark on the isolation of new compounds from the extracts of *H. formicarum*. In this study, methanol was used for maceration and Soxhlet because more polar compounds can be extracted from the young tubers.

## Materials and Methods

### Instruments

The $^{1}H$ and $^{13}C$-APT NMR spectra were recorded with Avance III 700 MHz Bruker in $CDCl_3$ with the chemical shifts, δ, in ppm and the values of coupling constants, *J*, in Hz. LC-MSToF spectra were taken on the Dionex/Bruker Micro ToFQ and FTIR (ATR) spectra were recorded on the Perkin-Elmer Spectrometer 400 FT-IR/FT-NIR. Column chromatography (Merck 7747; particle size 0.040 – 0.063 mm), vacuum liquid chromatography (Merck 7747; particle size 0.040 – 0.063 mm), radial chromatography (Merck 7749; particle size 0.040 – 0.063 mm), thin layer chromatography (Merck 5554; mesh 230 – 400).

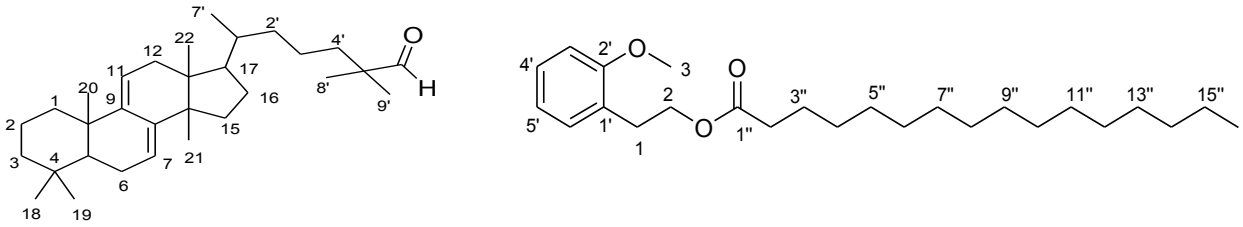
### Plant materials

Young tubers of *Hydnophytum formicarum* were bought in April 2015 from a medicinal plant seller at Kampung Lak Lok, Jertih, Besut, Terengganu. A voucher specimen (UKMB 40312) was deposited at the herbarium of Universiti Kebangsaan Malaysia Bangi (UKMB).

### Extraction and isolation

The air-dried young tubers of *Hydnophytum formicarum* were cut into small pieces and grounded into fine powder by using mechanical grinding machine. The powders (1.04 kg) were then extracted with methanol through two types of extraction: maceration in three days, and Soxhlet for a total of 18 hours. The maceration extraction produced 17.0 g of dark-brown concentrated extract after being evaporated by rotary evaporator. The methanol solution of the extract was extracted by using separatory funnel with *n*-hexane and chloroform to yield extracts of *n*-hexane (9.0 g), chloroform (5.0 g), as well as methanol (3.0 g) [3]. The *n*-hexane extract was subjected to vacuum liquid chromatography (VLC) by using silica gel 7747 (Merck) that eluted with increasing polarity of *n*-hexane and ethyl acetate. The eluents were combined based on their silica gel thin layer chromatography (TLC) 5554 (Merck) profile to give seven fractions (A-G). Fraction B (1.1 g) was further separated by radial chromatography (RC) by using *n*-hexane-ethyl acetate (9:1) to yield nine fractions ($B_1$-$B_9$). The $B_3$ fraction was pure to give 2-(2′-methoxyphenyl) ethyl palmitate (28.0 mg).

Meanwhile, the methanol solution of the Soxhlet extraction was evaporated to give 15.0 g (1.44 %) of a dark-brown extract after solvent removal by a rotary evaporator. The extract was subjected to VLC that eluted with increasing polarity of *n*-hexane and ethyl acetate. The eluents were combined based on their TLC profile to give seven fractions (A-G). Fraction C (1.2 g) was further purified by RC using *n*-hexane-ethyl acetate (7:3) to yield eight fractions ($C_1$-$C_8$). The $C_2$ fraction was pure to give hydnophaldehyde (38.0 mg).



## Results and Discussion

### Characterization Study

Hydnophaldehyde (**1**) (38.0 mg): white needles; $R_f$ = 0.94 (*n*-hexane-ethyl acetate, 7:3); ESI-MS (m/z): 461.3201 $[M+Na]^+$, $C_{31}H_{50}O$; FTIR (ATR) $cm^{-1}$: 2927 and 2870 ($Csp^3$–H), 1698 (C=O aldehyde), 1456 (C=C), 1385 ($Csp^3$-H), 750 ($Csp^2$–H). Data of 1-D and 2-D (HSQC, COSY, HMBC) for $^{1}H$ and $^{13}C$-APT NMR are in Table 1.

2-(2′-Methoxyphenyl)ethyl palmitate (**2**) (28.0 mg): white powders; $R_f$ = 0.69 (*n*-hexane-ethyl acetate, 9:1); ESI-MS (m/z): 413.2417 $[M+Na]^+$, $C_{25}H_{42}O_3$; FTIR (ATR) $cm^{-1}$: 2916 and 2849 (C$sp^3$-H), 1711 (C=O ester), 1458 and 1378 (C$sp^3$-H), 1268 and 1158 (C-O), 1032 (C$sp^2$-H), 1516, 1473 and 1463 (C=C aromatic), 718 (ortho subs. benzene). Data of 1-D and 2-D (HSQC, COSY, HMBC) for $^1$H and $^{13}$C-APT NMR are in Table 2.

Molecular structures of hydnophaldehyde **(1)** and 2-(2′-methoxyphenyl)ethyl palmitate (**2**) as shown in Figure 1.

Source: *[7]

Spectral data of $^{1}H$ and $^{13}C$-APT NMR as well as 2-D NMR in Table 1 confirmed that the compound is hydnophaldehyde or 4,4′,10′,13′,14′-pentamethylgona-7′,9′(11′)-diene-17′-yl(6)-2,2-dimethylheptanal. The ESI-MS gave molecular ion at *m/z* 461.3201 $[M+Na]^{+}$, which corresponded to the molecular formula $C_{31}H_{50}O$. To the best of our knowledge, hydnophaldehyde (steroid) that is isolated from *Hydnophytum formicarum* is a new compound. Based on Prachayasittikul et al, protocatechualdehyde (phenolic) has been isolated from *H. formicarum*. The presence of aldehydes among others in the phytochemical screening of *H. formicarum* ethanol extract supports the existence of hydnophaldehyde in the plant [8]. Figure 2 below shows the correlations between carbon and proton as well as proton and proton from the respective HMBC and COSY spectral data of hydnophaldehyde in Table 1.

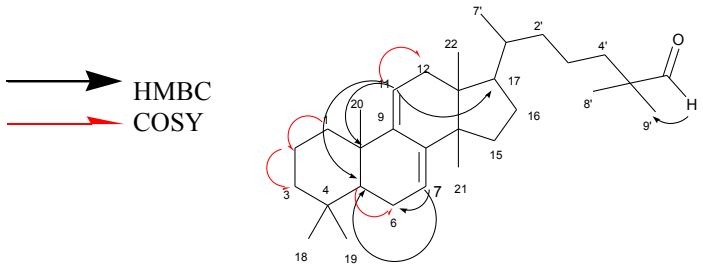

Figure 2. HMBC and COSY correlations of hydnophaldehyde (1)

The NMR spectral data ($^{1}H$ and $^{13}C$-APT) in Table 2 is in agreement that it is compound that is named as 2-(2′-methoxyphenyl) ethyl palmitate. The ESI-MS exhibited molecular ion at *m/z* 413.2417 $[M+Na]^{+}$, which is matched with the molecular formula $C_{25}H_{42}O_3$. A 107 species in Rubiaceae family that composed fatty acids in leaves proved that 2-(2′-methoxyphenyl) ethyl palmitate as an ester of palmitic acid is present in *Hydnophytum formicarum* [9]. Figure 3 shows the HMBC and COSY correlations of 2-(2′-methoxyphenyl) ethyl palmitate.

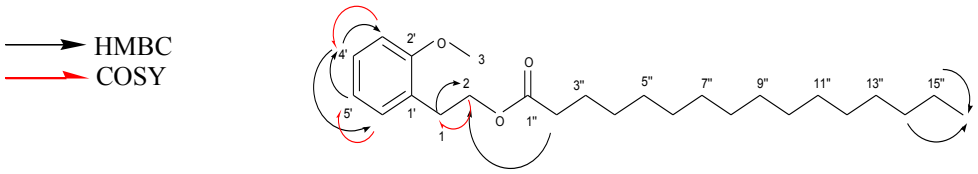

Figure 3. HMBC and COSY correlations of 2-(2′-methoxyphenyl)ethyl palmitate (2)

## Conclusion

Chromatographic separation of two methanol extracts that was derived from maceration and Soxhlet of powder for young tubers of *Hydnophytum formicarum* yielded two new compounds of hydnophaldehyde (4,4′,10′,13′,14′-pentamethylgona-7′,9′(11′)-diene-17′-yl(6)-2,2 dimethylheptanal) and 2-(2′-methoxyphenyl)ethyl palmitate. Hydnophaldehyde and 2-(2′-methoxyphenyl) ethyl palmitate can be used to evaluate their biological activities such as for antimicrobial, antioxidants, anti-cancer, and antitumor properties.

## Acknowledgement

We would like to thank the Ministry of Higher Education Malaysia and Universiti Kebangsaan Malaysia (UKM) for the financial support under DLP-2013-018 and LIV-2015-01 grants. Special thanks to School of Chemical Sciences and Food Technology, Faculty of Science and Technology, UKM and Centre for Research and Innovation Management (CRIM), UKM for the technical support on NMR, LC-MSToF and FTIR (ATR) instrumentation.

**Abstract**

An optical chemical sensor for determination of Cd(II) in aqueous solution has been developed by immobilizing 1-(2-pyridylazo)-2-naphtol (PAN) in poly(methyl methacrylate) (PMMA) as a matrix and 2-nitrophenyl octyl ether (NPOE) as a plasticizer. The adsorption of Cd(II) causes the color of the membrane to change from yellow to red-orange with the maximum absorbance ($\lambda_{max}$) at 556 nm. The sensor membrane gives the best response towards Cd(II) ion at pH 8.5, after 120 minutes of contact time, at 2 ppm Cd(II), and 2 mL solution. A linear Cd(II) calibration curve can be developed in the concentration range of 0.8 - 1.8 ppm with $R^2$ = 0.960. The limit of the detection and limit of quantification are 0.041 ppm and 0.126 ppm, respectively. The molar absorptivity is found to be 2.3 x $10^5$ L $mol^{-1}$ $cm^{-1}$. The proposed sensor membrane has been applied to the determination of Cd(II) in the river water with internal standard addition method. The observed percent recovery is in the range of 100.24 – 107.52%.

**Keywords**: optical chemical sensor, 1-(2-pyridylazo)-2-naphtol, Cd(II) analysis, poly(methyl methacrylate)

**Abstrak**

Reagen 1-(2-piridilazo)2-naftol (PAN) yang dipegun dalam poli(metil metaakrilat) (PMMA) dengan 2-nitrofenil oktil eter (NPOE) sebagai pemplastik untuk sensor kimia optik bagi penentuan ion Cd(II) dalam larutan akues telah dibangunkan. Jerapan ion Cd(II) telah menyebabkan penukaran warna dari kuning menjadi merah-oren dengan serapan maksimum pada ($\lambda_{max}$) iaitu 556 nm. Membran sensor memberikan tindak balas maksimum apabila dicelupkan dalam larutan Cd(II) pada pH 8.5, selepas 120 minit masa sentuhan pada kepekatan 2 ppm Cd(II) dan 2 ml isipadu larutan. Berdasarkan kajian yang dijalankan, julat linear lengkung kalibrasi kepekatan ion Cd(II) ialah 0.8 - 1.8 ppm dan nilai $R^2$ = 0.960. Had pengesanan dan pengkuantitian yang diperolehi masing – masing ialah 0.041 ppm dan 0.126 ppm. Daya penyerapan molar dikira pada 2.3 x $10^5$ L $mol^{-1}$ $cm^{-1}$. Membran sensor ini telah dikaji untuk menentukan kepekatan Cd(II) dalam air sungai yang dipaku kaesah larutan piawai dalam. Ia telah menghasilkan pemulihan semula pada nilai 100.24 – 107.52%.

**Kata kunci**: Sensor kimia optik, 1-(2-piridilazo)2-naftol, analisis Cd(II), poli(metil metaakrilat)

## Introduction

Cadmium (Cd) is one of the heavy metals that can pollute the environment even in a trace amount. Cd(II) ion in water also has a significant influence towards water quality and public health. The maximum permitted contents of Cd in waste and drinking water are 0.1 and 0.05 ppm, respectively [1]. Cd is harmful to health since it is both toxic and carcinogenic [2-4]. Therefore, a simple, rapid, sensitive and low-cost method of analysis is required for monitoring Cd(II) content in the environment.

The conventional standard methods for metal determination are atomic absorption spectrophotometer (AAS) and Flame-AAS [5, 6]. These methods are sensitive and selective. However, it is relatively expensive and requires a skilled person to do the job. The chemo-optic sensor is an alternative method for metal analysis. It is part of the green analytical methods since it can significantly reduce energy consumption, organic solvents, and gas emission. Therefore, it is much more environmentally friendly [7-10].

Several studies on optical chemical sensors have been carried out based on the immobilization of colored complexing reagents in an appropriate polymer membrane. For example, an optical chemical sensor for Cd(II) determination has been developed using various techniques such as in cellulose acetate membrane by immobilization of 1-(2-piridilazo)-2-naftol (PAN) [11], 2-amino-cyclopentene-1-dithiocarboxylic acid (ACDA) [12], and dithizone [13]. Immobilization of PAN in the poly-methyl methacrylate membrane has been applied in the determination of Cd(II), Ni(II), Cu(II), Zn(II), Pb(II), and Co(II) [14, 15]. Also, polyvinyl chloride (PVC) based chemo-optic sensor as a matrix for pyridylazo resorcinol (PAR) using tributhyl phosphate (TBP) as a plasticizer for Th(III) determination has also been described by Ensafi and Fouldagar [16].

1-(2-piridilazo)-2-naftol (PAN) possesses azo-nitrogen and OH groups (Figure 1). It reacts with transition metals to form a colorful complex. PAN is an unselective coloring reagent. However, its selectivity over other metal ions can be enhanced by adjusting the pH of the solution in accordance with the targeted metal ions [17]. Cd(II) in alkaline media forms a stable color complex with PAN, which can be extracted into organic solvents [17, 18].

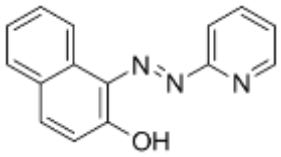

Figure 1. Molecular structure of PAN

In this study, we have developed a chemo-optic Cd(II) sensing method, which is simple, safe, inexpensive, environmentally friendly and oriented to green analytical chemistry. The sensing membrane is developed based on immobilization of PAN in poly-methyl methacrylate (PMMA) membrane using 2-nitrophenyl octyl ether (NPOE) as plasticizer.

## Materials and Methods

### Chemicals and instruments

Cadmium(II) nitrate [$Cd(NO_3)_2$], sodium hydroxide (NaOH), hydrochloric acid (HCl), copper(II) chloride ($CuCl_2$), zinc(II) nitrate [$Zn(NO_3)_2$], nickel(II) nitrate [$Ni(NO_3)_2$], iron(III) chloride ($FeCl_3$) and tetrahydrofuran (THF) were obtained from Merck. 1-(2-pyridylazo)-2-naphtol (PAN) and 2-nitrophenyl octyl ether (NPOE) were analytical grades and purchased from Sigma-Aldrich. Poly-methyl methacrylate (PMMA) was obtained by synthesis with an average molecular weight of about 220,000. The double distilled water was used as a solvent throughout the UV-Visible spectrophotometric measurements. The pH of the solution was adjusted by drop wise addition of either 0.10 M NaOH or 0.10 M HCl and monitored by using Thermo Scientific (ORION 4 STAR, pH-ISE Portable) pH-meter. A Shimadzu UV-Visible spectrophotometer UV-2450 model and A Shimadzu FTIR spectrophotometer, Prestige-21 type model, were used to measure the UV-Visible and FTIR spectra.

**Preparation of sensor membrane**
The sensor membrane was prepared by dissolving 0.4000 g PMMA, 0.0100 g PAN, and 120 µL NPOE in 10 mL THF, and stirring the mixture at a constant speed for 5 hours at room temperature. Subsequently, the reaction mixture was poured into a casting glass (5 cm × 12 cm) and kept at room temperature for 10 – 12 hours, until all the solvent evaporated. The membranes were released from the cast, washed with distilled water, dried at room temperature, and cut into rectangle shape (0.8 cm × 2 cm). The membrane thickness was c.a. 0.05 mm.

**Characterization of sensor membrane**
The FTIR spectra of PAN, NPOE, PMMA and PMMA-PAN membrane were recorded using A Shimadzu FTIR spectrophotometer.

**Determination of optimum pH**
The optimum pH was determined by measuring the absorbance of membranes that were previously soaked in 2 mL solution containing 2 ppm of the Cd(II) ion in the pH range of 7.0 – 9.0 for a defined time. The optimum pH was indicated by maximum absorbance at 556 nm.

**Range of linearity**
The linear range of absorbance of Cd(II)-PAN complex was studied at Cd(II) concentration of 0.2 – 2.0 ppm.

**Interfering ions**
The interfering ions including Cu(II), Zn(II), Ni(II), and Fe(III) were studied by measuring the absorbance of the solution in the presence of the interfering cations and Cd(II) in the concentration ratio of 1:1 at 556 nm and pH 8.5.

**Application in water sample**
The membrane was applied for analysis of Cd(II) in the stream water of "Kali Code" flowing across the City of Yogyakarta, Indonesia. A measured 100 mL of river water sample was acidified using $HNO_3$ 1.0 M until pH about 3, filtered off and stored in a propylene bottle at room temperature. For Cd(II) determination, the pH of the sample solution was adjusted to pH 8.5 by adding NaOH 0.1 M solution. Note: "Kali Code" is the name of the river that flows across City of Yogyakarta, Indonesia, starting from Merapi Mountain in the north to the Indian Ocean in the south.

## Results and Discussion

**Supporting matrix stability and sensor membrane response toward Cd(II)**
PMMA was chosen as a supporting matrix for PAN due to its hydrophobicity, transparency, resistance to acid, base and salt solutions [19], and low absorbance in the UV-Vis range [20]. These will keep the sensor membrane stable during analysis of Cd(II) in water and allow quantitative analysis by UV-Vis spectrophotometry.

As a ligand, PAN can form a colorful complex ion with a number of cations, that are Cd(II) [11, 14], Co(II) [15], Cr(III) [21]. The complex ions of PAN with those cations are formed through the coordination bond between -OH and azo-nitrogen groups of the phenolic ring with the cations. Based on known stoichiometry, the Cd(II)/PAN molar ratio is 1:2 [17, 22]. The reaction of metal complex formation is displayed in Figure 2.

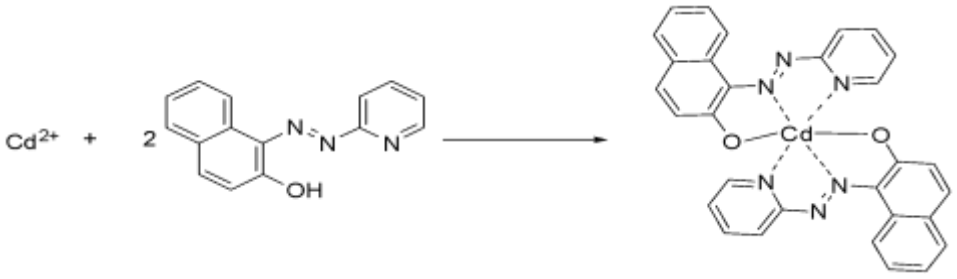

Figure 2. Reaction scheme for the complex formation of Cd(II) – PAN

**Membrane characterization**

The FTIR spectra of PAN immobilized in the membrane matrix are shown in Figure 3. It is clearly shown in the Fig. 3d that PAN has been successfully incorporated into the membrane. The peak at 3441 $cm^{-1}$ indicates a stretching vibration of –OH group of naphtol, whereas the peak at 2338 $cm^{-1}$ is due to the N=N group. The medium peak at 1605 $cm^{-1}$ is attributed to the N=O bond. Further, the peak at 1250 $cm^{-1}$ suggests the presence of $C_{aryl}$-O-$C_{alkyl}$ group. Both peaks reveal the existence of NPOE as a plasticizer in the membrane.

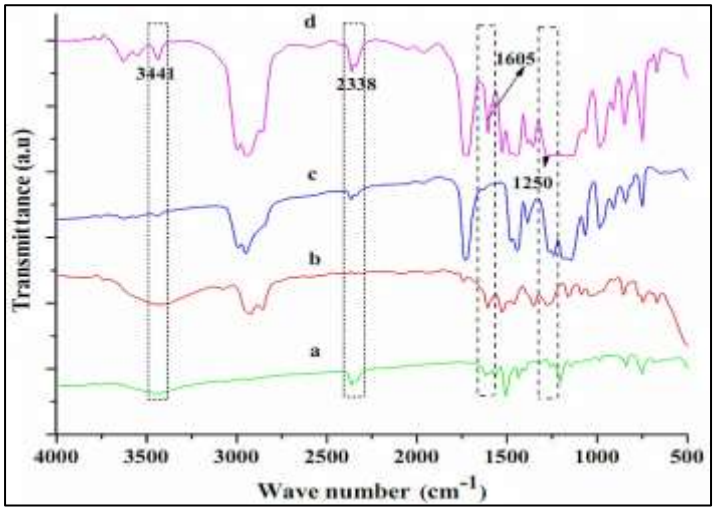

Figure 3. Infrared spectra of the membrane components (a) PAN, (b) NPOE, (c) PMMA and (d) PMMA-PAN membrane

**The effect of pH on sensing performance**

The pH of the test solutions plays an important role in obtaining a better membrane performance. The analyte solution has been subjected to pH variation, from 7.0 to 9.0. Figure 4 suggests that the solution pH of 8.5 gives the best response. It has been previously reported in many works that the best pH for Cd(II)-PAN complex formation is at pH 8.7 – 10 with $\lambda_{max}$ of 540 – 570 nm [17,22] or $\lambda_{max}$ of 550 – 560 nm [18]. In case of optimum pH of Cd(II)-PAN complex formation in the membranes, it has also been reported that the optimum pH in the PVC membrane using NPOE as plasticizer is at pH 8.0 and $\lambda_{max}$ of 558 nm [23]. Similarly, the optimum pH in the cellulose triacetate membrane using TEHP as a plasticizer is at pH 7.5 with $\lambda_{max}$ of 553 nm [11]. Therefore, our result of optimum pH at 8.5, is in good agreement with previously reported works. For this study, the absorbance of the membrane was recorded after 105 – 125 min of reaction.

Furthermore, at optimum pH, the amount of $OH^-$ ion in the solution is larger and the donor atom in the ligand tends to release $H^+$ ion (deprotonated) and thus becomes partially negative-charged species ($L^-$). This condition enhances the reaction between $Cd^{2+}$ or $[Cd(OH)]^+$ in the solution and PAN ligand in the matrix to form $CdL_2$. On the other hand, at lower pH, large amount of $H^+$ in the solution causes the formation of free metal ion ($M^{n+}$) and the hydroxyl group in the ligand remains protonated. This situation causes the interaction between metal ion and ligand much more difficult to occur due to charge repulsion between positive metal ion and positively protonated ligand. At higher pH (> 9.0), the absorbance is getting smaller possibly due to leaching process of PAN ligand from the membrane matrix as indicated by the red-color change of the solution. For all of the tested pH, the absorbance has been observed to reach its maximum value after 180 min of reaction.

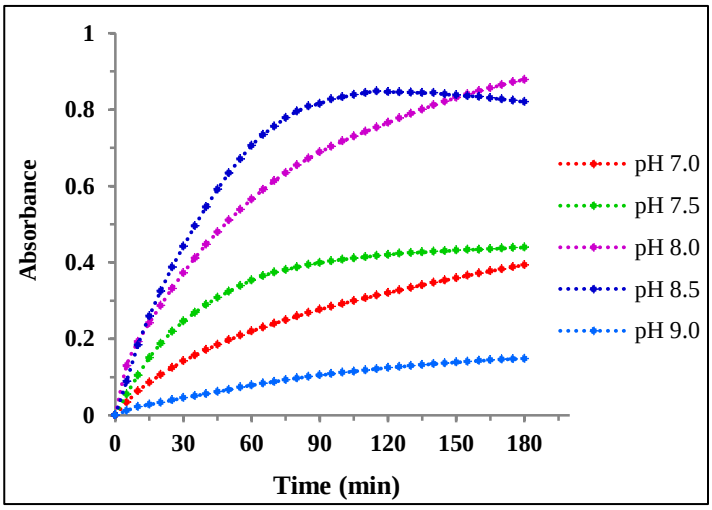

Figure 4. The response of sensor membrane at different pH with cadmium concentration of 2 ppm (n=3)

**Range of linearity**

The linear range of the sensor membrane for Cd(II) analysis was examined. The Cd(II) concentration was set at 0.2 – 2.0 ppm and the obtained data are shown in Figure 5. The absorbance linearly increases along with the increasing in the Cd(II) concentration, from 0.08 – 1.8 ppm. From the curve, it has been obtained that the detection limit of Cd(II) is 0.041 ppm with $R^2 = 0.960$.

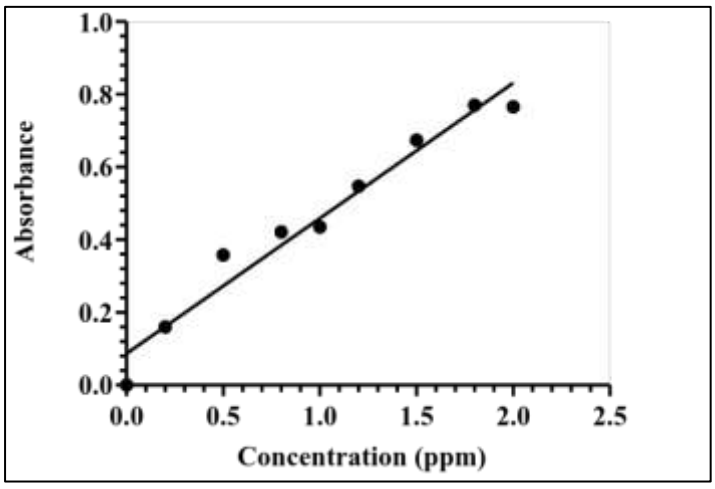

Figure 5. Calibration curve of Cd(II) sensor membrane. The absorbance was recorded at λ 556 nm

**Response of sensor membrane**

The UV-Vis spectra of sensing membrane before and after contact with Cd(II) solution are displayed in Figure 6. Before contact with Cd(II) solution, the sensor membrane has maximum absorbance ($\lambda_{max)}$ at 466 nm, and after contact with Cd(II) solution at pH 8.5, it shifts to 556 nm. The formation of complex Cd(II)-PAN in the sensor membrane exhibits significant bathochromic shift from 466 to 556 nm. It has been reported that the $\lambda_{max}$ of PAN and Cd(II)-PAN complex in chloroform is 470 nm and between 540 – 570 nm, respectively [22]. The slight difference in our results may be due to the sensitivity of PAN in different environments that lead to shift in $\lambda_{max}$

when it packs in the solid membrane matrices [24]. It is noteworthy to note that the cation permeability in the polymer matrix is lower than that in the solution. This may also cause the shift of $\lambda_{max}$.

For comparison, it has been reported that the $\lambda_{max}$ of PAN and Cd(II)-PAN complex in the CTA membrane is observed at 466 and 553 nm, respectively. The membrane was prepared by solvent mixing of 10 mL dichloromethane and 10 mL chloroform, and dried for 48 hours. By using this reported membrane, it has been found that the linear range of Cd(II) calibration curve was in the range of 0.01 – 5.0 ppm and the equilibrium time for complex formation was achieved after 150 minutes of reaction at pH 7.5 [11]. It is, therefore, obvious that our results is superior than those previously reported, especially in term of response time (120 minutes), required sample size (2 mL only), less usage solvent and shorter evaporation time, meaning that the preparation of the sensing membrane in our study produces less waste, reduces gas emission and needs shorter analysis time.

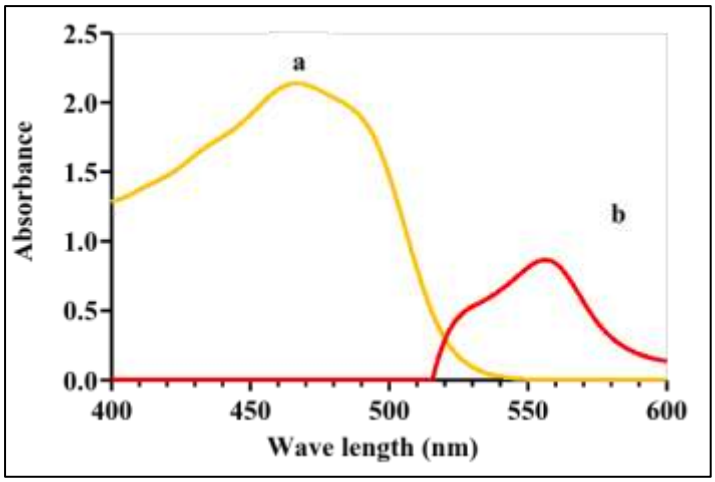

Figure 6. Absorption spectra of sensor membrane before (a) and after (b) contact with 2 ppm Cd(II) solution at pH 8.5

After contact with Cd(II) solution, the membrane color changes from yellow to red-orange as shown in Figure 7. The color intensity of the membrane increases along with the increase of the concentration of Cd(II) in the solution.

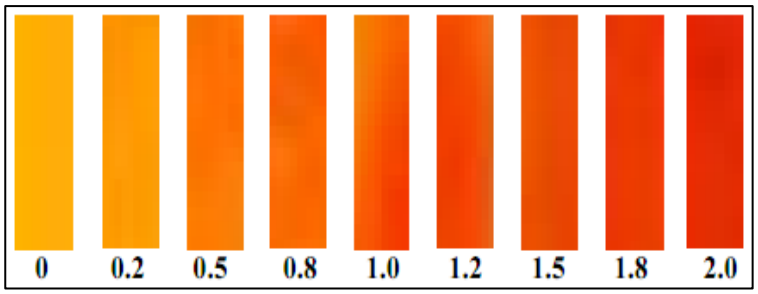

Figure 7. Progress of sensor membrane color change along with increase in Cd(II) concentration

**Effect of the other cations**

The response of the membrane towards Cd(II) ion in the presence of other cations such as Cu(II), Zn(II), Ni(II) and Fe(III) was tested. The experiment was conducted at the optimized conditions of Cd(II) analysis. The membrane was immersed separately in each solution containing both the interfering cation and Cd(II) ion at pH 8.5 for 120

min. The mole ratio of Cd(II)/interfering cation was set at 1:1, and the absorbance was measured at 556 nm. The results of the study are presented in Table 1.

Table 1. Effect of other cations on the sensing response

| No. | Cation | %Error* |

| 3. | Ni(II) | 2.05 |
| 4. | Fe(III) | 7.06 |
| 5. | Cu, Zn, Ni, Fe(III) | 33.35 |

*% Error was calculated using equation, $\{(A_{Cd(II)\text{-}cation} - A_{Cd(II)})/A_{Cd(II)}\} \times 100$ % [25] $A_{Cd(II)\text{-}cation}$ is the absorbance of sensor membrane in Cd(II) solution containing interference cation, and $A_{Cd(II)}$ is the absorbance of sensor membrane in Cd(II) solution without interference cation.

From Table 1, it is easily understood that the co-existence of Cu(II) in the solution causes the negative error (decrease in absorbance) of about 19% against the absorbance of single solution containing Cd(II)-PAN complex. It has been reported that Cu(II) ion can form stable complex, Cu(II)-PAN with PAN but the optimum condition of the complex formation is at pH 3.2 with $\lambda_{max}$ of 550 nm [17], while the optimum complex formation for Cd(II)-PAN is at pH 8.5. Because of the large difference in the formation pH of Cu(II)-PAN and Cd(II)-PAN complexes, it is expected that the competition between the two cations to interact with PAN not occur in the solution. The 19% decrease in absorbance of Cu(II)-PAN is most likely due to the decrease in the diffusion of the Cd(II) in the membrane sensor caused by the presence of Cu(II) ion.

Unlike Cu(II), the co-presence of Zn(II), Ni(II) and Fe(III) in the solution shows positive errors (increase in absorbance). From the literature, it is known that the best pH for the formation of Zn(II)-PAN and Ni(II)-PAN complexes is at pH 10 [22] and pH 4 – 10 [17], respectively. The Zn(II)-PAN in chloroform have $\lambda_{max}$ at 550 – 570 nm, which is quite close to the $\lambda_{max}$ of Cd(II)-PAN complex. Therefore, it is understandable that the co-existence of Zn(II) in the Cd(II) solution causes the absorbance of Cd(II)-PAN complex to increase.

Similarly, Fe(III)-PAN complex in chloroform can readily form at pH 4 – 8, with $\lambda_{max}$ at 775 nm [18, 22]. The closeness of the pH for the Fe(III) complexation with that of Cd(II) causes the competition between the two cations to form related complex with the ligand, hence the co-existence of Fe(III) in the solution contributes to the increase in the absorbance of the solution containing Cd(II)-PAN.

The co-addition of Cu(II), Zn(II), Ni(II), and Fe(III) altogether in the Cd(II) solution shows a large positive increase in absorbance of about 37%, which is much higher than the sum of individual effect. This may be explained from the point of view that the formation of Zn(II)-PAN, Ni(II)-PAN and Fe(III)-PAN is more dominant/favourable compared to the formation of Cu(II)-PAN when they are present altogether, as a result, the negative effect of Cu(II) vanishes and only positive effect is observed when the four cations exist together in the Cd(II) solutions.

**Analytical application of real samples**

The developed membrane has been applied to the analysis of Cd(II) in the river water of "Kali Code". Since most of the samples do not contain Cd(II) ion, for this purpose we have used internal addition standard method and the results are displayed in Table 2. From the table, it is clearly shown that the membrane produces a good percentage of recovery in the range of 100.25 – 107.52%. It is also observable from the table that Cd(II) content in the sample taken from location 1 and 2 could not be detected and only river water taken from location 3 contains sub-ppm of Cd(II). This result can easily be understood by considering the position of sampling points. Location 3 is located in the point where the river of "Kali Code" starts leaving city of Yogyakarta, meaning that the river water taken from this sampling point has received many waste such as domestic and industrial activities available along the river side

across the city of Yogyakarta. Some of the waste may contain heavy metals including Cd(II), therefore we detected Cd(II) in this sample. On the other hand, sampling points of location 1 and 2 are in the remote area, which is far away from domestic and industrial activities, therefore it is relatively still free from any pollutants, and this is becoming the reason that we could not detect the presence of Cd(II) ion in these two samples.

Table 2. Results of the Cd(II) analysis in the river water samples

| No. | River Water Sample | Cd(II) in Water Sample (ppm) | Added Cd(II) (ppm) | Cd(II) Found (ppm) | Recovery (%) |
|---|---|---|---|---|---|
| 1. | Location 1 | Not detected | 1 | 1.075 ± 0.041 | 107.52 |
| 2. | Location 2 | Not detected | 1 | 1.068 ± 0.008 | 106.78 |
| 3. | Location 3 | 0.046 | 1 | 1.002 ± 0.005 | 100.25 |

Notes: "Kali Code" is the name of river that flows across the City of Yogyakarta, Indonesia, starting from Merapi Mountain in the north to the Indian Ocean in the south. Location 1: 15 km from Merapi Mountain (before entering Yogyakarta City). Location 2: 13.5 km from location 1 (start entering Yogyakarta City). Location 3: 6.7 km from location 2 (before leaving Yogyakarta City).

## Conclusion

A chemo-optical sensing membrane for Cd(II) analysis has been developed by immobilization of PAN in a matrix of PMMA using NPOE as a plasticizer. The obvious change in membrane color after contact with analyte suggests the possible application of the method for qualitative detection and the linear response of absorbance along with the change in the analyte concentration provides its application in quantitative analysis. The membrane has been successfully applied to the analysis of Cd(II) in the natural water with satisfactory results as indicated by good percentage of recovery. The proposed optical chemical sensor membrane can be used as an alternative method for detection and determination of Cd(II) in ground water as well as in waste water, which offers simple, cheap, save and environmentally friendly technique. In the future, the developed sensing membrane can also be applied in periodic monitoring of Cd(II) pollution in water and may be developed for *in-situ* field analysis. Another possible prospective application is to develop membrane as "Cd(II) analytical kit", which can be used for quick and real time assessment of Cd(II) in the polluted area.

**Abstract**

A simple and sensitive spectrofluorimetric method for the determination of Al(III) based on the formation of Al-Morin-Triton X-100 ternary complex is described. The effect of other non-ionic surfactants, such as Tween 80, Tween 20 and octylglucoside (OG) on fluorescence analysis were also studied. The addition of Triton X-100 makes feasible the fluorimetric determination of submicrogram quantities of Al(III). The complex was excited at 410 nm and the fluorescence signal was measured at 495 nm. Maximum fluorescence signal was produced at pH 4.0 (acetic acid-acetate buffer), with 0.6% Triton X-100 and $1.35 \times 10^{-3}$ mol $L^{-1}$ Morin. The calibration graph is linear up to 7 mg $L^{-1}$ and the detection limit is 0.022 mg $L^{-1}$. The relative standard deviation is 1.81% for Al(III) at 5 mg $L^{-1}$. It was found that Zn(II) and $F^-$ produced highest interference.

**Keywords:** aluminum determination, fluorescence analysis, non-ionic surfactants, Triton X-100, Morin

**Abstrak**

Satu kaedah penentuan Al(III) secara spektrofluorimetri yang mudah dan sensitif berasaskan kepada pembentukan kompleks ternari Al-Morin-Triton X-100 dilaporkan. Kesan beberapa surfaktan tak-ionik yang lain seperti Tween 20, Tween 80 dan ositilglukos (OG) terhadap analisis berpendarflour turut dikaji. Penambahan Triton X-100 telah membolehkan penentuan secara pendarflour Al(III) dijalankan sehingga kepada kuantiti submikrogram. Kompleks teruja pada 410 nm dan isyarat pendarflour diukur pada 495 nm. Isyarat pendarflour maksimum dihasilkan pada pH 4.0 (menggunakan penimbal asetik asid-asetat), dengan 0.6% Triton X-100 dan 1.35 x $10^{-3}$ mol $L^{-1}$ morin. Graf kalibrasi adalah linear sehingga 7 mg $L^{-1}$ dan had pengesanan pula adalah 0.022 mg $L^{-1}$. Sisihan piawai relatif bagi penentuan 5 mg $L^{-1}$ Al(III) ialah 1.81%. Didapati juga ion Zn(II) dan $F^-$ menghasilkan gangguan bacaan yang tertinggi.

**Kata Kunci**: penentuan aluminum, analisis fluorimetrik, surfaktan tak-ionik, Triton X-100, Morin

## Introduction

It is known that Al(III) is a minor component in natural waters, its concentration being largely controlled by its low solubility, with typical levels in the range 0.5 – 5 µg $L^{-1}$ in seawater and 10–140 µg $L^{-1}$ in fresh waters [1]. As for

drinking water, the World Health Organization (WHO) has set the standard permissible level of Al(III) in drinking water at 200 μg $L^{-1}$ [2]. Al(III) ions also present several neurotoxic effects, and it has been suspected that Al(III) may be responsible for the cause of Alzheimer's disease, toxic effects on patients with renal failure and bone softening [3]. Sensitive analytical procedures are therefore required to study and monitor its level in the environment and its toxicology. While several methods have been developed for the determination of Al(III), spectrophotometry [4–6] and spectrofluorimetry [7–10] are the preferred techniques due to their simplicity, high precision and accuracy, high sensitivity, low cost and widespread availability of equipment.

Surfactants have been successfully used to improve current analytical techniques and in developing new ones. In micellar media, the sensitivity, selectivity and stability constants of reactions are greatly enhanced, and metal complex reactions are among them. As for fluorometric analysis, the intensity of molecular fluorescence is greatly influenced by the solvent effect and the presence of quenching impurities in the solvent. In some cases, it is possible to enhance the fluorescence and minimize the interferences by the incorporation of surfactants into the solution to be studied. The reasons for the increased fluorescence intensity in micellar solutions are not fully understood. Several mechanisms have been proposed by various authors. According to Sanz-Medel et al. in 1987, it is most likely due to (i) the effect of solubilization of neutral chelates and ligands within the micellar aggregates and (ii) the interaction of ionic complexes with surfactant molecules and aggregates having opposite charge [11]. Alternatively, Hinze et al. in 1984 proposed that the effect of the micelle appeared to result from the protection of the metal chelate from quenching in the bulk solvent [12]. From the literature, we have found that the use of cationic and anionic surfactants has little impact on enhancing the intensity of the metal–morin complexes; on the contrary, those surfactants decrease the fluorescence intensity and create unstable ternary complexes [13–15]. Therefore, we have decided to focus only on the use of non-ionic surfactants.

This paper investigated the reaction of Al(III) and morin in the presence of polyoxyethylene(9.5)-*t*-octyl-phenol (Triton X-100) and its potential for the determination of aqueous Al(III). The influences of various non-ionic surfactants on the fluorescence intensity of the Al(III)–Morin complex and their characteristics were also studied.

## Materials and Methods

### Instrument

Fluorescence spectra were obtained using Perkin-Elmer LS55 fluorescence spectrometer operated with 5.0 nm for excitation and emission slits.

### Reagents

All chemicals used were analytical grade unless stated otherwise. All solutions were prepared by using MilliQ distilled deionized water. Reagents used in this study were aluminum potassium sulphate dodecahydrate (Merck), morin (Fluka), polyoxyethylene(9.5)-t-octyl-phenol (Triton X-100), (Fluka), polyoxyethylene (20)sorbitol monolaurate (Tween 20), (BDH), polyoxyethylene(20)sorbitol mono-oleate (Tween 80), (BDH), octylglucoside (OG), (BDH) and ethanol 95% (Hmbg. Chemical).

The Al(III) stock solution (10 $mgL^{-1}$) was prepared daily by dissolving 0.1758 g of aluminium potassium sulphate dodecahydrate in water, adding 1% (v/v) sulphuric acid and diluting to 1 L with water. The morin solution ($5.0 \times 10^{-3}$ mol $L^{-1}$) was prepared by dissolving 0.1691 g of morin in 85 mL of 95% ethanol and diluting to 100 mL with water. All surfactants were used without further purification. The surfactants used in this study were prepared by diluting the surfactants to the percent required with water.

All of the buffer solutions (acetic acid-sodium-acetate buffer system), standard solutions for Al(III), ethanolic morin solution and non-ionic surfactants were prepared at room temperature of 25°C. The pH was measured to a pH of ± 0.01 with a Hanna Instrument model HI 2211 pH Meter.

### General procedure

To a solution containing 2 mL of Al(III), add 2 mL of buffer, 1 mL of morin solution ($1.35 \times 10^{-5}$ mol $L^{-1}$) and 3 mL of aqueous 0.6% v/v Triton X-100 solution. The mixture was diluted to volume in 25 mL standard flask with MilliQ water. The sample should be shaken briskly immediately prior to measurement the fluorescence. The fluorescence

intensity was measured at 495 nm, with excitation at 410 nm. All measurements were carried out three times, unless stated otherwise.

## Results and Discussion

An initial study was carried out to identify the level of the fluorescence enhancement obtained from a variety of non-ionic surfactants. It was found that sustained and superior enhancement was observed with the use of Triton X-100 compared with the other non-ionic surfactants (Figure 1). It is obvious that certain operational and preparation difficulties could be encountered with some surfactants, e.g. OG. High-viscosity materials were difficult to dissolve and could lead to phase separation if left overnight. Therefore, vigorous shaking of the samples must be performed immediately after the addition of the surfactant and again before the fluorescence measurements to obtain a homogeneous micelle system. Based on the degree of enhancement and the ease of operation, Triton X-100 was selected for further study.

The significance of the order of reagent addition was also examined. It was found that the fluorescent enhancement and its maximum intensity did not depend on this. The order of addition chosen was as follows: an aliquot of Al(III), the addition of acetic acid–acetate ion buffer solution, followed by morin solution and finally an aqueous Triton X-100 solution.

In common with all fluorescence techniques, the sensitivity is basically determined by the choice of an appropriate tool and working conditions. In this study, the experimental precision and sensitivity were found to be very dependent on reagent mixing. Therefore, the solutions should be briskly mixed immediately prior to measuring the fluorescence intensity.

The emission spectra of the Al(III)–morin complex in the presence of non-ionic surfactants are shown in Figure 1. It was found that the addition of Triton X-100 produced about fivefold enhancement and stabilization of fluorescence. The maximum fluorescence was obtained at 495 nm, corresponding to excitation at 410 nm. The enhancement of the fluorescent emission of Al–morin–Triton X-100 is owing to the surfactant's capabilities to (i) increase the solubility of hydrophobic species; (ii) create the microenvironment capable of producing a favourable polarity and acid–base equilibrium that in turn enhance its fluorescence efficiency and (iii) adopt a structure that protects the fluorescence of the analyte from external quenching. In addition, the unique structure of Triton X-100, which has a much shorter hydrophobic tail than the three other surfactants (Tween 20, Tween 80 and OG), also plays a massive role in enhancing the fluorescent emission of the ternary complex. According to Simoncic and Kert [16], the short hydrophobic tail of Triton X-100 can increase the hydrophobicity of the ternary complex and at the same time increases the attractive force (including van der Waals attraction between hydrocarbon parts) between Al(III) and morin. Therefore, it was found that Triton X-100 is also capable of enhancing the fluorescent emission compared with other non-ionic surfactants due to its distinctive structure, increasing the complex's hydrophobicity and the attractive force between Al(III) and morin.

Red-shifts (of around 20 nm) were observed in the fluorescence spectra of the Al(III) complexes in the presence of Triton X-100 and Tween 20. The red-shifts of $\lambda_{em}$ in the presence of non-ionic surfactants show that the contact between the Al(III) complex and non-ionic surfactants causes the excited state of the complex molecule to transform. According to Carrion Dominguez and Cirugeda [17], the Al(III) complexes may be fixed by the non-ionic surfactant, thus made more rigid and therefore the fluorescence quantum yield is increased.

The effect of the reaction variables on the fluorescence of the Al(III)–morin–Triton X-100 system was also studied. The fluorescence intensity of the Al(III)–morin–Triton X-100 system was measured over a variety of pH conditions in the range 2.0 – 7.0. The optimum pH was 4.0 (Figure 2) and the buffer solutions were prepared from acetic acid and sodium acetate. The result, (optimum pH at 4.0) was almost the same as reported in the literature, which used morin as the indicator but Genapol PF-20 as the surfactant [18]. Intensity measurements were recorded at the excitation and emission wavelengths giving the maximum intensity. In addition, these results were blank-corrected to minimize contributions from the variable composition buffer components.

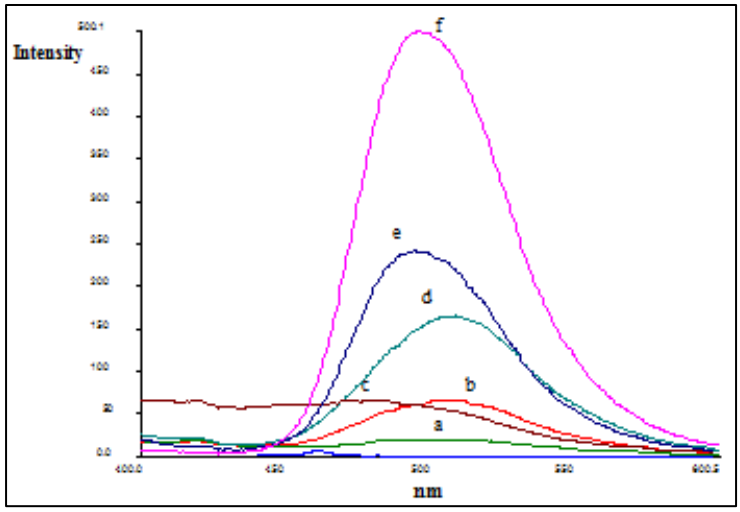

Figure 1. Emission spectra of (a) Al(III), (b) morin, (c) Al-morin-Tween 80, (d) Al-morin, (e) Al-morin-tween 20 and (f) Al-morin-Triton X-100. Conditions: Al(III) 5 mg $L^{-1}$; morin concentration $1.35 \times 10^{-5}$ mol $L^{-1}$; Triton X-100 0.6 % v/v; pH 4.0; $\lambda_{ex}$ 410 nm; $\lambda_{em}$ 495 nm

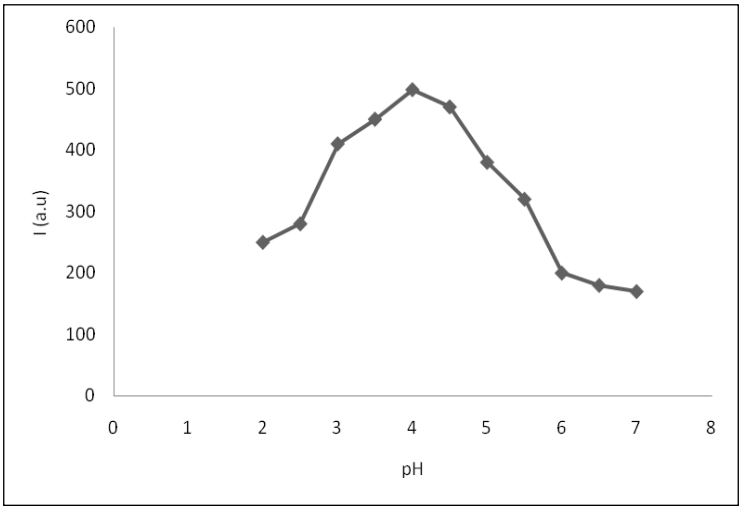

Figure 2. Effect of pH on the fluorescence intensity obtained from a 5 mg $L^{-1}$ Al(III) solution. Conditions: morin concentration $1.35 \times 10^{-5}$ mol $L^{-1}$; Triton X-100; 0.6 % v/v

The influence of the concentration of Triton X-100 on fluorescence intensity was studied with fixed concentration of Al(III) and morin and variable concentrations of Triton X-100 between 0 and 0.8% v/v. It was observed that as the Triton X-100 concentration increased, the fluorescence intensity increased until it reached 0.6% v/v (Figure 3). These gradual increases are attributable to the increased viscosity produced at the higher concentrations.

As mentioned by Hinze et al. in 1984, the metal complex and ligand compete in their interaction with the surfactant [12]. The ligand requires a surfactant concentration only slightly higher than the critical micelle concentration to achieve optimum interaction with the surfactant, whereas the complex requires a significantly higher concentration to yield maximum fluorescence. The viscous effect at high surfactant concentrations is not appreciable for morin alone. In all cases, the increase in fluorescence of the complex is much higher than with morin alone.

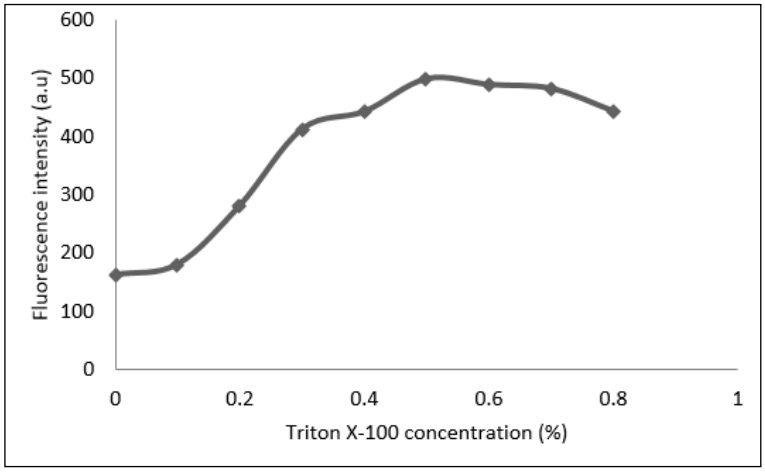

Figure 3. Effect of Triton X-100 concentration on the fluorescence intensity. Conditions: Al(III) 5 mg $L^{-1}$; morin concentration 1.35 $\times 10^{-5}$ mol $L^{-1}$; Triton X-100 0.6 % v/v; pH 4.0; $\lambda_{ex}$ 410 nm; $\lambda_{em}$ 495 nm

Figure 4 shows the effect of morin concentration at a fixed concentration of Al(III) (5 mg $L^{-1}$) and Triton X-100 (0.6% v/v). The fluorescence intensity of the complex is almost constant in the morin concentration range 1.35 $\times$ $10^{-5}$ – 1.70 $\times$ $10^{-5}$ mol $L^{-1}$. This optimum concentration range was achieved because these morin concentrations were sufficient to yield the Al(III)–morin complex in the presence of Triton X-100. This concentration (1.35 $\times$ $10^{-5}$ mol $L^{-1}$) was therefore employed for further studies.

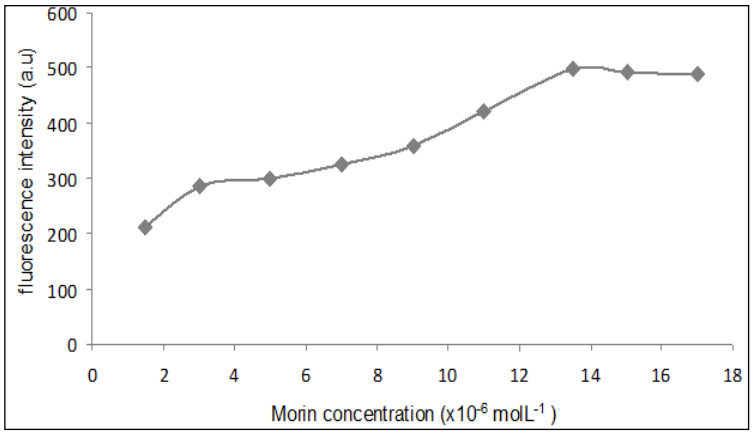

Figure 4. Effect of morin concentration to the formation of Al-morin-Triton X-100 complex. Conditions: Al(III), 5 mg L-1; Triton X-100, 0.6 % v/v

In addition, it is expected that a decrease in fluorescence intensity at higher morin concentrations will occur [19]. This is due to the higher self-quenching effect (the tendency of ions to collide with each other) that occurs between Al(III) and morin at higher concentrations of morin.

The calibration curve of Al(III) concentration versus relative fluorescence intensity ($(I - I_0)/I_0$) is shown in Figure 5, where $I$ was the measured fluorescence intensity at any Al(III) concentration and $I_0$ was the intensity in the absence of Al(III).

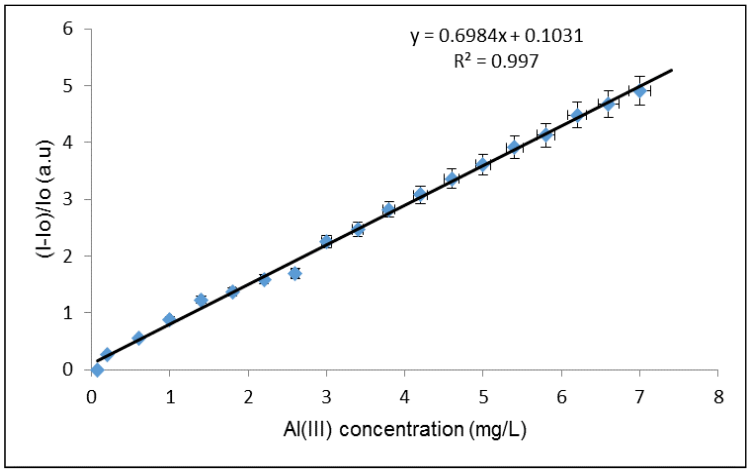

Figure 5. Calibration curve for Al(III)-morin-Triton X-100 complex system. Conditions: Al(III) 5 $mgL^{-1}$; morin concentration $1.35 \times 10^{-5}$ mol $L^{-1}$; Triton X-100 0.6 % v/v; pH 4.0; $\lambda_{ex}$ 410 nm; $\lambda_{em}$ 495 nm

The morin–Triton X-100 complex exhibited a linear emission response to Al(III) in the concentration range of $1.30 \times 10^{-6} - 2.59 \times 10^{-4}$ mol $L^{-1}$ (0.035 – 7.0 mg $L^{-1}$) with a correlation coefficient of $r = 0.997$. The detection limit (the concentration of the metal ion giving a signal equal to the blank signal plus three standard deviations of the blank) was found to be 0.022 mg $L^{-1}$. The calculated relative standard deviation, R.S.D., for eight replicate analyses of a sample containing 5 mg $L^{-1}$ of Al(III) was 1.81%.

The effect of various species present in the samples was studied too. A sample containing 2 $mgL^{-1}$ Al(III) was prepared in the presence of 10 $mgL^{-1}$ of Mg(II), Cu(II), Zn(II), Fe(III), Ca(II), Ba(II), $Cl^-$, $F^-$ and $SO_4^{2-}$. The results shown in Table 1 indicate little or no interference is observed in the presence of Mg(II), Ca(II), Ba(II), $Cl^-$ and $SO_4^{2-}$. However, Cu(II) Zn(II) and Fe(III) gave lower recovery due to slight quenching effect of these species on the fluorescence intensity of the Al(III)–morin–Triton X-100 complex. Interference from Fe(III) is expected since the ionic radius of Fe(III) is similar to the Al(III) ion. As for Cu(II) and Zn(II) ions, the interferences are due to the tendency of morin to form Cu(II)–morin and Zn(II)–morin complexes. However, the recovery could be improved with an introduction of 1,10-phenanthroline for reducing or eliminating the interferences of Fe(III) and hydroxylamine for Cu(II) to the samples as the masking agents [20]. As for the significant interference from $F^-$, it is also predicted since Al(III) forms a stable complex with this anion. Therefore, it is recommended that large amount of Be(II) as berilium chloride should be tried as to improve the recovery of Al(III) [21].

Table 1. Effect of interfering species on the recovery of 2 mg $L^{-1}$ Al(III) ion. Conditions: morin $1.35 \times 10^{-5}$ mol $L^{-1}$; Triton X-100 0.6 % v/v.

## Conclusion

The procedure described in this research offers a substantial improvement compared to other method, which utilizing an extraction steps in determination of Al(III) by fluorescence method. The use of Triton X-100 has eliminates the need to use an additional extraction steps for the sensitive and selective determination of Al(III). A five-fold sensitivity increased in the fluorimetric determination of Al(III) using morin was obtained by the addition of Triton X-100. The optimum conditions obtained at pH 4.0 in the presence of $1.35 \times 10^{-5}$ mol $L^{-1}$ morin and 0.6% v/v Triton X-100. A wide calibration range of $1.30 \times 10^{-6} – 2.59 \times 10^{-4}$ mol $L^{-1}$ (0.035 – 7.0 mg $L^{-1}$) and the detection limit of 0.022 mg $L^{-1}$ were achieved too by using the proposed method. Further study will be taken to apply this method to determine Al(III) ion in the real samples.

**Abstract**

Municipal solid wastes (MSW) collected from Padang Siding Landfill, Perlis were segregated and characterized in the laboratory. The main components of MSW found are paper, plastic, glass and large proportion of organic waste. Moisture content was measured for all the components. Paper and yard wastes recorded the highest percentage of 26.7% and 28.8%, respectively. Thermogravimetric analysis (TGA) shows that the thermal degradation of MSW samples ranged from 200 $^{o}$C to 800 $^{o}$C, indicating fast decomposition occurred at 370 $^{o}$C, 430 $^{o}$C and 700 $^{o}$C. Traditional method shows a lower error compared to the physical method in calculating the calorific values (CV) for MSW. Bio-oil production via fast pyrolysis route gave higher liquid yield of ~35% with high oxygen content of ~49 – 53%. Heavy oil recovered from hydrous pyrolysis experiments gave low yield of ~7 – 13%, however with low oxygen content of ~11 – 18%.

**Keywords**: Municipal solid waste, thermogravimetric analysis, calorific value, pyrolysis, hydrous pyrolysis

**Abstrak**

Sisa pepejal perbandaran (SPP) dikumpulkan dari tapak pelupusan Padang Siding, Perlis. Bahan buangan ini diasingkan dan dikategorikan di dalam makmal. Komponen utama MSW yang ditemui adalah kertas, plastik, kaca dan sebahagian besar sisa organik. Kandungan kelembapan diukur untuk semua komponen di mana kertas dan sisa dari laman telah mencatatkan peratus tertinggi sebanyak 26.7% dan 28.8% masing-masing. Analisis termogravimetrik menunjukkan degradasi terma sampel MSW adalah antara 200 $^{o}$C hingga 800 $^{o}$C, menunjukkan penguraian cepat berlaku pada 370 $^{o}$C, 430 $^{o}$C dan 700 $^{o}$C. Kaedah tradisional menunjukkan ralat yang lebih rendah berbanding dengan kaedah fizikal dalam mengira nilai kalorifik untuk SPP. Pengeluaran bio-minyak melalui laluan pirolisis pantas memberikan hasil cecair yang lebih tinggi ~35% dengan kandungan oksigen yang tinggi ~ 49 – 53%. Minyak berat diperoleh daripada eksperimen pirolisis berair memberikan hasil yang rendah ~ 7 – 13%, walau bagaimanapun dengan kandungan oksigen yang rendah ~ 11 – 18%.

**Kata kunci:** Sisa pepejal perbandaran, analisa termogravimetrik, nilai kalorifik, pirolisis, pirolisis berair

## Introduction

Municipal solid waste (MSW), also known as urban solid waste, is a type of waste that predominantly comes from household waste (domestic waste) with a small portion of commercial waste collected by municipality of a particular area. Generally, the solid waste is defined as the household's refusal and non-hazardous solid waste from industrial, commercial and institutional establishments, such as hospitals, market and yard wastes, and street sweepings [1]. MSW is a heterogeneous material and its physical composition is dependent on socio-economic level and climatic conditions [2].

Perlis Indera Kayangan is the smallest state in Malaysia which is located at the northern part of the Peninsular Malaysia. Its population is 227,025 as of 2010. The increase in population and industrial activities in Perlis has resulted in serious environmental problems including air quality deterioration, water and land pollutions. The amount of solid wastes generated in Perlis is approximately 221 tonnes/day [3]. The most popular disposal practice for MSW is landfilling. Landfilling is a universal solution that provides ultimate waste disposal and can be implemented easily. However, the setback of this approach is that it requires a large piece of land and does not employ the concepts of reduction and conversion of MSW. The MSW disposal in Perlis is located at Padang Siding landfill with an area approximately 50.876 hectare. Landfills face the problems of overfilling, overflowing of leachates leading to pollution of water resources, and uncontrolled dust emissions adversely affecting the human environment [4].

In order to justify the feasibility of energy recovery for the use of renewable energy, it is very important to determine the calorific value (CV) of MSW. Bomb calorimeter can be used for calorimetric measurement in which combustion is conducted under conditions of constant volume. Other important methods are physical composition and traditional methods where the energy content can be calculated using physical and proximate analysis, respectively.

One option of utilizing the MSW is energy recovery through various processes, such as combustion, pyrolysis, liquefaction and refuse-derived fuel [5]. Several researchers have pyrolyzed biomass residue to produce bio-oil under certain conditions [6 – 8]. Bio-oil is dark brown liquid which has a high heating value that can be used as fuels in boiler, diesel engines for power generation, or upgraded to produce fuels and bulk chemicals. However, direct usage of bio-oil as conventional fuels may present some difficulties due to high viscosity, poor heating value, corrosiveness and instability. The comparison of pyrolysis and hydrous pyrolysis of MSW has not been done in earlier studies and this study attempts to fill in the gap. The comparison is beneficial for engineers and policy makers to design an alternative solution for MSW.

A large portion of the waste has significant energy potential which can be utilized. The energy recovered can also reduce emissions that would otherwise be produced by other energy systems, such as fossil fuel thermal power plants [9]. An important criterion for the success of waste management plan is the accurate data on the quality and quantity of the waste generation. With this data, proper management strategies can be planned and put into actions. The data can also be used to predict the future trends of the quantity and quality of the MSW. This allows the authorities to take anticipating measures to manage MSW generated properly [10].

In order to justify the feasibility of energy recovery for the use of renewable energy, it is very important to determine the calorific value (CV) of MSW. Bomb calorimeter can be used for calorimetric measurement in which combustion is conducted under the condition of constant volume. Other important methods are physical composition and traditional methods where the energy content can be calculated using physical and proximate analysis, respectively.

In Perlis, there is less data available on the potential of MSW to be used as energy sources. To fill in the gap, this study was conducted to segregate and characterize the main components of MSW in the state. The energy contents of MSW generated were calculated. The production of bio-oil was performed via thermochemical conversion processes to investigate its potential to be used as a renewable energy.

## Materials and Methods

### Sample preparation

The solid waste samples were collected at Padang Siding landfill in Arau, Perlis. The sampling was carried out randomly at 5 different locations within the 0.12 $km^2$ landfill area of 0.6 m depth. These samples were brought back to the laboratory for analysis. The manual segregation process was conducted to calculate the MSW's components. After the completion of segregation, all the samples were mixed, washed (with water) and oven dried at 105 $^oC$ for 12 hours to eliminate external moisture. The samples (except glass) were shredded and sieved to obtain uniform size less than 1.5 mm for further experimental works. This sample was used for TGA analysis and pyrolysis experiments.

### Moisture-content determination

The collected samples were oven-dried at 105 $^oC$ for 5 hours to measure moisture-content. All the moisture content values used in this research were based on the wet basis, unless otherwise stated. The percentage of moisture content was calculated as follow:

$$Moisture\ (\%) = \left[\frac{Wet\ weight - dry\ weight}{Wet\ weight}\right] \text{ x } 100\% \quad (1)$$

### Thermogravimetric analysis

The thermogravimetric analysis was carried out by using a TGA/DSC 1 Mettler Toledo. The weight loss and the rate of weight loss were recorded continuously under dynamic conditions, as functions of time or temperature, in the range of 25 to 900 $^oC$. Purified nitrogen gas was used for the pyrolysis with a flow rate of 150 ml/min. The heating rate of 20 $^oC$/min was selected for this test. The temperature was increased to the setting value of 900 $^oC$ at the pre-selected heating rate and it was kept constant at this value until steady conditions were obtained.

### Proximate analysis

Proximate analysis was performed according to ASTM D2974 [11] using the thermogravimetric analyzer (TGA/DSC 1, Mettler Toledo) for determination of moisture, volatile matter, fixed carbon and ash in MSW. The experiment was performed under inert nitrogen gas and purified air with a constant flow rate of 150 ml/min and the heating rate of 20 $^oC$. The samples were weighed directly into the alumina crucible and the temperature was kept at isothermal for 0.5 minutes until a steady condition was obtained before ramping to the desired temperature [12]. The experiments were replicated at least twice to obtain reproducibility.

### Calorific value (CV)

The calorific values (CVs) of the samples were determined by using a bomb calorimeter (Model: C2000 basic, IKA co, Germany). The calculation was also made according to the model developed by Khan and Abu Ghrarah [13] as reported by Abu-Qudais and Abu-Qdais [5].

$$E = 23\ [F + 3.6\ (PA)] + 160\ (PL) \quad (2)$$

where E is the energy content of MSW (Btu/lb), PL is the percentage of plastic by weight, F is the percentage of food waste by weight and PA is the percentage of paper waste by weight.

For comparison, a traditional model reported by Abu-Qudais and Abu Qdais [5] had also been employed as follows:

$$E\ (Kcal/kg) = 45B - 6W \quad (3)$$

where B is the combustible volatile matter in MSW (%) and W is the water percentage weight on dry basis (%).

### CHNO analyses

The elemental analyses of the oils were determined using Thermo Electron FlashEA 1112 elemental analyser. Vanadium pentoxide (2-3 mg) was used to determine the Sulphur content and the amount of Sulphur found was too small and negligible for the calculation of this research.

**Pyrolysis experimental procedure**

Fast pyrolysis was conducted in a fixed-bed reactor as in our previous study [7]. The experimental device consisted of a tube reactor with a volume of 250 $cm^3$, equipped with a K-type thermocouple , an electric heater, a nitrogen cylinder, a cold trap, water bath and product effluent. The condensation temperature was set at 0 $^oC$ for all experiments. The amounts of sample used in all experiments were 5 mg per run. The bio-oil yield was collected from oil collector and weighed to calculate the percentage. For all experiments, whenever the pyrolysis temperature was reached, it was immediately cooled down to 100 $^oC$ within 4 minutes. Experiments were repeated 5 times to ensure the reproducibility of the results.

Nitrogen flow rate and condensation temperature were kept constant at 100 $cm^3$/min and 0 $^oC$, respectively. The pyrolysis experiments were conducted using fixed bed pyrolyser at pyrolysis temperature of 470 $^oC$, particle size of 0.60 mm, holding time at 1 minute. Experiments were repeated 5 times to ensure the reproducibility of the results.

**Hydrous experimental procedure**

Hydrous experiments were conducted using a Parr 4740 series stainless steel (75 ml cylindrical) pressure vessel at pre-set temperatures (380, 420 and 480 $^oC$) for 1 hours. After sealing the vessel and attaching the pressure gauge, it was purged 10 times with nitrogen gas to remove the air, and then 2 bar of nitrogen gas was introduced to provide an inert atmosphere. The reactor was heated in a fluidised sand bath. Temperature was monitored by an additional K-type thermocouple which was connected to a computer and recorded every 10 s. The reacted product washing procedure had been reported in the previous study [14]. Hydrous pyrolysis was also conducted at 380, 420 and 480 $^oC$ with sample to water mass ratio of 1:6, using 75 ml reactor for 1 hour. The pressures recorded for these experiments were in the range of 280 – 300 bar.

## Results and Discussion

**Waste segregation and moisture content**

Table 1 shows the average compositions after the segregation process. Plastic and glass were the highest proportion in the samples collected with approximately 46%. Similarly, papers contributed approximately 21%, ranked as the third largest component. The other smallest components were polystyrene, yard wastes and wood with 1.4%, 3.5% and 8.0%, respectively. Food waste consists of approximately 12%, as such, it can be inferred that the management of organic waste has not been properly done.

Table 1. Characterization of MSW from Padang Siding landfill

| Sample | Food Waste (%) | Paper (%) | Plastic (%) | Polystyrene (%) | Rubber (%) | Yard waste (%) | Glass (%) | Wood (%) |
|---|---|---|---|---|---|---|---|---|
| 1 | 37.80 | 1.50 | 13.90 | 1.20 | 24.70 | 6.40 | 0.00 | 14.50 |
| 2 | 2.80 | 4.00 | 15.40 | 2.20 | 11.30 | 7.80 | 46.20 | 10.20 |
| 3 | 12.50 | 16.80 | 14.20 | 0.60 | 6.90 | 0.00 | 43.90 | 5.20 |
| 4 | 5.30 | 24.70 | 48.40 | 2.70 | 0.00 | 0.00 | 11.50 | 7.40 |
| 5 | 0.00 | 56.20 | 12.40 | 0.30 | 0.00 | 3.40 | 24.90 | 2.90 |
| Average | 11.68 | 20.64 | 20.86 | 1.40 | 8.58 | 3.52 | 25.3 | 8.04 |

Note: Mud and gravel had been removed from the samples

Moisture contents of the MSW components are summarized in Table 2. As expected, paper, polystyrene, and yard wastes had the highest proportion with 26.7%, 25.0%, and 28.8%, respectively. Rubber had the lowest percentage of moisture with 10.2%. The high moisture content is normally attributed to the climate of the area. Perlis is a tropical climate state with a large amount of rainfall obtained throughout the year. The annual rainfall is approximately 2,700 mm and may increase up to 6,000 mm in the catchment region. On top of this, the average air humidity in Perlis is above 80% [15].

Table 2. Moisture content of MSW components from Padang Siding, Perlis Landfill

| Waste Components | Wet weight (kg) | Dry weight (kg) | Moisture Content (%) |
|---|---|---|---|
| Food waste | 0.780 | 0.682 | 12.6 |
| Paper | 0.030 | 0.022 | 26.7 |
| Plastic | 0.286 | 0.238 | 16.8 |
| Polystyrene | 0.024 | 0.018 | 25.0 |
| Rubber | 0.510 | 0.458 | 10.2 |
| Yard waste | 0.132 | 0.094 | 28.8 |
| Wood | 0.300 | 0.268 | 10.7 |

**Proximate and TGA analysis**

Proximate analysis was carried out in order to determine the moisture content (dry basis), volatile matter content, fixed carbon content and ash content in the waste samples. The analysis was conducted for the combination of yard wastes, plastic, paper, polystyrene, wood and rubber. Table 3 tabulates the proximate analysis for 5 samples collected from Padang Siding Landfill. Volatile matter had 68% in average and offered high percentage of condensable gas. The thermochemical conversion method is the best option as condensable gas is promising in amount. The proximate analysis conducted in previous studies set in Penang, Malaysia, shows that the investigated MSW comprised of 44.66% of moisture content, 44.55% of volatile matter, 8.56% of ash content and 2.23% of fixed carbon content [16]. Typically, based on the proximate percentages range for moisture content in residential, MSW is about 15% to 40%, volatile matter comprises approximately 40% to 60% and the range for fixed carbon is from 4% to 15% [17].

Table 3. Proximate analysis of MSW from Padang Siding landfill[a]

| Variable (wt. %) | Sample | | | | | Average |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | |
| Moisture content | 7 | 10 | 5 | 7 | 5 | 7 |
| Volatile matter | 53 | 71 | 68 | 71 | 79 | 68 |
| Fixed carbon | 10 | 7 | 10 | 10 | 2 | 8 |
| Ash content | 30 | 12 | 17 | 12 | 14 | 17 |

Note: [a] dry basis

The TG analysis is usually used for thermal characterization, calculation of the pyrolysis conversion and evaluation of reactivity and kinetic parameters [7]. In this research, the purpose of TG analysis was to look into the degradation profile for MSW. Figure 1 shows the thermal decomposition of MSW. The initial curve indicates that there was moisture loss of up to 105 $^{o}$C. The decomposition was gradually increased starting from 200 $^{o}$C until it had a fast decomposition reaching 350 $^{o}$C. Up to 400 $^{o}$C, the remaining residue was 40% and about 60% was decomposed. The decomposition produced approximately 15 to 17% of ash content. This result is in agreement with the waste compositions described earlier. The carbon residues ranged between 10 to 17% pose significant carbon deposition during refinery upgrading (e.g. catalytic cracking), whereas the values above 20% are considered problematic. The decomposition trend was observed to be influenced by the waste compositions, such as paper, wood and plastic. For each TG experiment, the weight loss of MSW as a function of temperature cannot be simulated by considering a single decomposition reaction [18]. The remaining others slowly degraded over 350 $^{o}$C until 800 $^{o}$C. They are 4 zones indicated as A, B, C and D in thermogravimetric curve and this is presented clearly in the DTG curve.

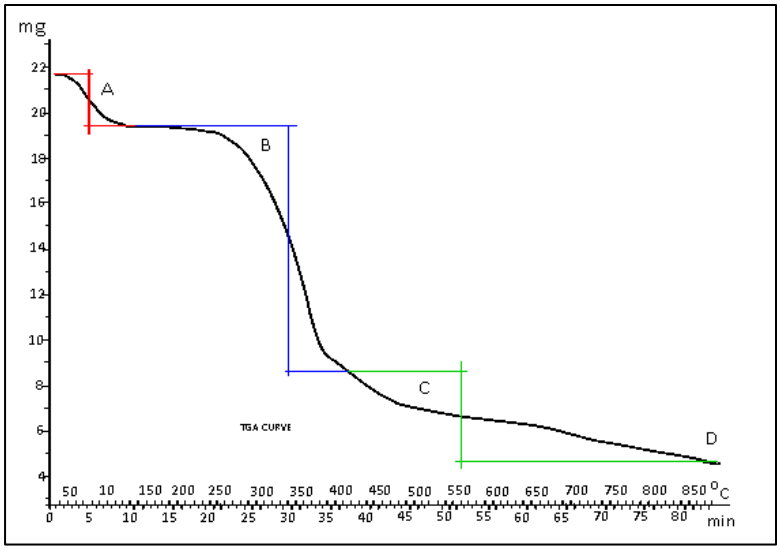

Figure 1. TGA curves for MSW samples

Figure 2 shows the DTG evolution profiles for MSW samples. Zone A indicated moisture loss curve while Zones B, C and D were attributed to the waste compositions. The fast decomposition occurred at three regions which were at 350 °C, 430 °C and 700 °C. The fast decomposition at zone B was caused by the degradation of materials, such as wood and yard wastes. Based on the DTG evolution profiles, material at zone B started to decompose at temperature ranging from 200 °C to about 400 °C, with $T_{max}$ at 350 °C. It was followed by the degradation of plastic and the fast decomposition was shown at C. Zone C recorded the burn-out temperature starting from 400 °C and ended at 480 °C. The more stable materials, such as rubber, gradually degraded and recorded fast decomposition at 700 °C. Small percentage of rubber contributed to the small peak at 700 °C. The burn-out temperature occurred at 600 °C with $T_{max}$ at 750 °C. The differences in the DTG profiles showed the difference in the complexity of MSW components. Shen and Qinlei reveal three steps in their previous study due to the emission and combustion of the volatiles with the char combustion [19].

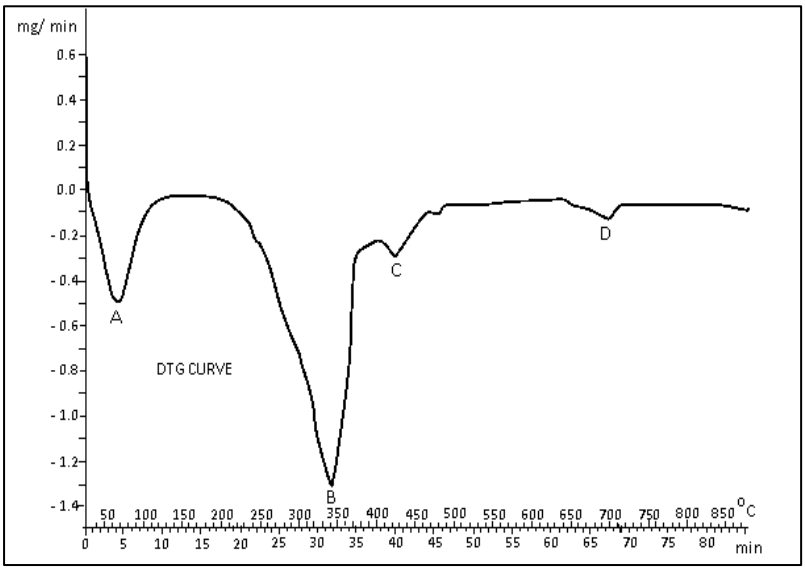

Figure 2. DTG curves for MSW samples

**Calorific values (CVs)**

Table 4 shows the calorific values of MSW by using bomb calorimeter, calculations employing physical composition and proximate analysis techniques. The calorific values ranging from 2200 to 4500 kcal/kg were obtained for all samples by using bomb calorimeter. Sample No. 4 had the highest value while sample No.1 recorded the lowest. Kathirvale et al. reported that the calorific values of the Malaysian MSW ranged between 1500 and 2600 kcal/kg [20]. The CVs calculated employing physical composition gave values ranging from 1601 to 5550 kcal/kg while proximate analysis technique gave values ranging from 2343 to 4000 kcal/kg. In physical composition, sample No. 4 gave the highest value with 5550 kcal/kg. This was attributed to the composition of paper and plastic and it is in agreement with PL/PA ratio as reported by Abu-Qudais and Abu-Qdais [5]. Traditional method shows a lower error compared to the physical method. The result from traditional method analysis is useful in calculating CVs in MSW study compared to the physical method.

Table 4. Comparison of CVs determined by different methods

| Waste Sample | Calorific Value (kcal/kg) | | |
|---|---|---|---|
| | Bomb Calorimeter | Physical Composition | Traditional Method |
| 1 | 2200 | 1802 | 2343 |
| 2 | 2500 | 1601 | 3135 |
| 3 | 3451 | 2212 | 3030 |
| 4 | 4500 | 5550 | 4000 |
| 5 | 3480 | 3717 | 3525 |

**Thermochemical processes**

The pyrolysis experiments were conducted using fixed bed pyrolyser at pyrolysis temperature of 470 $^{o}$C and the bio-oil produced was ~ 35%. The hydrous pyrolysis were conducted at 380, 420 and 480 $^{o}$C to investigate the effect of temperature on product distribution (Figure 3). The high gas yield obtained at 480 $^{o}$C (42%) had resulted in the decrease of liquid products due to the further thermal decomposition [21]. As decomposition to form gas occurred when the temperature had increased to 480 $^{o}$C, the oil plus water yield decreased to 42%. Of this, 6% was recovered as heavy oil while approximately 10 – 12% of heavy oil was recovered at 380 and 420 $^{o}$C.

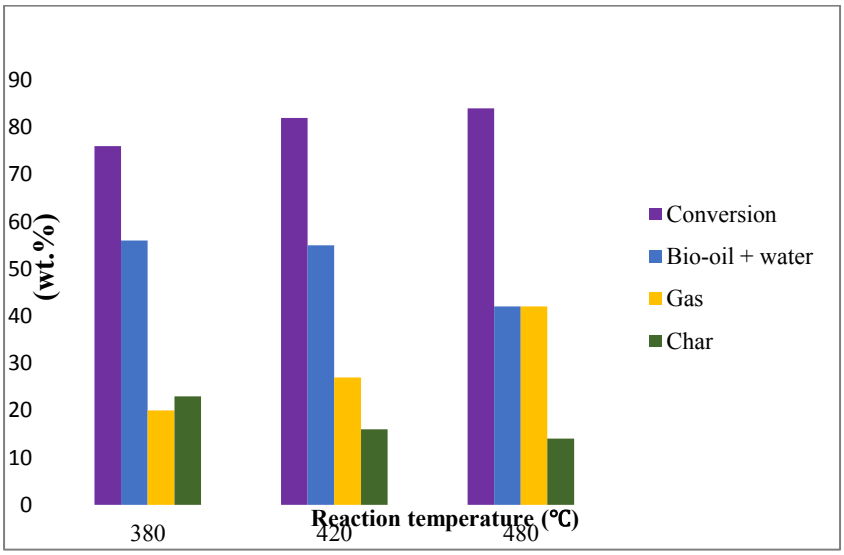

Figure 3. Effect of reaction temperature on product yields using MSW sample to water mass ratio of 1:6 for 1 hour

Table 5 presents the elemental compositions of the bio-oils and heavy oils obtained from pyrolysis and hydrous experiments. An increase in temperature gave low oxygen contents (~11%) for heavy oil from hydrous pyrolysis and bio-oils obtained from direct fast pyrolysis had high oxygen content (~49 – 53%).

Table 5. Elemental analyses of bio-oils and heavy oils from pyrolysis and hydrous pyrolysis experiments

| Runs | Samples | C (%) | H (%) | N (%) | *O (%) |
|---|---|---|---|---|---|
| Pyrolysis | Bio-oil 1 | 42.0 | 7.0 | 0.3 | 50.7 |

## Conclusion

The MSW in Perlis mainly consists of plastic and paper followed by food waste, wood, yard waste and polystyrene. Referring to the wide range of wastes, the thermogravimetric analysis displays a broad range of degradation temperature starting from 200 $^{o}$C to 800 $^{o}$C. DTG curves illustrate the fast decompositions that occurred at 350 $^{o}$C, 430 $^{o}$C and 700 $^{o}$C which represent different waste components. For each TG experiment, the weight loss of MSW due to temperature cannot be simulated by considering a single decomposition reaction. CVs calculation employing traditional method gave a lower error compared to the physical method. The physical composition method could be employed for MSW CVs calculation if the MSW compositions are influenced by ratio of plastic to paper. Bio-oil production via fast pyrolysis route gave higher liquid yield of ~35% with high oxygen content of ~49 – 53%. Heavy oil recovered from hydrous pyrolysis experiments gave low yield of ~7 –12%, however with low oxygen content of ~11 – 18%.

**Abstract**

A simple and rapid microextraction method termed as ultrasound-assisted surfactant enhanced emulsification microextraction (UASEME) was developed for the determination of fluoranthene (FLU) and phenanthrene (PHE) in aqueous samples followed by gas chromatography-mass spectrometry (GC-MS). Six important parameters, that affect the extraction efficiency of polycyclic aromatic hydrocarbons (PAHs) were evaluated and the results were as follows; extraction solvent (toluene), volume of extraction solvent (30 µL), surfactant (Tween 20), volume of surfactant (15 µL), extraction time (2 minutes) and with no salt addition. Under the optimum conditions, the method showed good linearity over the concentration range from 1 – 1000 µg $L^{-1}$ with correlation coefficients ($R^2 \geq 0.9932$), acceptable limits of detection (0.3 µg $L^{-1}$) and limits of quantification (1.0 µg $L^{-1}$) for both analytes. Good relative recovery values, in the range of 91.75 – 104.1%, were obtained for tap water samples. The relative standard deviations (RSDs) were 1.62 – 10.32% ($n$ = 3). The proposed method was applied for the determination of FLU and PHE in tap water and sugarcane juices.

**Keywords:** ultrasound-assisted, surfactant, emulsification, polycyclic aromatic hydrocarbons, gas chromatography-mass spectrometry

**Abstrak**

Satu kaedah pengekstrakan mikro yang mudah dan cepat disebut kaedah ultrabunyi-dibantu surfaktan diperkuat pengemulsian dibangunkan bagi penentuan fluorantin (FLU) dan fenantrin (PHE) di dalam sampel akueus diikuti oleh kromatografi gas-spektrometri jisim (GC-MS). Enam parameter penting, mempengaruhi kecekapan pengekstrakan hidrokarbon aromatik polisiklik

(PAH) telah dinilai dan keputusan adalah seperti berikut; pengekstrakan pelarut (toluena) jumlah pelarut pengekstrakan (30 µL), surfaktan (Tween 20), jumlah surfaktan (15 µl), masa pengekstrakan (2 minit) dan tanpa tambahan garam. Di bawah keadaan yang optimum, kaedah ini menunjukkan kelinearan baik pada julat kepekatan 1 –1000 µg $L^{-1}$ dengan pekali korelasi ($R^2 \geq$ 0.9932) dan had pengesanan yang diterima (0.3 µg $L^{-1}$) dan had kuantifikasi (1.0 µg $L^{-1}$) untuk kedua-dua analit. Nilai perolehan semula yang baik dalam julat 91.75 – 104.1%, telah diperoleh bagi sampel air paip. Sisihan piawai relatif (RSDs) adalah 1.62 – 10.32% ($n$ = 3). Kaedah yang dicadangkan telah digunakan untuk penentuan FLU dan PHE dalam sampel air paip dan jus tebu.

## Introduction

Polycyclic aromatic hydrocarbons (PAHs) are organic compounds with two or more benzene rings categorized by the European Union (EU) and the US Environmental Protection Agency (US EPA) as priority pollutants due to their mutagenic and carcinogenic properties [1]. PAHs are ubiquitous in the environment and have mainly been found in the process of incomplete combustion of oil spill, fossil fuels, wood and etc [2]. Fluoranthene (FLU) and phenanthrene (PHE) are listed as priority pollutants by the US EPA and the action and risk levels of FLU and PHE are described in the Dutch Government Quality Standards for the assessment soil and water contamination [3]. Since PAH compounds exist at very low concentrations in the environment and the presence of a high level of matrix interferences in samples, the determination of these compounds in environmental samples is complicated. Thus, a fast and effective sample pre-treatment method is critical to eliminate major interferences and enrich the target analytes before instrumental analysis.

Liquid-liquid extraction (LLE) [4] and solid phase extraction (SPE) [4, 5] are conventional sample preparation methods that have been employed for the determination of PAHs. However, these classical pre-concentration methods involve several phase operations with the consumption of large volumes of toxic organic solvent that lead to environment-unfriendly processes [6]. Researchers are devoted to the development of a microextraction method to overcome these problems as it is environmental friendly and consumes a minimum amount of organic solvent. Several microextraction methods have been developed for the determination of PAH compounds including liquid phase microextraction (LPME) [7], static- liquid phase microextraction (S-LPME) [8] and ultrasound assisted emulsification microextraction (UAEME) [9]. Although there are various established analytical methods nowadays, the application of microextraction on sugarcane samples is still unexplored. A micro implementation of liquid-liquid extraction (LLE), namely liquid-phase microextraction (LPME) has become a very popular sample pre-treatment technique because it combines extraction and enrichment of target analytes with a relatively inexpensive cost, is easy to operate and nearly solvent-free [10].

Ultrasonic-assisted emulsification microextraction (UAEME) is developed for the extraction of organic compounds from water samples [11]. This method has proven to be an efficient tool in the formation of the emulsification phase and acceleration of mass transfer between two immiscible phases [12]. A relatively new method is developed using surfactants as the emulsifier in the UAEME method for detection of selected carbamate compounds in water samples [13]. Surfactants are known as surface active agents since they have both hydrophilic and hydrophobic moieties [13]. Due to their amphiphilic structure, they are able to react both in water and immiscible phases and thus can be used as emulsifiers to enhance the dispersion of the water-immiscible phase into the aqueous phase [13]. The newly introduced method incorporated with the surfactant has greatly shortened the time of extraction required due to the effective combination of surfactant and ultrasound radiation [14]. USAEME has been previously employed for the determination of poly-brominated flame retardants in water samples [13] and for determination of PAHs in water samples [15, 16]. In the UASEME method, the extraction procedure is carried out under the simultaneous actions of ultrasound radiation and surfactant, shortening the time for analysis [13]. Ultrasound radiation leads to the fragmentation of one of the phases, resulting in the rapid emulsification of the mixture [9].USAEME provides very high extraction efficiencies in a short time, since the high contact surface between both liquids facilitates the mass transfer from the sample solution to the extraction solvent [9]. This developed method provides many advantages such as excellent enrichment factors, simplicity, stability, easy to operate, low cost and low consumption of organic solvents [15].

In this study, a new microextraction method termed UASEME incorporated with Tween 20 was developed prior to GC-MS determination of FLU and PHE in tap water and sugarcane juice samples. Six parameters were optimized including the type of extraction solvent, type of surfactant, volume of extraction solvent, volume of surfactant, salt addition and extraction time. Based on the results obtained, the proposed method is applicable for the analysis of selected PAHs in aqueous matrices due to its simplicity, efficiency and sensitivity. To the best of our knowledge, there is no paper reported on the determination of FLU and PHE in aqueous matrices using this method.

## Materials and Methods

### Chemicals and reagents

Fluoranthene (FLU) and phenanthrene (PHE) (Figure 1) were obtained from Toronto Research Chemicals INC (Toronto, Canada). HPLC-Grade toluene, n-hexane, iso-octane, and 1-octanol were purchased from QReC Asia Sdn. Bhd. (Selangor, Malaysia). Analytical grade surfactants (Tween 80, Tween 20 and DC193C) were purchased in their chemically pure form from Fisher Scientific (Selangor, Malaysia). Ultrapure water of 18.2 MΩ was purified by a Sartorious system, model Arium 611 D1 (Stedim Biotech, Gottingen, Germany). Stock standard solutions (1000 µg $L^{-1}$) of FLU and PHE were prepared in a solvent mixture of methanol and acetonitrile (1:1) and stored in the dark at 4 °C. The working standard solutions were prepared daily by the dilution of stock solution in ultrapure water prior to extraction and analysis.

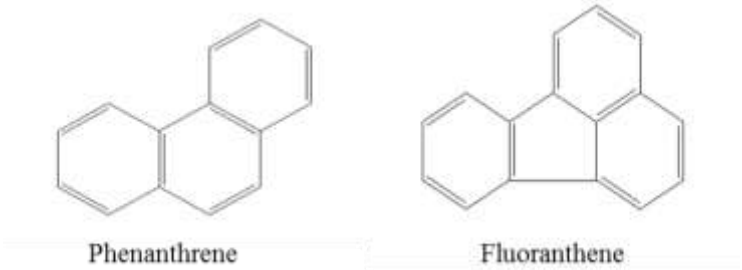

Figure 1. 2D-structures of selected polycyclic aromatic hydrocarbons

### GC-MS operating conditions

All analyses were performed using Agilent GC system Model 7890A with mass spectrometry analyser Model 5975C (Palto Alto, USA). Helium gas was used with a constant flow rate of 1mL $min^{-1}$. Splitless injections were performed at 250 °C and the volume of injection was 1 µL. The chromatographic condition was carried out on an Agilent HP 5-MS column (30 m x 0.25 mm I.D., 0.25 µm film thickness). The oven temperature applied was initially programmed at 150 °C for 3 minutes. After that, the temperature was raised up to 250 °C at 10 °C per minute. The transfer line and ion source temperature were fixed at 280 °C. Data were collected and quantified in the scan of the mass spectrometer analyzer. The retention time of PHE and FLU were recorded under optimized chromatographic conditions at 8.90 and 11.75 minutes, respectively. Electron impact mass spectra were recorded at 70 eV and the detector voltage was set at 1.0 kV. The chromatographic data were processed using MSD Chemstation E.01.01 Agilent Technology software.

### Samples collection

The optimized UASEME method was applied to the analysis of aqueous matrices. Tap water samples were obtained from the laboratory in the Integrative Medicine Cluster, Advanced Medical and Dental Institute, Universiti Sains Malaysia, Penang. Sugarcane juice samples were purchased from street vendors and local stores in Kedah and Penang, Malaysia. The sugarcane juice samples were centrifuged for 15 minutes at 3500 rpm prior to extraction. The pellet layer was discarded before the microextraction procedure. The samples were filtered through a 0.45 µm Whatman nylon membrane filter to remove unwanted particles and stored in refrigerator (4 °C) prior to use.

### Ultrasound-assisted surfactant enhanced emulsification microextraction

The ultrasound-assisted surfactant enhanced emulsification microextraction (UASEME) procedure is illustrated in Figure 2. Firstly, 15 µL of Tween 20 was added into a 10-mL volumetric flask followed by the addition of 30 µL toluene. Then, 10 mL sample solution spiked with PAHs was immediately added into the volumetric flask. Next, the

mixture was sonicated for 2 minutes. After sonication, two immiscible phases were formed and 20 µL of the upper layer was collected using a micro syringe. Finally, the clean extract was diluted with 80 µL of methanol prior to GC-MS analysis. Quantification for all data was calculated based on the peak area of analytes.

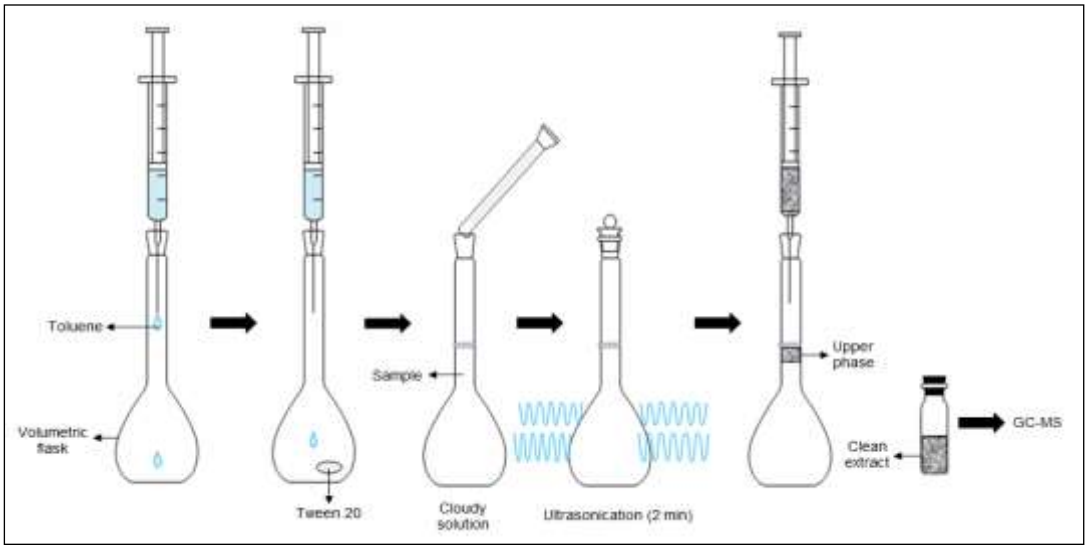

Figure 2. Schematic of UASEME procedure

## Results and Discussion

### Optimization of UASEME procedure

In order to obtain the optimum extraction and detection conditions for FLU and PHE, several parameters that potentially affect the extraction performance of UASEME were thoroughly investigated, namely type and volume of extraction solvent, type and concentration of surfactant, extraction time and salt addition. All optimization parameters were conducted in triplicates using 1000 µg $L^{-1}$ of PHE and FLU spiked in water.

### Effect of type and volume of extraction solvent

A good selection of extraction solvent should meet some important criteria such as (a) less dense than water; (b) low solubility in water; and (c) able to form a stable emulsion system in the presence of an emulsifier after sonication and has the ability to extract the targeted analytes [12, 13]. In this study, four solvents were tested namely toluene, n-hexane, iso-octane and 1-octanol. The result showed that toluene gave the highest extraction efficiency compared to other solvents (Figure 3a). This might probably due to the lower viscosity of toluene, which leads to a rapid and efficient emulsification process [15]. Thus, toluene was selected as the extraction solvent for subsequent experiments.

To optimize the volume of extraction solvent, different volumes of toluene (20, 25, 30, 35, 40, 45, 50, and 55 µL) were evaluated. The results indicated that the peak areas of all analytes reached maximum when using 30 µL of toluene as extraction solvent (Figure 3b). However, the peak areas of all analytes decreased gradually when more volume of toluene was used. This may be due to the dilution effect; as the amount of extraction solvent is increased, the volume of the floating phase (upper phase) will also increase [17]. Therefore, 30 µL of toluene as extraction solvent was used for further analysis.

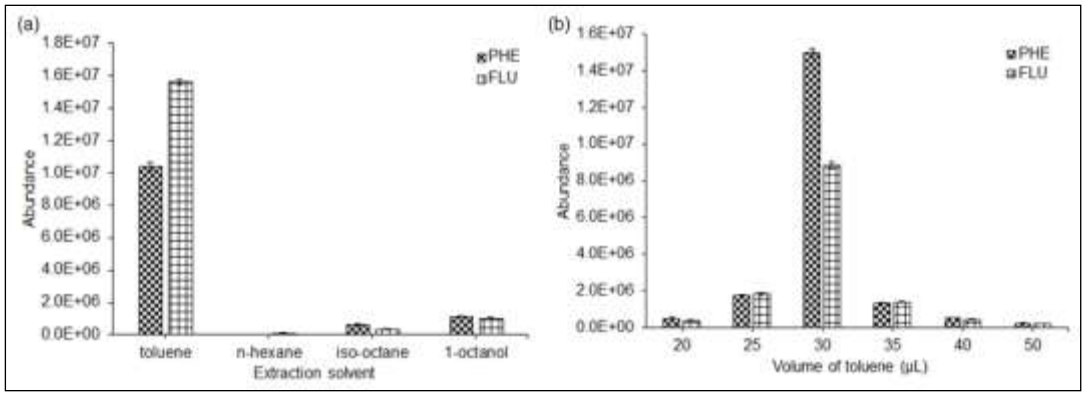

Figure 3. Effect of extraction solvent (a) and volume of toluene (b) on UASEME methods on the extraction of PHE and FLU from spiked water (n = 3 in each case)

**Effect of type and volume of surfactant**

The selection of a suitable surfactant is very crucial in order to obtain higher extraction efficiency for the targeted analytes. Under ultrasound radiation, the surfactant enhances the rate of emulsification process between the water-immiscible extraction solvent and aqueous solution. Upon completion of emulsification process, the extraction solvent is dispersed as fine droplets in the sample solution, which accelerate the mass transfer process of the analytes from the aqueous phase to the organic phases. A suitable hydrophilic-lipophilic balance (HLB) is the primary criterion for the selection of surfactant. The effects of three non-ionic surfactants (Tween 20, Tween 80 and DC193C) on the extraction efficiency of UASEME were investigated. The results showed that Tween 20 gave the highest extraction efficiency for both analytes compared to without the use of surfactant, DC193C and Tween 80 (Figure 4a). The occurrence of this phenomenon may be due to the hydrophobic properties of Tween 20 which interact ideally with the non-polar FLU and PHE compounds. A strong hydrophobic interaction between Tween 80 and PAHs contributed to less extraction efficiency of analytes toward the extraction solvent as indicated by the suppression of GC-MS chromatographic responses.

The volume of surfactant is important in the UASEME method as it will affect the mass transfer rate of the analytes. The effect of Tween 20 amount used was investigated by varying its volume from 0 to 25 µL. Based on the results obtained (Figure 4b), the extraction efficiency began to decrease as the volume of Tween 20 increased. This was probably due to the fractionation of the analytes which was incorporated into the micelle when the surfactant concentration was higher than the CMC, thus increasing the solubility of analytes in the sample solution [18]**.** Therefore, 15 µL of Tween 20 was used in the subsequent extractions.

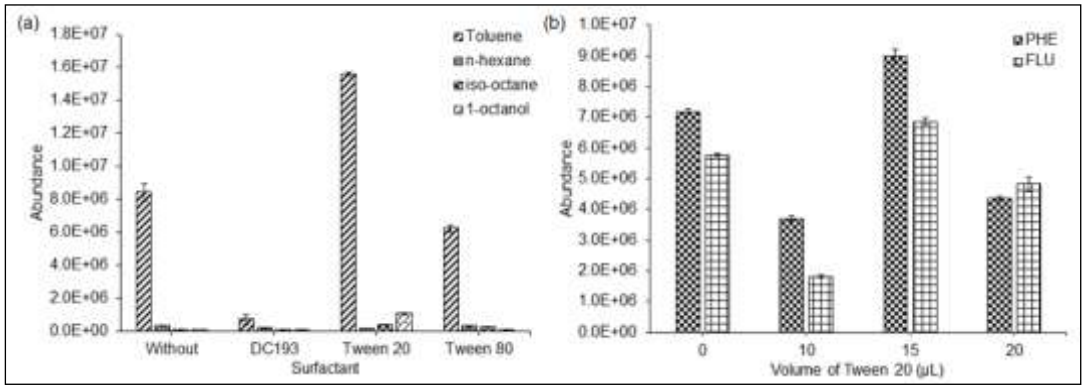

Figure 4. Effect of surfactant (a) and volume of Tween 20 (b) on UASEME methods on the extraction of PHE and FLU from spiked water sample (n = 3 in each case)

**Effect of extraction time and salt addition**

In this study, the interval time from the beginning of the emulsification to the moment before the injection into the vial is known as the ultrasound extraction time. The effect of extraction time in this method was studied over the range from 0 to 5 minutes with other experimental conditions kept constant (Figure 5a). The results showed that the peak area increased continuously from 0 to 2 minutes of extraction time. It revealed that the contact surface between the extraction solvent and aqueous sample was infinitely larger [14]. However, when the extraction time was prolonged to 3 minutes, the extraction efficiency of the analytes decreased. This occurrence was probably due to the longer sonication time which produced heat to the sample vial and caused the analytes' degradation [19]. Hence, 2 minutes was used as the optimum extraction time in the UASEME method.

Generally, the addition of salt into the sample solution may reduce the solubility of polar analytes and enhance their partitioning into the extraction solvent or organic phase. The effect of the NaCl addition on the UASEME method's efficiency was evaluated and studied in the range from 0 to 12% (w/v). The results showed that there was no significant increment with the addition of salt during UASEME (Figure 5b) due to the relatively non-polar characteristics of FLU and PHE. Hence, no salt was added in the subsequent UASEME method analysis.

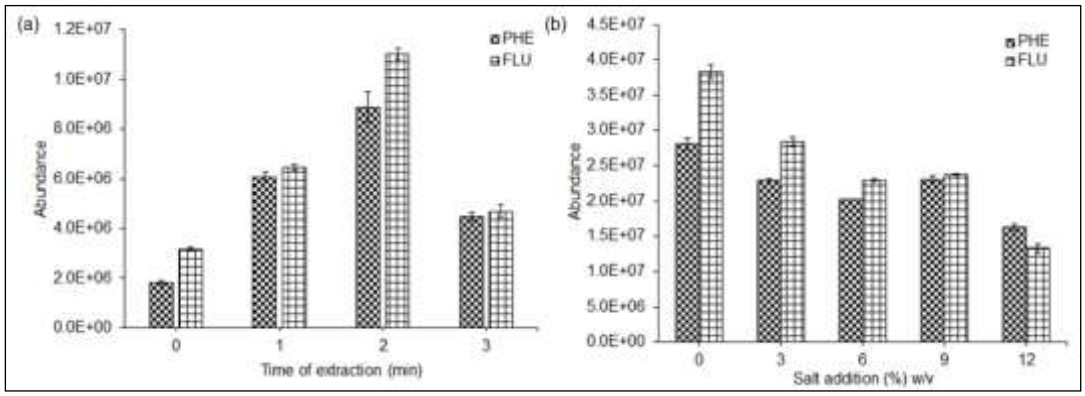

Figure 5. Effect of extraction time (a) and salt addition (b) on UASEME methods on the extraction of PHE and FLU from spiked water sample (n = 3 in each case)

**Method validation**

The analytical performance of the proposed UASEME method was evaluated in terms of its linearity, limits of detection (LODs), limits of quantification (LOQs), precision and recovery under the optimized extraction conditions. Method validation was carried out based on the ICH Harmonised Tripartite Guideline [20]. The calibration curves were plotted in the concentration range between 1 to 1000 µg $L^{-1}$ using at least five spiked concentrations in distilled water. Good linearity was observed for PHE and FLU with the coefficient of determination, $R^2$ of 0.9932 and 0.9968, respectively (Table 1). LODs were calculated as three times the signal-to-noise ratio (S/N = 3) and LOQs were measured as ten times the signal-to-noise ratio (S/N = 10). The LODs and LOQs for PHE and FLU obtained in this study were 0.3 and 1.0 µg $L^{-1}$, respectively. Under the optimized UASEME conditions, the enrichment factors (EFs) of 21.8 and 30.6 were obtained for PHE and FLU, respectively. EF was calculated using the following Equation 1:

$$EF = C_1/C_0 \quad (1)$$

where $C_1$ and $C_0$ are the final concentrations of analytes found in the clean extract and initial concentration in the original sample solution, respectively.

Table 1. Validation data of UASEME method for selected polycyclic aromatic hydrocarbons in spiked water samples

| Analyte | Linear Range (μg $L^{-1}$) | Linear Equation | $R^2$ | LOD (μg $L^{-1}$) | LOQ (μg $L^{-1}$) | EF |
|---|---|---|---|---|---|---|
| PHE | 1 – 1000 | y = 15419 x + 13043 | 0.9932 | 0.3 | 1.0 | 21.8 |
| FLA | 1 – 1000 | y = 5609.9 x - 34604 | 0.9968 | 0.3 | 1.0 | 30.6 |

The analytical characteristics of the proposed UASEME method were compared with other reported methods for the analysis of PAHs in water samples (Table 2). Although the developed method produced a lower sensitivity of analytes compared to most methods used for PAHs determination, the use of 30 μL of toluene and 15 μL of Tween 20 in UASEME is more environmentally friendly and beneficial as an alternative microextraction method for the analysis of PAHs in aqueous samples. In addition, the proposed method is rapid and the extraction process can be accomplished within 5 min, which is useful for routine analyses of PAHs.

**Real sample analysis**

To evaluate the applicability of the proposed method, the procedure was performed as an analysis of PAHs in one tap water and nine sugarcane juice samples. Analyses of these samples were conducted under the optimum conditions of UASEME. From the blank analyses, no PHE and FLU were detected in all samples. The non-spiked and spiked tap water samples were analysed in triplicate and the typical chromatograms of blank and spiked samples at 100 μg $L^{-1}$ are shown in Figure 6. The accuracy of the developed method was determined by spiking analytes at three different concentration levels (1, 50 and 100 μg $L^{-1}$) into the tap water samples. The relative recovery was calculated as the percentage of mean values of the extracted PAHs peak area (triplicates) against the peak area of PAHs derived from the calibration curve. Table 3 shows a recovery of 91.75 – 104.1% for both analytes with RSDs of 1.62 – 10.32%. The obtained results demonstrated that the proposed UASEME method is applicable for low and high concentrations of PAHs in aqueous matrices.

## Conclusion

In brief, the results indicated that the UASEME method can be used as a simple and efficient sample preparation technique for trace analysis of PAHs in aqueous samples prior to GC-MS analysis. This method also uses a minimum amount of extraction solvent and surfactant for each extraction. Therefore, the new UASEME method can be potentially used as an alternative 'green' microextraction for the detection of PAHs in aqueous matrices. Future investigations can be focused on the combination of the developed method with other microextraction methods such as dispersive micro-solid phase extraction and magnetic solid phase extraction to improve the sensitivity and detection limits of the studied analytes.

**Abstract**

In this work one step activation was introduced to potassium hydroxide (KOH) modified palm kernel shells. Various concentration of potassium hydroxide was used to activate and impregnate palm kernel shell before calcined at 600 $^{o}$C for 2 hours. All the prepared samples were characterized using Fourier Transform Infrared spectroscopy (FTIR), Nitrogen Adsorption Analysis and Field Emission Scanning Electron Microscope (FESEM), respectively. The basicity and basic strength of the prepared samples were determined using back titration methods. Following the preparation, the samples were used as base heterogeneous catalyst in palm oil transesterification reaction using dimethyl carbonate (DMC). Analysis of the products were performed using Gas Chromatography-Flame Ionization Detector (GC-FID) while to check the possibility of leaching, that is the presence of potassium in the biodiesel X-ray Fluorescence (XRF) spectroscopy was used. FTIR analysis of the raw palm kernel shell showed the presence of various functional groups. However, after the activation most of the functional groups were eliminated. A high BET surface area of 1054 $m^2$/g was obtained from 10% AC/K, while the BET surface area for 15%, 20% and 25% AC/K decreases. This study shows, as the percentage of one step activation potassium doped carbon increases, the basic strength increases and followed by the increase in biodiesel production with leaching free reaction. The percentage conversion of biodiesel for 10% AC/KOH, 15% AC/KOH, 20% AC/KOH and 25% AC/KOH calculated were 35%, 45%, 63% and 67%, respectively.

**Keywords**: one step activation, dimethyl carbonate, biodiesel, leaching free

**Abstrak**

Dalam kajian ini pengaktifan satu langkah diperkenalkan dengan menggunakan kalium hidroksida (KOH) terubahsuai tempurung kelapa sawit. Pelbagai kepekatan kalium hidroksida digunakan bagi mengaktifkan dan menepukan tempurung kelapa sawit sebelum dikalsin pada 600 $^{o}$C selama 2 jam. Kesemua sampel yang telah disediakan dianalisis mengunakan teknik spektroskopi Inframerah Transformasi Fourier (FTIR), Analisis Penjerapan Nitrogen dan Mikroskopi Medan Pancaran Imbasan Elektron (FESEM). Kebesan dan kekuatan bes sampel yang disediakan ditentukan melalui pentitratan kembali. Sampel yang telah disediakan digunakan sebagai pemangkin bes heterogen untuk transesterifikasi minyak kelapa sawit dengan dimetil karbonat (DMC). Hasil yang didapati dianalisis dengan menggunakan Gas Kromatografi – Pengesan Pengionan Nyala (GC-FID) manakala untuk mengkaji kemungkinan larut resap iaitu kehadiran kalium dalam biodiesel, spektroskopi sinar-X pendarflour (XRF) digunakan. Analisis FTIR tempurung kelapa sawit mentah menunjukkan kehadiran pelbagai kumpulan berfungsi. Walaubagaimanapun, selepas pengaktifan dan karbonisasi, kebanyakan kumpulan berfungsi ini telah disingkirkan. Luas permukaan BET yang tinggi iaitu 1054 $m^2$/g telah diperolehi daripada 10% AC/KOH, manakala luas permukaan BET untuk 15%, 20% dan 25% AC/KOH menurun. Hasil kajian menunjukkan apabila peratus penepuan karbon dalam pengaktifan satu langkah oleh kalium meningkat, kekuatan bes turut meningkat diikuti oleh peningkatan hasil biodiesel dalam tindak balas bebas

larut resap. Peratus penukaran biodiesel untuk 10% AC/K, 15% AC/K, 20% AC/K dan 25% AC/K adalah masing-masing 35%, 45%, 63% dan 67%.

**Kata kunci:** pengaktifan satu langkah, dimetil karbonat, biodiesel, bebas larut resap

## Introduction

Activated carbons (AC) are important material, which have been widely used in various industrial applications, which include separation/purification of liquid or gas and removal of heavy metal [1]. In the preparation of heterogeneous catalyst, activated carbon has proved to be highly effective as catalyst support. Activated carbon can be produced from a variety of raw material mostly coal and agricultural by products or lignocellulosic materials. Production of activated carbon from agricultural by products is preferable since it is more cost effective. There are numerous study regarding the production of activated carbon from agricultural by products such as coconut shell [2, 3], pistachio nut shell [4], sugar cane Bagasse [5], olive stones [6] and macadamia nut-shell [7]. Palm kernel shell (PKS) is one of the most abundant agricultural waste produce since palm oil industry is one of the major industries in Malaysia. Hence, palm kernel shell would be a better choice to be utilized for the raw material in the production of activated carbons.

Due environmental concerns, biodiesel has received many attentions to be used as an alternative diesel fuel since it has a unique advantage such as being biodegradable, non-toxic and suitable for domestic production. Biodiesel is a mono alkyl ester of long chain fatty acids obtain from transesterification reaction of triglyceride such as vegetable oil or animal fat with simple alcohol as shown in Figure 1.

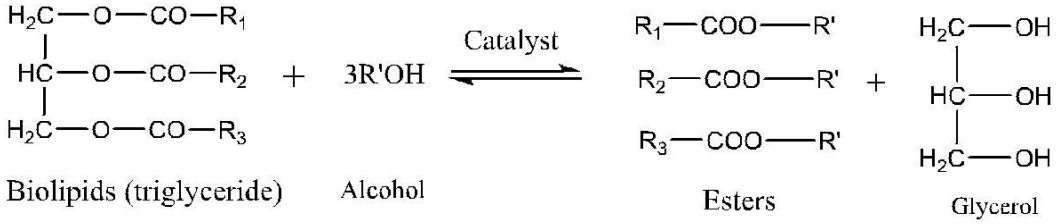

Figure 1. Transesterification of triglyceride with alcohol

Glycerol is produce as the undesired by product in this reaction. The separation process of glycerol could be costly and technically difficult. In this study dimethyl carbonate (DMC) will be introduced as a reagent to replace alcohol in the transesterification reaction. Free glycerol biodiesel can be obtained because fatty acid glycerol carbonates (FAGCs) is form and can be easily remove from the biodiesel as shown in Figure 2.

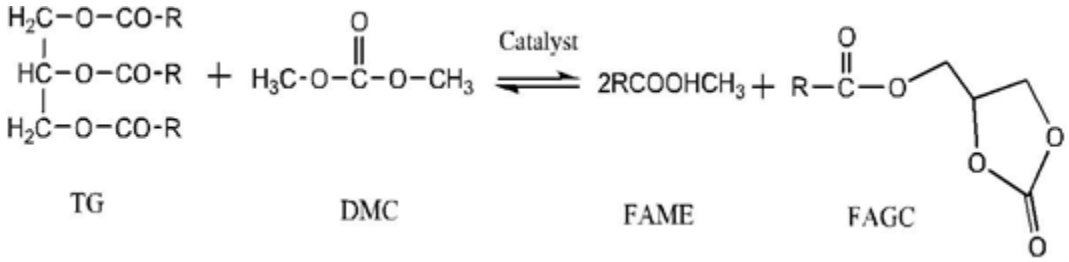

Figure 2. Transesterification of triglyceride with DMC

Another problem normally occur in the production of biodiesel is leaching [8]. In conventional method, normally part of the alkali metal catalyst would leach into the biodiesel, thus reducing the biodiesel quality. The removal of

the catalyst would require a series of repeated washing and this will contribute to environmental problem. By immobilizing the catalyst in a suitable support can prevent the leaching problem and therefore separation can be easily done through centrifugation or filtration.

In this study, activated carbon from palm kernel shell was produced through one-step activation using potassium hydroxide (KOH) as activating agent Potassium doped activated carbon (AC/K) were then tested as a potential heterogeneous base catalyst in production of biodiesel from palm oil. In addition, by considering the advantages offered by DMC, it was chosen as a reagent and reactant in this reaction replacing alcohol.

## Materials and Methods

This locally available palm kernel shell (PKS) were collected from the Kulai palm oil mill. Refined oil was purchased from local markets. Potassium hydroxide (KOH), n-hexane, n-heptane were purchased from QREC while dimethyl carbonate and 37% HCL were purchased from MERCK.

### Preparation of AC/K catalyst

The base activation was carried out by using a liquid state KOH impregnation at different concentration. KOH solution at 10%, 15%, 20%, and 25% concentration were prepared by dissolving KOH pallets in deionized water in a 100-mL volumetric flask. About 10g of dried PKS were impregnated with different percentage concentration of KOH in a hot plate and stirred for 5 hours and dried in an oven overnight at 100 $^{o}$C. The impregnated carbon was further calcined in a furnace at 600 $^{o}$C for 2 hours and finally dried in an oven for 24 hours. All the samples were labeled as 10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K according to the respective KOH percentage concentration.

### Transesterification reaction with DMC

The reaction was conducted by mixing the palm oil and DMC with a 1:9 ratio in a two-necked 250-mL round bottom flask immersed in paraffin oil to control the temperature. The flask is equipped with a reflux and a magnetic stirrer. Firstly, the catalyst was added to the DMC and vigorously stirred with slight heating for 30 minutes until completely dissolved. About 10 g of palm oil were added into the mixture of catalyst and DMC then the mixture was refluxed at temperature close to the boiling point of DMC (80 – 90$^{o}$C). The reaction condition for are based on methodology reported by previous study [9,10]. After reflux, the mixture allowed to cool at room temperature and transferred into 15ml centrifuge tube. The mixture was centrifuged at 3000rpm for 30 minutes to separate the excess DMC and catalyst from the solution. The biodiesel was then collected for characterization by filtering out the catalyst.

All materials were characterized using Thermogravimetric Analyzer (TGA), Fourier Transform Infrared (FTIR), Nitrogen Adsorption Analysis-(BET) surface area, Field Emission Scanning Electron Microscope (FESEM) and Energy Dispersive X-ray fluorescence (XRF). While the transesterification reaction of palm oil with DMC to produce biodiesel was performed using gas chromatography – flame ionization (GC – FID) and Gas Chromatography – mass spectrometry (GC-MS).

## Results and Discussion

### Thermogravimetry analysis of raw palm kernel shell

Thermogravimetry analysis (TGA) is commonly used to study the thermal decomposition of agricultural by product. Raw palm kernel shell was first analyzed using diamond TG/DTA Perkin Elmer to estimate the optimum carbonization temperature for the activation process. Figure 3 shows the TGA thermogram of raw-PKS subjected in a temperature range 50 – 800 $^{o}$C at a heating rate of 10 $^{o}$C/min under air flow and nitrogen gas flow.

From the thermogram shown in Figure 3, there are various weight losses which can be separated into four different stages from stage I to IV. During stage I, 11.5% of weight loss occurred at the temperature of 50 – 130 $^{o}$C. This is due to the elimination of moisture in the raw material. Major weight loss of 47.4% occurs at temperature range from 240 – 360 $^{o}$C which is at stage II. It is assumed that the decomposition of the major components of lignocellulose biomass including hemicellulose, cellulose and lignin occur at this stage [11]. In stage III, at temperature of 360 °C to 450 °C, it shows the final decomposition or weight loss which corresponding to lignin decomposition and

charcoal oxidation. The percentage weight lost recorded at this region were 16% and it is believed that most of these lignocellulosic materials in raw-PKS were decomposed. As reported by some researchers, lignin was gradually lost at temperature from 200 °C to 720 °C [12].

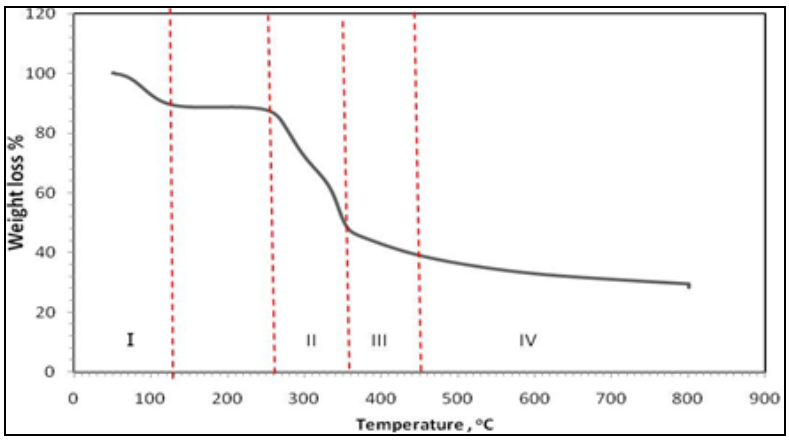

Figure 3. TGA curve of raw PKS

No significant change in weight loss on the stage IV for at which the temperature is around 450 °C. Total weight loss occurs at 800 °C. This is probably caused by the formation of volatile tar as the predominant product during the volatilization [13]. It is also believed that the organic compound in raw samples was completely carbonized at 500 °C. To ensure complete decomposition of organic compounds and liberation of volatile temperature for activation of activated carbon was set at 600 °C.

**Fourier transfer infrared spectroscopy analysis**

Fourier transfer infrared spectroscopy (FTIR) was employed to identify the variety of functional group presence in the raw-PKS and activated carbon. It also provides information on the effect of the activation process that has been carried out as an evidence of the phase transformation which occurred in both raw-PKS and AC/K catalyst. Figure 4 shows the spectra of raw-PKS and the prepared 10%, 15%, 20% and 25% AC/K catalyst.

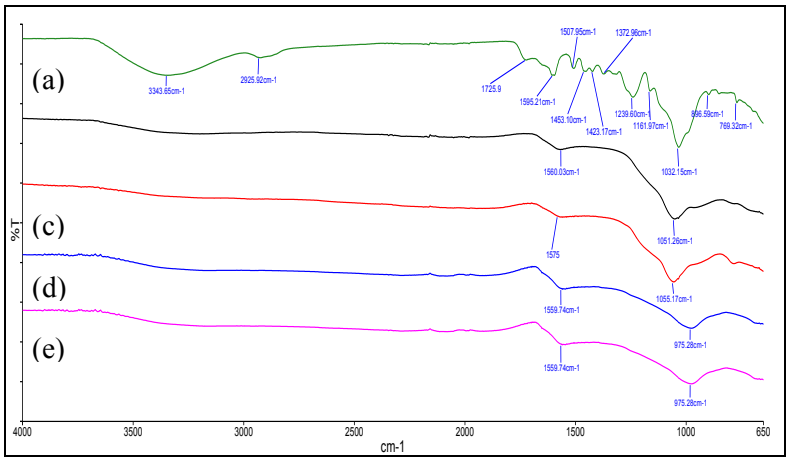

Figure 4. FTIR spectrum of (a) raw-PKS (b) 10%AC/K (c) 15%AC/K (d) 20%AC/K (e) 25%AC/K

Raw-PKS shows additional extra bond compares to AC/K. These extra bands are at 3343 $cm^{-1}$ which is usually assign to hydrogen bond OH group [6]. The absorption band at 2025.92 $cm^{-1}$ which was due to the C-H stretching in

methyl and methylene groups. This band is different to the C-H vibrations band for $–CH_3$-and $CH_2=$, which are located around 1372.96 $cm^{-1}$ and 1453.10 $cm^{-1}$, and is very useful for identifying the methylene and methyl groups in each compound [14]. Moreover, peak at 1735 $cm^{-1}$ which represents the stretching of (C=O) carbonyl groups. The bands at 1595.21 $cm^{-1}$, 1507.95 $cm^{-1}$ and 1423 $cm^{-1}$ indicated the presence of C=C stretching of aromatic compounds. Another peak at 1239.90 $cm^{-1}$ and a subsequent small rise in 1161.97 $cm^{-1}$ could be assigned to the stretching of C-O in ester, ethers or phenol groups. The strong band at 1032.15 $cm^{-1}$ could be attributed to the (C-OH) alcohols group. From the analysis of the FTIR spectrum, carbonyl group, ether, esters, alcohols and the phenol groups can be suggested as the main oxygen group present in the raw PKS. This result supported by the thermogram of TGA analysis. The spectrum of raw PKS is quite similar to the study reported by previous study [15].

However, for the prepared AC/K at 10%, 15%, 20% and 25% concentration spectra illustrated less absorption peak compared with raw-PKS. From the spectra, it can be observed that most of the absorption peaks of functional groups were disappeared. This phenomenon might be explained as the process of carbonization in which most of the functional group presented in the raw-PKS were evaporated as volatile materials upon heating which indicated the activation process have taken place [16]. The spectra of prepared 10%, 15%, 20% and 25% AC/K showed a decreasing trend in the broad peak of C-O around 900-1300 $cm^{-1}$ and the C=C absorption band around 1500 –1650 $cm^{-1}$. This result in agreement by the previous studies [11, 17] indicating that by increasing the amount of activating agent, the activation reaction would increase and more weak bonds disappeared by thermal degradation.

**Nitrogen adsorption analysis**

The single point nitrogen gas adsorption characterization was performed to study the surface area of the prepared AC/K catalyst. The specific BET surface area, SBET of 10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K samples are shown in Figure 5.

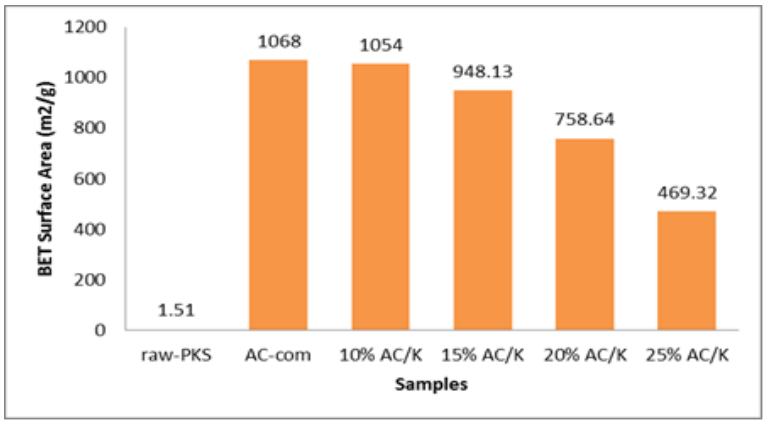

Figure 5. Single point BET surface area of raw PKS, AC-Com and prepared AC/K

Lowest surface area is shown in the raw-PKS which is 1.51 $m^2/g$. This is because of the dense structure of raw-PKS with lack of pores. After activation, there is an increase in the surface area of the activated carbon. This shows that potassium hydroxide, KOH successfully act as an activating agent. However, there is a significant reduction in the specific BET surface area as the percentage concentration of KOH loading increases from 10% to 25%. Further increased in percentage of KOH loading caused the surface area of other activated carbons to decrease. The reduction of BET surface area may be caused by the filling of potassium hydroxide molecules into the pores of the activated carbon. The excessive amounts of KOH would promote a vigorous gasification reaction and diminished the carbon framework leading to a dramatic decrease of accessible area. Besides, an excessive KOH molecule might decompose following the reactions in equation 1 and 2 [18,19].

$$2KOH \rightarrow K_2O + H_2O \quad (1)$$

$$H_2O + C \rightarrow CO + H_2 \quad (2)$$

**Field emission electron microscope**

The morphological structure of raw-PKS and AC/K was characterized by field emission electron microscope (FESEM). Information on the structural change in the raw-PKS before and after activation we thoroughly studied. Figure 6 shows the FESEM micrographs of raw-PKS with 2.50KX magnifications. A dense and planar image with some occasional cracks can be seen. This mainly due to high percentage composition of lignin, a phenolic polymer that provides structural strength to the plant and give its hard and rough wood like structure.

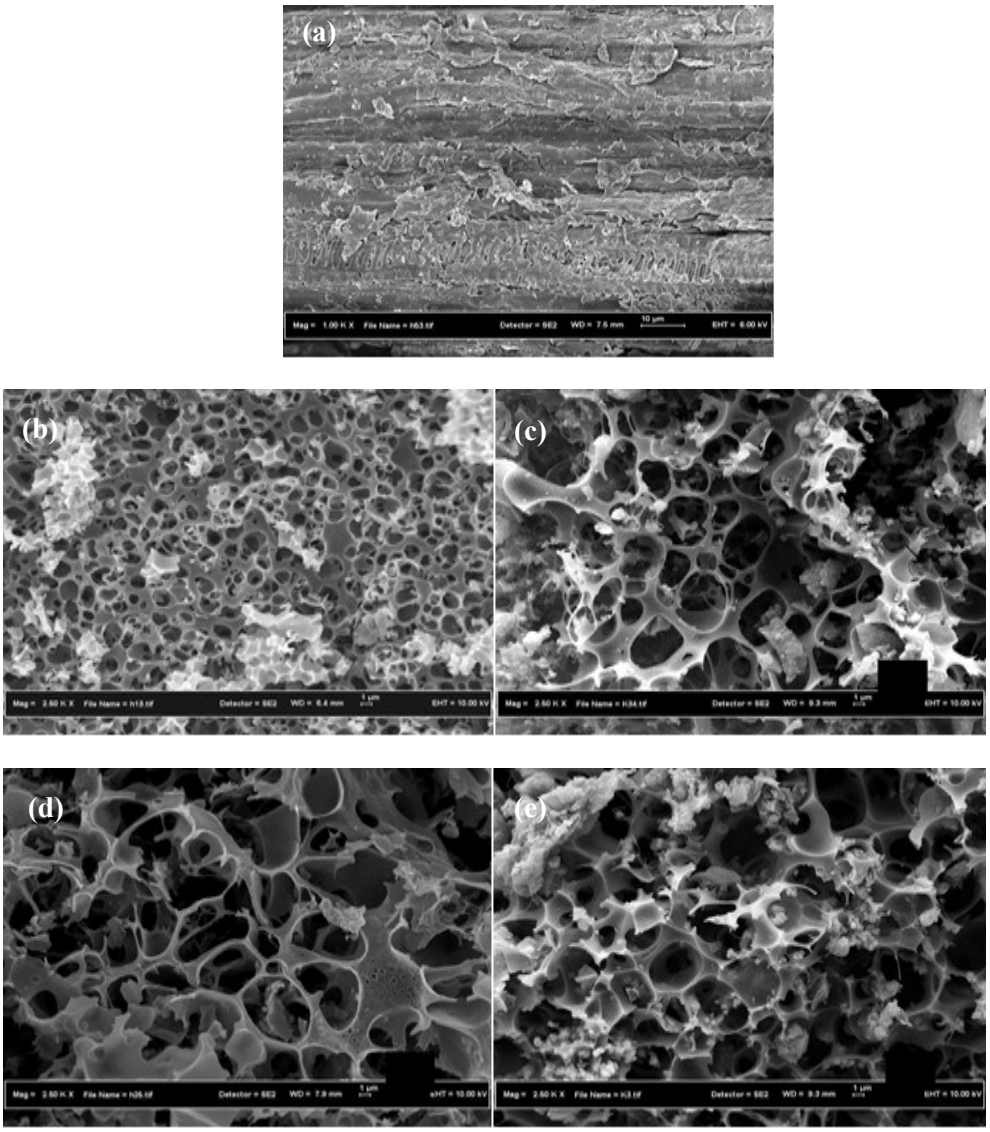

Figure 6. FESEM image of (a) raw PKS (b) 10%, (c) 15%, (d) 20% and (e) 25% AC/K with magnification of 2.50KX

Figure 6 (a – d) shows the FESEM micrograph at 2.50KX magnification of prepared AC/K at 10%, 15%, 20% and 25% concentration respectively. The FESEM micrographs reveal the presence of cavities and pores with different size and shapes. The development of pore and cavities in the AC/K is the result of the release of volatile

components and the evaporation of KOH from the spaces, which were previously occupied by the reagent. Pore structure is one of the important characteristic in the heterogeneous catalysis process as the pore structure helps in the dispersion of the catalytic species throughout the carbon and thus increasing the catalytic performance [20]. The development of porosity by KOH activation is associated with the gasification reaction and formation of potassium species such as potassium dioxide, potassium carbonate and hydrogen [21]. However, as the percentage concentration of potassium hydroxide increase, a larger and wider pore can be seen. Beyond the optimum value, the excessive KOH would promote vigorous gasification reaction and may cause the excessive carbon burn-off, which can destroy the carbon framework, which collapse of some pore walls leading to a dramatic decrease of accessible area [22].

**Back titration analysis**

Determination of the amount of the basic site of the prepared AC/KOH catalyst was performed by the back titration method. This method was suggested in determining the amount of basic site of the bulk catalyst [23]. This analysis is important to identify the best prepared AC/KOH. Their basicity should be known first before applying as a catalyst for transesterification reaction. Figure 7 shows the amount of basic sites recorded in millimole per gram for the prepared 10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K, respectively.

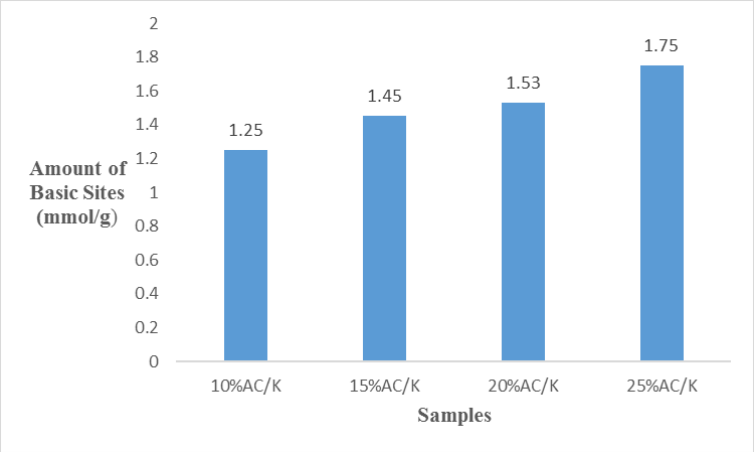

Figure 7. Amount of basic site of prepared AC/K catalyst

From the Figure 7, 25% AC/K shows highest amount of basic site of 1.75 mmol/g, follow by 20% AC/K and 15% AC/K, which have a basic site of 1.53 and 1.45 mmol/g respectively. While for 10% AC/K it shows a lower basic site of 1.25 mmol/g. It was found that the basic site increase with increase of percentage of KOH concentration. In addition, KOH can decompose into potassium species such as potassium oxide that acts as active site, which probably contribute to the basicity of the catalyst. Thus, increase the amount of KOH loading will probably increases the production of active site. This result in agreement with studies reported by Intarapong et al. [24], which found that the basicity and the activity of the catalyst increased with increased of the potassium loading to the $ZrO_2$.

**Analysis and determination of transesterification product**

The biodiesel obtained from the reaction process was analyzed to investigate the effectiveness of 10%, 15%, 20% and 25% AC/K as catalyst to catalyze the transesterification reaction of palm oil with DMC. Gas chromatography method was used for analysis and for the confirmation of the components in biodiesel produced. The biodiesel, which is fatty acid methyl esters (FAMEs), was firstly analyzed by GC-FID to determine the percentage conversion.

Figure 8 shows typical example of the GC chromatogram of the FAMEs. The elution order for the FAMEs obtain in the transesterification reaction with different percentage concentration catalyst is similar. The composition of FAME obtained including Methyl myristate (C14:0), Methyl palmitate (C16:0), Mehyl stearate (C18:0), Methyl

oleate (C18:1) and Methyl linoleate (C18:2). Methyl palmitate and Methyl oleate are the main methyl esters for palm oil biodiesel. While Methyl myristate, Methyl stearate and Methyl limoleate exist in small percentage of the biodiesel. This data agrees with data reported in previous works [25,26].

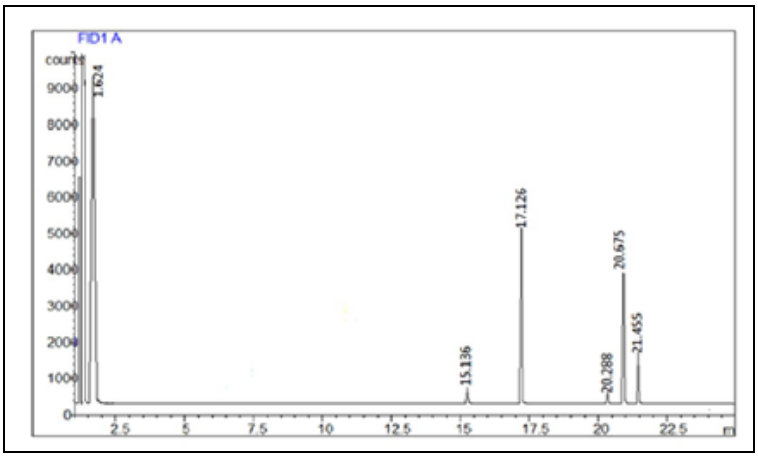

Figure 8. GC chromatograms of biodiesel using 25% AC/K catalyst

From the chromatogram obtained, percentage conversion of the biodiesel was calculated. Besides that, X-ray Fluorescence (XRF) analysis were done to determine the possibility of potassium leaching into the biodiesel after the reaction. Table 3.1 shows percentage conversion and the potassium content in the biodiesel produced from prepared 0% AC/K, 10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K.

Table 1. Percentage conversion and potassium content of the biodiesel

| Samples | Percentage Conversion (%) | Potassium (wt.%) |
|---|---|---|
| AC-Com | 0 | ND |
| 10%AC/K | 35 | ND |
| 15%AC/K | 45 | ND |
| 20%AC/K | 63 | ND |
| 25%AC/K | 67 | ND |

ND: not detected

An increasing trend can be seen in the percentage conversion of biodiesel. For 10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K the percentage conversion of biodiesel were 35%, 45%, 63% and 67% respectively. As the basicity of the catalyst used increase, the percentage conversion also increases. In addition, this proved that the production of biodiesel does not always depend on the surface area of the catalyst as reported in previous studies [26, 27]. As for the XRF analysis, it shows that there is no potassium content detected in the biodiesel after the reaction. This showed that by using DMC, the alkali catalyst in the one step activated KOH modified carbon do not dissolve or leach out into the reaction medium.

## Conclusion

The prepared AC/K KOH was identified and could be an effective and potential heterogeneous base catalyst in transesterification of palm oil and DMC. The used of DMC in this reaction can prevent the leaching of KOH into the biodiesel and the transesterification produced glycerol free-FAME. The percentage conversion of biodiesel for

10% AC/K, 15% AC/K, 20% AC/K and 25% AC/K were 35%, 45%, 63% and 67%, respectively. Highest percentage conversion was obtained from 25% AC/K, although it has the lowest surface area compared with others. This showed that, the production of methyl ester in biodiesel not always depend on the large surface area. In addition, from the study, it shown that the basicity and the basic strength of the prepared AC/K play an important role in the catalytic performance of the catalyst. Increase in the basicity and basic strength of the catalyst. Higher percentage loading of potassium increased the basicity of the catalyst, which gives a significant impact to the percentage conversion of biodiesel.

**Abstract**

The presence of naphthenic acid (NA) in petroleum crude oil may cause serious corrosion problem for refinery processing equipment. In this work, an alternative method to remove NA is investigated based on the catalytic deacidification reaction to achieve the target of lowering the total acid number (TAN) as required by PETRONAS to be less than 1. Ammoniated polyethylene glycol ($NH_3$-PEG) was formulated as a deacidifying agent with various concentrations ranging from 100 – 1000 mg/L for crude oil. Cerium oxide based catalyst supported on alumina was synthesized via wet impregnation method and characterized using X-ray diffraction spectroscopy (XRD), Brunauer–Emmett–Teller (BET) and thermogravimetry analysis-differential thermal analysis (TGA-DTA). Parameters such as amount of basic chemical dosing, type of metal oxides, catalyst calcination temperature and reusability of catalyst on the removal of NA was studied. The results showed the TAN value for crude oil was reduced by 70.6% to a TAN of 0.74 mg KOH/g by using 1000 mg/L of $NH_3$-PEG dosing aids by $Ce/Al_2O_3$ catalyst calcined at 1000 $^oC$.

**Keywords**: total acid number, naphthenic acid, metal oxide catalyst, ammoniated polyethylene glycol, alumina

**Abstrak**

Kehadiran asid naftenik (NA) dalam minyak mentah boleh menyebabkan masalah hakisan yang serius kepada peralatan pemprosesan penapisan. Di dalam kajian ini, satu kaedah alternatif untuk menyingkir NA telah disiasat berdasarkan tindak balas penyahasidan pemangkin untuk mencapai sasaran jumlah nombor asid (TAN) kurang daripada 1 seperti yang dikehendaki PETRONAS. Larutan ammonia polietilena glikol ($NH_3$-PEG) telah diformulakan sebagai ejen penyahasidan dengan pelbagai kepekatan antara 100 – 1000 mg/L. Mangkin serium oksida disokong dengan alumina telah disintesis menggunakan kaedah pengisi tepuan basah dan dicirikan menggunakan spektroskopi pembelauan sinar-X (XRD), Brunauer–Emmett–Teller (BET) dan analisis termogravimetri – analisis pengkamiran terma (TGA-DTA). Parameter seperti jumlah dos kimia bes, jenis logam oksida, suhu pengkalsinan mangkin dan kebolehgunaan mangkin terhadap penyingkiran NA telah dikaji. Hasil kajian menunjukkan nilai TAN bagi minyak mentah telah dikurangkan sebanyak 70.6% kepada TAN 0.74 mg KOH/g dengan menggunakan 1000 mg/L dos $NH_3$-PEG dibantu oleh mangkin $Ce/Al_2O_3$ dikalsinkan pada 1000 $^oC$.

**Kata kunci:** nombor jumlah asid, asid naftenik, mangkin, ammonia polietilena glikol, alumina

## Introduction

The initial concern about naphthenic acid corrosion dates back to the previous century, and it keeps drawing the attention of refineries until today [1]. Naphthenic acid (NA) is a complex mixture of cyclic or acyclic aliphatic organic compounds characterized by a carboxyl reactive group [2] and constitutes about 50 wt.% of the total acidic compounds in crude oil [3].Total acid number (TAN) refers to the amount of NA found in the crude oil and was measured using ASTM D664 method. TAN represents milligram of KOH per gram liquid needed to neutralize 1 g of acid present in the sample. If the acidic species in the petroleum cannot be removed during the refinement, it will influence the quality of the final product, causing problems, equipment failures, and environmental pollution. Several efforts are focused on the development of the current approaches to refine acidic crudes by blending with non-acidic crudes so that the TAN of the blend is no higher than about 0.5 mg KOH/g [4]. The drawback of this approach is that it limits the amount of acidic crude that can be processed. The acidic crudes can be treated with inorganic bases such as potassium and sodium hydroxide to neutralize the acids [5]. This approach, however, forms an emulsion which is very difficult to break and undesirably leaves potassium or sodium in the treated crude. Catalytic removal of NA has been studied for many years. It has been reported that transition metal catalyst could reduce the acidity of crude oil under hydrogen atmosphere but, this process consumes large amounts of hydrogen [6] and it has not been commercialized yet. In order to solve this problem, the catalytic deacidification process was investigated in this work by using different metal oxides as catalyst supported on alumina to assist in the deacidification process together with the $NH_3$-PEG as basic chemical agent.

## Materials and Methods

### Materials

All the materials were purchased from QRëC™ and used without further treatment. 2-propanol and toluene were used as extraction solvents. Ammonia solution 28% mixed with polyethylene glycol (MW 300, 400 and 600) were used as deacidifying agents. Phenolphthalein indicator solution, 1% in ethanol was used as an indicator in the deacidification process. Potassium hydroxide pellets and barium hydroxide were used as titrants. The feedstock used in this study was crude oil obtained from Petronas Penapisan Melaka, Malaysia labelled as crude B with a TAN of 2.52 mg KOH/g.

### Preparation of 0.4 % $NH_3$-PEG

Ammonia solution (40 mL) was added dropwise into a sample bottle containing 9.96 mL polyethylene glycol. The mixture of $NH_3$-PEG was vigorously stirred using a magnetic bar for an hour. The reaction of $NH_3$ with PEG to form $NH_3$-PEG was hastened by soaking the bottle in an ice bath. The solution, which was then ready for blending with the crude oil, was set aside in a dark bottle to avoid sunlight penetration.

### Catalyst preparation

The catalyst was synthesized by wet impregnation method according to the report by Toemen et al. [7].The required amount of cerium nitrate in a beaker was dissolved with a small amount of distilled water. The solution was then mixed via continuous stirring using a magnetic bar for 30 minutes at ambient temperature to homogenize the mixture. Alumina beads with diameters of between 4 to 5 mm were used as support material. The support was dipped into the catalyst solutions for 24 hours and then transferred onto an evaporating dish lined with glass wool. Subsequently, it was aged in an oven at 80 – 90 $^oC$ for 24 hours to eliminate moisture and allow coating of the metal on the surface of the supported catalysts.

This was followed by calcination in the furnace at 400, 700, 900 and 1000 $^oC$ for 5 hours using a ramp rate of 10 $^oC$/min to eliminate all metal precursors, excess water and impurities. The developed catalysts were analyzed by BET, FESEM-EDX and XRD to characterize the physicochemical properties of the catalyst.

### Catalysts characterization

Potential catalyst was characterized by several techniques to study its physicochemical properties. The information obtained is highly useful in order to understand the relationship between the properties and its catalytic performance towards the deacidification activity. In this research, the characterization techniques used were X-ray diffraction spectroscopy (XRD), Brunauer–Emmett–Teller (BET) and thermogravimetry analysis-differential thermal analysis (TGA-DTA).

**Total acid number (TAN) determination**

An amount 0.2 g crude B was measured and placed in a titration beaker. As much as 40 mL of the titration solvent, which is a mixture of toluene: 2-propanol: distilled water (50:49.5:0.5) was poured into the crude oil sample in the titration beaker. After that, 100 ppm of 4% $NH_3$–PEG solution together with the prepared catalyst was added into 0.1 – 0.15 g crude oil sample. The solution was heated to 35 – 40 $^{o}$C to stimulate the catalyst in the mixture. The petroleum crude oil sample was then titrated with potassium hydroxide solution (0.01 mol/L). Total acid number value for crude B (TAN = 2.52 mg KOH/g) was determined by semi-micro color indicator titration method. The indicator used was phenolphthalein solution (0.1 mL), the end-point for the titration method was indicated when the stable red color was observed. The titration method was performed on crude B before and after the catalytic deacidification technology. In order to express the results, TAN value of the sample was calculated in milligrams of potassium hydroxide per gram of sample (mg KOH/g) by using the equation below (Equation 1):

$$\text{TAN} = \frac{56.1 \times c \times (V_{KOH} - V_B)}{m} \quad (1)$$

where c is the concentration of the standard volumetric potassium hydroxide solution (in mol/L), $V_{KOH}$ is the volume of titrant required for the determination (in mL), $V_B$ is the volume of titrant required for the blank test, (in mL), and m is the mass of the test portion (in gram).

## Results and Discussion

**Catalytic deacidification of Crude B: Effect of different molecular weight of PEGs**

The deacidification activities for crude B increased significantly when using PEG with molecular weights of 300, 400, 600 and 1500 as shown in Figure 1. This observation is proven by the decrease in TAN values of crude B along these PEGs. Lower TAN values of 1.68mg KOH/g were obtained for crude B by using both MW PEG of 600 and 1500. These results showed that the deacidification activities for crude B were decreased by using these PEGs. However, in this work, PEG with MW 600 was chosen as the solvent for deacidification agent due to higher percentage of NA removal for crude B and its cheaper cost compared to other PEGs.

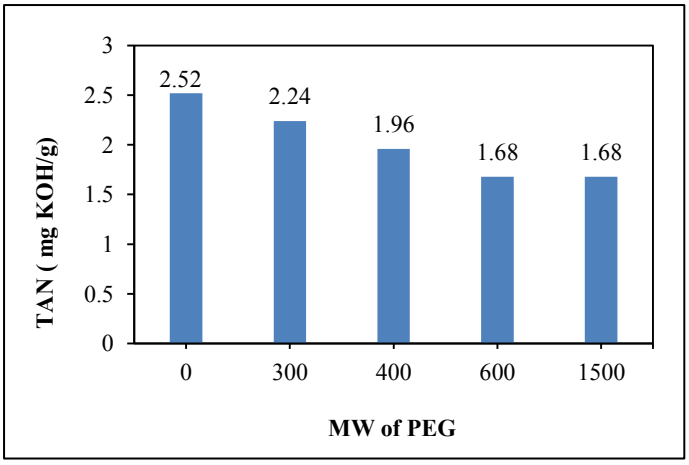

Figure 1. Effect of the different molecular weights of PEG on TAN values of crude B. [Initial TAN value for crude B (2.52 mg KOH/g)]

**Effect of different basic chemical dosing**

The deacidification performances of different dosing amount of $NH_3$-PEG in the range of 100-2500 mg/L were compared in order to select a suitable dosing amount for removal of naphthenic acid in the crude oil sample and the result is presented in the Figure 2.

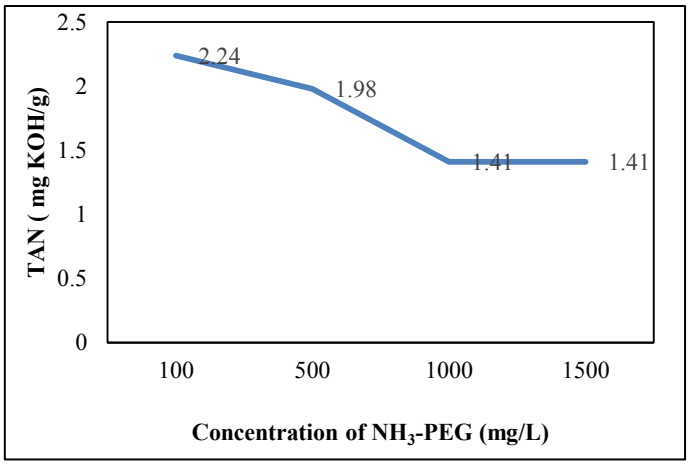

Figure 2. Effect of different dosing amount of $NH_3$-PEG on the TAN value.

It could be seen from Figure 2, the TAN number of crude B decreased with increasing dosing amounts of $NH_3$-PEG. When the dosing rose to 1000 mg/L the TAN number was decreased to 1.41 mg KOH/g and after that the curve become flat. The amount of dosing employed in the study should be appropriate enough to react with the NA in the crude oil B, because huge amounts of $NH_3$-PEG may form a stable emulsion, which would probably stabilize the NA in crude B and reduce the deacidification reaction. Even though high concentration of $NH_3$-PEG was added, there is no change of the TAN value. This explained that using 1000 mg/L is sufficient to deacidify the acid in crude B because if the concentration was increased more than 1000 mg/L it will cause operational difficulties and waste.

**Effect of different metal oxides and calcination temperatures of catalyst**

In the preparation of the catalyst, the types of metal oxide catalyst and calcination temperatures are determinant of catalyst activity. The catalytic deacidification was carried out under reaction temperature ranging between 35 to 40$^{o}$C with addition of 100-1000 mg/L of $NH_3$-PEG dosing in the presence of $Ce/Al_2O_3$, $Zn/Al_2O_3$ and $Sn/Al_2O_3$ catalysts calcined at different temperatures of 400, 700 and 1000$^{o}$C for 5 h. Figure 3 portrays the effect of different metal oxide catalysts prepared at different calcination temperatures towards the catalytic deacidification process.

A noticeable difference was recorded for the catalytic deacidification process fulfilling the expected target of TAN to be less than one. An increase in the calcination temperature for all catalysts from 400 to 1000 $^{o}$C caused a decrease of the TAN value for crude B. For these studies, the $Ce/Al_2O_3$ catalyst calcined at 1000 °C gave the lowest value of TAN of 0.74 mg KOH/g followed by $Sn/Al_2O_3$ catalyst calcined at 1000 $^{o}$C (TAN = 1.68 mg KOH/g) and $Zn/Al_2O_3$ catalyst calcined at 1000 $^{o}$C with a TAN of 1.41 mg KOH/g. As for the $Ce/Al_2O_3$ catalyst, the calcination temperature below than 1000 $^{o}$C cannot reduce the TAN value below than one due to incomplete metal oxide formation and the amorphous properties of this catalyst which produced less amount of basic surface active sites available for the catalytic deacidification reaction. However, an increase in the calcination temperature up to 1000 $^{o}$C for this catalyst managed to reduce the TAN below than one due to its polycrystallinity properties as shown in XRD data which generated a larger amount of total basic surface active sites led to a successful catalytic deacidification reaction. Furthermore, excellent redox properties of CeO due to the very fast reduction of $Ce^{4+}/Ce^{3+}$ as reported by Ayastuy et al. [8] results in the formation of oxygen vacancies at the surface, making the NA removal more efficient. Thus, Ce calcined at 1000 $^{o}$C was chosen as the catalyst to be further optimized in this study.

**Reusability testing over $Ce/Al_2O_3$ catalyst**

The potential $Ce/Al_2O_3$ catalyst calcined at 1000 $^{o}$C was tested several times under optimum reaction conditions in order to study the reusability of this catalyst. It was tested by using the same catalyst until the catalyst was deactivated. After one catalytic reaction was completed, the catalyst was rinsed with 2-propanol to remove any adsorbed naphthenic acid compounds. The catalyst was then dried in an oven at 80 $^{o}$C and re-used for the second reaction. The process was repeated for the next consecutive run. Figure 4 shows the plot of reusability testing over

$Ce/Al_2O_3$ catalyst. It can be seen that the TAN value was maintained (0.74 mg KOH/g) until the fifth cycle. However, the catalyst started to deactivate (spent catalyst) at the sixth testing as a slight decrease in the activity is seen as indicated by the increasing TAN value to 0.84 mg KOH/g.

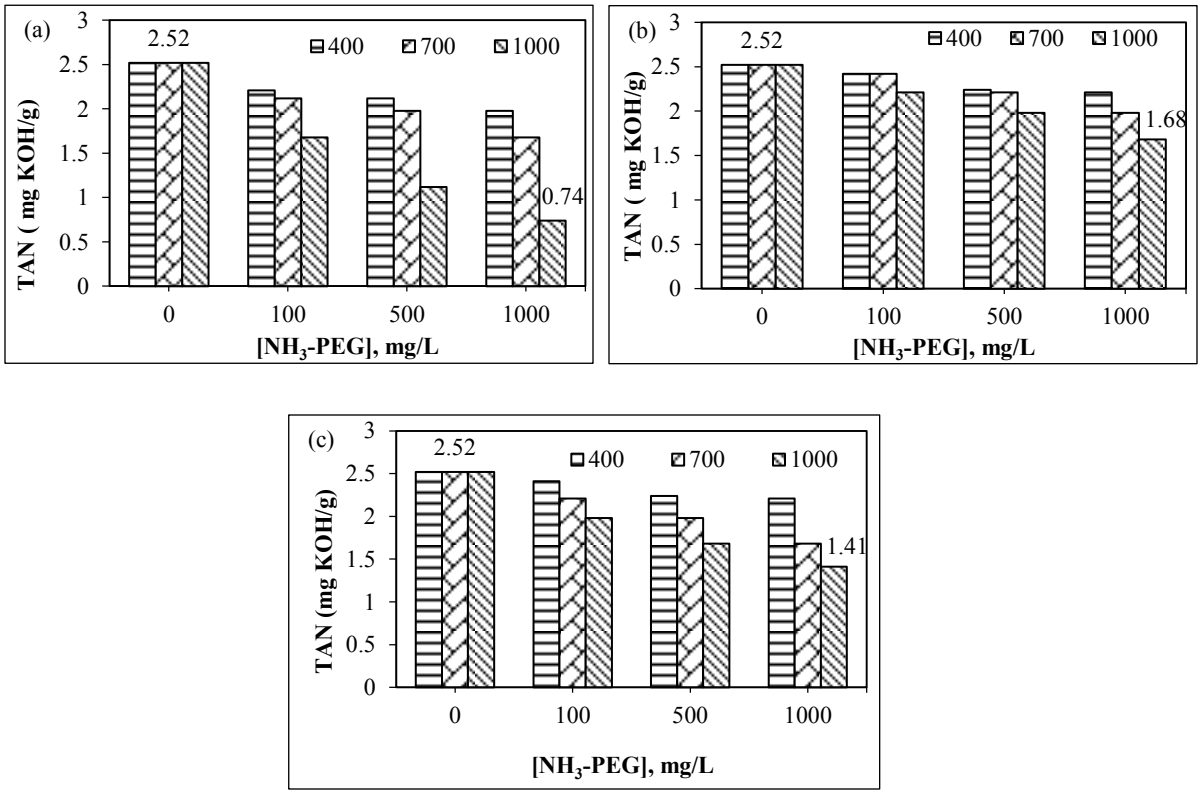

Figure 3. Effect of a) Ce, ) Zn and c) Sn catalysts supported on alumina calcined at 400, 700 and 1000 $^oC$ on the reduction of TAN value

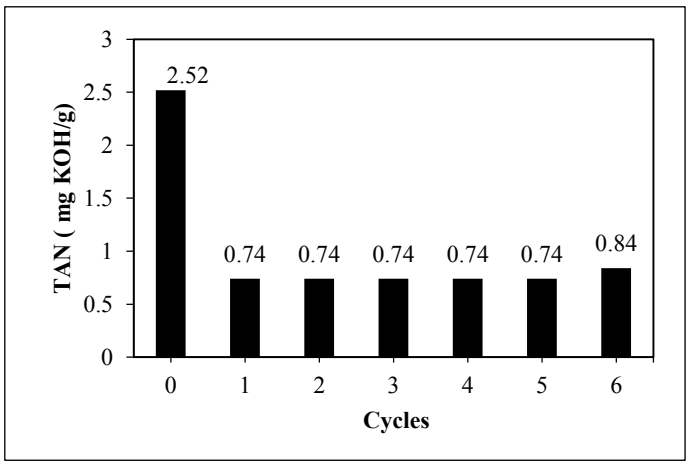

Figure 4. TAN value for six cycles of catalytic deacidification. Reaction conditions: Catalyst = $Ce/Al_2O_3$, calcination temperature of catalyst: 1000 $^oC$.

**Characterization of the potential catalyst: TGA-DTA**

After aging the catalysts which had been prepared by wetness impregnation method in an oven for 24 hours at 80 – 90 ◦C, the catalyst was analyzed by using TGA-DTA. Figure 5 shows the TGA thermogram of $Ce/Al_2O_3$ catalyst which illustrate four significant weight lost curves which occurred at 80, 130, 250 and 480 ◦C.

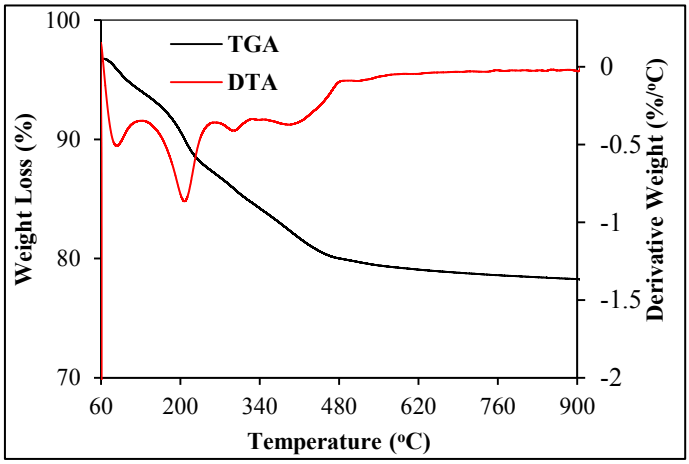

Figure 5. TGA-DTA thermogram of $Ce/Al_2O_3$ catalyst after aging in an oven for 24 hours at 80 – 90 °C.

The total weight loss for this sample is 16.69%. Freewater molecule and nitrate compound was removed from the supported catalyst starting from a temperature of 80 °C until 340 °C. Meanwhile at 480 °C onward; nitrate compounds and surface hydroxyl molecule were decomposed from the samples [9]. From this investigation, the calcination temperature of 400 °C is insufficient to remove all the nitrate compounds that originate from the metal precursor. This observation is in agreement with the results shown in "effect of different metal oxides and calcination temperatures of catalyst" in which using $Ce/Al_2O_3$ catalyst calcined at 400 °C, the TAN value of crude B cannot be reduced to lower than one as the catalyst calcined at this temperature resulted in incomplete formation of metal oxide.

**BET analysis**

One of the most characteristic properties of the surface of a solid is its ability to adsorb gases and vapors. The potential catalyst of fresh and spent $Ce/Al_2O_3$ were characterized by nitrogen adsorption analysis. Table 1 summarizes their BET surface area and BJH desorption average pore diameter.

Table 1. BET surface area and BJH desorption average pore diameter of the fresh and spent forms of $Ce/Al_2O_3$ catalyst

| Condition | SBET ($m^2g^{-1}$) | Pore Diameter (A) |
|---|---|---|
| Fresh | 70 | 19 |
| Used | 62 | 25 |

Isotherm shape depends on the solid porous texture. Figure 6 shows the NA isotherm of fresh and used $Ce/Al_2O_3$ catalyst. NA/desorption isotherm of $Ce/Al_2O_3$ catalyst prepared exhibit the characteristic of mesoporous structure with Type IV with incorporation of some mesopores with the presence of hysteresis loop type H3. Results showed that the surface area of used catalyst (70 $m^2/g$) was slightly decreased than fresh $Ce/Al_2O_3$ catalyst (62 $m^2/g$) probably due to some surface areas which were covered with contamination from crude oil during catalytic

deacidification reaction. However, this occurrence does not affect the catalytic activity after using for one time as proved by catalytic deacidification in reusability testing.

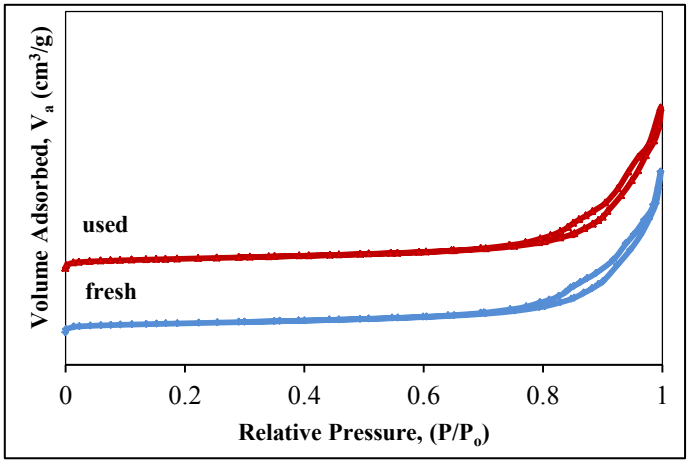

Figure 6. Nitrogen adsorption-desorption isotherms for fresh and used $Ce/Al_2O_3$ catalyst

Figure 7 shows the pore size distribution curves of the fresh and used $Ce/Al_2O_3$ catalyst calcined at temperature of 1000°C. The pore size distributions calculated from the desorption branch by the Barret–Joyner–Halenda (BJH) method were very similar for both samples, presenting a very wide pore distribution covering the range of 19–40 nm.

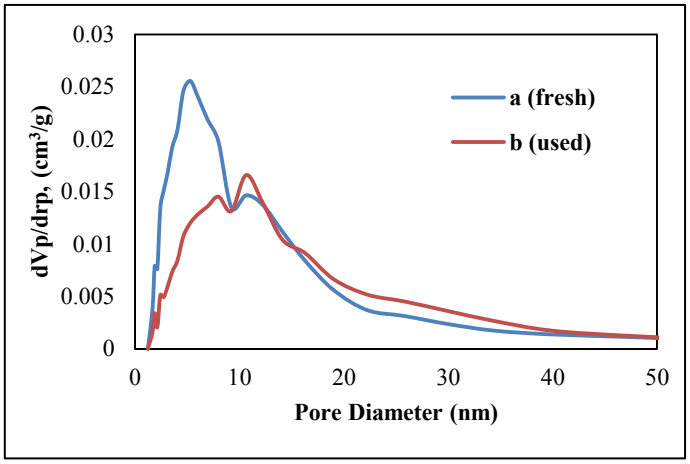

Figure 7. Pore size distribution of a) fresh and b) used $Ce/Al_2O_3$ catalyst calcined at 1000 °C for 5 hours

**XRD analysis**

In order to confirm the reusability of the $Ce/Al_2O_3$ catalyst, the diffractograms of fresh and used $Ce/Al_2O_3$ catalysts, both calcined at 1000 °C for 5 hours are compared in Figure 8 to investigate any transformation that occurred on the surface of this catalyst before and after being used (after 1st catalytic testing) in the catalytic deacidification process of crude B. Both diffractograms displayed the polycrystallinity phase dominated by the $CeO_2$ (fcc) species and some of the alumina orthorhombic (o) phase. The $CeO_2$ species for both fresh and used catalysts showed 2θ valuesat 28.6, 47.5, 56.5, 32.9, 76.6 and 78.9°. Meanwhile the alumina orthorhombic phase occurred at 2θ of 67.3 and 36.5°. This data shows that no change in the diffractograms of both fresh and used catalysts occurs which indirectly prove that

the $Ce/Al_2O_3$ catalyst possesses a higher thermal stability, smaller rate of deactivation and higher reusability.This is shown via the reusability testing, whereby the catalyst can be used up to the fifth cycle with an excellent catalytic deacidification activity.

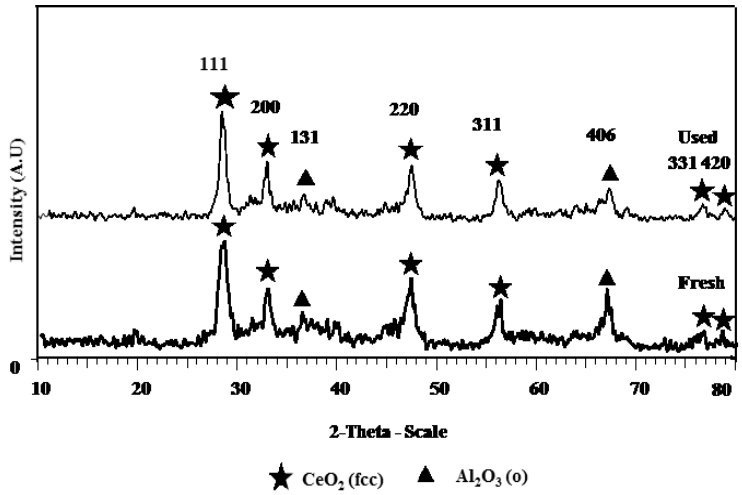

Figure 8. XRD diffractograms of fresh and used $Ce/Al_2O_3$ catalysts calcined at 1000 $^oC$ for 5 hours

## Conclusion

The technology applied was successful in meeting the PETRONAS benchmark of a TAN less than 1 mg KOH/g for crude oil B. The result from the catalytic deacidification process revealed that $Ce/Al_2O_3$ catalyst prepared at a calcination temperature of 1000 $^oC$ has the potential to enhance the reduction of TAN in crude oil. Physical characterization by BET analysis showed that this catalyst has the largest surface area. This revelation is significant as a greater surface area offers more surface-active sites for catalytic deacidification to take place. Furthermore, XRD diffractograms portrayed unchanged composition after this catalyst is used in the catalytic deacidification reaction which indirectly proved that this catalyst possesses a higher thermal stability, smaller rate of deactivation and higher reusability.

**Abstract**

Production of ethylene from ethanol dehydration was investigated over $H_3PO_4$ (10 wt.% to 30wt.%)-modified cerium oxide catalysts synthesized by wet impregnation technique. The prepared catalysts were characterized using scanning electron microscope (SEM), $N_2$ adsorption-desorption method, X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR) and thermogravimetric analysis (TGA) for the physicochemical properties. The ethanol catalytic dehydration was carried out in a fixed-bed reactor at 673-773 K and at ethanol partial pressure of 33 kPa. The effects of phosphorus loading on catalyst and reaction temperatures were investigated in terms of catalytic activity towards product selectivity and yield. Overall, the selectivity and yield of ethylene increased with the temperature and phosphorus loading. The highest ethylene selectivity and yield were 99% and 65%, respectively, at 773 K and 33 kPa over the 30 wt.% $H_3PO_4$-modified cerium oxide.

**Keywords**: ethylene production, ethanol dehydration, $H_3PO_4$ modification, cerium oxide

**Abstrak**

Penghasilan etilena daripada pendehidratan etanol telah dikaji dengan mangkin serium oksida terubahsuai $H_3PO_4$ (10 wt.% hingga 30 wt.%) yang dihasilkan melalui kaedah pengisitepuan. Mangkin disediakan telah dicirikan menggunakan mikroskop elektron imbasan (SEM), kaedah penjerapan-nyahjerapan $N_2$, pembelauan sinar-X (XRD), spektroskopi inframerah transformasi Fourier (FTIR) dan analisis termogravimetri (TGA) untuk mengetahui sifat fizikokimia mangkin. Tindak balas pendehidratan etanol dengan mangkin dilakukan di dalam reaktor turus terpadat pada julat suhu 673 – 773 K dan tekanan separa etanol 33 kPa. Pengaruh muatan $H_3PO_4$ dan suhu tindak balas kimia dalam pendehidratan etanol telah dikaji. Secara keseluruhan, kepilihan dan hasil etena meningkat dengan muatan $H_3PO_4$ dan suhu tindak balas kimia. Kepilihan dan hasil etena tertinggi masing-masing ialah 99% dan 65% pada 773 K dan 33kPa untuk mangkin serium oksida terubahsuai $H_3PO_4$ 30 wt.%.

**Kata kunci:** penghasilan etilena, pendehidratan etanol, pengubahsuaian $H_3PO_4$, serium oksida

## Introduction

The increasing demand of ethylene is due to its uses in producing polyethylene, one of the primary components in the most of the plastic and in petrochemical industry [1]. Besides that, ethylene acts as precursors for surfactant chemicals such as ethylene oxide or ethylene glycol. With increased demand, global ethylene production has grown at an average rate of almost 4.5% per year from 2009 – 2014. Currently steam cracking of hydrocarbon from fossil fuel is still dominating the production market because of the high production cost and energy consumption

associated with catalytic dehydration pathway. Due to the increasing demands for energy, stricter environmental regulations, and continued depletion of fossil feedstock, alternative and renewable energy resources have attracted increased interest in recent research. In the view of potential limitations of ethylene availability from the current sources, catalytic dehydration of ethanol (especially bioethanol) to ethylene has become a completely renewable process for producing ethylene [2].

Ethanol dehydration is a process in which water molecules are removed, or the equivalent of water molecules removed from ethanol to produce ethylene when heated together with catalyst. There are two reactions that occur in parallel during catalytic dehydration of ethanol as in Equation (1) to (2):

$$C_2H_5OH \leftrightarrow C_2H_4 + H_2O \qquad +44.9 \text{ kJ/mol} \qquad (1)$$

$$2C_2H_5OH \leftrightarrow C_2H_5OC_2H_5 + H_2O \qquad -25.1 \text{ kJ/mol} \qquad (2)$$

The low temperature favors the side reaction to produce diethyl ether; in contrast, higher reaction temperature is theoretically favoring the main reaction (ethanol dehydration). The dehydration reaction is endothermic and need 390 calories per gram of ethylene produced. The temperature of diethyl ether formation is mainly between 423 K and 573 K, while ethylene formation is favoured between 593 K and 773 K.

Acidic catalysts are often used in ethylene production from ethanol dehydration. The traditional homogeneous catalysts used are sulfuric acid or phosphoric acid in almost all industrial scale processes [1]. The former usually requires higher reaction temperatures and yields lower ethylene selectivity [3]. Due to the low yield and byproducts formation, sulfuric acid and phosphoric acid have been replaced by heterogeneous catalysts such as alumina.

Many studies have been carried out with different technologies and using various acidic heterogeneous catalysts such as alumina, silica, zeolites, metal oxides and heteropolyacids [4 - 7]. Among those studied catalysts, gamma alumina ($\gamma$-$Al_2O_3$) and HZSM-5 zeolite have drawn the most attention for their high activity and selectivity. HZSM-5 has been widely used in alcohol dehydration reactions due to its uniform pore structure, high surface area, and adjustable acidity. Low reaction temperature (>473 K) favors the reaction towards ethylene production from ethanol dehydration over HZSM-5. HZSM-5 can achieve 60 – 80% ethylene yield at relatively low reaction temperature (473 – 573 K) [8]. Besides of the reaction temperature, the catalyst surface acidity is a significant catalytic performance factor. HZSM-5 has high concentration of strong acidic sites, which exist at low Si/Al ratios helps in ethylene production. However, the high acidity also leads to render HZSM-5 zeolite unstable and low anti-coking property [9]. On the contrary, $\gamma$-$Al_2O_3$ has high surface area (50 –300 $m^2 g^{-1}$) and thermal stability up to 873 K that make it widely used in industrial. The ethanol dehydrate over $\gamma$-$Al_2O_3$ can achieve greater than 90% to form ethylene. The disadvantage of $\gamma$-$Al_2O_3$ is high reaction temperature needed for ethanol catalytic dehydration. Another problem is that water can deactivate active sites on $\gamma$-$Al_2O_3$ and inhibit the formation rate of ethylene and diethyl ether [10].

The weak acid centers and relatively strong acid centers of the catalyst are the active sites of ethanol intramolecular dehydration to ethylene [6]. However, the strong acid centers can easily lead to ethylene polymerization. Hence, surface acidity of catalyst need to adjust using additives to improve catalyst stability and high ethylene selectivity. In continuation of discovering new catalyst for ethanol catalytic dehydration, we report the use of ceria-based catalysts for the aforementioned reaction. The use of cerium oxide as the support bring advantages such as its high oxygen mobility associated with oxygen vacancies and oxygen storage capacity. Due to the high effectiveness of cerium oxide used as a support and the (phosphostic acid ad), many studies have been carried out by employing cerium oxide as catalyst for ethanol conversion reactions especially steam reforming reactions [11 - 15]. As mentioned earlier , the surface acidity of catalyst is improtant in this reaction. Thus, pure $CeO_2$ catalysts as well as phosphoric acid ($H_3PO_4$) doped $CeO_2$ catalysts were prepared to study the behavior of $CeO_2$ towards kinetics of ethanol dehydration.

Therefore, the aim of this study is to investigate the feasibility of ethanol dehydration over $H_3PO_4$-modified cerium oxide catalysts on new catalyst application for this reaction. The synthesized catalysts were characterized using

scanning electron microscope (SEM), energy dispersion X-ray spectroscopy (EDX), $N_2$ adsorption-desorption method, X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR) and thermogravimetric analysis (TGA) for the physicochemical properties.

## Materials and Methods

### Catalysts preparation

Cerium nitrate salt $Ce(NO_3)_2$ was procured from Sigma-Aldrich, USA. The ceria support was prepared by thermal decomposition of $Ce(NO_3)_2.6H_2O$ at 873 K for 2 hours and then crushed to powder. The modified cerium oxide phosphate catalyst (10PA-$CeO_2$) was prepared by impregnating the 10 wt.% aqueous solution of $H_3PO_4$ into 90 wt.% of the ceria support followed immediately by magnetic stirring for 3 hours. The solution was then magnetic-stirred for 3 hours under ambient condition. Thereafter, the impregnated catalyst was oven-dried for 12 hours at 373 K. During the first 6 hours of the drying process, the catalyst was manually stirred using a glass rod for each hour to maintain relative homogeneity of the slurry. Post 12 hours, the calcination of the dried catalyst was carried out in a muffled furnace model Carbolite RHF1400 for 5 hours at 773 K with heating rate of 5 K $min^{-1}$. The catalyst was then cooled to room temperature and ground for physicochemical characterization and reaction studies. The resulting 20PA-$CeO_2$ and 30PA-$CeO_2$ were prepared by the similar procedure with 20 wt.% and 30 wt.% of phosphoric acid, respectively.

### Catalyst characterization

The fresh modified cerium oxide phosphate catalysts were characterized using several methods. The phase structure of the catalysts was characterized by X-ray diffraction (Rigaku Miniflex Instrument) using X-ray source from CuKα (λ=1.542 Å) at 30 kV and 15 mA. $N_2$ physisorption was conducted to determine the textural property of the synthesized catalysts. The information about the surface morphology of the catalyst and the elemental chemical compositions were determined using SEM analysis employing Hitachi TM3030Plus with a magnification of 5kx which was also equipped with energy-dispersive X-ray spectroscopy (EDX). Thermogravimetric-difference thermal analysis (TG) technique of samples before and after reaction was carried out to monitor the thermal profile of fresh and spent catalysts. Fourier Transform Infrared Spectroscopy (FTIR) (Perkin Elmer Spectrum 100) was also employed to determine the nature of chemical bonding of the catalysts.$NH_3$-TPD was carried out in a ThermoFinnigan TPDRO 1100. The catalyst was pre-treated with $N_2$ at 423 K for 15 minutes. $NH_3$-TPD is used to determine the amount of acidic sites and their distribution in strength. The adsorption of $NH_3$ was carried out at room temperature for 45 min and after saturation was achieved, $N_2$ was purged in to eliminate the $NH_3$ that remained in the gas phase. Analysis of desorption of $NH_3$ was done under the flow of helium at temperature of 323 to 1273 K, at the rate of 20 K $min^{-1}$.

### Catalytic activity

The reaction was conducted in a fixed-bed reactor at ethanol partial pressure of 33 kPa with WHSV of 240 $h^{-1}$, in the temperature range of 673 – 773K. The reactor was loaded with 0.3 g of catalyst and introduced with pure ethanol (≥99.9%) with a HPLC pump. The gaseous products were collected and identified using GC to identify the quantity of targeted product. The GC instrument used was Shimadzu GC-2014 with two packed column, column temperature and flame ionizer detector temperature at 333 K and 473 K, respectively. Ethanol conversion and products selectivity were calculated by Equation (3) and (4), respectively [16, 17]:

$$X_{Ethanol} = \frac{\sum \text{Total gas products},F_i}{2 \text{ x molar flow rate of ethanol in the feed}} \text{ x } 100 \quad (3)$$

$$S_i = \frac{F_{C_2H_4}}{\Sigma \text{ Total gas products},F_i} \times 100 \quad (4)$$

where F is define as molar flow rate and *i* is refer to $C_1$, $C_2$, $C_3$, $C_4$ and $C_5$ species.

## Results and Discussion

### Catalyst characterization

Figure 1 illustrates XRD diffractogram of $CeO_2$ and 10, 20, 30PA-$CeO_2$. Based on Figure 1, the high intensity peaks recorded at 2θ readings of 28.6°, 33.1°, 47.48° and 56.36° which corresponding to (111), (200), (220) and

(311) crystal planes respectively.The XRD patterns obtained of the synthesized catalysts were compared with the standard data for $CeO_2$ (JCPDS card No. 34-0394).This also indicated that the $CeO_2$'s structure maintained well for all modified catalysts [18]. The structure of catalysts became less crystalline as affected by $H_3PO_4$ loading. There are additional small peaks found for 20PA-$CeO_2$ and 30PA-$CeO_2$ at 2θ readings of 21°, 27° and 43° which can be ascribed to $CeP_2O_7$ species (JCPDS card No. 30-0164). $CeP_2O_7$ is a crystalline product in which every Ce atom is joined to six oxygen and every P to four oxygen, with a connectivity of four and six. The P atoms are joined in pairs through shared O atom to form $P_2O_7^{4-}$ units, each of it shared its six remaining oxygen with the $CeO_6$ octahedral. The appearance of $CeP_2O_7$ is normally occurred when cerium oxide reacted with phosphoric acid at temperature around 623 K to 1073 K. In this case, the modified cerium oxide phosphate catalysts were prepared at 773 K in a furnace which causes the formation of $CeP_2O_7$ species [19].

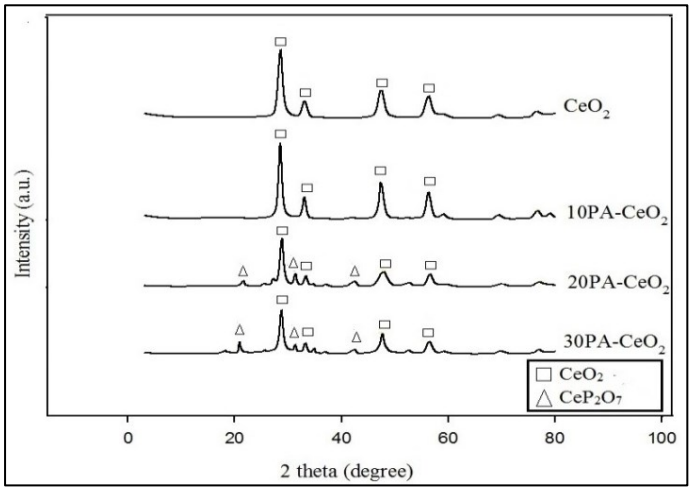

Figure 1. X-ray diffraction profiles of $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts

SEM micrographs of modified cerium oxide phosphate catalysts at 20 µm resolution are shown in Figure 2. Based on the Figure 2, most of the samples were agglomerated together. The SEM images shown in Figure 2 reveal the morphology of all samples is similar with formation of irregular and bulky surface which is typical of thermally-synthesized wet impregnated catalyst. Meanwhile, it is clearly proved that the addition of $H_3PO_4$ did not alter the surface morphology of the catalysts, and that the $H_3PO_4$ has blended intimately with the $CeO_2$ support to form a single phase.

The fresh catalysts were also subjected to the FTIR scanning and the spectra collected are shown in Figure 3. The spectra were recorded in the wave number that ranged 4000 – 400 $cm^{-1}$. Significantly, transmission band representing N-O stretch which normally can be found at wavenumber 3000 $cm^{-1}$ is absent in Figure 3. This indicates that the entire nitrate group was successfully removed during the thermal decomposition of nitrate-salt to yield pure $CeO_2$. The transmission band at wave number 550.73 $cm^{-1}$ represents the Ce-O stretch. In addition, the bands at wavenumber around 900 – 1000 $cm^{-1}$ represent the O=P=O asymmetric stretching modes of phosphate or polyphosphate species[20]. As shown in Figure 3, the intense band found around 1000 – 1600 $cm^{-1}$ increase as the loading of phosphorus increase. This is due to the introduction of phosphorus onto the $CeO_2$ catalyst whereby the O=P=O asymmetric increases. The same results observed in previous study [21]. This proves that introduction of $H_3PO_4$ has been successfully carried out.

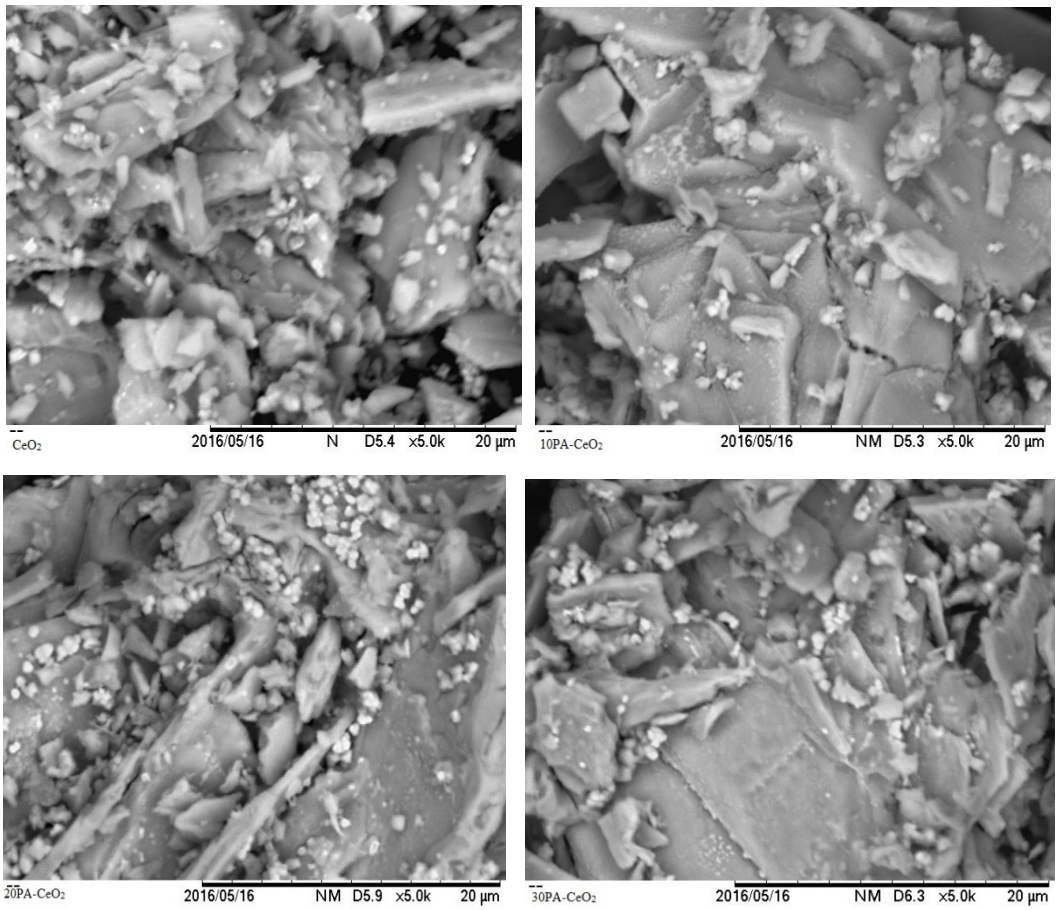

Figure 2. SEM images of $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts

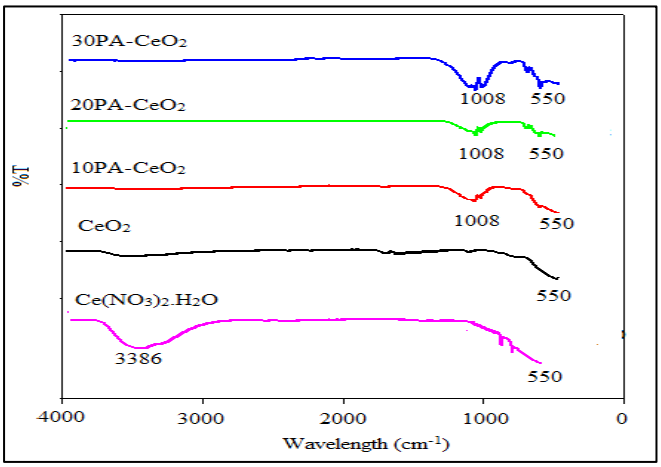

Figure 3. FTIR results of $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts

Table 1 provides the BET specific surface area, mesopore volume and pore diameter of pure $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts that were obtained from $N_2$ physisorption. Both the BET specific surface area and

mesopore volume decreased with $H_3PO_4$ loading, to the tune of nearly 90% reduction for the 30 wt.% $H_3PO_4$ loading. The reduction of pore dimension or pore blockage of the $CeO_2$ by the introducing of phosphoric acid in the treatment [22]. In contrast, the pore diameter recorded an increment, from 14.0 nm improved to 18.8 nm when the $H_3PO_4$ weight was increased. This could be due to the creation of wider pore mouth on the surface of $CeO_2$ resulting from the acid attack that occurred at the employed calcination temperature.

Table 1. Textural properties of the $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts

| Fresh Catalyst | BET Specific Surface Area ($m^2\ g^{-1}$) | Pore Volume ($cm^3\ g^{-1}$) | Pore Diameter (nm) |
|---|---|---|---|
| $CeO_2$ | 71.6 | 0.2545 | 14.0 |
| 10PA-$CeO_2$ | 35.5 | 0.1461 | 16.3 |
| 20PA-$CeO_2$ | 20.2 | 0.0833 | 16.3 |
| 30PA-$CeO_2$ | 9.9 | 0.0461 | 18.8 |

Thermo-desorption profiles of $NH_3$ were carried out to determine the acid-base properties of the as-synthesized catalysts. The acid strength can be categorized into weak acidic site (373-523 K), moderate acidic site (523-673 K) and strong acidic site (673- 823 K), respectively, based on the desorption temperature. Table 2 shows the resulting acid amount of $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts. From Table 2, it can be observed that there are three types of acid sites with variable amounts, at 819 μmol $g^{-1}$, 188 μmol $g^{-1}$ and 548 μmol $g^{-1}$, respectively, for weak, moderate and strong acids found in $CeO_2$ catalyst. The introduction of $H_3PO_4$ generates moderate acid sites by suppressing the strong acid sites of $CeO_2$. The amount of moderately-strong acid site has increased substantially, increasing incrementally to 837 μmol $g^{-1}$ for 10PA- $CeO_2$, 1238 μmol $g^{-1}$ for 20PA- $CeO_2$ and 1532 μmol $g^{-1}$ for 30PA- $CeO_2$, respectively. This may be due to the nature of $H_3PO_4$, which is a moderately-strong acid with pKa value of 6.9 x $10^{-3}$. Moreover, the strong acid site which was inititally present on the surface of pure $CeO_2$ was dimishing with the $H_3PO_4$ loading, decreased from 548 μmol $g^{-1}$ for pure $CeO_2$ to just 284 μmol $g^{-1}$ for 30PA-$CeO_2$ catalyst. As the loading of phosphoric acid on $CeO_2$ increases, the total acid amount increases.

Table 2. The total surface acidity and acid strength distribution of $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts

| Catalysts | Acid Amount (μmol $g^{-1}$) | | | Total Acid Amount (μmol $g^{-1}$) |
|---|---|---|---|---|
| | Weak Acid Site (373-523 K) | Moderate Acid Site (523-673 K) | Strong Acid Site (673-823 K) | |
| $CeO_2$ | 819 | 188 | 548 | 1555 |
| 10PA-$CeO_2$ | 850 | 837 | 413 | 2100 |
| 20PA-$CeO_2$ | 838 | 1238 | 385 | 2461 |
| 30PA-$CeO_2$ | 823 | 1532 | 284 | 2639 |

**Catalytic performances of modified cerium oxide phosphate catalysts**

Table 3 shows the product distribution over $CeO_2$ and 10, 20, 30PA- $CeO_2$ catalyst at different reaction temperature and ethanol partial pressure 33 kPa. Cerium oxide catalyst presented lowest catalytic performance among all synthesized catalysts. The pure $CeO_2$ catalyst, under the same reaction condition as aforementioned, the conversions recorded were 1.25%, 2.45% and 6.89%, respectively. This reveals that the acidity amount found in $CeO_2$cannot protonate the hydroxyl group of $C_2H_5OH$ which explains its low activity. The selectivity decreases with the increasing reaction temperature. This is due to higher hydrocarbons formation with almost 35% at 773 K. $CeO_2$ presents highest number of strong acidic sites which lead to the higher hydrocarbons formation [16], [22]. Hence, there were over 45% of hydrocarbons formed over $CeO_2$ catalyst at high temperature.

Table 3. Product distributions of ethanol dehydration over $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts at 33 kPa and 673 – 773 K

| Variable | $CeO_2$ | | | 10PA-$CeO_2$ | | | 20PA-$CeO_2$ | | | 30PA-$CeO_2$ | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Temperature (K) | | | Temperature (K) | | | Temperature (K) | | | Temperature (K) | | |
| | 673 | 723 | 773 | 673 | 723 | 773 | 673 | 723 | 773 | 673 | 723 | 773 |
| Ethanol conversion (%) | 1.23 | 2.45 | 6.89 | 4.79 | 8.96 | 29.90 | 9.39 | 35.73 | 41.31 | 15.97 | 38.02 | 59.74 |
| Selectivity (%) | | | | | | | | | | | | |
| Ethylene | 68.71 | 53.76 | 47.20 | 47.2 | 54.60 | 70.39 | 94.11 | 95.35 | 98.33 | 96.14 | 98.55 | 99.21 |
| Higher hydrocarbons | | | | | | | | | | | | |
| $C_3$ | 0.28 | 0.81 | 3.25 | 0.01 | 1.18 | 0.28 | 0 | 0.01 | 0.01 | 0 | 0.01 | 0.01 |
| $C_4$ | 7.73 | 21.13 | 22.93 | 0.14 | 6.32 | 2.17 | 0.2 | 0.14 | 0.11 | 0.2 | 0.11 | 0.14 |
| $C_5$ | 19.78 | 0 | 8.01 | 0.44 | 4.01 | 3.78 | 3.30 | 0.44 | 1.12 | 3.30 | 1.12 | 0.44 |
| $C_6$ | 0 | 14.90 | 0.10 | 0 | 0 | 0.14 | 0 | 0 | 0 | 0 | 0 | 0 |

The ethanol conversion, ethylene selectivity and total acid amountwere correlated for the synthesized catalysts in Figure 4. Upon doing with $H_3PO_4$, the ethylene selectivity and ethanol conversion increase as the loading of $H_3PO_4$ increase. The addition of $H_3PO_4$ into $CeO_2$ catalyst causes the amount of strong acidic sites decrease. This change suppresses the formation of higher hydrocarbons and improves the ethylene production. Although 10PA-$CeO_2$ did not present a high catalytic performance with low ethanol conversion 4.79%, 8.96% and 29.90% for 673 K, 723 K and 773 K, respectively, but it showed increasing trend in terms of catalytic performance as compared to pure $CeO_2$. This indicates that the surface acidity of 10PA-$CeO_2$ was unable to catalyze the formation of products. Among all $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts, the 30PA-$CeO_2$ catalyst showed the best catalytic performance. On this catalyst, the products are dominated by ethylene under all reaction condition with over 95% of ethylene selectivity.

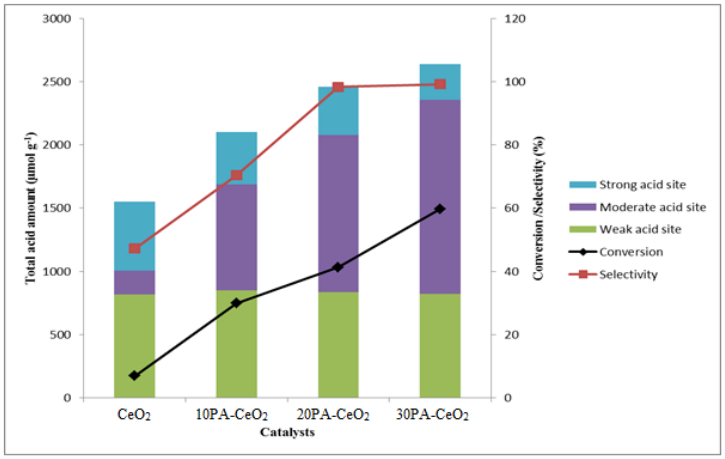

Figure 4. Relationship between catalytic performances and acid amounts

The presence of moderate weak acidic sites in this catalyst helps to suppress the formation of higher hydrocarbons meanwhile improved the ethylene production and selectivity. Besides that, based on the $N_2$ physisorption results $CeO_2$ has a large BET surface area and high porosity which lead to the $C_2H_5OH$ molecules would have voyage

profound into the arrangement of passage systems that exists in the pristine $CeO_2$. The blockage of pore volume after the addition of $H_3PO_4$ helps in reducing the multiple adsorptions of ethanol whereby results in the improvement in ethylene selectivity [22].

In addition, 10, 20 and 30PA-$CeO_2$ present an increasing trend in both ethanol conversion and ethylene selectivity as the temperature increases. Among all the $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts, 30PA-$CeO_2$ catalyst showed the best catalytic performance. With increasing reaction temperature, both ethanol conversion and ethylene selectivity increased, *viz*. conversion of ethanol increased from 15.97% at 673 K to 59.74% at 773 K, whilst the ethylene selectivity improved from a low of 96.14% at 673 K to 99% at 773 K. This showed that the dehydration activity of 30PA-$CeO_2$ catalyst improved with reaction temperature. This indicates that $H_3PO_4$ functioned more effectively with reaction temperature, *i.e*. its acidity property can be tailored to the reaction temperature and thus, able to protonate the hydroxyl group of $C_2H_5OH$ molecule.

**Post reaction study**

Among all $CeO_2$ and $H_3PO_4$-modified $CeO_2$ catalysts, 30PA-$CeO_2$ catalysts showed the best catalytic performance. The 30PA-$CeO_2$ catalyst was collected for post reaction characterization. The used 30PA-$CeO_2$catalysts at different reaction temperatures (673 K, 723 K and 773 K) were collected and were subjected to further examinations. Figure 5 shows the SEM image of the post-reaction 30PA-$CeO_2$ catalysts. It can be visualized that there are not much changes to the catalysts' morphology. In addition, no visible carbon formation was found after the reaction. This result suggests that the addition of 30wt% phosphoric acid enhance the stability of catalysis by weakening the strong acidic sites into moderate weak acidic sites. This prevent the double bond which is π bond found in $C_2H_4$ is electron rich from being attracted toward the acidic catalyst surface and form single C-C bond which lead to coke formation [23].

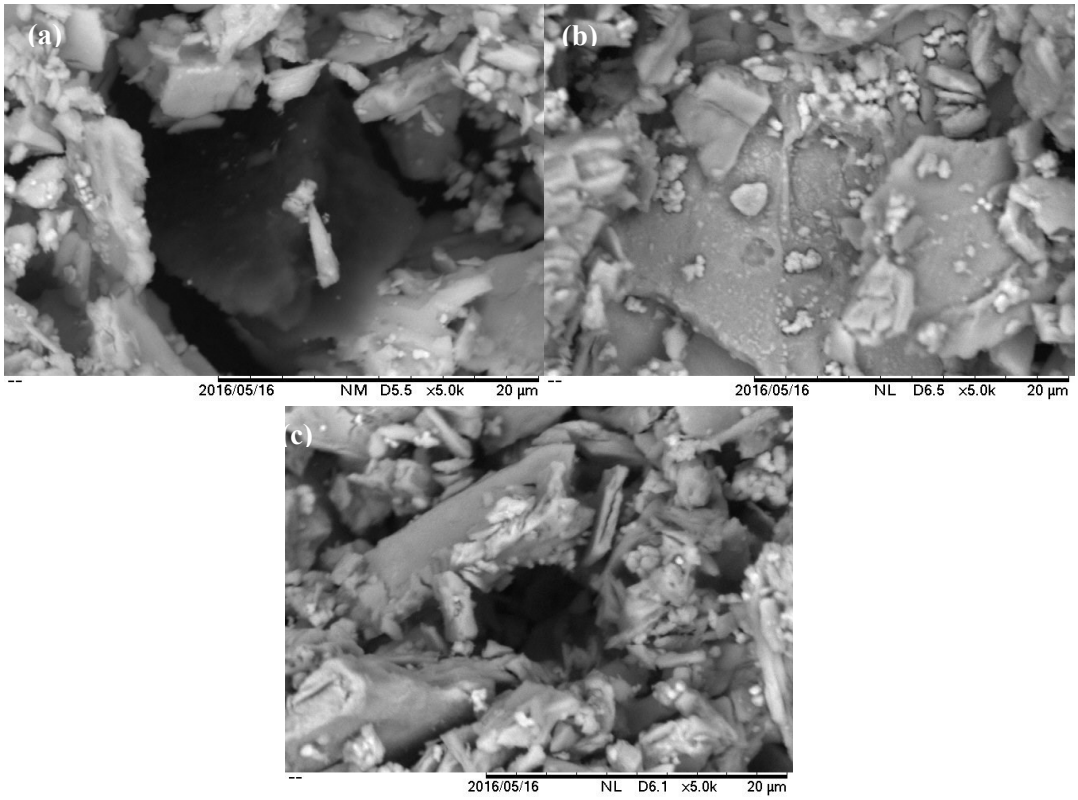

Figure 5. SEM images of 30PA-$CeO_2$ catalysts at ethanol partial pressure 33 kPa and (a) 673 K (b) 723 K and (c) 773 K.

TG analysis was performed to study the thermal profile of the spent 30PA-$CeO_2$ catalysts. The TG analysis was performed from 298 K to 1173 K, each time. As shown in Figure 6, weight loss in the used catalyst at all reaction temperatures are small. Indeed, the total weight loss of used 30PA-$CeO_2$ at reaction temperature 673 K was about 0.84 wt.%. For the used 30PA-$CeO_2$ catalyst at reaction temperatures of 723 K and 773 K, the weight losses at 873 K and 1073 K were 0.86 wt.% and 0.915 wt.%, respectively. This weight loss can be ascribed to the loss of water in catalyst and was consistent with the SEM results where no visible carbon formation was found. The results obtained also indicate that 30PA-$CeO_2$ catalyst was thermally stable.

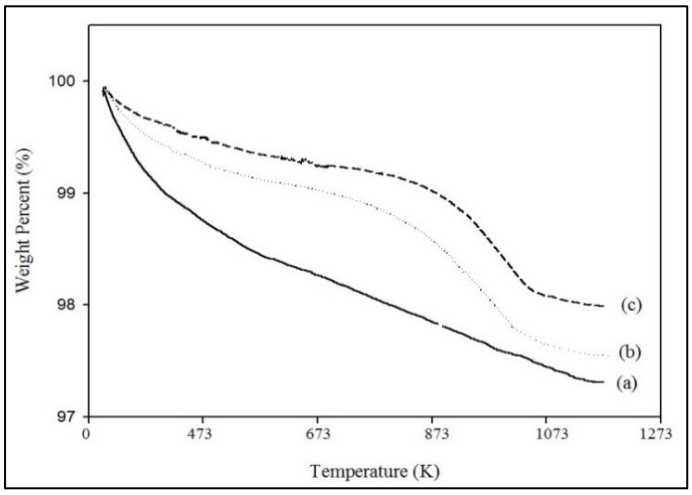

Figure 6. TGA profiles of used 30PA- $CeO_2$ catalysts at (a) 673 K, (b) 723 K and (c) 773 K

## Conclusion

This project focuses on the catalytic performance of ethanol to ethylene on $H_3PO_4$-modified $CeO_2$ (various loadings of $H_3PO_4$) catalysts and the influences of $H_3PO_4$ on ethanol conversion over the synthesized catalysts. The addition of phosphorus acid to the $CeO_2$ catalyst improved the catalytic performance and catalyst stability for ethanol dehydration to ethylene. These improvements are due to the tuned acid sites and reduction of BET specific surface areaby preventing coke formation and blocking the accessibility of reactants to the acid sites.The $H_3PO_4$-modified $CeO_2$ catalysts showed increasing trend in ethanol conversion and ethylene selectivity with the loading of phosphorus. The post reaction analyses on the 30PA-$CeO_2$ catalyst (the best performing catalyst) also showed that the introduction of $H_3PO_4$ acid has helped in maintaining coke-free surface that would have otherwise caused catalyst deactivation. This can be attributed to the mild acidity sites available on the 30PA-$CeO_2$ catalyst.

**Abstract**

The gas phase dehydration of glycerol to acrolein over a series of supported silicotungstic acid (HSiW) on γ-$Al_2O_3$ nanoparticle ($W_{10}$-Al, $W_{20}$-Al, $W_{30}$-Al and $W_{40}$-Al) has been investigated. The catalysts were characterized by temperature programmed desorption, nitrogen adsorption–desorption, thermogravimetric analysis, X-ray diffraction, field-emission scanning electron microscopy and energy dispersive X-ray techniques. The large pore diameters (>21 nm) of the prepared catalysts alleviated the coke deposition effect. The acidity of the samples increased from 2 to 2.6 mmol/g.cat by varying HSiW loadings from 10 to 40 wt.% on γ-$Al_2O_3$ nanoparticle. The highest acrolein yield achieved was 74.1% at 94% glycerol conversion over $W_{20}$-Al catalyst for 10 wt% glycerol feed concentration and 300 ˚C reaction temperature in 3 hours. The combined physicochemical characteristics of $W_{20}$-Al made it more superior compared with other samples in the current study.

**Keywords**: acrolein, dehydration, glycerol, supported silicotungstic acid

**Abstrak**

Penyahhidratan gliserol fasa gas kepada akrolein dengan menggunakan satu siri asid silikotungstik disokong (HSiW) terhadapnanopartikel γ-$Al_2O_3$ ($W_{10}$-Al, $W_{20}$-Al, $W_{30}$-Al, dan $W_{40}$-Al) telah dikaji. Mangkin-mangkin tersebut dicirikan oleh penyahjerapan suhu terprogram, penjerapan-penyahjerapan nitrogen, analisis termogravimetrik, pembelauan sinar X, mikroskop pengimbasan elektron pancaran medan, dan teknik penyerakan tenaga sinar X. Diameter liang besar (>21 nm) bagi mangkin yang disediakan dapat mengurangkan kesan pemendapan kok. Keasidan sampel meningkat daripada 2 hingga 2.6 mmol/g.cat dengan mengubah beban HSiW daripada 10 hingga 40 wt.% pada nanopartikel γ-$Al_2O_3$. Hasil akrolein tertinggi yang dicapai adalah 74.1% pada 94% penukaran gliserol terhadap mangkin $W_{20}$-Al bagi 10 wt.% kepekatan suapan gliserol dan 300 °C suhu tindak balas dalam masa 3 jam. Ciri-ciri gabungan fizikokimia $W_{20}$-Al menjadikannya lebih unggul berbanding sampel lain dalam kajian semasa.

## Introduction

Production of value added chemicals from renewable sources as substitute for conventional petroleum-based processes is a hot issue recently. The huge glycerol availability due to large scale production of biodiesel worldwide provides spectacular opportunities for researchers to evaluate its application as a bio-renewable feedstock in future refineries [1, 2]. In addition, glycerol characteristics such as bio-degradability, non-toxicity, and its multi functional structure made it as one of the top 12 most important bio-based chemicals in the world [3]. Glycerol can be used in

production of more than 2000 value-added chemicals [4, 5]. One of the most important products which can be produce from glycerol during a bio-based process is acrolein which is a substitute for petroleum based propylene oxidation process [6]. Acrolein is one of the versatile intermediates in chemical industry due to its wide utilization for acrylic acid, superabsorbent polymer, 1,3-propanediol, and many more polymers or polyesters production.

Wide ranges of studies have been reported for application of solid acid catalysts such as heteropoly acids [7 – 9], zeolites [10, 11], and metal oxides [12 – 14] in gas or liquid phases of glycerol dehydration to acrolein during the last decade, but still there is no catalyst which exhibit long-term stability without severs deactivation with prospect for industrialization. Among various reported catalysts, supported heteropoly acid (HPA) is attracted much attention due to its stronger acidity (Bronsted acidic sites) and higher activity compared to other catalysts. It is reported that the Bronsted acidic site is more effective than Lewis acidic site for acrolein production [15]. The low specific surface area (1 – 10 $m^2/g$) and thermal stability are the main limitations of HPAs. Therefore, to overcome these drawbacks HPAs are often support on a carrier such as alumina, zirconia, and silica. Alumina showed better results due to strong electrical interaction with HPAs and also enhancement of their thermal stability [16]. However, application of $Al_2O_3$ nanoparticles as a support for HPAs is never reported before. Suitable pore structure and high surface acidity are the key components for higher activity of catalyst for acrolein production [17, 18].

One of the main obstacles for industrialization of bio-based glycerol dehydration to acrolein is fast deactivation of catalyst by coke deposition. For example, the Cs-HPW catalyst is reported as the highest active catalyst in gas phase dehydration of glycerol to acrolein with 98% acrolein selectivity at 100% glycerol conversion, but this catalyst only could last for a few hours and its activity dropped dramatically beyond this time [19]. Some catalyst characteristics such as small pore diameter, very strong acidic sites, and high reaction temperature promote coke deposition [16]. Various researchers proposed different methods for slowing down or eliminating the coke deposition on the catalyst surface such as co-feeding of oxygen or hydrogen. However, this process may increase the probability of explosive conditions or oxidation of products which finally decrease the acrolein selectivity. Besides, some other researchers studied the catalyst structure by addition of noble metals to improve catalyst activity and stability [20, 21]. The main objective of this study is to synthesize a supported HSiW catalyst with $\gamma$-$Al_2O_3$ nanoparticles for the first time to obtain a catalyst with high surface acidity, large specific surface area, large pore diameter and high thermal stability for increasing glycerol conversion and its selectivity to acrolein.

## Materials and Methods

### Catalyst preparation

A series of catalysts with various HSiW loadings (10, 20, 30, and 40 wt.%) on $\gamma$-$Al_2O_3$ were prepared by the incipient-wetness impregnation method. In this method, aqueous HSiW solutions were added drop-wise to the $\gamma$-$Al_2O_3$ nanoparticles support. The slurries were rigorously stirred for 12 h followed by drying at 110 ˚C for 18 hours. The HSiW-$Al_2O_3$ supported catalysts were denoted as $W_{10}$-Al, $W_{20}$-Al, $W_{30}$-Al, and $W_{40}$-Al for 10, 20, 30 and 40 wt.% of HSiW loading, respectively.

### Characterization

Nitrogen adsorption/desorption at -196 ˚C was employed to determine the BET specific surface area, pore volume, and average pore diameter (Thermo Scientific, SURFAR). Prior to analysis, the sample was degassed under vacuum at 200 ˚C for 4 hours for purification and complete removal of adsorbed moisture. The BJH method was used for average pore diameter calculation. Thermogravimetric analysis (TG-DTA) of prepared catalyst was performed using a THERMO TGA instrument in a temperature range of 30 to 800 ˚C with a ramp rate of 10 K/min under nitrogen flow. The morphology of the samples was observed by Field Emission Scanning Electron Microscopy (FESEM, HITACHI, SU-8000) with the STEM detector. The total acidity of the prepared catalysts was determined by temperature programmed desorption of ammonia ($NH_3$-TPD) using the Micrometrics Auto Chem II instrument. A specific amount of catalyst was dried at 200 ˚C for 1 hour by saturation of $NH_3$ at 60 ˚C for 0.5 hour before the physically adsorbed $NH_3$ was removed by helium purging at 60 ˚C for 0.5 hour. X-ray diffraction (XRD) was used to determine the structure of the prepared catalysts and to evaluate the degree of crystallinity. The XRD patterns were obtained by D5000 Siemens instrument using Cuk$\alpha$ radiation (40 kev, 40 mA). The patterns were scanned in the 2$\theta$ range of 10 – 80˚ (step width 0.05˚, 1s per step).

**Catalytic reaction**

The gas phase dehydration of glycerol was conducted under atmospheric pressure in a vertical fixed bed quartz reactor (30 cm length, 11 mm i.d.) using 0.5 – 1 g catalyst sandwich between plugs of glass wool. Prior to reaction, the catalyst was pretreated at 300 ˚C under nitrogen ($N_2$) flow (1200 ml/h) for 1 hour. Liquid aqueous solution of glycerol (10 wt.%) introduced to the pre-heater (300 ˚C) by a syringe pump for complete vaporization and then swept into the reactor with 2 ml/h flow rate. Gas hourly speed velocity (GHSV) of the inert carrier gas was 1200 $h^{-1}$. The products and unconverted glycerol were condensed in a water-ice–salt bath (-5 ˚C) and collected each hour for analysis. n-Butanol was added to the condensed products as internal standard. The final solution was analyzed by a gas chromatograph (GC), which equipped with capillary column (DB Wax; 30 m × 0.53 mm × 0.25 μm) and FID detector. To achieve effective product separation, the column was held at 40 ˚C for 4 minutes before the temperature was ramped up to 200 ˚C with a rate of 12 K/min. The glycerol conversion, product selectivities and yields are defined by equations (1) to (3):

$$Con_{Gl}(\%) = \frac{M_{Gl,\ in\ \ feed} - M_{Gl,\ in\ \ outlet}}{M_{Gl,\ in\ \ feed}} \times 100\% \quad (1)$$

$$Sel_N(\%) = \frac{M_{C\ \ in\ \ product}}{M_{C\ \ in\ \ Gl,\ \ feed} - M_{C\ \ in\ \ Gl,\ \ outlet}} \times 100\% \quad (2)$$

$$Yield_N(\%) = Con_{Gl}(\%) \times Sel_N(\%) \quad (3)$$

where, $M_{Gl}$, $M_C$, $Con_{Gl}$, $Sel_N$, and $Yield_N$ are moles of glycerol, moles of carbon for each product, glycerol conversion, selectivity and yield of each product (N), respectively.

## Results and Discussion

**Surface area and pore structure analysis**

The textural characteristics, specific surface area ($S_{BET}$), pore volume ($V_P$), average pore diameter ($D_P$) of supported HSiW catalysts derived from nitrogen physisorption isotherms are presented in Table 1. The specific surface areas of bulk γ-$Al_2O_3$ and HSiW are 143.2 and 8.2 $m^2/g$, respectively. By increasing the HSiW loading from 10 to 40 wt.% on the γ-$Al_2O_3$, the surface areas of the prepared catalysts decreased from 140.5 to 76.6 $m^2/g$. The reduction of surface area during the catalyst preparation steps was due to the plugging of pores by agglomeration [22], crystallization of active compounds (HSiW), and formation of monolayer HSiW surface with less surface area [23]. Impregnation of HSiW on γ-$Al_2O_3$ also led to reduction of pore volume from 0.5 to 0.2 $cm^3/g$ for pure γ-$Al_2O_3$ to $W_{40}$-Al. In fact, the highest amount of HSiW loading on alumina diminished approximately 50% of the pore volume. The average pore diameter seems to be not effected and it remained stable with about 21 nm.

Table 1. Bulk and supported samples surface area ($S_{BET}$), pore volume (Pv), and pore diameter (Pd)

| Catalyst | $S_{BET}$ ($m^2/g$) | $V_p$ ($cm^3/g$) | $D_p$ (nm) |
|---|---|---|---|
| HSiW | 8.2 | 0.02 | 10.3 |
| $Al_2O_3$ | 143.2 | 0.5 | 22.5 |
| $W_{10}$-Al | 140.5 | 0.4 | 21.0 |
| $W_{20}$-Al | 125.7 | 0.4 | 21.5 |
| $W_{30}$-Al | 115.7 | 0.4 | 21.1 |
| $W_{40}$-Al | 76.6 | 0.2 | 21.6 |

**Acidity ($NH_3$-TPD)**

The prepared catalysts were analyzed by temperature programmed desorption of ammonia ($NH_3$-TPD) to determine the amount and strength of acidity (Table 2 and Figure 1). The strength of acid sites was divided into three categories of weak (150 – ≤300 ˚C), medium (300 – ≤450 ˚C), and strong (>450 ˚C). The position and area of the TPD peaks are closely related to the acid amount and strength [24]. The total acidity of bulk HSiW and γ-$Al_2O_3$

were 1.62 and 1.2 mmol/g.cat, respectively. The HSiW possessed the highest acid strength due to its weak and strong acidic sites compared to the $\gamma$-$Al_2O_3$ with only weak acidity.

Table 2. $NH_3$-TPD acidity of bulk and supported silicotungstic acid catalysts

| Cat | Weak (100 – 300 ˚C) | | Medium (300 – 450 ˚C) | | Strong (>450 ˚C) | | Total[c] |
|---|---|---|---|---|---|---|---|
| | Peak (˚C)[a] | Acidity[b] | Peak (˚C) | Acidity | Peak (˚C) | Acidity | |
| HSiW | 131 & 250 | 0.02 | - | - | 530 | 1.6 | 1.62 |
| $Al_2O_3$ | 127 & 287 | 1.2 | - | - | - | - | 1.2 |
| $W_{10}$-Al | 132 | 1 | 300 | 1 | - | - | 2 |
| $W_{20}$-Al | 137 | 0.5 | 301 | 1.8 | - | - | 2.3 |
| $W_{30}$-Al | 135 | 0.5 | 311 | 2 | - | - | 2.5 |
| $W_{40}$-Al | 136 | 0.6 | 317 | 2 | - | - | 2.6 |

[a] Peak position, [b]Acid amount ($NH_3$/Cat, mmol/g), [c] Total acidity (mmol/g.cat)

The acidity increased significantly from 2 to 2.6 mmol/g.cat by increasing the HSiW loading from 10 to 40 wt.% on $\gamma$-$Al_2O_3$. All the samples displayed two peaks at 135 and 300 ˚C which related to the weak and medium acidic sites. Also, the strength of the medium acid sites was higher than the weak ones. For instance, the $W_{30}$-Al and $W_{40}$-Al approximately have 4 times (2 mmol/g.cat) stronger medium acidic sites than their weak acidic sites (0.5-0.6 mmol/ g cat). Also, $NH_3$ peak positions of weak and medium acidity showed small shifts from 132 – 136 ˚C and 300 – 317 ˚C which confirmed increasing the acidic cites strength (Figure 1). The main reason is the electric interaction between HSiW and support ($\gamma$-$Al_2O_3$). In fact, during the impregnation process the hydroxyl groups on the surface of $\gamma$-$Al_2O_3$ were protonated with water which caused a positive charged surface. Finally, the HSiW addition leads an electric interaction. The strength of this interaction depends on the type of support which is stronger for alumina [7, 16].

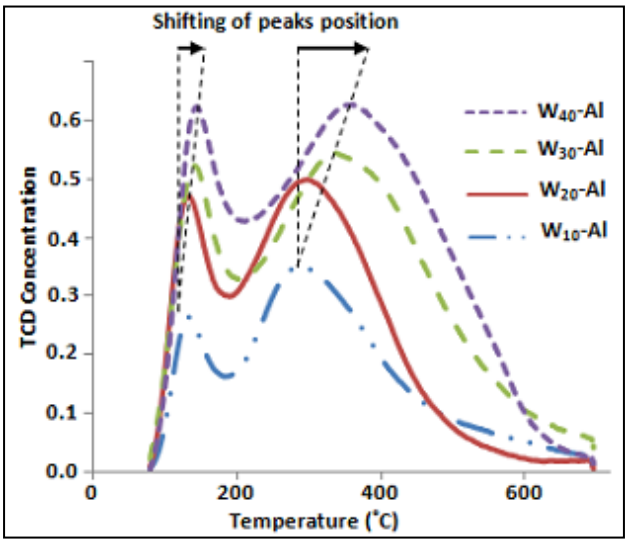

Figure 1. $NH_3$-TPD profiles of supported ($W_{10\text{-}40}$-Al) samples

**X-ray diffraction**

The X-ray diffraction (XRD) patterns of the supported HSiW (10 – 40 wt.%) on $\gamma$-$Al_2O_3$ nanoparticles are shown in Figure 2. The pure HSiW illustrates three main peaks (2$\theta$ = 10.9˚, 25.5˚, and 34.7˚) which attributed to its Keggin

anions. Besides, the diffraction peaks related to the pure γ-$Al_2O_3$ appeared at $2\theta$ = 18.75˚, 36.9˚, 44.2˚ and 67.3˚. However, increasing the HSiW loading from 10 to 40 wt.% on the support caused a reduction in diffraction peaks of γ-$Al_2O_3$ and also the reduction magnitude surged. It is noted that none of the supported catalysts illustrates peaks attributed to the HSiW Keggin structure, which demonstrated high dispersion of HSiW on the support. Similar results reported previously [25 – 27]. The main reason for highly uniform dispersion of HSiW on the γ-$Al_2O_3$ surface is the size of the Keggin anions (D = 1.2 nm) and the large specific surface area of γ-$Al_2O_3$ nanoparticles ($S_{BET}$ = 143.2 $m^2$/g). Atia et al. [16] mentioned that only >80 wt.% HSiW loading can saturate the support surface. In fact, XRD can detect HSiW crystals whenever high concentration of HSiW saturate the γ-$Al_2O_3$ surface and then some HSiW molecules cannot reach the support meso-pores and crystallise as separate phase.

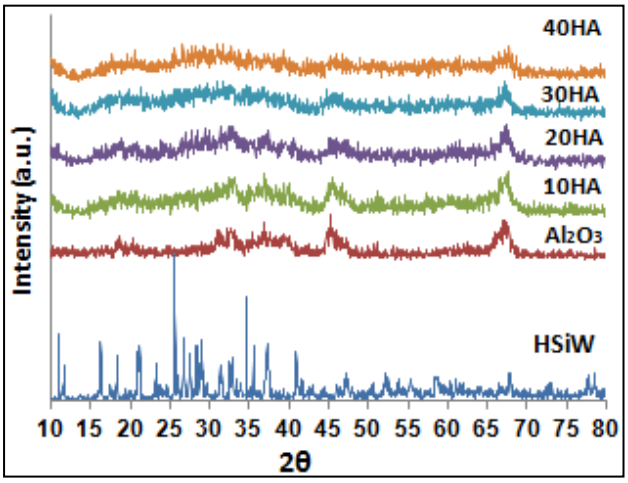

Figure 2. XRD patterns of the pure and supported prepared catalysts

**Thermal stability**

Figure 3 displays the TG-DTA curves of pure γ-$Al_2O_3$, HSiW, and supported $W_{20}$-Al samples. It can clearly be seen that pure γ-$Al_2O_3$ lost weight with heating from 30 to 800 ˚C. The alumina DTA curves exhibits a broad band peak at 70 ˚C which related to the loss of physically adsorbed water. Afterwards, only a little weight loss observed at 250 ˚C which attributed to the dehydroxylation of hydroxyl groups. Both TG and DTA curves of the bulk HSiW registered three steps of weight losses. The first two weigh losses of 8% and 3% at 85 and 200 ˚C, respectively are referred to the loss of physically absorbed water and removal of water from HSiW hydrated heteropoly acid [28, 29]. However, the third weight loss (1%) at 500 ˚C related to decomposition of the HSiW Keggin anions [16]. Further loading of $WO_3$ led to new broad band at 3500 $cm^{-1}$ crystallite planes, respectively.

Finally the prepared $W_20$-Al catalyst shows one broad peak at 80 ˚C corresponds to the loss of physically adsorbed water (DTA curve). The second weight loss observed at 350 ˚C which attributed to the removal of structural water molecules. However, no important structural changes were observed in the rest of analysis which confirmed high thermal stability of the $W_{20}$-Al sample. In fact, this high stability of $W_{20}$-Al catalyst was referred to the electronic interaction between HSiW and γ-$Al_2O_3$ [7, 24]. Scheme 1 depicts different decomposition steps of HSiW and it clearly confirmed that full decomposition happened in >500 ˚C and the second weight loss of $W_{20}$-Alat 350 ˚C was not the decomposition peak. Remarkably, the prepared catalyst showed high stability even in high temperatures compared to some similar catalysts in previous studies such as HSiW/SBA-15, 30%HSiW-Al, 20%HSiW/A5, 20%HSiW/AS4 which were unstable at temperatures above 480 ˚C [16, 20, 24].

$$H_4SiW_{12}O_{40}nH_2O \xleftrightarrow[<200\ \ ^\circ C]{-nH_2O} H_4SiW_{12}O_{40} \xleftrightarrow[>500\ \ ^\circ C]{-2H_2O} SiW_{12}O_{38} \rightarrow 12WO_3 + SiO_2$$

**Morphological analysis**

The surface morphology of the fresh and used $W_{20}$-Al samples was examined by FESEM (Figure 4). HSiW seems to be dispersed on the external surface of the alumina and filling the voids between the particles with in a gain (Figure 4a-b). As results the specific surface area decreased from 143.2 to 125.7 $m^2/g$ for pure γ-$Al_2O_3$ and $W_{20}$-Al catalyst respectively according to the BET results.Fortunately, no dramatic change in catalyst surface morphology was observed after dehydration reaction (Figure 4c-d). Indeed, FESEM study demonstrated that the catalyst morphological characteristics remain unaffected during the reaction due to high hydrothermal stability of catalyst (confirmed by TGA results), similar results reported elsewhere [30 – 32].The EDX analysis results related to the fresh $W_{20}$-Al sample are exhibited in Figure 4e. The EDX mapping confirms an extremely uniform distribution of alumina (Figure 4f) and tungsten (Figure 4g) elements throughout the $W_{20}$-Al catalyst. In addition, the EDX analysis reveals 71.83% and 17.34% weight percentages of Al and HSiW in this catalyst which found to be very close to the theoretical values of 80 and 20 wt% of γ-$Al_2O_3$ and HSiW, respectively (Figure 4h).

**Catalytic performance**

Application of bulk samples (HSiW and γ-$Al_2O_3$) in gas phase dehydration of glycerol could not obtain more than 38.1% selectivity of acrolein. These results demonstrate that the strong Lewis acid sites samples (γ-$Al_2O_3$) and even

the strong Bronsted acid site catalyst (HSiW) were not suitable for high acrolein selectivity. Indeed, the strong Lewis acid sites increase the byproducts production and the strong Bronsted acids enhanced coke formation on catalyst surface. Therefore, impregnation of HSiW on support ($\gamma$-$Al_2O_3$) is required to increase the glycerol conversion and acrolein selectivity.

The gas phase dehydration of glycerol to acrolein was investigated by the $\gamma$-$Al_2O_3$ supported HSiW (10 to 40 wt.%) catalyst at different temperatures (280, 300, and 320 ˚C) in 3 hours reaction time (Table 3). The results indicated that increasing the HSiW loading from 10 to 20 wt.% led to higher acrolein selectivity but HSiW loading above 20% slightly reduce the selectivity of acrolein or remained constant. Indeed, impregnation of HSiW on $\gamma$-$Al_2O_3$ caused a significant increase in catalyst activity compared to the pure HSiW due to increase in the total amount of catalytically active protons in the supported catalyst. On the other hand, well dispersed catalyst provides higher accessibility of glycerol molecules to the active compounds of supported catalyst. However, the main reason for reduction of acrolein selectivity or catalyst activity for HSiW loading above 20 wt.% is deposition of a huge amount of active compounds (HSiW) over $\gamma$-$Al_2O_3$ which cause second surge in the acid strength. Consequently, the coke deposition process on the surface of catalyst increase which has negative effect on acrolein selectivity [33].

The highest acrolein selectivity of 74.1% obtained over the $W_{20}$-Al supported catalyst with 94% glycerol conversion at 300 ˚C. Also, increasing the temperature from 280 to 320 ˚C has significant impact on glycerol conversion. The reaction conversion increased from 90% to 97% for 280 to 320 ˚C, respectively. All the reaction products such as ethanal, propanol, acetic acid, and hydroxyacetone selectivities are summarized in Table 3.

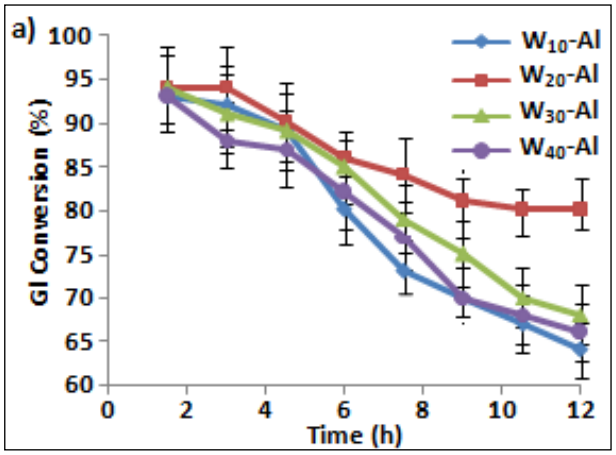
[a] Reaction condition: Feed: 2 ml/h, 10 wt% aqueous glycerol solution, Carrier gas: 20 ml/min, Reaction temperature: 300˚C, Time on Stream (TOS = 3 h), 0.5 g catalyst weight. [b] Acrolein yield, [c] Acrolein, [d] Ethanal, [e] Propanal, [f] Hydroxyacetone, [g] Allyl alcohol, [h] Acetic acid.

The strong interaction between HSiW and $\gamma$-$Al_2O_3$ is required for long-life stability of catalyst [34]. The TG-DTA results demonstrated the strong binding between HSiW and $\gamma$-$Al_2O_3$ with high catalyst stability. In addition, the



BET results also indicated that supported $W_{20}$-Al catalysts have large pore diameter (> 21nm) which is one of the main reason for high stability of this catalyst. In fact, pore size >4 nm providing a required space for Keggin anions (D = 1.2 nm) and also increase the interaction between adsorbed glycerol molecules and Keggin units [16]. Furthermore, large pore diameter significantly reduces the effect of internal mass transfer limitations [35].

The glycerol conversion related to all the prepared catalysts decreased steadily during 12 hours reaction time. However, $W_{20}$-Al recorded the least conversion reduction among all the tested samples (Figure 5a). The acrolein selectivities for all four samples are exhibited in Figure 5b. All samples exhibit dramatic reduction in acrolein selectivity except for the most active and stable catalyst, $W_{20}$-Al, which displayed a difference of only 11.6% from 74.1 to 62.5%. The $W_{20}$-Al sample was more active than $W_{10}$-Al due to the approximately 2 times stronger medium acidic sites (1.8 mmol/g.cat) of $W_{20}$-Al compared to the $W_{10}$-Al (1 mmol/g.cat). However, $W_{20}$-Al only showed 0.2 mmol/g.cat less medium acidity compared to the $W_{30}$-Al and $W_{40}$-Al samples. In fact, the $W_{20}$-Al, $W_{30}$-Al and $W_{40}$-Al samples showed similar nature of acidity (high medium acid strength). The differences in the total acidity of these samples were only 0.2 – 0.3 mmol/g.cat.

$$\text{The number of acid sites} = \left(\frac{Total\ \ acidity\ \ (NH_3 - TPD)}{Surface\ \ area\ \ (BET)}\right)\left(\frac{mmol}{m^2}\right) \quad (4)$$

for $W_{20}$-Al was lower than the $W_{30}$-Al and $W_{40}$-Al samples. The number of acid sites increased from 0.018 to 0.034 mmol/$m^2$ by surging the HSiW loading from 20 to 40 wt.%. In fact, the $W_{40}$-Al sample registered double acid sites amount (0.034 mmol/$m^2$) compared to the$W_{20}$-Al. Therefore, the main reason for significant reduction of catalyst activity for $W_{30}$-Al and $W_{40}$-Al samples was higher number of active sites which enhance the coke deposition process on the catalyst surface and deactivate the catalyst faster.

As stated in Table 3 and Figure 5b the acrolein selectivity for $W_{30}$-Al and $W_{40}$-Al samples were initially high; however, as more coke was deposited on the catalyst surface, the selectivity dwindled during 12 hours of reaction time. Consequently, the optimum amount of HSiW loading was found to be 20 wt.%. For above 20 wt.% HSiW loading, the catalyst activity remained stable in the first hour of reaction, but then its activity and acrolein selectivity declined dramatically (Figure 5a-b). Figure 5c exhibits long-term stability of $W_{20}$-Al catalyst during 30 hours reaction time. The stability of $W_{20}$-Al sample with 61.8% acrolein selectivity at 78% glycerol conversion prevailed up to 30 hours.

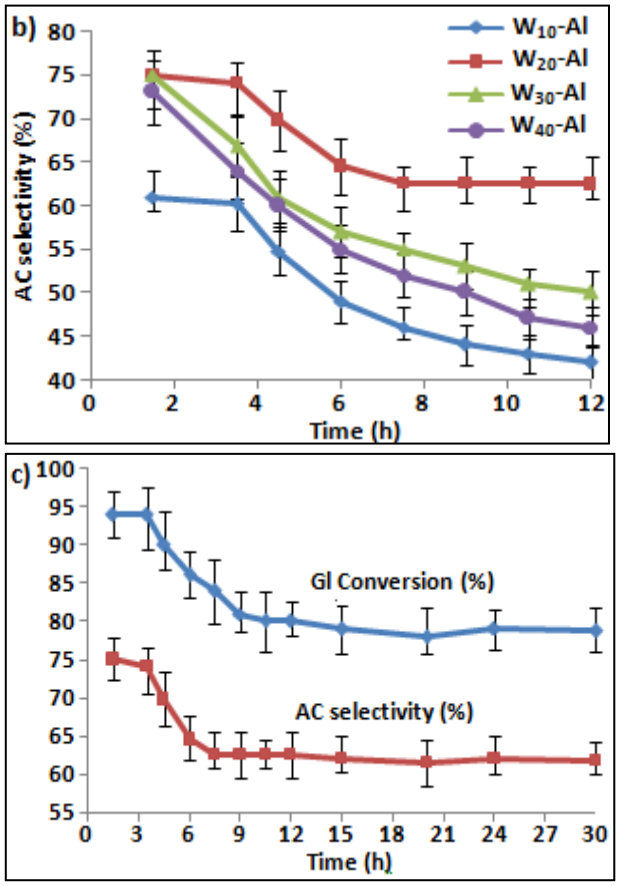


Figure 5. (a) Glycerol conversion versus time and (b) Acrolein selectivity versus time for W10-Al, W20-Al, W30-Al, and W40-Al samples at 300 ˚C, 12 hours reaction time, 2 ml/h glycerol feed, and 20 ml/min carrier gas flow (c) Long-term stability investigation of W20-Al sample in 30 hours

## Conclusion

A series of supported silicotungstic acid on aluminum oxide nanoparticle catalysts were prepared and examined in gas phase dehydration of glycerol to acrolein at different temperatures (280, 300, and 320 ˚C). The $W_{20}$-Al catalyst could achieved 74.1% acrolein selectivity with 94% glycerol conversion at optimum reaction condition of 300 ˚C temperature, 10 wt.% glycerol feed concentration and 0.5 wt.% catalyst amount. The characterization results prove that the $W_{20}$-Al large pore diameter (21.5 nm) was the key component for long-life stability of catalyst. In addition, high surface acidity, medium acid cite strength and availability of acid sites on the surface of $W_{20}$-Al catalysts led to the highest acrolein selectivity and glycerol conversion among all the synthesized samples.

**Abstract**

Sodalite (SOD) is a microporous zeolite with pore size about 2.8 Å which limits its role as catalyst for the reaction involving bulky molecules. To overcome this disadvantage, mesotemplate can be added to create mesoporosity in the synthesis of SOD. A series of SOD samples was synthesized using dual templates approach by mixing tetrapropylammonium hydroxide (TPAOH) with different quaternary ammonium cations. The samples were characterized using X-ray Diffraction (XRD), Fourier Transformation Infrared (FTIR) and $N_2$ adsorption analysis. From $N_2$ adsorption analysis, only SOD sample prepared by mixing TPAOH with organosilane (SOD-TO) showed the characteristic of mesoporosity with a narrow pore size distribution peak centered at *ca.* 66 Å. The basicity properties of all SOD samples were evaluated by Hammett indicators test and back titration method. While, the basicity property of SOD-TO was compared with the microporous SOD (Na-SOD) using TPD-$CO_2$ analysis. All SOD samples were tested in the Knoevenagel condensation reaction of benzaldehyde and diethyl malonate, giving diethyl-2-benzylidenemalonate as the main product. The results showed that SOD-TO catalyst which possessing the highest amount of basicity and the highest surface area with mesoporosity character gave the highest percentages of conversion and yield of Knoevenagel reaction.

**Keywords:** sodalite, basic catalyst, dual templates approach, mesoporous sodalite, Knoevenagel condensation reaction

**Abstrak**

Sodalit (SOD) ialah zeolit mikroliang dengan liang bersaiz sekitar 2.8 Å yang menghadkan peranannya sebagai mangkin untuk tindak balas yang melibatkan molekul – molekul yang besar. Untuk mengatasi kekangan ini, mesotemplat boleh ditambahkan dalam sintesis SOD bagi mengwujudkan mesoliang dalam SOD. Satu siri SOD telah disintesis menggunakan pendekatan dwi templat dengan campuran tetrapropilamonium hidroksida (TPA) dengan pelbagai kation amonium kuaterner. Semua sampel telah dicirikan menggunakan pembelauan sinar-X (XRD), Inframerah Tranformasi Fourier (FTIR) dan analisis penjerapan $N_2$. Daripada analisis penjerapan $N_2$, sampel SOD yang disintesis hasil campuran TPA dengan organosilana (SOD-TO) sahaja yang menunjukkan ciri-ciri mesoliang dengan puncak penyebaran sempit saiz liang berpusat di *ca.* 66 Å. Ciri-ciri kebesan untuk semua sampel SOD telah dinilai menggunakan ujian petunjuk Hammett dan kaedah titratan berbalik. Manakala, ciri-ciri kebesan SOD-TO telah dibandingkan dengan SOD mikroliang (Na-SOD) menggunakan analisis TPD-$CO_2$. Semua sampel SOD telah diuji dalam tindak balas kondensasi Knoevenagel antara benzaldehid dan dietil malonat yang menghasilkan dietil-2-benzilidenemalonat sebagai hasil utama. Keputusan menunjukkan mangkin SOD-TO yang mempunyai jumlah kebesan dan luas permukaan yang paling tinggi dengan kehadiran ciri mesoliang dalam strukturnya memberikan peratusan penukaran dan hasil yang paling tinggi bagi tindak balas Knoevenagel.

**Kata kunci:** sodalit, mangkin bes, pendekatan dwi templat, sodalit mesoliang dan tindak balas kondensasi Knoevenagel

## Introduction

Zeolites are microporous crystalline aluminosilicate solids made up from corner-sharing of $SiO_4^-$ and $AlO_4^-$ tetrahedra. These tetrahedra are linked together by sharing all the oxygen atoms, forming a uniformly pores or channels of molecular dimensions [1]. Microporous zeolites are widely used as catalysts in organic catalytic reactions due to their excellent catalytic performance such as large surface area, environment friendly, easy work-up and shape-selectivity [2]. However, in reactions involving large molecules, the sole presence of micropores in zeolites limit the diffusion of large molecules and lead to poor catalytic performance [3]. Therefore, many studies have been focusing on synthesizing zeolites with proper pore size in order to accelerate the conversion of large molecules. One of the best strategies is by synthesizing a new zeolite that consists of micropores and mesopores (2 – 50 nm) in one material. This strategy leads to the formation of hierarchical porous zeolites or also known as mesoporous zeolites [4]. Mesoporous zeolites offer some advantages such as fast diffusion and accessible for large molecules [5].

There are many methods to introduce mesopores in the zeolite structure. The most common methods used are post-synthetic method and templating method [6]. Desilication and dealumination are examples of post-synthetic method. This method has some drawbacks such as reducing the number of active sites and non-uniform nature of the mesopore formation [7]. Recently, the synthesis of mesoporous zeolites has been done by templating methods. This can be achieved by introducing various templates such as “hard” or “soft” templates into the zeolites during the synthesis process. This low cost method allowed reducing in the number of synthetic steps during the preparation [8]. Among these two templates, soft templating approach has been widely used for synthesizing mesoporous zeolites. Some examples of soft templates are surfactants and polymers [9]. The major advantage by using soft templates is the easily removed of the templates by a calcination process [10]. Instead of using single soft template, the mesopore zeolites can also be synthesized by mixing two soft templates. This strategy is known as dual templates method by which the small molecular template is used as structure directing agent whereas the large molecular template is used to create mesopores [11].

The formation of mesoporous zeolites gives lots of advantages in many applications especially in various catalytic reactions. They are primarily useful in improving the catalytic performances of conventional zeolites that having only micropores [12]. Some examples of catalytic reactions that used mesoporous zeolites are cracking, alkylation, isomerization and hydrogenation [13]. Knoevenagel condensation reaction is another example of catalytic reactions being catalyzed by mesoporous zeolites (alkaline X and Y zeolites) [14]. This reaction involved the condensation of carbonyl compounds with active methylene and catalyzed by a base catalyst. Some important intermediates produced from Knoevenagel condensation reactions have significant applications in industries such as therapeutic drugs, perfumes and cosmetics [15].

In this work, we focused on the synthesis of mesoporous sodalite (SOD). SOD is an example of zeolite, consisting of a four membered ring with the smallest pore openings size of about 2.8 Å in the zeolite family. In addition, SOD is an example of basic zeolite with high aluminium content (Si/Al = 1) and high stability in basic solution [16]. However, the presence of ultrafine micropores in its structure limit only to the reaction involving small reactants. Therefore, this work is expected to solve the problem by synthesizing mesoporous SOD in order to catalyze Knoevenagel condensation reaction involving large reactants. This mesoporous SOD was synthesized by dual templates approach using different quaternary ammonium cation templates and mixed with tetrapropylammonium hydroxide (TPAOH). The catalyst activity was tested in the Knoevenagel condensation reaction of benzaldehyde with diethyl malonate.

## Materials and Methods

### Catalyst preparation

A series of SOD samples were prepared by following the molar ratio of the previous study; $1.7SiO_2$: 15NaOH: $Al_2O$: $80H_2O$: 0.3templates [17]. First, sodium hydroxide solution was prepared by dissolving NaOH pellets (NaOH; Merck; 15 g) in distilled water (18 mL). The NaOH solution was then divided into two portions equally.

One portion of the NaOH solution was mixed with fume silica ($SiO_2$; Fluka; 1.28 g) to form silicate solution. The other portion was mixed with sodium aluminate ($NaAlO_2$; Riedel-de Haë; 1.28 g) to form aluminate solution. Next, tetrapropylammonium hydroxide (TPAOH; Merck; 0.85 mL) was added into the silicate solution followed by dimethyloctadecyl[3-(trimethoxysilyl)propyl] ammonium chloride (Organosilane; Sigma-Aldrich; 2.09 mL). The mixture was stirred until clear solution was formed. The resulting solution was then added dropwise into the aluminate solution and stirred of about 1 hour. The resulting solution formed was transferred into stainless steel autoclave and heated at 150 °C for 24 hours for the precipitation of SOD. The SOD product was collected by filtration and washed using distilled water until the filtrate solution reached to pH 7. The product was then dried at 60 °C overnight and calcined at 550 °C for 6 hours.

The procedures were repeated for different mixture of templates: the mixture of TPAOH with cetyltrimethylammonium bromide (CTAB; Fisher Scientific), dodecyltrimethylammonium bromide (DTAB; Sigma-Aldrich) and dimethyldioctadecylammonium bromide (DDAB; Sigma-Aldrich). As comparison, microporous SOD (Na-SOD) was synthesized using the same method without the presence of templates.

**Characterizations**
X-ray diffraction (XRD) patterns were recorded on powder diffractometer (Bruker Advance D8, 40 kV, 10 mA) using a Cu-Kα radiation source in the range of 5 – 50°. The FTIR analysis was recorded in the range of 400 to 4000 $cm^{-1}$ using Perkin Elmer 1600 series spectrometer. The BET analysis of the samples was determined by $N_2$ adsorption-desorption isotherms using a Micromeritics ASAP 2010 instrument. The samples were outgassed at 90 °C for 1 hour and heated up again at 350 °C for 4 hours before being subjected to $N_2$ adsorption. The surface area measurement was derived from the Brunauer – Emmett - Teller (BET) theory and the pore size distributions based on Barrett, Joyner and Halenda (BJH) theory.

**Basicity measurements**
Basicity of all SOD samples was determined using Hammett indicators and back titration method. In the case of the former, the procedure was followed from previous study with some modifications [18]. An activated solid SOD sample was shaken with 2 mL solution of Hammett indicators in ethanol and left to equilibrate. The color changed was noted. The following Hammett indicators were used; bromothymol blue ($pK_a$ = 7.2), phenolphthalein ($pK_a$ = 8.2) and 4-nitroaniline ($pK_a$ = 18.4).

In the back titration method, an amount of activated solid SOD sample was suspended in 10 mL of distilled water. It was shaken and left for 1 day. After one day, the solution was filtered. Then, the filtrate was mixed with 5 mL of 0.05 M HCl (Qrëc). The resulting solution was next titrated against 0.02 M of KOH (Qrëc) using phenolphthalein as the indicator. End point was noted when the colorless color of the phenolphthalein changed to pink.

Basicity comparison between Na-SOD sample and mesoporous SOD with highest BET surface area was done by Temperature Program Desorption of $CO_2$ (TPD-$CO_2$) using AutoChem II 2920 Micromeritics Chemisorption analyzer. Sample was heated in a stream of He gas at the flow rate of 20 mL/min to 500 $^oC$ at the heating rate of 10 $^oC$/min for 2 hours and then cooled to 50 $^oC$. After cooling, the $CO_2$ gas was introduced at the rate of 20 mL/min for 30 minutes. After that the gas flow was changed to He as carrier gas. The TPD-$CO_2$ was carried out in the temperature range of 50 to 1000 $^oC$ at heating rate of 10 $^oC$/mL and He rate of 20 mL/min.

**Catalytic testing**
Knoevenagel condensation reaction of benzaldehyde and diethyl malonate was carried out in this study. The catalyst samples were first activated at 500 °C for 2 hours. Equimolar solutions of benzaldehyde (0.02 mol) and diethyl malonate (0.02 mol) were added into a 50 mL round bottom glass reactor. The 0.05 g catalyst powder was then added to the solution. $N_2$ gas was then bubbled through the solution to remove dissolved oxygen to avoid formation of benzoic acid. Lastly, the solution was connected to the condenser and refluxed in an oil bath at 150 °C for 24 hours with stirring. Products of reaction were separated and analyzed using Gas Chromatography model Agilent 6890N Series equipped with flame ion detector (FID) using Ultra-1 column. Meanwhile, the components of the product produced in the reaction were identified by using Gas Chromatography-Mass Spectroscopy (GC-MS) model Perkin Elmer Clarus 680.

## Results and Discussion

### Catalyst characterizations

Figure 1 shows the XRD patterns of the as-synthesized SOD samples. The patterns exhibited six diffraction peaks at 2θ = 14.10°, 24.40°, 31.60°, 34.70°, 37.60° and 48.80° correspond to $d_{[110]}$, $d_{[211]}$, $d_{[310]}$, $d_{[222]}$, $d_{[321]}$ and $d_{[330]}$ planes respectively. These patterns are assigned to SOD crystal phase pattern after comparing with the previous study [19]. Among the SOD samples, SOD-TO showed broader XRD peaks which indicated a smallest crystallite size in its structure. In some cases, mixture of phases could be seen for SOD. It can be observed that the XRD pattern for SOD-TDDAB sample produced two peaks at certain 2θ. However, the extra peaks could not be identified and not matched with other type of zeolites. As for other SOD samples, peaks with high intensity were observed. The diffraction peak at (211) corresponding to the most intense peak was selected to calculate the crystallite size using Debye-Scherrer equation. The results correspond to the crystallite size of all SOD samples are shown in Table 1. The values suggested that all SOD samples were composed of nano-sized crystals. In addition, the values also suggested that the crystallite size increases as the wideness of the diffraction peak decreases. The SOD-TO sample has the smallest crystallite size as compared with other SOD samples which indicated that this sample consists of a highly nanocrystalline nature of the framework due to the presence of small crystallite size.

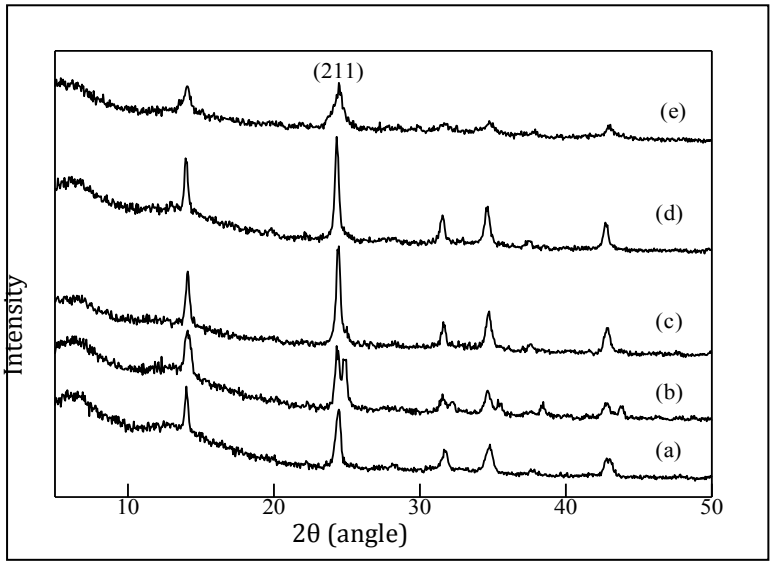

Figure 1. XRD diffractograms of (a) Na-SOD, (b) SOD-TDDAB, (c) SOD-TCTAB, (d) SOD-TDTAB and (e) SOD-TO

Table 1. Crystallite size of all SOD samples

| Samples | Crystallite size (nm) |
|---|---|
| Na-SOD | 18 |
| SOD-TDDAB | 23 |
| SOD-TCTAB | 25 |
| SOD-TDTAB | 26 |
| SOD-TO | 17 |

Figure 2 shows the IR spectra of as-synthesized SOD samples. Each SOD sample showed a broad absorption band at around 980 $cm^{-1}$. This band can be assigned to the internal vibration of T-O-T (T = Si or Al) asymmetric stretch.

However, except SOD-TO sample, all other SOD samples showed additional absorption band at around 920 $cm^{-1}$. This band could be assigned to the Si-O stretching mode of surficial silanol group (Si-OH). This band might be produced due to the hydroxylation of silica upon exposure to water. In addition, each of SOD samples showed absorption bands in the region of 650 – 740 $cm^{-1}$ that can be due to the symmetric stretch of T-O-T (T = Si or Al). While, the absorption band around 450 – 465 $cm^{-1}$ represents the internal vibration of T-O-T bending (T = Si or Al). The characteristic absorption band at 428 – 436 $cm^{-1}$ also represent the vibrations of T-O-T (T = Si or Al) bending that related to the pore opening of the SOD unit. The absorption bands discussed are related to the characteristic of SOD framework as found by previous study [20].

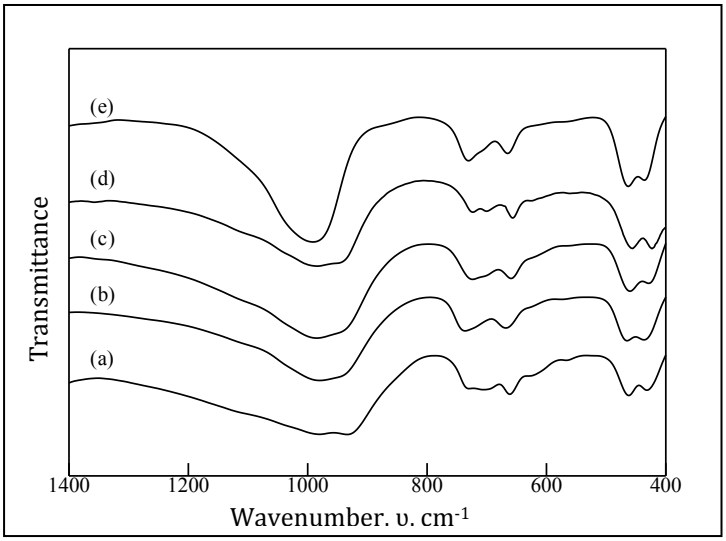

Figure 2. IR spectra of (a) Na-SOD, (b) SOD-TDDAB, (c) SOD-TCTAB, (d) SOD-TDTAB and (e) SOD-TO

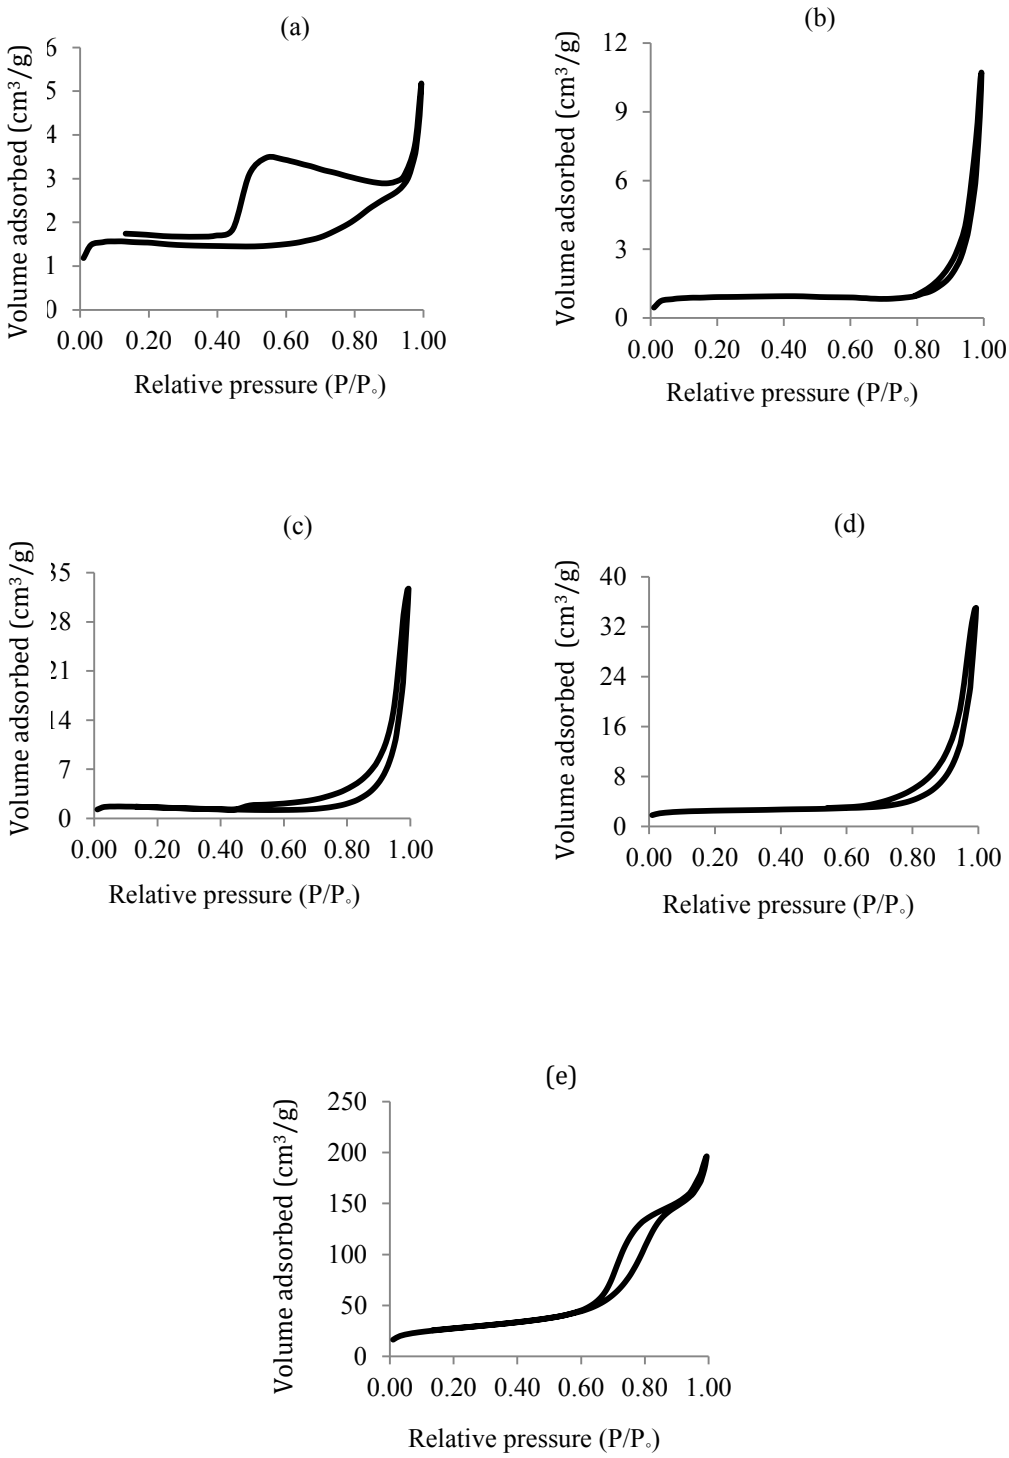
Figure 3 shows the BET adsorption-desorption isotherm of all SOD samples while Figure 3B shows the BJH pore size distributions of all SOD samples. Based on Figure 3A, the BET adsorption-desorption isotherm of the SOD-TO sample (see Figure 3 (e)) exhibited type IV isotherm with a H1 type hysteresis loop which was typical of mesoporous solids. This hysteresis loop produced was due to the capillary condensation in mesopore channels. As for other SOD samples, the isotherms can be classified as type II isotherm with a non-uniform type H3 hysteresis loop. While, the Na-SOD sample produced type II isotherm with type H2 hysteresis loop. Thus, only SOD-TO sample showed the successfully formation of mesoporosity in its structure based on the obtained isotherm. The presence of mesoporous structure in the SOD-TO sample was confirmed with a narrow pore size distribution peak centered at *ca.* 66 Å as shown in Figure 4 (e). In addition, the higher specific surface area and larger pore volume were attributed to the presence of mesoporous structure in the SOD-TO as shown in Table 2. As for other SOD samples, they exhibited broader pore size distributions ranging from 30 Å to 475 Å and some even extended to the macropore range. This suggested that those samples inhibited the characteristic of an ordered mesoporous solid with very low BET surface area as shown in Table 2.



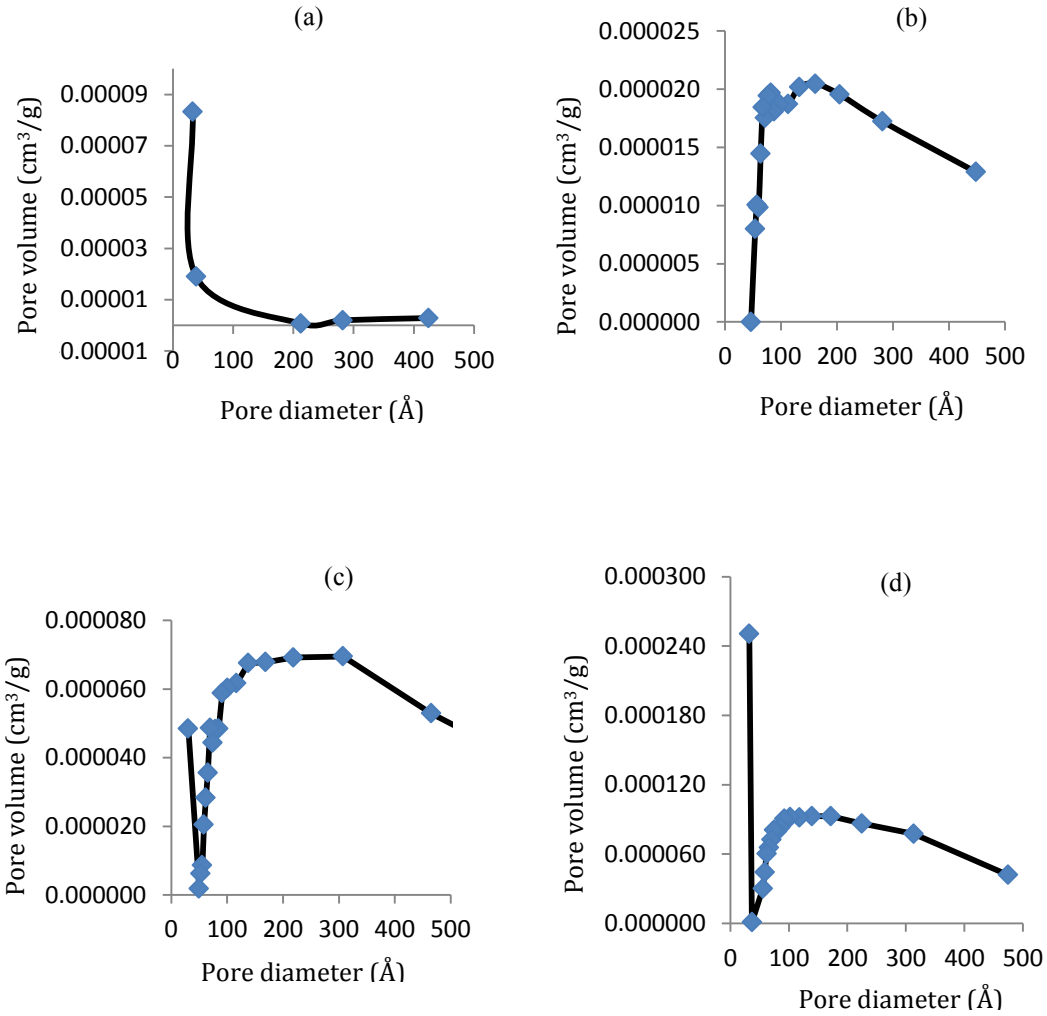


Figure 3. BET adsorption-desorption isotherm of (a) Na-SOD, (b) SOD-TDDAB, (c) SOD-TCTAB, (d) SOD-TDTAB and (e) SOD-TO

Table 2. $N_2$ adsorption-desorption data of all SOD samples

| Samples | BET Surface Area, $S_{BET}$ ($m^2/g$) | t-plot Micropore Area ($m^2/g$) | External Surface Area, $S_{Ext}$ ($m^2/g$) | BJH Desorption Cumulative Volume of Pores ($cm^3/g$) |
|---|---|---|---|---|
| Na-SOD | 6.8 | 6.0 | 0.8 | 0.007 |
| SOD-TDDAB | 3.3 | 2.4 | 0.9 | 0.012 |
| SOD-TCTAB | 6.8 | 5.8 | 0.9 | 0.051 |
| SOD-TDTAB | 9.1 | 6.6 | 2.5 | 0.049 |
| SOD-TO | 94.2 | 19.2 | 75.0 | 0.285 |

**Basicity measurements**

The basic strength of the SOD samples was estimated by using Hammett indicators. A change in color was observed for bromothymol blue from orange to dark blue and colorless to pink for phenolphthalein indicators. None of the samples were able to change the color of 4-nitroaniline. Hence, the strength of the basicity of all SOD samples prepared in this study was estimated in the range: $8.2 \leq pKa \leq 18.4$ as shown in Table 3.

Table 3. Basic strength of all SOD samples

| Samples | Hammett Indicators | | | Basic Strength |
|---|---|---|---|---|
| | Bromothymol Blue | Phenolphthalein | 4-nitroaniline | |
| Na-SOD | +* | + | -* | $8.2 \leq pKa \leq 18.4$ |
| SOD-TDDAB | + | + | - | $8.2 \leq pKa \leq 18.4$ |
| SOD-TCTAB | + | + | - | $8.2 \leq pKa \leq 18.4$ |
| SOD-TDTAB | + | + | - | $8.2 \leq pKa \leq 18.4$ |
| SOD-TO | + | + | - | $8.2 \leq pKa \leq 18.4$ |

*(+) = color changed, (-) = color unchanged

The similar strength of all the samples suggested that the basicity strength is contributed by the type of counter cation used and not the porosity. In this study, similar alkali cation which was $Na^+$ was used as the counter cation during the synthesis of all sodalite samples.

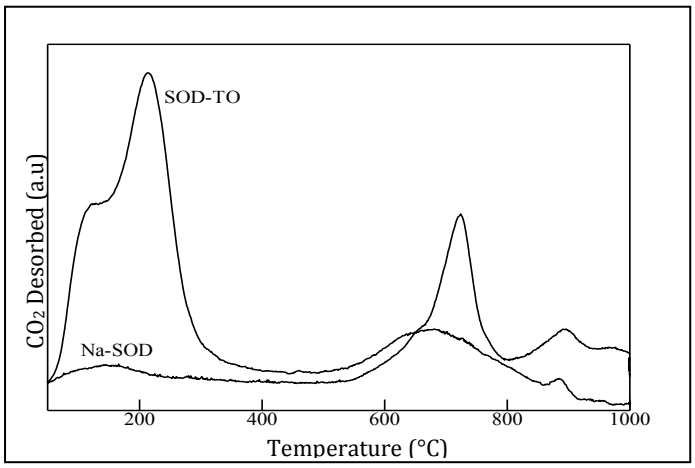
The amount of basicity of the SOD samples was evaluated by back titration method. Results found that the average amount of basicity of all SOD samples synthesized with the presence of templates is more than two fold higher than the SOD synthesized without the presence of templates, Na-SOD as shown in Table 4. Among the SOD samples synthesized with the presence of templates, it was found that the SOD-TO sample possess the highest average amount of basicity as compared with other SOD samples. This result indicated that the highest basic sites were present in the SOD-TO sample and lead to the highest amount of basicity. This could be due to the mesopore structure present in the sample, which more accessible of the reactant for the basic sites.

Table 4. Average amount of basicity of all SOD samples

| Sample | Amount of Basicity (mmol/g) | | | Average Amount of Basicity (mmol/g) |
|---|---|---|---|---|
| | (i) | (ii) | (iii) | |
| Na-SOD | 0.60 | 0.80 | 0.80 | 0.73 |
| SOD-TDDAB | 1.72 | 1.76 | 1.76 | 1.75 |
| SOD-TCTAB | 1.64 | 1.68 | 1.68 | 1.67 |
| SOD-TDTAB | 1.68 | 1.72 | 1.72 | 1.71 |
| SOD-TO | 1.80 | 1.80 | 1.84 | 1.81 |

Comparison of the strength and the amount of basicity for mesoporous SOD-TO and microporous Na-SOD samples were measured using TPD-$CO_2$ analysis. The basicity profiles of SOD-TO and Na-SOD samples are presented in Figure 5. Four peaks were found for the SOD-TO sample which centred at 131.7, 210.4, 688.8 and 895.4 °C with the amount of $CO_2$ desorbed of 0.1098, 1.0632, 0.2789 and 0.4242 mmol/g, respectively. Meanwhile, three peaks were observed for the Na-SOD sample which centred at 142.0, 723.5 and 875.5 $^oC$ with the amount of $CO_2$ desorbed of 0.0867, 0.4278 and 0.2946 mmol/g, respectively.

Since the activation temperature of the catalyst for the catalytic study was carried out at 500 °C, thus the amount of $CO_2$ desorbed was compared in the range of temperature below 500 °C. It was observed that at temperature below 500 °C, the amount of $CO_2$ desorbed for the SOD-TO sample was higher than that of the Na-SOD sample. In this study, the peaks with broader width and high peak area for the SOD-TO sample was found at around 300 °C. This suggested that within this range of temperature, more $CO_2$ was desorbed from SOD-TO sample. From the results, at temperature below 500 °C, the amount of basic site for the SOD-TO sample is higher than the Na-SOD sample. This phenomenon should be due to the presence of mesoporosity in the SOD-TO sample that leads to the increase in the basic sites available for $CO_2$ to react. Thus, more $CO_2$ is physically attached within the mesopores channels of the SOD-TO sample. It is also suggested that the interaction of $CO_2$ with the basic site in the mesopore channels is not very strong and can be easily detached at lower temperature



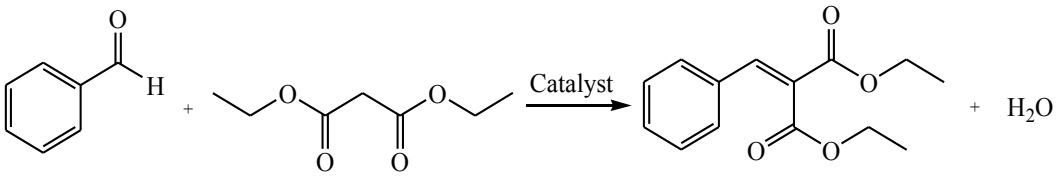


Figure 5. TPD-$CO_2$ analysis for the SOD-TO and Na-SOD samples

**Catalytic activity study**

The catalytic activity of all SOD samples was tested as base catalysts in the reaction Knoevenagel condensation reaction between benzaldehyde and diethyl malonate. The reaction was expected to give an enone which was diethyl-2-benzylidenemalonate as the major product as shown in Scheme 1.

Benzaldehyde Diethyl-malonate Diethyl-2-benzylidenemalonate

Scheme 1. Equation of Knoevenagel condensation reaction between benzaldehyde and diethyl malonate

Since the results of the reaction showed that the reactants were converted into products, it was suggested that all SOD catalysts synthesized in this study were active for the Knoevenagel condensation reaction. As shown in Scheme 1, it was deduced that only one product produced from the reaction. However, two side products were obtained from this reaction. The most probable compounds produced as side products belong to ethyl cinnamate as a major side product and diethyl 2, 2- bis(hydroxy(phenyl)methyl) malonate as a minor side product. The reactivity of the SOD catalysts was studied in term of percentages of conversion and selectivity. Besides, the percentage of yield for all SOD catalysts was calculated based on the major product. The percentages of yield, conversion and selectivity of the SOD catalysts are listed in Table 5. SOD-TO produce the highest percentage of conversion (96.29%) followed by SOD-TDDAB (95.84%), Na-SOD (95.63%), SOD-TDTAB (42.02%) and SOD-TCTAB (13.25%) after 24 hours reaction. The higher percentage conversation of SOD-TO could be due to the higher possibility of reactants to access to the active basic sites present in their mesopores. In addition, the SOD-TO catalyst possessed the higher amount of basicity indicated the higher amount of the active basic sites is available. From Table 5, the SOD-TO catalyst showed the highest percentage of yield for the major product as compared with other SOD catalysts which was 34.80%.

Table 5. Percentages of conversion, selectivity and yield of all SOD catalysts

| Sample | Conversion (%) | Selectivity (%) | | | Yield (%) |
|---|---|---|---|---|---|
| | | Major Product | Major Side Product | Minor Side Product | |
| Na-SOD | 95.63 | 18.66 | 61.05 | 20.29 | 17.84 |
| SOD-TDDAB | 95.84 | 22.88 | 68.11 | 9.01 | 21.93 |
| SOD-TCTAB | 13.25 | 72.30 | 0.91 | 26.79 | 9.58 |
| SOD-TDTAB | 42.02 | 59.83 | 3.15 | 37.02 | 25.14 |
| SOD-TO | 96.29 | 36.14 | 45.66 | 18.20 | 34.80 |

## Conclusion

Mesoporous sodalite (SOD-TO) was successfully synthesized in the presence of tetrapropylammonium hydroxide (TPAOH) and organosilane templates using molar oxide ratio of $1.7SiO_2$: $15NaOH$: $Al_2O_3$: $80H_2O$: 0.3 templates. On the other hand, the rest of sodalite samples synthesized using TPAOH mixed with quaternary ammoniums other than organosilane, only produced microporous sodalite. All the as-synthesized samples showed the XRD patterns of sodalite phase indicating the successful formation of sodalite phase crystal. While, FTIR results revealed that all absorption patterns shown by all the as-synthesized samples are related to the characteristic of sodalite framework. From $N_2$ adsorption analysis, SOD-TO showed the successful formation of mesoporosity contains mesoporous-microporous hierarchical structure with the highest BET surface area. All the as-synthesized sodalite samples

showed the basicity strength in the range: $8.2 \leq pKa \leq 18.4$ with mesoporous SOD-TO sample showed the highest amount of basicity. TPD-$CO_2$ analysis found that the mesoporous SOD-TO sample gave higher strength and amount of basic sites than the Na-SOD sample at temperature below 500°C. The SOD-TO catalyst with the highest amount of basicity and the highest surface area is most active, giving the highest percentages of conversion and yield in the Knoevenagel condensation reaction of benzaldehyde and diethyl malonate.

# PALLADIUM PINCER COMPLEXES AS CATALYSTS FOR SELECTIVE ACTIVATION AND FUNCTIONALIZATION OF 1-PROPANOL

## (Kompleks Paladium Pincer Sebagai Mangkin untuk Pengaktifan dan Pefungsian Terpilih 1-Propanol)

**Abstract**

Selective activation and functionalization of saturated C-H bonds in the original Shilov system used a combination of $PtCl_4^{2-}$ and $PtCl_6^{2-}$ in aqueous solution to transform methane into methanol and/or methyl chloride. On the other hand, palladium phosphinito PCP pincer halides ($PdX\{C_6H_3\text{-}2,6\text{-}(OPr^i_2)_2\}$, X=Cl, Br, I) have been developed for the Heck reactions of aryl halide, and they are believed to operate by an alternative Pd(II)/Pd(IV) mechanism, made this catalyst potentially used for the Shilov type reaction. Palladium pincer complexes showed selectivity for terminal functionalization of 1-propanol at lower temperature. Successful substitution of $PtCl_4$ by the less expensive oxidation system, $CuCl_2$ and air was achieved. In the presence of $CuCl_2$, the Wacker-like oxidation is apparently involved in the reaction. The phosphorous donor palladium pincer complexes showed better activity and selectivity than other types of palladium pincer complexes such as NCN-Pd-Br and SCS-Pd-Cl.

**Keywords**: C-H bonds activation, palladium pincer complexes, 1-propanol, selective functionalization, Shilov system

**Abstrak**

Pengaktifan dan pefungsian terpilih ikatan C-H tepu pada sistem asal Shilov menggunakan kombinasi larutan akueus daripada $PtCl_4^{2-}$ dan $PtCl_6^{2-}$ untuk mengubah metana menjadi metanol dan/atau metil klorida. Selain itu, paladium fosfinito PCP pincer halida ($PdX\{C_6H_3\text{-}2,6\text{-}(OPr^i_2)_2\}$, X=Cl, Br, I) telah digunakan untuk tindak balas Heck daripada aril klorida, dan dipercayai beroperasi melalui mekanisme alternatif Pd(II)/Pd(IV), menjadikan mangkin ini berpotensi untuk digunakan pada tindak balas jenis Shilov. Kompleks – kompleks paladium pincer menunjukkan kepilihan terhadap pefungsian terminal 1-propanol pada suhu rendah. Kejayaan penggantian $PtCl_4$ oleh sistem pengoksidaan yang lebih murah iaitu $CuCl_2$ dan udara telah dicapai. Dengan kehadiran $CuCl_2$, tindak balas pengoksidaan Wacker terlibat secara tidak langsung. Kompleks pincer paladium dengan penderma fosforus menunjukkan aktiviti dan kepilihan yang lebih baik dibandingkan dengan jenis lain dari kompleks paladium pincer, seperti NCN-Pd-Br dan SCS-Pd-Cl.

**Kata kunci**: pengaktifan ikatan C-H, kompleks paladium pincer, 1-propanol, pefungsian terpilih, sistem Shilov

## Introduction

Selective activation and functionalization of C-H bonds in alkanes is one of the biggest challenging problems in chemistry. The abundant saturated hydrocarbons are underutilized and require an efficient method to transform

them into more valuable products [1, 2]. Alkanes are not readily able to participate in chemical reactions because they have no empty orbital of low energy or filled orbital of high energy [3]. Several practical processes can be used to convert alkanes directly into more valuable products. However, they usually require harsh conditions that are difficult to control to prevent conversion of the alkanes into the thermodynamically stable and unattractive products carbon dioxide and water.

It was reported that low valent precious metal complexes will oxidatively add to alkane C-H bonds to give an alkyl hydride. The attempt to activate and functionalize C-H bond of alkanes was first reported by Shilov in 1970 [4]. The reaction has been found to be selective for the least substituted carbon of the alkane. The system which is now known as the "Shilov-system" is platinum catalyzed C-H bond activation and functionalization in aqueous media. In Shilov chemistry, the C-H bond is activated and functionalized by metal complexes with unique selectivity. Activation and functionalization at the terminal position is preferred. The use of 1-propanol as a substrate gives several advantages, it is possible to distinguish whether the pincer complexes catalyze a Shilov-type reaction or if only a Fenton-type reaction occurs. In the Shilov system, the main product would be 1,3-propanediol, while the formation of 1,2-propanediol would indicate that a radical reaction had taken place. Another advantage is that it is miscible in aqueous media. Thus the reactions can be carried out in simple glassware and at atmospheric pressure [5]. The general equation and the proposed mechanism of the reaction are as follow (equation 1 and Figure 1):

$$R\text{-}H + H_2O + PtCl_6^{2-} \xrightarrow[120\ ^oC]{\text{catalyst } PtCl_4^{2-}} R\text{-}OH\ (+\ R\text{-}Cl) + PtCl_4^{2-} + 2HCl \qquad (1)$$

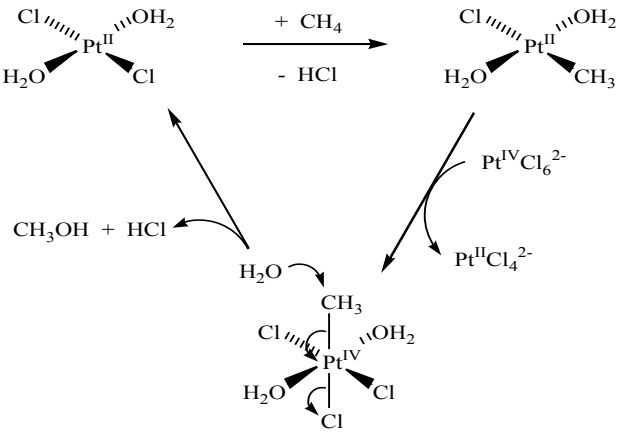

Figure 1. Proposed catalytic cycle for the platinum-catalyzed oxidation of alkanes in aqueous solution

As seen in Figure 1, the C-H activation is catalytic in Pt(II). It is also shown that the Shilov system requires a stoichiometric amount of Pt(IV) as oxidant which is one of the drawbacks of this system. Also, the presence of metallic platinum promotes the over-oxidation of the Shilov reaction's product. Pt(IV) plays dual roles in the reaction, as stoichiometric oxidant and also to prevent the formation of metallic platinum by suppressing the disproportionation of Pt(II), another drawback of the Shilov system [5]. Introducing a strong chelating ligand such as a pincer ligand into the platinum complex would be expected to stabilize Pt(II) from undergoing disproportionation. The use of pincer platinum complexes in the Shilov-type reaction has been reported [6, 7]. The most interesting result is that Pt(IV) can be replaced by the cheaper, $CuCl_2$ oxidant. However, the activity of pincer complexes to catalyze Shilov-type chemistry is reduced upon this substitution [8]. This leads to the exploration of the use of different metal pincer complexes as catalysts.

Previously, in Heck reaction, palladium pincer complexes were proposed to proceeds through Pd(II)/Pd(IV) chemistry rather than the typical Pd(0)/Pd(II) cycles [9]. It is arguable that palladium pincer complexes might proceed through Pd(II)/Pd(IV) cycles when applied in the Shilov-type system in the analogy to the platinum analogs. Here we report the development of palladium pincer complexes as catalysts for alkane hydroxylation. Four types of pincer complexes seen in Figure 2 were tested in the Shilov reaction to see if minor changes in the ligand would have any effect on the catalytic activity. Furthermore, the possibility of using $CuCl_2$ as primary oxidant was also investigated.

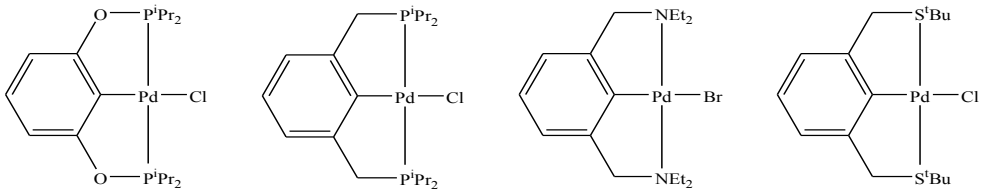

Figure 2. Pincer palladium complexes tested as hydroxylation catalysts

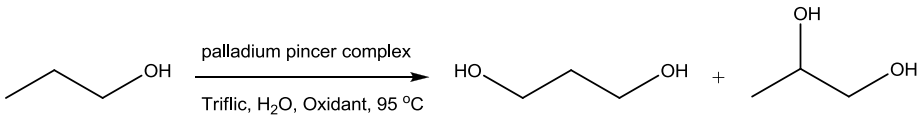
## Materials and Methods

### Materials



$PtCl_4$ (Pressure Chemicals), $K_2PtBr_6$ (Pressure Chemicals), trifluoromethanesulfonic acid (Aldrich), trifluoroacetic acid (Aldrich), acetic acid (Aldrich), 1-propanol (Fisher Scientific), $CuCl_2{\cdot}2H_2O$ (Fisher Scientific), $Cu(OAc)_2.H_2O$ (Fischer Scientific), hydrochloric acid (Aldrich) and hydrogen peroxide (30%, Fisher Scientific) were used as purchased. Complexes **1** [9], **2** [10], **3** [11] and **4** [12] were prepared according to the published procedures.

### Hydroxylation of 1-propanol catalysed by palladium pincer complexes

Water (3 ml), trifluoromethanesulfonic acid or trifluoroacetic acidoracetic acidorhydrochloric acid (3.33 mmol), the complex **1** or other type of palladium pincer complexes (0.18 mmol), and oxidant ($PtCl_4$, $K_2PtBr_6$, $CuCl_2{\cdot}2H_2O$, $Cu(OAc)_2.H_2O$) were added to a round bottom flask equipped with a condenser. 1-propanol was added portion wise over a 4 hours period (4 x 1 ml, total 56 mmol). The flask was heated in the range from 65 to 95 $^oC$ and the mixture was treated dropwise with 30% hydrogen peroxide at the rate of 1.0 to 2.0 ml/hour from a syringe pump. After eight hours, the resulting mixture was analyzed by gas chromatography – mass spectrometry (GC-MS).

## Results and Discussion

In order to test the reactivity of palladium pincer complexes in Shilov type chemistry, the original oxidant, $PtCl_4$, was used coupled with $H_2O_2$ as co-oxidant, as seen on equation 2. De Vries et al. used $H_2O_2$ to oxidized Pt(II) to Pt(IV) in the presence of the strong acid trifluoromethanesulfonic acid [5]. The result is shown on Table 1.

[a]All reactions were carried out in the presence of $PtCl_4$ and $H_2O_2$ unless otherwise noted. The resulting mixtures were analyzed by GC. Nevertheless, the formation of 1,3-diol and 1,2-diol conformed by $^1$H and $^{13}$C NMR [b]TON is the average of three runs. TON=mol of product/(mol of palladium complex + mol of $PtCl_4$) [c] $^{31}$P NMR at 65 ppm corresponds to phosphorous oxide and at 188 ppm corresponds to complex **1**.

The rates of the addition of $H_2O_2$ must be controlled as such to prevent the formation of Pt(0), a black precipitate resulting from the disproportionation of Pt(II), once Pt(IV) is reduced to Pt(II) in the cycle. Apparently, at lower rates of $H_2O_2$, complex **1** quickly underwent redox reaction with $PtCl_4$ but not following the Shilov reaction's pathway as no 1,3-propanediol was formed. Result on 1$^{st}$ entry showed that the rate of $H_2O_2$ at 1 ml/h was not fast enough to oxidize Pt(II) to Pt(IV). The rate of $H_2O_2$ addition to 2 ml/h resulted in the decomposition of complex **1** as shown by $^{31}$P NMR. Slightly reduced rate of $H_2O_2$ addition at 1.9 ml/h resulted in similar yield to that observed previously using the analogous platinum complex as catalyst.

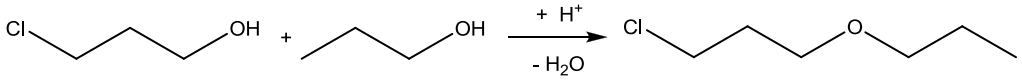
Unlike the platinum analog, the Shilov reaction with the palladium pincer complexes showed ligand dependency. Changing the atom donor from phosphorous to nitrogen or sulphur resulted in poor turnover numbers. Unfortunately, the reaction only lasted 3.5 hours before the PCP pincer complex decomposed into a detectable black precipitate. Blank tests in the presence of $PtCl_4$, entry 7 and 8, confirmed that the product only formed in the presence of the catalyst. Even though the Shilov reaction is dominant, the formation of radical products was also significant as shown by the presence of 1,2-propanediol. The ratio between 1,3-propanediol and 1,2-propanediol is 3:1. It was considered that the higher reaction temperature of 95 $^oC$ might promote the formation of radical products. Experiments carried out at the lower temperature of 65 $^oC$ are presented in Table 2.

Table 2. Hydroxilation of 1-propanol in the presence of complex 1 at 65 $^oC$ [a]

| Entry | Oxidant | Acid | TON | |
|---|---|---|---|---|
| | | | 1,3-diol | 1,2-diol |
| 1 | $PtCl_4$ | Triflic | 3 | 0.8 |
| 2 | $PtCl_4$ | Trifluoroacetic | 3 | 0.8 |
| 3 | $PtCl_4$ | Acetic | 1 | 4 |
| 4 | $PtCl_4$ | Triflic[b] | 2 | 0 |

[a] Reactions were carried out in the presence of $H_2O_2$ as secondary oxidant. TON is the average of three runs. Catalysis with complex **2** showed very similar results with complex **1**. Complex **3** and **4** always decomposed prematurely. [b] In the presence of 1 ml THF

Reducing the temperature resulted in reduced solubility of $PtCl_4$ compounds and in turn gave less turnover number. Introducing different acids was done to solve this problem with no success. However, a new conclusion was made that in the presence of acetic acid more radical product was formed.



A critical drawback with the Shilov reaction is the use of expensive Pt metal as oxidant. Substituting Pt with another cheaper redox metal is desirable. The best candidate was $CuCl_2$. In the catalytic reaction of the Wacker process, $CuCl_2$ is widely known to do redox reactions with Pd [13, 14]. Introducing $CuCl_2$ to the reaction almost did not result in any type of products as shown in Table 3. Apparently $H_2O_2$ oxidized the catalyst at a higher rate than the redox reaction between $CuCl_2$ and palladium pincer complexes. Introducing another source of copper, $Cu(OAc)_2$, resulted in a very significant turnover number of products. However, as mention earlier, acetic ion promotes the formation of radical reaction as more than twice as much 1,2-propanediol was formed.

Table 3. Impact of copper salt in the presence of complex 1[a]

| Entry | Oxidant | Additive | TON[b] | |
|---|---|---|---|---|
| | | | 1,3-diol | 1,2-diol |
| 1 | $CuCl_2$ | Triflic | Trace | - |
| 2 | $Cu(OAc)_2$ | Triflic | 15 | 45 |
| 3 | $Cu(OAc)_2$ | Trifluoroacetic | 17 | 41 |
| 4 | $Cu(OAc)_2$ | Acetic | Trace | Trace |
| 5 | $Cu(OAc)_2$ | - | Trace | Trace |

[a] Reactions were carried out in the presence of $H_2O_2$ at 0.5 ml/h. The temperature of the reactions was 65 $^oC$. [b] TON is the average of three runs. TON = mol of diol/mol of palladium complex. Similar results were showed by complex **2.** Complex **3** and **4** produced only trace amount of product

Information from the Wacker system led to a better understanding of the Shilov reaction in the presence of palladium pincer complexes and $CuCl_2$ [13, 14]. The reaction was then carried out in the presence of $CuCl_2$, water, HCl and at temperature of 65$^oC$ to give two kinds of products 1,3-propanediol and 3-chloro-1-propanol. However, the GC spectrum showed neither one of those expected products. Instead, one very dominant peak appeared at a higher retention time as shown in Figure 3. Mass spectrum fragmentation study showed that the compound at 10.46 minutes is a chloro compound. The compound at 10.46 minutes has m-1 at 135. Apparently 3-chloro-1-propanol compound was formed but in the acidic solution it quickly reacts with the starting material to form an ether compound, as seen on equation 3.

(3)

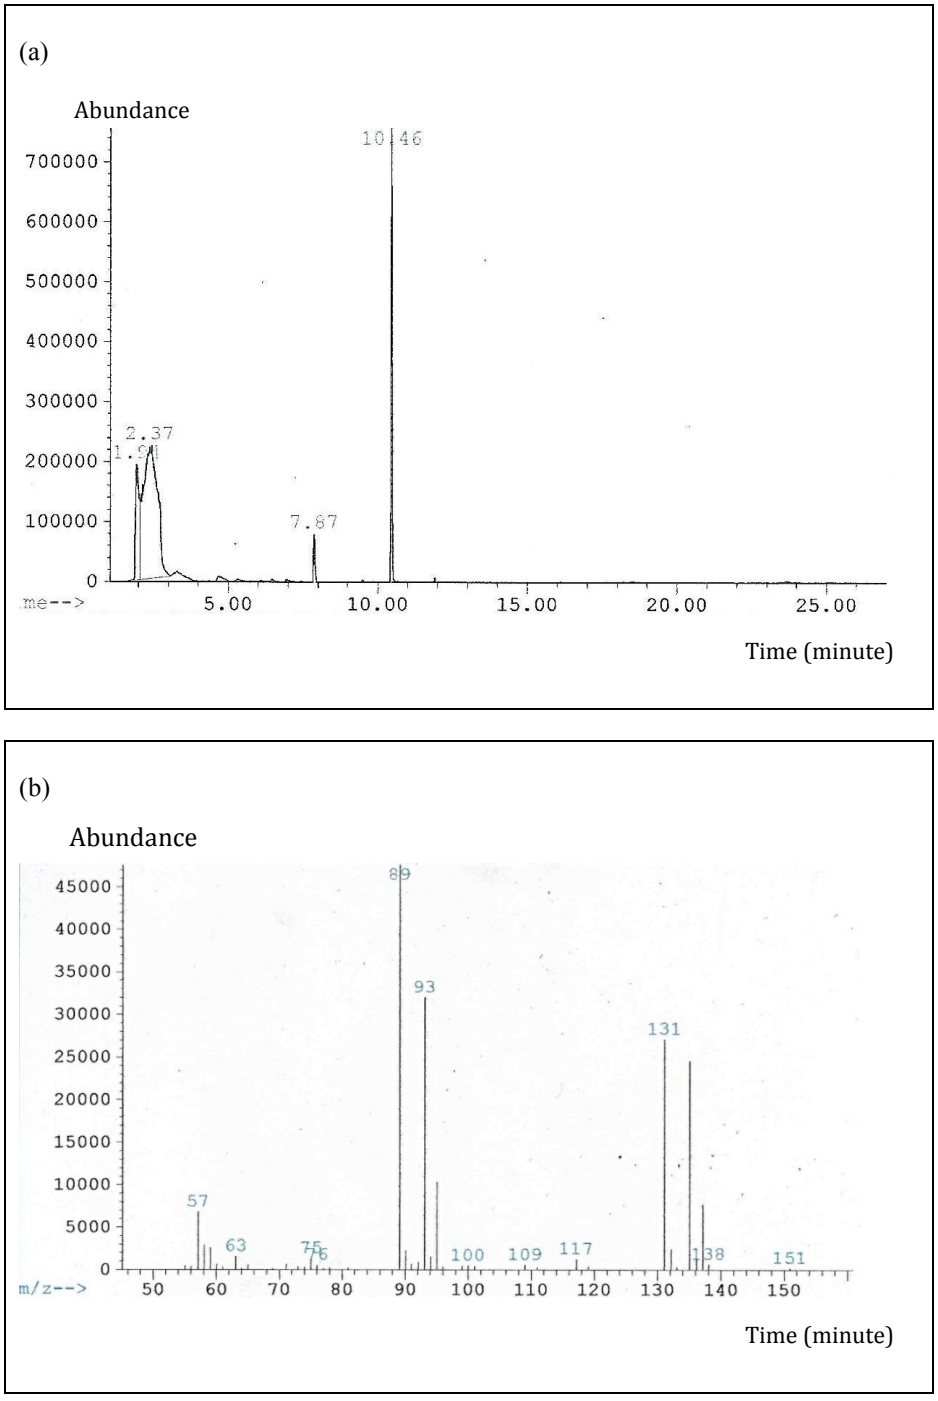


Figure 3. GC spectrum of (a) the Wacker-type reaction of hydroxylation of 1-propanol and (b) the mass spectrum of ether complex at retention time of 10.46 minutes

The appearance of ether in the products led to a conclusion that there is a Lewis acid present in the solution, as alcohol would be converted to ether in the presence of a strong acid or Lewis acid [15]. Figure 3(b) features a peak

at 93 that belongs to the 3-chloro-1-propanol which also results from loss of 43 molecular mass or a fragment of $CH_3CH_2CH_2$-. Detailed on mass fragmentation of ether compound can be seen Figure 4 below.

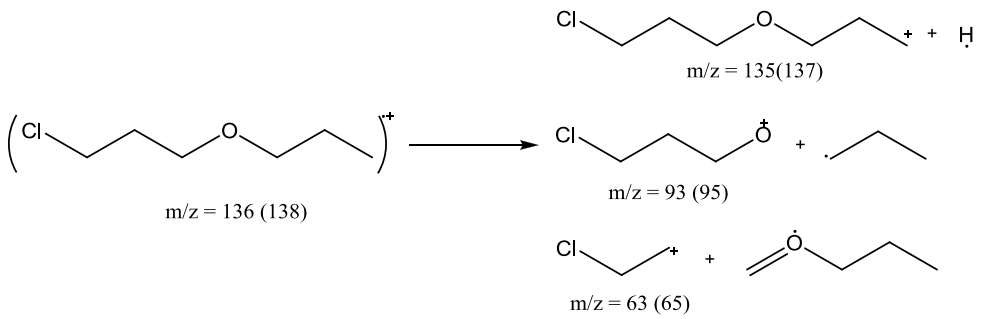

Figure 4. Detailed on mass fragmentation of ether compound

Experiments showed that the ether compound can be obtained in the presence of HCl and $CuCl_2$ or complex **1**, suggesting that complex **1** acts as a catalyst in Shilov type chemistry as well acting as a Lewis acid [16]. Therefore, reducing the catalyst loading, consequently reducing the amount of Lewis acid, was expected to reduce the rate of formation of ether. Figure 5 shows the result from reaction with lower catalyst loading of complex 1.

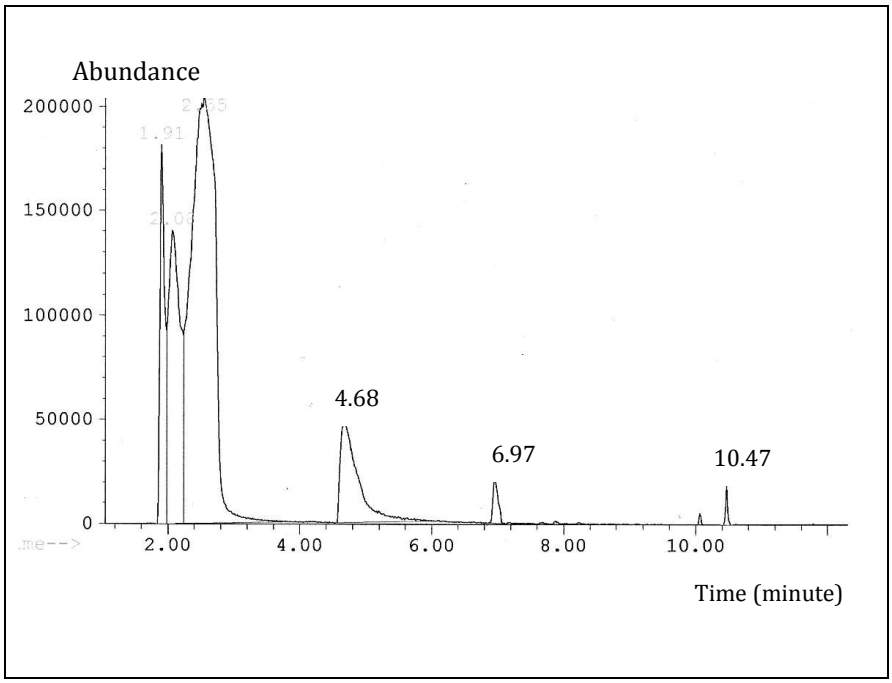

Figure 5. Hydroxylation of 1-propanol at lower catalyst loading

The peak at 4.68 minutes is 3-chloro-1-propanol complex with turnover number of 23. This is the highest turnover number that was attained in all of the Shilov-type experiments with palladium pincercomplexes. Furthermore, this condition was the best in terms of not producing radical reactions. The dominance of 3-chloro 1-propanol in the products suggests that in the presence of $CuCl_2$, the nucleophilic attack by $OH^-$ is less effective. This phenomenon is also known in the Wacker process where use of $CuCl_2$ as oxidant instead of CuCl results in product dominated by

chloro compound [17]. One concern with using $CuCl_2$ and HCl system in our reaction is that since the dominant product is the chloro compound and the source of chloride in the system is either $CuCl_2$ or HCl or both, then as the reaction progresses, the concentration of $CuCl_2$ or HCl will decrease. Less $Cl^-$ might reduce the re-oxidation of Cu(I) complex into Cu(II) complex, and eventually slow down the reaction.

## Conclusion

Palladium pincer complexes are catalysts for Shilov-type chemistry by showing selectivity for terminal functionalization of 1-propanol at lower temperature. A cheaper alternative oxidant $CuCl_2$ and air was successfully applied, adapted from the Wacker process. The phosphorous palladium pincer complexes showed better activity and selectivity than other types of palladium pincer complexes such as NCN-Pd-Br and SCS-Pd-Cl.

Lanthanum oxide based catalyst was revealed as one of potential catalyst to convert carbon dioxide to wealth product methane in simulated natural gas. To produce higher conversion of carbon dioxide, the Response Surface Methodology utilizing Box-Behnken design (BBD) was used to optimize the lanthanum oxide based catalysts by three critical parameters which were calcination temperature, based ratio and catalyst dosage. The maximum $CO_2$ conversion was achieved at 1000 $^oC$ calcination temperature using 7 g of catalyst for 60% based loading. The optimization result from BBD is in good agreement with experimental data. The optimize parameters gave 99% of $CO_2$ conversion determined using Fourier Transformation Infrared (FTIR) and yielded about 50% of $CH_4$ at reaction temperature of 400 °C. X-ray Diffraction (XRD) analysis showed an amorphous structure with $RuO_2$ as active species and Field Emission Scanning Electron Microscope (FESEM) illustrated the catalyst surface was covered with small and dispersed particles with undefined shape. EDX analysis revealed that when the calcination temperature was increased, the mass ratio of Ru increased.

**Keywords**: Box-Behnken design, optimization, response surface methodology, lanthanum oxide

**Abstrak**

Mangkin asas lanthanum oksida adalah salah satu mangkin berpotensi menukarkan karbon dioksida kepada produk metana yang banyak dalam simulasi gas asli. Untuk menghasilkan penukaran karbon dioksida yang tinggi, kaedah gerak balas permukaan menggunakan reka bentuk Box-Behnken (BBD) untuk mengoptimumkan mangkin asas lantanum oksida oleh tiga parameter kritikal yang mana suhu kalsin, nisbah asas, dan dos mangkin. Maksimum penukaran $CO_2$ dicapai pada suhu kalsin 1000 $^oC$ menggunakan 7 g mangkin untuk 60% nisbah asas. Keputusan pengoptimuman dari BBD adalah selari dengan data eksperimen. Parameter yang optimum memberikan 99% penukaran $CO_2$ apabila ditentukan menggunakan Inframerah transformasi Fourier (FTIR) dan menghasilkan 50% metana pada suhu tindak balas 400 $^oC$. Analisis pembelauan sinar-X (XRD) menunjukkan struktur amorfus dengan $RuO_2$ sebagai aktif spesis dan Mikroskop Imbasan Elektron Pancaran Medan ( FESEM ) menunjukkan permukaan mangkin diselaputi dengan partikel yang bersaiz kecik dan terserak sekata tanpa bentuk. Analisis EDX menunjukkan apabila suhu kalsin meningkat, nisbah jisim Ru meningkat.

**Kata kunci:** reka bentuk Box-Behnken, pengoptimuman, kaedah gerak balas permukaan, lantanum oksida

## Introduction

Nowadays, industrial pollution control has facing challenges when industrial demands have been increased which would affect the environment and social sustainability. Therefore, new technologies are needed to reduce $CO_2$ emission at high efficiency to meet the requirement of Kyoto Protocol which has limited the greenhouse gas

emission to the environment. Natural gas is one of demanding industrial request for the fuel transportation. However, the higher percentage of $CO_2$ content in natural gas has been decreased the quality and price of natural gas.

Recently, the removal of these sour gases via chemical conversion techniques becomes the most promising technique. Catalysts for the $CO_2$ methanation have been extensively studied because of their application in the conversion of $CO_2$ gas to produce methane, which is the major component in natural gas [1]. Methanation of carbon dioxide is the reaction for chemical fixation of carbon dioxide that is considerably faster than the reactions to form other hydrocarbons or alcohols. Thus, the methanation reaction is suited for treating a huge amount of carbon dioxide [2]. Besides, methanation has received attention from a viewpoint of environmental protection because the emission of $CO_2$ in the atmosphere brings about global warming by the greenhouse effect and these harmful gases can simultaneously be converted to useful methane gas [3]. This process can increase the purity and quality of the natural gas without wasting the undesired components but fully used them to produce high concentration of methane.

From the previous study, trimetallic Ru/Co/La (5:35:60)/$Al_2O_3$ calcined at 1000 $^oC$ showed a promising performance with 99% of $CO_2$ conversion and 50% $CH_4$ formation [4]. This observation showed that $La_2O_3$ is able to increase adsorption of $CO_2$ to the surface of catalyst. Other than that, Wan Abu Bakar et al. also reported that when cobalt oxide doped with noble metal (platinum), it gives higher $CO_2$ conversion with 70% and yielded 47% methane [5]. This can be concluded that noble metal would increase the cobalt reducibility in catalyst supported on alumina [6]. Therefore, in this paper, the potential catalyst was optimized to determine the optimum parameters for Ru/Co/La (5:35:60)/$Al_2O_3$ to obtain higher $CO_2$ conversion and $CH_4$ formation by using Box-Behnken design.

## Materials and Methods

### Catalyst preparation

Wet impregnation method was used to prepare $Al_2O_3$ supported catalyst by impregnating the catalyst solution on $Al_2O_3$ beads support. Then, alumina beads with diameter of 3 mm was immersed into the catalysts solution for 20 minutes and it was then dried at 80 $^oC$ for 24 hours and calcined at 400 $^oC$, 700 $^oC$, 900 $^oC$, 1000 $^oC$, and 1100 $^oC$ for 5 hours. For catalytic activity measurements, reactions of methanation were performed from ambient temperature up to 400 $^oC$ with temperature rate of 5 $^oC$/ min. $CO_2$ and $H_2$ gases were introduced into the reactor system in a stoichiometric ratio of 1:4. Screening on the product gas stream was done by using FTIR analysis.

### Characterization

The surface morphology and physical properties of the catalysts were characterized by Field Emission Scanning Electron Microscope (FESEM) – Energy Dispersion X-ray (EDX), and X-ray Diffraction (XRD). The surface morphology of the samples was analyzed using Zeiss Supra 35VP FESEM with the energy of 2.0 kV and 50 000 x magnification couple with EDX analyzer and 1500x magnification. Prior to the analysis, the sprinkled sample was coated with gold as conducting material by gold sputter at $10^{-1}$ Mbar using Bio Rad Polaron Division SEM coating system machine. The XRD patterns of the powder samples were recorded at 2θ between $10^o$ to $80^o$ using a Bruker Advance D8 with Siemens 5000 diffractometer. The Cu $K_\alpha$ radiation operates at 40 kV and 40 mA with $\lambda = 1.5418$ Å.

### Design of experiment

A three variables Box-Behnken design for response surface methodology were used to study the effect of calcination temperature ($^oC$), Based loadings (%), and catalyst dosage (g) on catalytic activity of methanation reaction using Design Expert Software, version 7.1 (Stat-Ease Inc., USA). Analysis of variance, ANOVA, is a statistical decision-making tool used for detecting any differences in average performances of tested parameters [7]. Analysis of variance (ANOVA) was used to check the adequacy of the model for the responses in the experimentation.

## Results and Discussion

### Characterization: X-ray diffractogram analysis for lanthanum oxide based catalyst

Figure 1 shows the diffractogram of Ru/Co/La (5:35:60)/$Al_2O_3$ calcined at 400 °C, 700 °C, 900 °C, 1000 °C and 1100 °C. XRD diffractogram for calcination temperature of 400 ºC showed very low degree of crystallinity and an amorphous phase. This could be attributed to the alumina support which can be assigned at $2\theta$ of 66.47 ° ($I_{100}$) as $Al_2O_3$ with cubic phase. Tang et al. claimed that the support only exhibits broad diffraction peaks when calcined at below 500 ºC [8].

For Ru/Co/La (5:35:60)/$Al_2O_3$ calcined at 700 °C, the diffractogram also showed an amorphous peak indicating the atom are arranged almost in a regular pattern. At calcination temperature of 700 °C, three peaks of $Al_2O_3$ with cubic phase were appeared at $2\theta$ = 45.83 ° ($I_{100}$), 66.97 ° ($I_{100}$), and 60.45 ° ($I_{75}$). Furthermore, at 900 °C calcination temperature exhibited of $Al_2O_3$ cubic phase which could be observed at $2\theta$ values of 67.034º ($I_{100}$), 45.863º ($I_{100}$), and 37.604º ($I_{80}$). The shifting peaks occurred due to decrease lattice spacing parameter which can be supported by decreasing lattice value from 0.991 Á (110) to 0.246 Á (440) [9]. The peaks for cobalt oxide were only observed at 32.173º ($I_{662}$). Formation of new peak which belong to $RuO_2$ with tetragonal phase were revealed at the $2\theta$ values of 28.135º ($I_{999}$), and 35.793º ($I_{751}$).The diffractograms of catalyst calcined at 1000 °C and 1100 °C exhibited similar peaks with the catalyst calcined at 900 °C. Nevertheless, the diffractogram of catalyst calcined at 1100 °C showed few new peaks. Three of them were at $2\theta$ values of 33.958º, 36.146º, and 42.741º which were assigned to the lanthanum aluminium oxide with hexagonal phase. Other peaks corresponding to the alumina corundum with rhombohedral phase could be observed at $2\theta$ values 43.347º and 57.492º. From the overall diffractograms, it could be suggested that the calcination temperature affects the performance of catalytic activity by increasing of crystal lattice in order to produce narrower peaks [10].

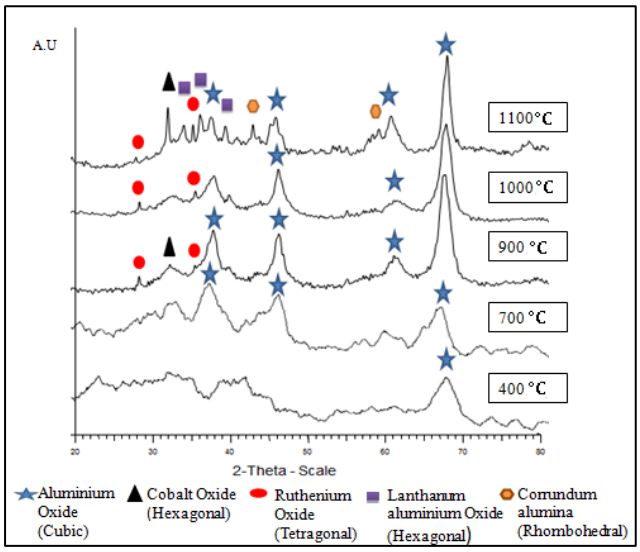

Figure 1. Diffractogram of various calcination temperatures of Ru/Co/La (5:35:60)/$Al_2O_3$ catalysts

### Field emission scanning electron microscope analysis for lanthanum oxide based catalyst

The micrographs of the supported catalysts showed a rough surface morphology. In general, there was no significant change in morphologies for the entire sample after calcination. A typical FESEM micrograph for Ru/Co/La (5:35:60)/$Al_2O_3$ sample is illustrated in Figure 2. From the micrograph in Figure 2, the surface particles of the fresh catalyst agglomerated, possibly due to the calcination process. The particles were in spherical shape. It was also noted that the pore of the catalyst is slightly visible. When it is small particle, the surface area is higher thus, adsorption process easy to occur. This is in a good agreement with the XRD analysis which exhibited very broad peaks denoting an amorphous character for the Ru/Co/La (5:35:60)/$Al_2O_3$ catalyst. Nevertheless, the catalyst Ru/Co/La (5:35:60) /$Al_2O_3$ calcined at 1100 °C showed many square shaped particles were formed on

the catalyst surface. This square shaped was belong to $Al_2O_3$ rhombohedral phase as shown in the XRD diffractogram in Figure 1 as similarly discussed by Mat Rosid et al. [4].

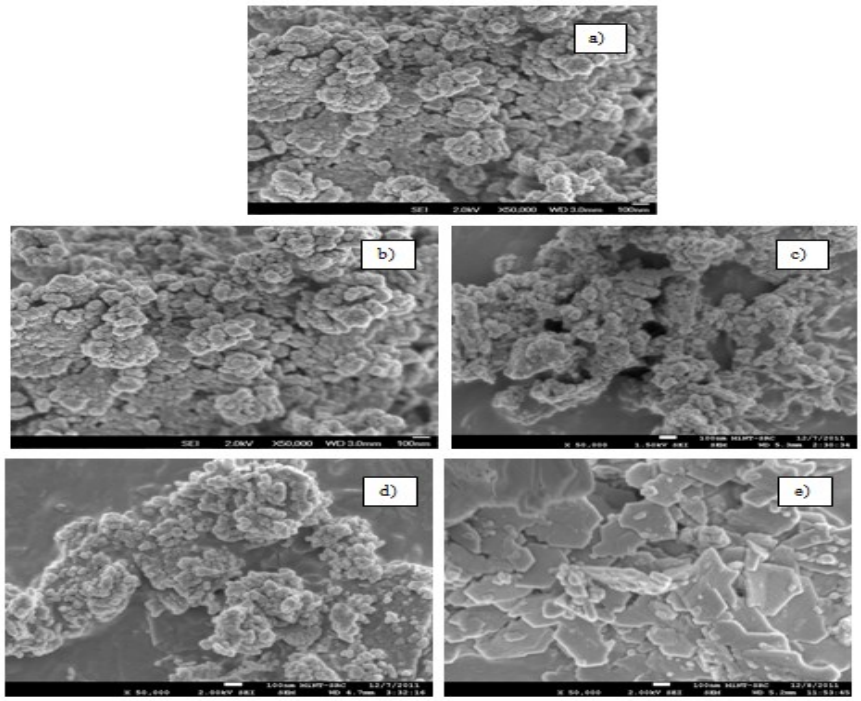

Figure 2. FESEM micrographs of Ru/Co/La (5:35:60)/$Al_2O_3$ catalyst calcined at a) 400 $^oC$, b) 700 $^oC$, c) 900 $^oC$, d) 1000 $^oC$ and e) 1100$^oC$ for 5 hour in 50000x magnification

**Energy dispersive X-ray analysis for lanthanum oxide based catalyst**

Table 1 shows the elemental composition of the EDX analysis for Ru/Co/La (5:35:60)/$Al_2O_3$ catalyst calcined at 400 $^oC$, 700 $^oC$, 900 $^oC$, 1000 $^oC$ and 1100 $^oC$. From the table, it was observed that atomic ratio of Al is quite high which suggested that the catalyst surface is dominated by the Al from the support. The entire elements were detected on the catalyst surface. At 1000 $^oC$ calcination temperature, the La and Co revealed the higher atomic ratio compared to Ru. It might due to Ru have been incorporated into the pore of alumina. Although the tiny amount of atomic mass of Ru on the catalyst surface, it still enhances the high catalytic activity towards methanation reaction [11].

Table 1. Elemental composition from EDX analysis at various calcination temperatures for 5 hours

| **Calcination Temperature ($^oC$)** | **Atomic Ratio (%)** | | | | |
|---|---|---|---|---|---|
| | **Al** | **O** | **La** | **Co** | **Ru** |
| 400 | 35.72 | 44.14 | 4.58 | 1.69 | 0.13 |
| 700 | 36.48 | 42.68 | 3.16 | 1.81 | 0.35 |
| 900 | 36.89 | 52.47 | 5.94 | 1.89 | 0.40 |
| 1000 | 32.83 | 20.73 | 11.45 | 7.38 | 0.42 |
| 1100 | 43.96 | 40.28 | 8.57 | 5.56 | 0.47 |

**Catalytic activity measurement: Effect of calcination temperature**

From the catalytic screening of $CO_2$ conversion, the potential catalysts which was Ru/Co/La/$Al_2O_3$ catalyst was proceed with different calcination temperatures to elucidate the optimum calcination temperature on the potential catalyst. The catalytic activity is summarized in Table 2. The Ru/Co/La/$Al_2O_3$ catalyst showed an increasing catalytic activity with Co as a dopant with increasing calcination temperature. It was possibly due to the Ru enhance the dispersion of Co on the catalyst surface. It also has been reported by Kok et al. that $La^{3+}$ promotes for the formation of new active sites while Ru could increase the degree of Co reduction and this improve the catalytic activity [12]. According to Perego and Villa, calcination process would give some effects towards the catalyst such as loss of chemically bonded water or CO, modified the texture and structure through sintering, generate active phase and stabilize the mechanical properties [13].

Table 2. Percentage conversion of $CO_2$ in $CO_2/H_2$ methanation reaction catalyzed by lanthanum oxide based catalysts with dopant (Co) and co-dopant (Ru) after calcined at different temperatures for 5 hours

| **Catalyst** | **Calcination Temperature (°C)** | **Reaction Temperature (°C)** | | | | | |
|---|---|---|---|---|---|---|---|
| | | **100** | **200** | **250** | **300** | **350** | **400** |
| | | **% Conversion of $CO_2$** | | | | | |
| Ru/Co/La (5:35:60)/$Al_2O_3$ | 400 | 2.18 | 14.69 | 25.62 | 29.45 | 30.79 | 32.89 |

**Effect of based loadings**

The plot effect of based loadings is shown in Figure 3. The results obtained showed that when the based loading of La was increased, the $CO_2$ conversion was decreased. This might due to excessive amount of La has been blocking the active surface on catalyst. This re supported with He et al. 2011 [14] and Mat Rosid et al. 2015 [15] which have stated that excessive amount of based loading will enhance the particle to nucleate which will inhibit the growth of crystal on active site. Therefore, the optimum based loading was obtained at 60%.

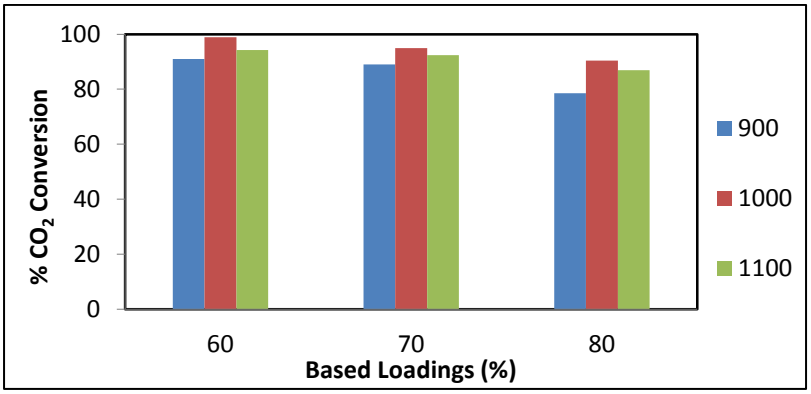

Figure 3. Catalytic performance of $CO_2$ conversion from methanation reaction over Ru/Co/La/$Al_2O_3$ catalyst calcined at 900 °C, 1000 °C and 1100 °C for 5 hours with various based loadings

**Effect of catalyst dosage**

Catalyst dosage is one of the parameter that affects the catalytic activity. Figure 4 shows that when the catalyst dosage is increase, the $CO_2$ conversion is increased. This is in agreement with Londhe and Gupta study which stated that when the catalyst dosage is increased, the fraction of the gases adsorbed over catalyst surface and the reaction products formed is increased [16].

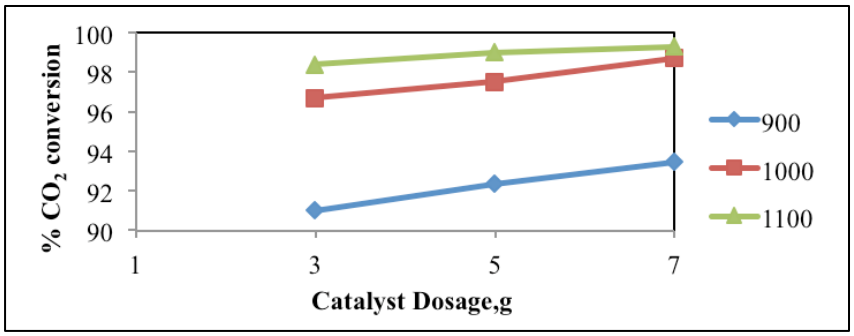

Figure 4. Catalytic performance of $CO_2$ conversion from methanation reaction over $Ru/Co/La/Al_2O_3$ catalyst calcined at 900 $^oC$ , 1000 $^oC$ and 1100 $^oC$ for 5 hours with various catalyst dosages

**Methane gas formation**

The formation of methane over the potential catalyst showed low percentage of methane at lower temperature which yielded 2.74% and 8.51% at 200 $^oC$ and 250 $^oC$, respectively. However, when the reaction temperature reached 300 $^oC$, the percentage formation of methane yielded 43.40% of $CH_4$. The increased of methane formation was 50% at 400 $^oC$ reaction temperature as discussed by Mat Rosid et al. [4].

**Statistical analysis: Box-Behnken design**

The selection of levels was carried out based on the results obtained in the preliminary study. Table 3 shows the experiment design for $CO_2$ conversion with 17 runs of experiment. The predicted values are accordance with actual value from the experimental data. Results obtained after carrying out ANOVA is presented in Table 4. The Model F-value of 122.87 implies the model was significant. Values of "Prob > F" less than 0.0500 indicate model terms are significant. In this case A, B, $A^2$, $B^2$ are significant model terms. Values greater than 0.1000 indicate the model terms are not significant. From the ANOVA, it can be observed that catalyst dosage (c) is not a significant model terms. This can be supported from the experimental data which showed that the $CO_2$ conversion (Figure 4) does not highly differ for each catalyst dosage. The "Lack of Fit F-value" of 0.28 implies the Lack of Fit is not significant relative to the pure error. Non-significant lack of fit is good.

To modify regression model accuracy, the ultimate model equation in terms of coded factors after excluding the insignificant items was obtained as follows:

$$CO_2 \text{ conversion} = 93.46 + 1.48A - 2.25B - 0.18C - 1.47AB - 0.22AC - 0.66BC - 2.26A^2 + 1.43B^2 + 1.17C^2$$

**Optimization of parameters by Box-Behnken design**

The optimization of critical parameters was run to obtain highest $CO_2$ conversion by using numerical hill-climbing algorithms. The $CO_2$ conversion was set to 99% and all parameters was kept in range. The optimum parameters were verified experimentally and it give almost exact value of $CO_2$ conversion as suggested by Box-Behnken design.

## Conclusion

The Box-Behnken design was successfully applied for the optimization of catalytic methanation reaction to give the optimum parameters to obtain highest $CO_2$ conversion. The maximum $CO_2$ conversion was achieved at 1000 $^oC$ calcination temperature using 7 g of catalyst for 60% based loading. The optimize parameters gave 99% of $CO_2$ conversion determined using FTIR and yielded about 50% of $CH_4$ at reaction temperature of 400 °C. The active species in this methanation reaction was $RuO_2$ as observed in X-ray Diffraction (XRD) analysis and Field Emission Scanning Electron Microscope (FESEM) illustrated the catalyst surface was covered with small and dispersed particles with undefined shape. EDX analysis revealed that when calcination temperature increased, the mass ratio of Ru increased.

# SYNTHESIS OF ZnO/rGO NANOHYBRID FOR IMPROVED PHOTOCATALYTIC ACTIVITY

## (Sintesis Nanohibrid ZnO/rGO Untuk Mempertingkatkan Aktiviti Fotopemangkinan)

**Abstract**

Nanohybrids of zinc oxide/reduced graphene oxide (ZnO/rGO) with varying graphene oxide content were prepared via precipitation and were subsequently utilised in the photodegradation of methyl orange (MO) under UV light irradiation. The prepared photocatalysts were characterized by X-ray Diffraction (XRD), Field Emission Scanning Electron Microscopy (FESEM), Transmission Electron Microscopy (TEM) and Raman spectroscopy. The surface area and the band gap energy of the photocatalysts were determined by the Brunauer-Emmett-Teller method and UV-visible spectroscopic analysis. The ZnO/rGO nanohybrids produced had smaller particle sizes and lower band gap energy than that of ZnO. All the ZnO/rGO nanohybrids demonstrated better photocatalytic efficiency in the photodegradation of MO compared to ZnO. ZnO/rGO10 exhibited the highest photocatalytic activity with a rate constant that was four times higher than pure ZnO and about 40% enhancement in the photocatalytic activity for the removal of methyl orange within 3 hours. The enhanced photocatalytic performance of the ZnO/rGO photocatalysts was due to the efficient transfer of photogenerated electrons to the graphene sheet that inhibited the recombination of electron-hole pairs.

**Keywords**: zinc oxide, reduced graphene oxide, nanohybrid, precipitation method, photocatalysis

**Abstrak**

Nanohibrid zink oksida/grafin oksida terturun (ZnO/rGO) dengan kandungan grafin oksida yang berbeza telah disediakan melalui kaedah pemendakan dan seterusnya digunakan dalam fotodegradasi metil jingga (MO) di bawah sinaran cahaya UV. Fotopemangkin yang disediakan telah dicirikan dengan menggunakan pembelauan sinar-X (XRD), mikroskopi pengimbasan elektron (FESEM), mikroskopi transmisi elekron (TEM) dan spektroskopi Raman. Luas permukaan dan tenaga jurang jalur fotomangkin telah ditentukan menggunakan kaedah Brunauer-Emmett-Teller dan analisis spektroskopi UV-sinar nampak. Nanohibrid ZnO/rGO yang terhasil mempunyai saiz zarah yang lebih kecil dan tenaga jurang jalur yang lebih rendah berbanding dengan ZnO. Nanohibrid ZnO/rGO mempamerkan kecekapan fotopemangkinan yang lebih tinggi dalam fotodegradasi MO berbanding dengan ZnO. ZnO/rGO10 mencatatkan aktiviti fotopemangkinan yang tertinggi dengan pemalar kadar empat kali ganda lebih tinggi daripada ZnO dan peningkatan 40% dalam aktiviti fotopemangkinan degradasi metil jingga dalam masa 3 jam. Peningkatan prestasi fotopemangkinan pemangkin ZnO/rGO adalah disebabkan oleh kecekapan pemindahan fotojanaan elektron ke lembaran grafin yang seterusnya menghalang penggabungan semula pasangan elektron-lubang.

**Kata kunci:** zink oksida, grafin oksida terturun, nanohibrid, kaedah pemendakan, fotopemangkinan

## Introduction

Water pollution due to effluents from textile industries, especially dyes is a cause of serious concern. It is estimated that 1% to 15% of the dye is lost during the dyeing processes which is subsequently released into natural water resources and the wastewater system [1]. When released into the water, dyes may change the colour of the water, impact light penetration and reduce the solubility of gases [2].This in turn, has a serious impact on the aquatic ecosystem. Dyes are also stable and difficult to be biodegraded due to their synthetic origins and complex aromatic structures [3]. Hence, it is important to treat water resources and wastewaters containing such organic pollutants. Photocatalysis has long been introduced as a means of water decontamination [4]. Photocatalysis involves utilizing electron- hole pairs generated upon the irradiation of light to degrade organic molecules adsorbed on the surface of the photocatalyst [5]. This green technique can be performed in an ambient environment and may also oxidize organic carbon into carbon dioxide [6].

The use of zinc oxide (ZnO) as a photocatalyst has several advantages including a low production cost, wide band gap (~3.37 eV), high stability and catalytic activity, better sensitivity in UV light and the presence of its many active sites with high surface reactivity [7-9]. However, the fast recombination of the electron-hole pairs of ZnO has limited its catalytic efficiency [10]. Recently, many attempts have been carried out to enhance the performance of ZnO photocatalysts by modifications with noble metal loading, ion doping or the incorporation of electron-accepting materials to extend the light absorption range to the visible light region or to suppress the electron–hole recombination process [11].

Graphene, a two-dimensional (2D) single-layered carbon sheet with an $sp^2$ network of carbon atoms has excellent conductivity, good chemical stability, mechanical flexibility, a high mobility of charge carriers and a large specific surface area [12].These properties enable graphene to be an ideal support in combination with semiconductor photocatalysts. Graphene can be prepared by reducing graphene oxide (GO) [13]. The presence of oxygen-containing functional groups on the surface of the reduced graphene oxide (rGO) also makes graphene an excellent supporting material by anchoring strongly to the metal oxide nanostructure [14, 15].

Many methods have been used to fabricate ZnO photocatalysts hybridised with rGO, including solvothermal [16], chemical deposition [11], hydrothermal [15, 17, 18] and sol- gel [19] methods. Herein, we report a simple precipitation method to prepare ZnO/rGO nanohybrids with zinc acetate dihydrate and graphene oxide (GO) as the starting materials, and ammonia as both the precipitator and reductant. This study is focused on determining the effect of rGO on the structure and photocatalytic activity of ZnO.

## Materials and Methods

### Materials

Zinc acetate dihydrate ($(CH_3COO)_2Zn.2H_2O$) and 25% ammonia solution ($NH_3$) were purchased from Merck. Methyl orange (MO) ($C_{14}H_{14}O_3N_3SNa$), a model pollutant, was obtained from Bendosen. All chemicals were used without further purification.

### Synthesis of graphene oxide

GO was synthesized using a modified Hummers method [20]. In a typical experiment, graphite flakes, $H_2SO_4$:$H_3PO_4$ (320:80 ml) and $KMnO_4$ (18g) were mixed together under magnetic stirring. The mixture was stirred for 3 days to allow the oxidation of graphite, where the colour of the mixture changed from dark purplish green to dark brown. The colour of the mixture changed to bright yellow after the addition of $H_2O_2$ solution. The graphite oxide formed was washed three times with 1M HCl aqueous solution and repeatedly with deionized water using a centrifugation force of 10,000 g until wash-water with a pH of 4 – 5 was obtained.

### Preparation of ZnO/rGO nanohybrid photocatalyst

The ZnO/rGO nanohybrid was synthesized by mixing 10 ml of 1mg/ml GO with 100 ml 0.3M zinc acetate dihydrate solution followed by the addition of ammonia solution until a pH 10 of was achieved. The precipitate was later filtered and washed several times with deionised water and dried overnight in an oven at 100 °C. The dried powder was then calcined at 400 °C for 2 hours and labelled as ZnO/rGO10. In order to study the effect of GO content on the physicochemical properties and photocatalytic activity, three different nanohybrids were prepared by

changing the initial volume of the GO solution. ZnO/rGO nanohybrids with a volume ratio of 5:100, 10:100 and 20:100 of GO and Zinc acetate dihydrate solution were denominated as ZnO/rGO5, ZnO/rGO10 and ZnO/rGO20. For comparison, pure zinc oxide (ZnO) was also obtained using the same method without adding any GO.

**Characterization**

The phase and crystallinity of the samples were analysed using Philips PW 3040/60 MPD X-ray diffractometer with Ni-filtered $CuK_{\alpha}$ radiation. The X-ray diffraction (XRD) pattern were recorded in the 2θ range of 20° - 80° at a scanning rate of 2°/min. The surface morphology of the samples was studied using Field Emission Electron Microscopy (FESEM) (FEI Nova Nanosem 230 combined with EDX) and Transmission Electron Microscopy (TEM) (Hitachi H-7100). The surface area of the samples was determined using a BET surface area analyzer (BELSorp Mini II). Raman spectroscopy (WITec Alpha 300R) was used to study the disordered crystal structure of the carbon based material and to confirm the presence of rGO. Diffuse reflectance spectra were recorded using a Shimadzu UV-3600 spectrophotometer in order to determine the band gap energy of the prepared samples.

**Photocatalytic activity experiment**

The photocatalytic performance of the prepared photocatalysts was evaluated in the photodegradation of methyl orange (MO) under the illumination of a 6W UVA lamp for 3 hours. In a typical experiment, 0.5g of photocatalyst was suspended in a photoreactor containing 500 ml of MO solution (10 ppm). The resultant solution was magnetically stirred in the dark for 30 minutes to reach an adsorption-desorption equilibrium prior to UV irradiation. An amount 5 ml of test samples were taken at predetermined time intervals and were immediately filtered with a 0.45 µm cellulose nitrate filter. The concentration of MO in the test samples was determined (Perkin Elmer Lambda 35 UV-Vis Spectrometer) at a wavelength of 464.3 nm.

## Results and Discussion

**X-ray diffraction**

Figure 1 displays the XRD patterns of pure ZnO and ZnO/rGO nanohybrid photocatalysts. The diffraction peaks observed in the XRD pattern of the prepared photocatalysts were consistent with the hexagonal wurtzite phase of ZnO (JCPDS No. 36-1451). The peaks at 2θ=31.8°, 34.4°, 36.2°, 47.5°, 56.6°, 62.8°, 66.4°, 68.0°, 69.1°, 72.5° and 77.0° are associated with the 100, 002, 101, 102, 110, 103, 200, 112 and 203 crystalline planes of ZnO, respectively. However, no characteristic peak for rGO was observed in the XRD patterns due to its low content and its relatively low diffraction intensity compared to ZnO [21-23]. The average crystallite size of ZnO and the ZnO/rGO nanohybrid photocatalysts was calculated using Scherrer's equation and the data is shown in Table 1. It was also observed that the intensity of the diffraction peaks of the ZnO/rGO nanohybrids decreased as the rGO content increased. This indicated that the crystallinity of ZnO deteriorated as the concentration of ZnO in the ZnO/rGO nanohybrids decreased when compared to pure ZnO [24]. Kuo and co-workers [25] reported that an increase in the concentration of the dopant led to the formation of stresses because of the difference in ionic size of zinc and the dopant. ZnO/rGO nanohybrids were observed to have smaller crystallite sizes when compared to pure ZnO. This was due to the presence of the dopant, (rGO) which hindered the growth of crystal grains[26].

Table 1. Physical characteristics of ZnO and ZnO/rGO nanohybrids.

| Photocatalyst | Crystallite Size (nm) | Surface Area ($m^2g^{-1}$) | Band Gap Energy (eV) |
|---|---|---|---|
| ZnO | 43 | 5.15 | 3.16 |
| ZnO/rGO5 | 32 | 7.78 | 3.05 |
| ZnO/rGO10 | 36 | 9.70 | 3.08 |
| ZnO/rGO20 | 32 | 7.48 | 3.05 |

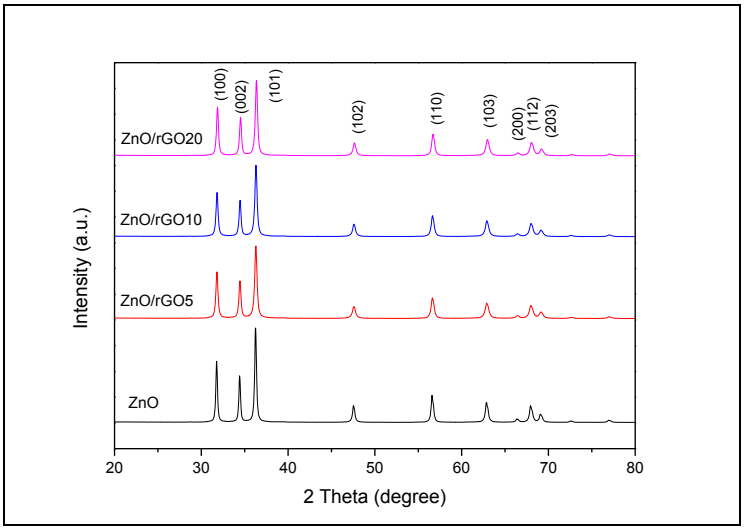

Figure 1. XRD patterns of ZnO and ZnO/rGO nanohybrid photocatalysts

**Morphology**

The surface morphology of the ZnO and ZnO/rGO nanohybrid photocatalysts, determined using TEM and FESEM, is shown in Figures 2 and 3, respectively. TEM images revealed the presence of ZnO on the surface of the graphene sheet. The ZnO nanoparticles were nearly spherical in shape, self-assembled and were randomly distributed on the graphene sheets. The formation of spherical ZnO nanoparticles could have been due to the addition of $OH^-$ that increased the reaction rate, thus forming more nuclei in a short time [5]. The two- dimensional graphene sheets were not perfectly flat but rough with wrinkles. EDX were used to distinguish the components present in the samples. As shown in Figure 4, carbon (C), zinc (Zn) and oxygen (O) were the main elements present in the ZnO/rGO nanohybrid photocatalysts with no unexpected elements being detected. This confirmed the purity of the samples.

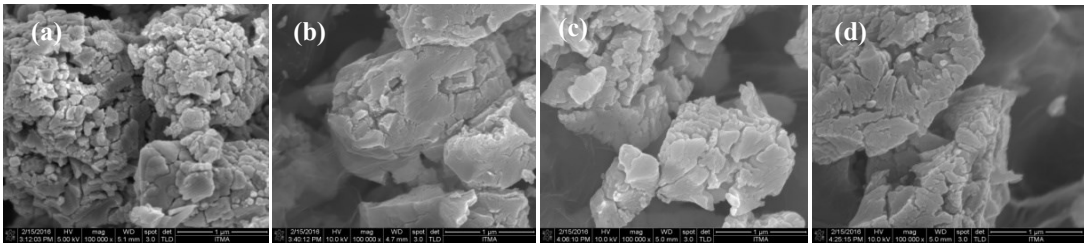

Figure 3. FESEM images of (a) ZnO, (b) ZnO/rGO5, (c) ZnO/rGO10 and (d) ZnO/rGO20

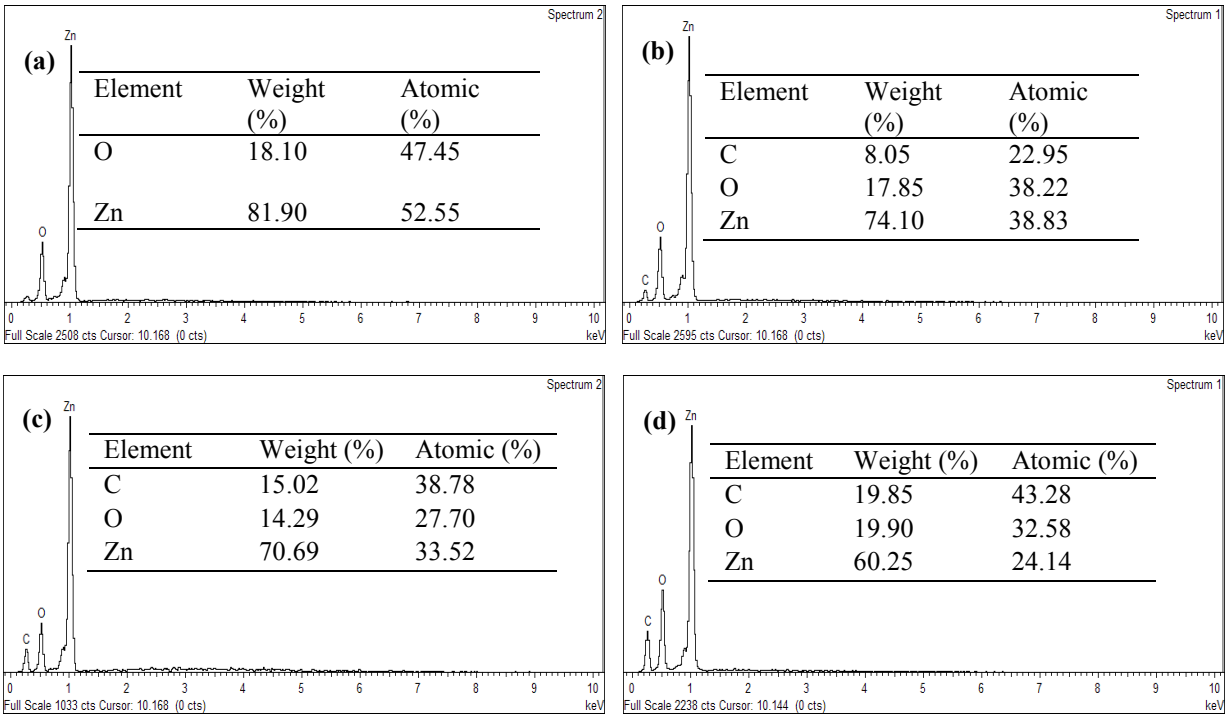

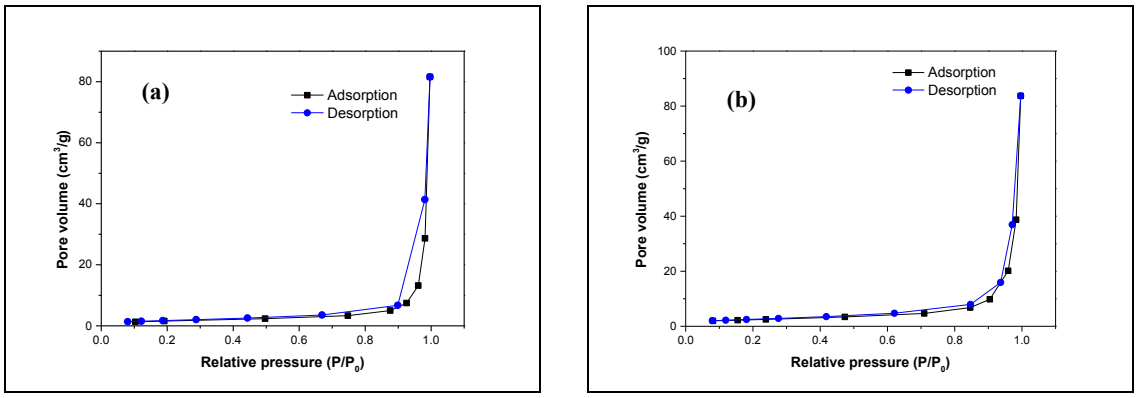

Figure 4. EDX spectra of (a) ZnO, (b) ZnO/rGO5, (c) ZnO/rGO10 and (d) ZnO/rGO20

**Surface area and porosity**

The BET surface areas of the ZnO and ZnO/rGO nanohybrid photocatalysts were obtained from the nitrogen adsorption- desorption isotherm and the results are represented in Table 1. Both the ZnO and ZnO/rGO nanohybrid photocatalysts met the type V $N_2$ adsorption- desorption isotherms with H3 hysteresis loop where there was a weak adsorbent- adsorbate interaction. The high adsorption at a relative pressure $P/P_0$ close to 1.0 also suggested the formation of large mesopores and macropores. Meanwhile, the presence of type H3 loop suggested the occurrence of macropores which are not completely filled with pore condensate [27]. It was observed that there was an improvement in the surface area of the ZnO/rGO nanohybrids compared to ZnO where graphene was incorporated. The nanohybrids were expected to have better photocatalytic performance than ZnO as the high surface area enhanced the efficient adsorption and transfer of organic molecules in a photochemical reaction via π-π conjugation between the organic molecules and graphene sheet [28].

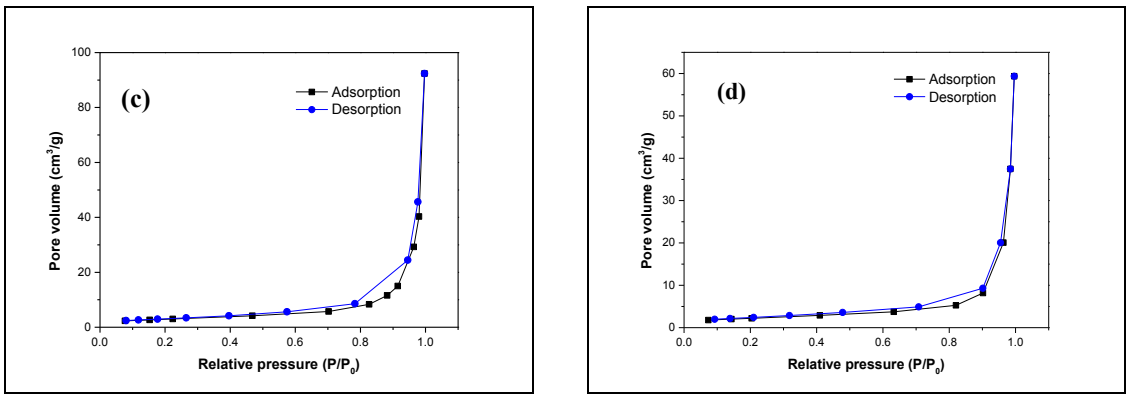

Figure 5. Nitrogen adsorption-desorption isotherm of (a) ZnO (b) ZnO/rGO5 (c) ZnO/rGO10 and (d) ZnO/rGO20

**Raman spectroscopy**

Figure 6 shows the Raman spectra of GO, rGO and ZnO/rGO10. The characteristic Raman peaks of all three samples showed similar D and G band structures of carbon, which was 1362 $cm^{-1}$ and 1605 $cm^{-1}$; 1352 $cm^{-1}$ and 1605 $cm^{-1}$; 1355 $cm^{-1}$ and 1605 $cm^{-1}$ for GO, rGO and ZnO/rGO10, respectively. The D band refers to the presence of disorder in the graphene structure while the G band refers to the presence of an $sp^2$ carbon type structure [29]. The D band in ZnO/rGO10 was slightly blue shifted by 7 $cm^{-1}$ compared to GO. This was due to the interaction between ZnO and rGO [28]. Similar D and G bands for rGO and ZnO/rGO10 also suggested that the structure of rGO was maintained in the nanohybrid. However, there was a change in the electronic conjugation state of the GO as indicated by the change in the G and D band intensities after being incorporated into ZnO [12, 30]. The intensity ratios ($I_D/I_G$) increased from 0.87 in GO to 0.98 in ZnO/rGO10 implying that the GO was successfully reduced and more $sp^2$ domains (graphene sheets) had formed [31]. This also indicated that the introduction of ZnO increased the defects or disorders in the GO sheet [32], hence confirming the formation of the ZnO/rGO nanohybrid.

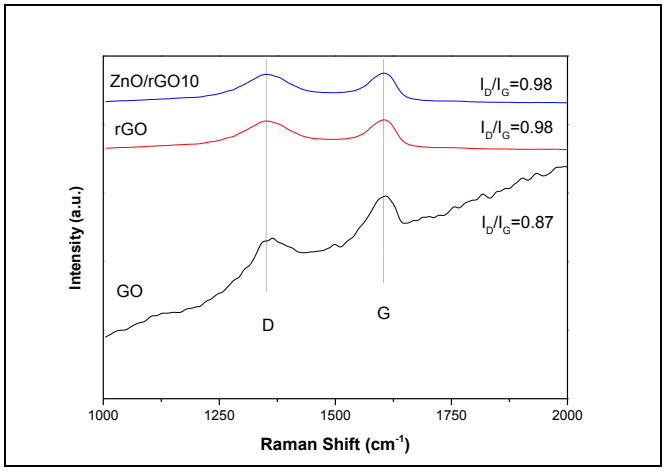

Figure 6. Raman spectra of GO, rGO and ZnO/rGO10

**UV- visible diffuse reflectance spectroscopy**

Figure 7 shows that both ZnO and ZnO/rGO nanohybrids had similar maximum absorptions at 360 nm. There was an enhancement in the absorption intensity of the ZnO/rGO nanohybrids corresponding to the increase in GO

content in both the UV and visible regions as a result of the increase in the surface electric charge of the oxides and the modification of the fundamental process of electron- hole pair formation during irradiation [33, 34]. The band gap energy of both ZnO and ZnO/rGO nanohybrids were determined by the extrapolation of the linear relationship between $(\alpha hv)^2$ and hv [35]:

$$(\alpha hv)^2 = K\ (hv\ -\ E_g) \tag{1}$$

where $\alpha$ is the absorption coefficient, $K$ is the proportionality constant and $v$ is the frequency of photons.

A plot of $(\alpha hv)^2$ as a function of photon energy, $hv$ for all samples is illustrated in Figure 7 with the band gap values listed in Table 1. The band gap energy of pure ZnO was slightly higher than that of the ZnO/rGO nanohybrids. The reduction in band gap energy could be attributed to the formation of Zn-O-C chemical bonds in the nanohybrid [17, 36, 37]. This also indicated that the presence of graphene influenced the electronic energy level of the ZnO nano-particles. As the band gap energy reduced, more photons were prone to be absorbed by the nanohybrid which in turn would enhance the photocatalytic efficiency.

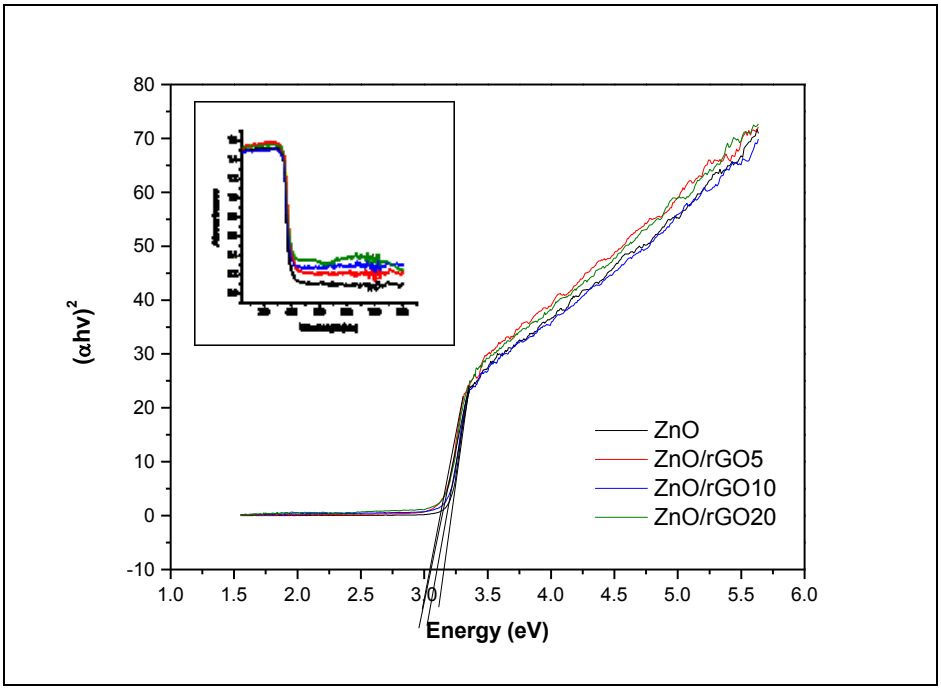

Figure 7. The plots of $(\alpha hv)^2$ versus $hv$ and UV spectrum (inset) for ZnO, ZnO/rGO5, ZnO/rGO10 and ZnO/rGO20

**Photocatalytic activities**

The photocatalytic performance of both the ZnO and ZnO/rGO nanohybrid photocatalysts were evaluated by degrading methyl orange under the irradiation of UV light and the results are depicted in Figure 8. By comparison, only 53% of MO was degraded using pure ZnO after 180 minutes of irradiation. However, the ZnO/rGO nanohybrids were found to show more prominent photocatalytic efficiency, with 80%, 97% and 77% of MO photodegraded for ZnO/rGO5, ZnO/rGO10, and ZnO/rGO20, respectively.

In principle, the photocatalytic degradation of MO by ZnO and ZnO/rGO nanohybrids is an interface process and follows the Langmuir-Hinshelwood model where it obeys the following assumptions: (i) limited adsorption sites on the catalyst's surface, (ii) monolayer coverage of the catalyst surface with single adsorptions on each site, (iii) reversible adsorption reactions, (iv) homogeneous catalyst surface and (v) zero interactions between the molecules

adsorbed[38]. In this study, $H_2O$, $O_2$ and dye (MO) were adsorbed on the surface of the catalyst in adjacent sites. The reaction then occurred between the adsorbed molecules and the radicals generated before the products ($CO_2$ and $H_2O$) were desorbed from the catalyst's surface.

$$ZnO + h\nu \rightarrow e_{CB^-} + h^+_{VB} \quad (2)$$

$$H_2O + h^+_{VB} \rightarrow OH\bullet + H^+ \quad (3)$$

$$O_{2(ads)} + eCB^- \rightarrow O_2^{\bullet -} \quad (4)$$

$$OH^-_{(ads)} + h^+_{VB} \rightarrow OH_{(ads)}\bullet \quad (5)$$

$$OH_{(ads)}\bullet + OH\bullet \rightarrow H_2O_2 \quad (6)$$

$$H_2O_2 + O_2^{\bullet -} \rightarrow OH\bullet + OH^- + O_2 \quad (7)$$

$$Dye_{(ads)} + OH\bullet \rightarrow CO_2 + H_2O \quad (8)$$

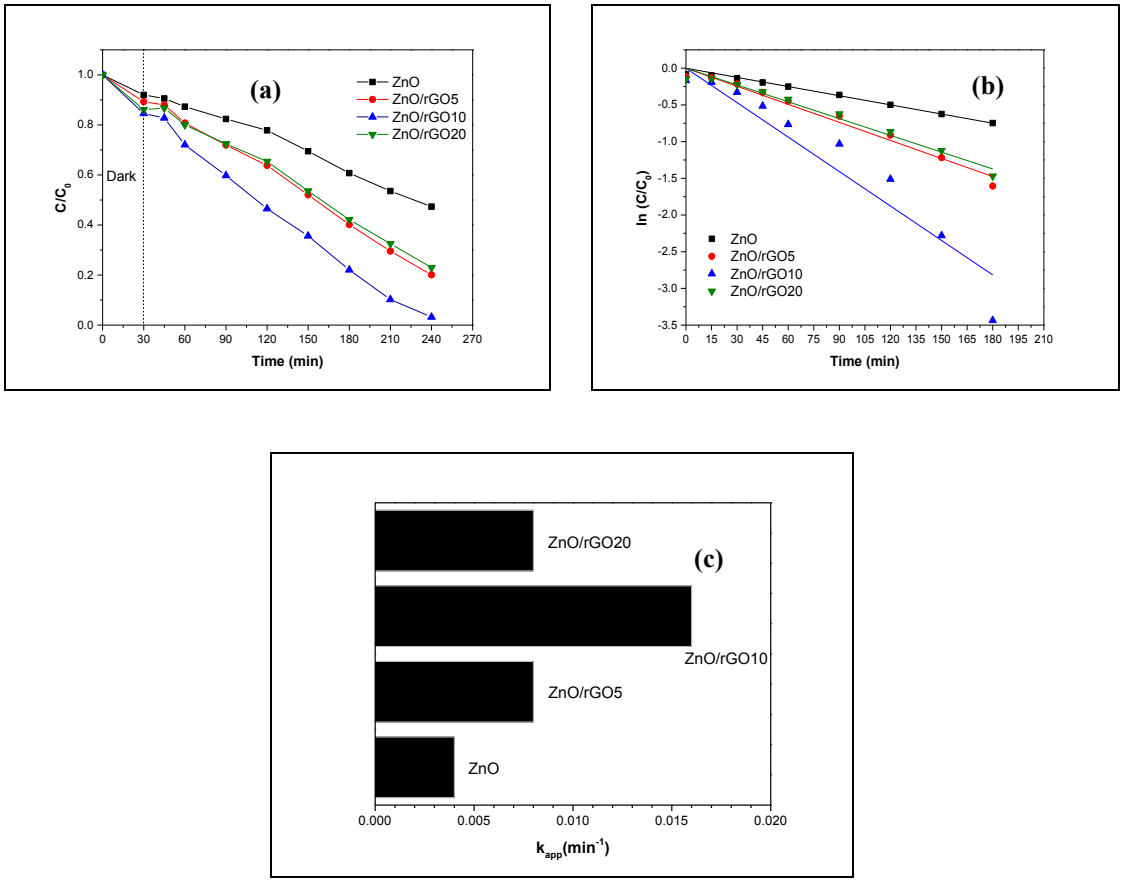

Figure 8. Photodegradation of MO by pure ZnO and ZnO/rGO nanohybrid photocatalysts: (a) reaction profile (b) kinetics and (c) apparent rate constant [condition: 0.5 g of photocatalyst, 10 ppm MO, pH = 6.6]

The data for the photocatalytic degradation of MO was fitted to the Langmuir-Hinshelwood kinetics model and the plot of $\ln(C/C_0)$ vs time (Figure 8b) showed that the photodegradation of MO followed a pseudo first order reaction. The pseudo first order kinetics for MO degradation was calculated as follows:

$$\ln(C/C_0) = \_kt \quad (9)$$

where C (mg/L) is the initial concentration of MO, $C_0$ (mg/L) is the concentration of MO at time t (min) and *k* ($min^{-1}$) is the pseudo first order rate constant. The apparent rate constants, $k_{app}$, were determined from the slope of the plot and is illustrated in Figure 8c. It was clear that the ZnO/rGO nanohybrid photocatalysts exhibited higher photocatalytic activities than pure ZnO. The photocatalytic activity increased as the GO content increased until it reaches the optimum, in the order of ZnO/rGO10 > ZnO/rGO5 > ZnO/rGO20 > ZnO. ZnO/rGO10 had the best photocatalytic activity with a kinetic rate constant 0.016 $min^{-1}$, which was four times higher than pure ZnO. The results were comparable with that reported in literature [21, 28].

The enhancement in the photocatalytic performance of the ZnO/rGO nanohybrids could be attributed to the strong interactions between ZnO and rGO and the defect sites of graphene. Graphene, with a two- dimensional conjugation structure [39], acted as an excellent electron acceptor. When ZnO was irradiated with UV light, the electrons were excited from the valence band to the conduction band, leaving behind holes in the valence band. These excited electrons could also be transferred from the conduction band of ZnO to the graphene sheet. The effective transfer of photoelectrons from the conduction band of ZnO to graphene prolonged the electron-hole pairs recombination hence promoting the separation of electron- hole pairs of ZnO [40, 41]. More charge carriers were produced from the reactive species which eventually helped in the degradation of MO [42]. The schemetic mechanism of the photocatalysis is shown in Figure 9. Moreover, the ZnO/rGO nanohybrid had a smaller particle size, larger surface area and lower band gap energy compared to ZnO. Such structural changes in ZnO increased the light absorption and the adsorption of MO on the surface of the catalyst; hence increasing the photocatalytic activity of the photocatalysts. However, a high content of GO (ZnO/rGO20) led to a decrement in the photocatalytic activity. Gayathri and co-workers [43] have reported that, at a higher graphene content, the graphene sheets tended to clasp together and appeared like multi-layer graphene after heat treatment. Excess GO also caused a shielding of the active sites on the catalyst surface, and led to the scattering of photons [31, 44, 45]. Since the light absorption of the photocatalyst was reduced, the excitation efficiency of ZnO was also lowered, consequently reducing the photocatalytic activity of the photocatalysts.

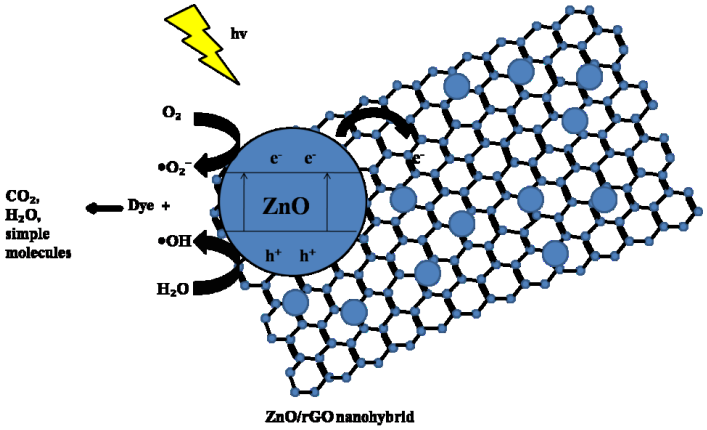

Figure 9. Mechanism of photodegradation

## Conclusion

A series of ZnO/rGO nanohybrids with different GO content was successfully synthesized via a simple and inexpensive precipitation method. The ZnO particles were formed on the surface of the graphene sheet. The presence of GO during the synthesis inhibited the crystal growth of ZnO that led to the formation of smaller-sized ZnO particles. ZnO/rGO nanohybrids showed better photodegradation activity compared to ZnO in degrading methyl orange due to their smaller particle sizes and lower band gap energy. ZnO/rGO10 exhibited the highest photocatalytic activity with a kinetic rate constant that was four times higher than pure ZnO. The enhanced photocatalytic activity of the nanohybrids could be attributed to the presence of rGO, an excellent electron acceptor

which enhanced the active transfer of photogenerated electrons of ZnO to the rGO sheet, thereby retarding the charge carrier recombination, thus enhancing the charge separation.

**Abstract**

A mesoporous Fe-Ni catalyst was prepared by microwave combustion method by using glycine as a fuel to help the combustion occur in the microwave. The bimetallic catalyst synthesized was intend to accelerate the production of hydrogen via decomposition of formic acid. The hydrogen produced supposedly can substitute the energy source used now especially from fossil fuels to contribute to the reduction of greenhouse effect. The catalyst sample was characterized by powder X-ray diffraction (XRD), scanning electron microscopy (SEM) and $N_2$ adsorption-desorption isotherm (BET). From the BET isotherms, a type IV isotherm was observed, indicate the presence of mesoporous solid. XRD diffractograms of Fe-Ni have well-defined diffraction patterns with strong and sharp diffraction peaks, indicating that they are crystalline. The SEM images show the presence of voids and pores in the sample and spongy structure which also consisted of very fine crystalline. The selectivity for $H_2$ formation using the prepared bimetallic catalyst was achieved ranging of 94 to 99% for 120 minutes at optimum conversion of formic acid and merely at room temperature.

**Keywords**: iron nickel catalyst, hydrogen energy, microwave combustion method, $H_2$ selectivity

**Abstrak**

Mangkin Fe-Ni yang bersifat mesoporos telah disediakan dengan menggunakan kaedah pembakaran oleh gelombang mikro dengan bantuan glisin sebagai bahan bakar. Mangkin dwilogam yang disintesis bertujuan untuk mempercepatkan penghasilan hidrogen melalui penguraian asid formik. Hidrogen yang dihasilkan diharapkan dapat menggantikan sumber tenaga yang digunakan dewasa ini terutama daripada bahan api fosil supaya dapat mengurangkan kesan rumah hijau. Sampel mangkin dicirikan dengan pembelauan sinar-X (XRD), mikroskopi pengimbasan elektron (SEM), dan isoterma penyerapan-penyahjerapan $N_2$ (BET). Daripada isoterma BET, isoterma jenis IV telah dikenalpasti, menandakan kehadiran pepejal mesoporos. Difraktogram XRD bagi Fe-Ni menunjukkan corak yang terbentuk dengan puncak yang baik dan tajam, menunjukkan mangkin tersebut merupakan hablur. Imej SEM menunjukkan kehadian ruang dan pori di dalam sampel dan berstruktur span dimana ia juga terdapat hablur yang sangat halus. Keterpilihan terhadap penghasilan gas $H_2$ menggunakan mangkin dwilogam FeNi adalah 94 – 99% pada masa tindak balas 120 minit pada peratus penukaran asid fomik yang optimum pada suhu bilik.

**Kata kunci:** mangkin ferum nikel, tenaga hidrogen, kaedah pembakaran gelombang mikro, kepilihan $H_2$

## Introduction

Global warming has been continuously increases the attention among scientists and the earth community. This popular problem was resulted from both human activity and natural variability [1]. The emission of greenhouse and

toxic gases such as NOx and $SO_2$ to the atmosphere is the main reason of global warming other than environmental pollution due to the combustion of fossil fuel [2]. This all things happened because the source of energy nowadays is mainly from fossil fuels and scientist has found a way to change from petroleum to hydrogen as a new technology of energy source.

Hydrogen as a future energy carrier is very dependable due to its clean combustion pathways and high gravimetric energy density [3]. However, hydrogen has a very low volumetric energy density at atmospheric conditions [4]. To obtain a balanced gravimetric and volumetric hydrogen storage density, pure hydrogen can be stored in compressed gases or liquid form. Formic acid has been recognized as a potential hydrogen storage material due to its high gravimetric energy density, nontoxicity, and can be safely handled in aqueous solution [4]. This organic compound which is in liquid form at room temperature has limited uses including as a preservative and antifungal agent and it's also contribute in the production of leather and could act as a lime scale remover [5]. Levulinic acid production from cellulosic biomass [6, 7] and glucose [8, 9] will produce formic acid as a side product and due to the redundancy of formic acid, it makes sense that we utilize the acid to make something useful for the earth and mankind.
To produce hydrogen, formic acid needs to react in the present of catalyst. Formic acid can undergo two path of reaction that is dehydration (1) and dehydrogenation (2).

$$HCOOH \longrightarrow H_2O + CO \quad \Delta G_{298K} = -14.9 \text{ kJ mol}^{-1} \tag{1}$$
$$HCOOH \longrightarrow H_2 + CO_2 \quad \Delta G_{298K} = -35.0 \text{ kJ mol}^{-1} \tag{2}$$

Carbon monoxide that liberated from reaction (1) is toxic to fuel cell catalysts which will reduce the catalytic performance [4, 10]. In order to avoid formic acid undergoing dehydration, the type of active catalyst used in the reaction at low temperature must be taken into account. Flaherty et al. [11] in their studies on decomposition of formic acid on the molybdenum (Mo) and molybdenum carbide (C-Mo) surfaces show that at 350 – 450 K, dehydration is the dominant pathway on clean Mo (110) with ~5% or less formic acid undergoing dehydrogenation, while C-Mo (110) selectively promotes 70 – 75% of hydrogen. Hence, the type of catalyst use is very important and here, we report the characteristic of nanoalloy catalyst at different ratio of Fe and Ni composition.

## Materials and Methods

### Synthesis of bimetallic nanoalloy catalysts

All chemicals were of analytical grades and were used without further purification. Fe-Ni bimetallic catalysts were prepared by microwave combustion method with the weight percentage (wt%) of Fe to Ni as 99:1, 97:3 and 95:5. In order to prepare $NiFe_2O_4$, $Fe(NO_3)_2.9H_2O$ and $Ni(NO_3)_2.6H_2O$ with ratio stated before were mixed in a crucible porcelain in the presence of glycine as fuel. The mixture was then put into a microwave with a power of 240 W for 3 minutes. The voluminous sponge-like product was produced and washed with distilled water and ethanol. The washed product was dried at 115 ºC in an oven for 24 hours. The product was then reduced in hydrogen gas at 500 ºC for 1 hour to get Fe-Ni bimetallic. The compositions of final obtained catalysts are (100-x)Fe:xNi (x = 0, 1, 3 and 5) in weight percentage ratio, which labelled as F100, FN991, FN973 and FN955, respectively.

### Characterization of catalyst

Brunauer-Emmett-Teller (BET) surface area of every catalyst were analysed by $N_2$ adsorption and desorption isotherms. In this research, the BET instrument used was Micromeritics ASAP 2020. Samples were degassed at 350 ºC for 4 hours prior to the analysis and $N_2$ adsorption was carried out at -196 ºC. X-ray diffraction (XRD) diffractogram of the produced catalysts were recorded on a Bruker AXS D8 Advance using a Cu Kα radiation source (40 kV, 40 mA). Scans were taken over the 2θ range from 10º to 80º and wavelength, λ = 0.154 nm. 1 gram of sample was put on sample holder. The data obtain from the analysis was compared with standard peak data reported by Joint Committee on Powder Diffraction Standard (JCPDS) to get the structure and identity of the sample. The surface morphology of the catalyst was observed by variable pressure scanning electron microscopy (VPSEM).

**Decomposition of formic acid and product analysis**

Catalytic decomposition of formic acid by the produced catalyst was performed at room temperature (25 ºC) in a closed reactor containing formic acid with 50% concentration. The produced gases were analyzed using gas chromatography equipped with thermal conductivity detector (GC-TCD). The gases were collected from a gas bag connected to the reactor every 30 minutes and the volume released were recorded until 120 minutes.

## Results and Discussion

Table 1 shows the BET surface area of the synthesized catalyst. The BET surface area of the catalysts ranging from 5.64 to 9.02 $m^2/g$. The low surface area is due to the high temperature of the reaction in the microwave [12]. The surface area of the catalysts are gradually decreases as the percentage of Ni in the catalyst increase. The $N_2$ adsorption-desorption isotherms of the catalysts are shown in Figure 1. For all of them, a type IV isotherm is observed, indicate the presence of mesoporous solids [13]. A similar result has also been reported by Feyzi et al. (2010) [14] in the study of iron nickel oxide Fischer-Tropsch synthesis (FTS) catalyst. This result may be due to the electronic structure of the catalyst. Having greater surface area does not guarantee the excellency of catalytic activity as reported by Mandal et al. [15]. As in our work, F100 has larger BET surface area than FN991 but in term of $H_2$ selectivity, FN991 was more efficient than F100 as stated in Figure 4.

Table 1. Surface properties of catalyst

| Catalyst | $S_{BET}$ ($m^2/g$) | $V_{pore}$ ($cm^3/g$) | $d_{pore}$ (Å) |
|---|---|---|---|
| F100 | 9.02±0.09 | 0.048±0.010 | 235.30±2.0 |
| FN991 | 7.69±0.04 | 0.034±0.009 | 171.80±2.0 |
| FN973 | 7.30±0.05 | 0.028±0.007 | 182.81±2.0 |
| FN955 | 5.64±0.08 | 0.026±0.007 | 257.65±2.0 |

$S_{BET}$: BET surface area; $V_{pore}$: total pore volume;
$d_{pore}$: average pore diameter

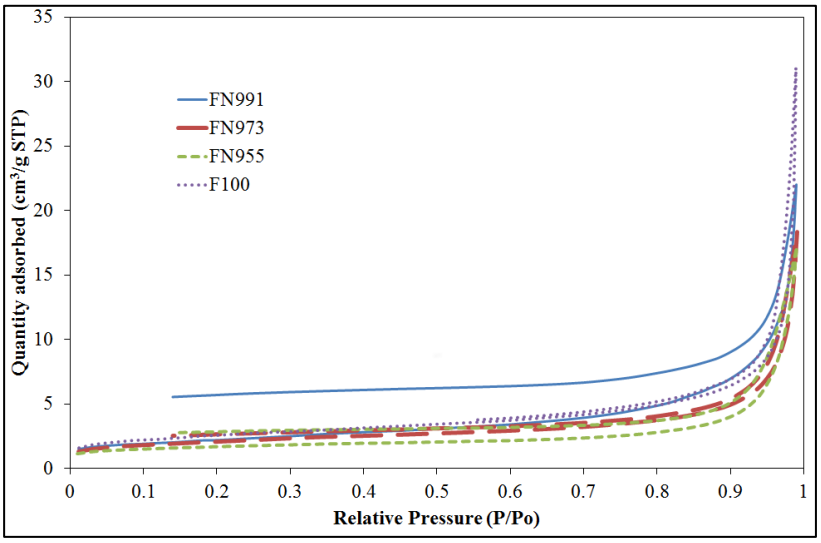

Figure 1. BET analysis of $N_2$ adsorption-desorption isotherms

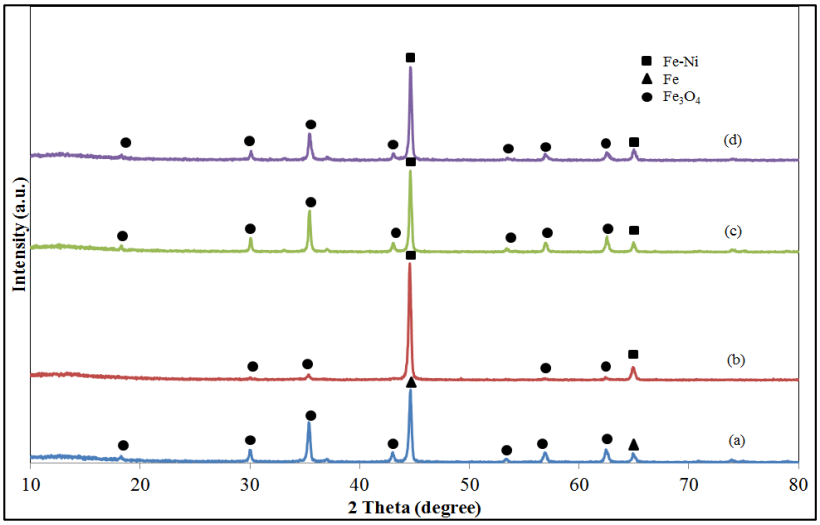
XRD diffractograms for fresh Fe and FeNi bimetallic catalysts are shown in Figure 2. The XRD pattern of all the samples have well-defined diffraction patterns with strong and sharp diffraction peaks, indicating that they are crystalline. For F100 catalyst, two phases were detected; Fe (JCPDS file: 03-065-4899) and $Fe_3O_4$ (JCPDS file:

01-080-6402). For the Fe-Ni catalysts, besides the diffraction peaks of FeNi (JCPDS file: 01-080-7663), the diffraction peak of $Fe_3O_4$ also detected. A comparatively low intensity of $Fe_3O_4$ phase was detected on FN991 catalyst than other percentage ration. This indicate that low nickel composition is easy to reduce to form pure metallic.



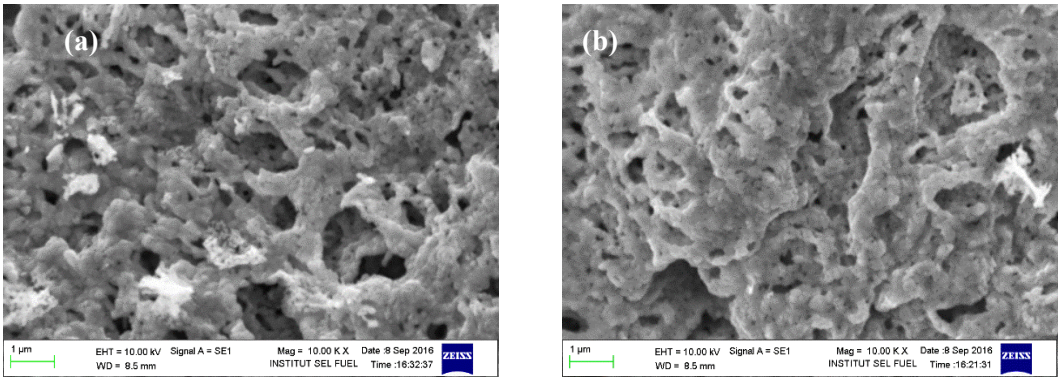


Figure 2. XRD diffractograms of prepared (a) F100, (b) FN991, (c) FN973 and (d) FN955

The SEM images in Figure 3 (a-d) show the porous structures of the prepared Fe and FeNi catalysts by microwave combustion method. Their morphological characteristics were investigated by variable pressure scanning electron microscope (VPSEM). As can be seen in Figure 3, the SEM images show the presence of voids and pores in the samples, which can be attributed to the release of large amount of gas during the combustion process. The sample has a spongy structure and one can see that the formation of multigrain agglomeration consisted of very fine crystallite.

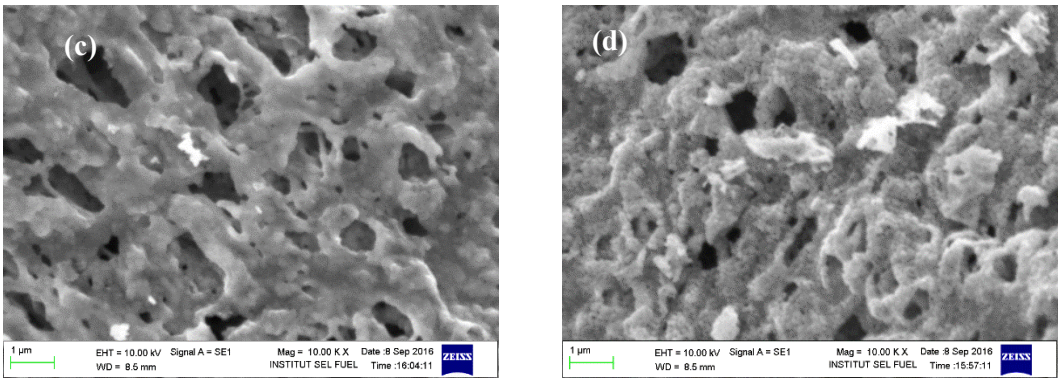

Figure 3. SEM images of prepared (a) F100, (b) FN991, (c) FN973 and (d) FN955

Figure 4 shows the graph of $H_2$ production against time. As the time increases, the activity of catalyst decreases. The FN973 catalyst was showed a significant decrement in activity compared to other catalysts. This degradation of the catalysts activity is due to the decreases of formic acid concentration during the reaction process which some of them consumed and decompose into hydrogen and carbon dioxide [4]. It was found that the FN991 catalyst showed the most excellent $H_2$ selectivity. The selectivity for $H_2$ formation was 94-99% even at maximum conversion of formic acid.

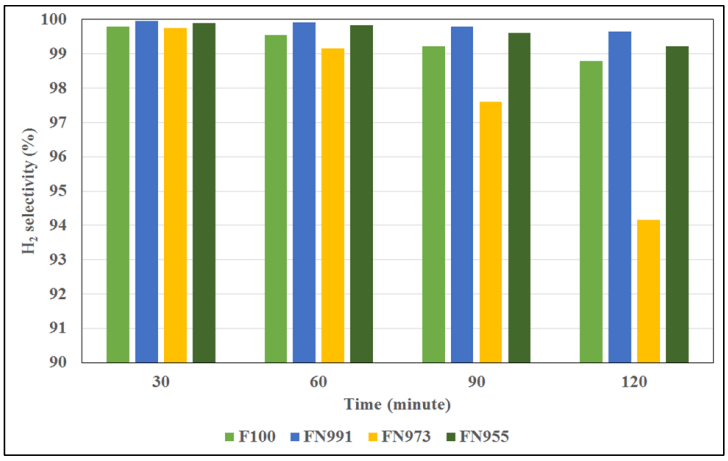

Figure 4. Production of $H_2$ for 120 minutes

## Conclusion

In this study three bimetallic alloy have been successfully prepared by microwave combustion method using glycine as a fuel. The doping of Ni in the catalyst increase the activity of the produced catalyst. FeNi bimetallic were found to be an active catalyst for the formic acid decomposition at room temperature to produce hydrogen with selectivity ranging of 94 – 99% for 120 minutes at room condition. The lower Ni content at 1 wt.% showed a relatively higher selective to hydrogen rather than produce $CO_2$ gas. The utilization of low cost transition metal such as Fe and Ni to produce catalyst for dehydrogenation of formic acid may represent a new approach to develop an efficient catalyst.

**Abstract**

This study was carry out to investigate the effect of 3% rhodium on the reduction behaviour of iron oxide by (10%, v/v) carbon monoxide in nitrogen as a reductant. The Rh/$Fe_2O_3$ samples were prepared by impregnation method and the reduction behavior of Rh/$Fe_2O_3$ and pure $Fe_2O_3$ were investigated by using temperature programmed reduction (TPR). The prepared samples and the reduced phases were characterized by X-ray diffraction spectroscopy (XRD). The results indicate that Rh/$Fe_2O_3$ give a better reducibility compared to $Fe_2O_3$ with a complete reduction at 650 °C, which is 250 °C lower than $Fe_2O_3$. The TPR results indicate that the reduction of $Fe_2O_3$ proceed in three steps reduction ($Fe_2O_3$ → $Fe_3O_4$ → FeO → Fe) with $Fe_3O_4$ and FeO as intermediate states while for Rh/$Fe_2O_3$ as the TPR result showed the overlapping of second and third peak ($Fe_3O_4$ → FeO and FeO → Fe) at higher temperature. Addition of Rh may possibly reduce the formation of stable FeO that stable at higher temperature by accelerates the direct reduction of $Fe_3O_4$→ Fe so the reduction process of $Fe_2O_3$ become faster. The XRD pattern shows the diffraction peaks of Rh/$Fe_2O_3$ is more intense with improved crystallinity for the characteristic peaks of $Fe_2O_3$ compared to pure $Fe_2O_3$. No visible sign of rhodium particles peaks in the XRD spectrum that indicates the Rh particles loaded onto the iron oxide are well dispersed. The well dispersed Rh onto the iron oxide and the ability to reduce the sintering effect to the iron oxide also has been confirmed by FESEM. The study shows that addition of Rh gives a better reducibility of iron oxide is also due to the ability of Rh to interact with CO as confirmed by the thermodynamic data with higher surface area compared to $Fe_2O_3$.

**Keywords**: temperature programmed reduction, rhodium, ferum oxide, carbon monoxide

**Abstrak**

Kajian ini dijalankan untuk melihat pengaruh 3% rodium kepada kelakuan penurunan ferum oksida di mana karbon monoksida (10%, v/v) di dalam nitrogen digunakan sebagai agen penurunan. Sampel Rh/$Fe_2O_3$ disintesis menggunakan kaedah impregnasi dan kelakuan penurunan dikaji menggunakan teknik suhu penurunan berprogram (TPR). Fasa - fasa yang terbentuk dicirikan menggunakan teknik pembelauan sinar X (XRD). Keputusan menunjukkan Rh/$Fe_2O_3$ memberikan kelakuan penurunan yang lebih baik berbanding $Fe_2O_3$ sahaja dengan penurunan lengkap berlaku pada suhu 650 °C dimana suhu penurunan berkurangan sebanyak 250 °C berbanding suhu penurunan lengkap $Fe_2O_3$. Profil TPR menunjukkan bahawa penurunan ferum oksida melalui tiga langkah tindak balas penurunan ($Fe_2O_3$ → $Fe_3O_4$ → FeO → Fe) dengan $Fe_3O_4$ dan FeO merupakan fasa perantara, sementara, Rh/$Fe_2O_3$ pada suhu penurunan tinggi menunjukkan pertindihan diantara puncak kedua dan puncak ketiga ($Fe_3O_4$ → FeO and FeO → Fe). Penambahan Rh didapati mengurangkan penghasilan FeO yang stabil pada suhu tinggi dengan

menggalakkan penurunan terus $Fe_3O_4$→ Fe menjadikan tindak balas penurunan lebih cepat. Difraktogram XRD bagi Rh/$Fe_2O_3$ menunjukkan peningkatan pada kehabluran puncak $Fe_2O_3$ berbanding ferum oksida tulen. Tiada puncak tambahan diperhatikan dimana ia menjelaskan bahawa zarah Rh yang dimuatkan pada ferum oksida telah tersebar dengan baik. Penyerakan yang baik oleh Rh di atas ferum oksida telah menunjukkan pengurangan kesan pensinteran terhadap ferum oksida yang telah dibuktikan melalui FESEM. Kajian menunjukkan penambahan Rh memberikan kesan yang baik kepada proses penurunan ferum oksida berdasarkan kebolehan Rh untuk berinteraksi dengan gas CO yang telah disahkan oleh pengiraan termodinamik dan peningkatan kepada luas permukaan berbanding $Fe_2O_3$ tulen.

**Kata kunci:** suhu penurunan berprogram, rodium, ferum oksida, karbon monoksida

## Introduction

The reduction behaviour of the iron species were highly important in such application in industry and some chemical processes [1, 2]. The reduction process of $Fe_2O_3$ is not a simple process which may include several steps relies on factors such as temperature, concentration reduction gas used, particle size, crystallinity and additives [3]. This reduction process of iron oxide involves several possible structural changes and complex compositions in the intermediate oxides such as hematite ($Fe_2O_3$) → magnetite ($Fe_3O_4$) → wüstite (FeO) → iron (Fe) and in most cases the reactions were usually simultaneous [2]. Pineau et al. investigate the effect of temperature on the reduction behaviour of iron oxide and proposed several reduction routes depending on the formation of metastable wüstite [4]. The reduction of $Fe_2O_3$ to metallic Fe can be a two-step ($Fe_2O_3$→ FeO → Fe) or three-step mechanisms ($Fe_2O_3$→ FeO → Fe) depending on temperature and affected the formation of metastable wüstite [5]. When the reduction temperature reached 570 °C and above, magnetite can be reduced to wüstite so higher temperature is needed to its reduction to metal iron [6].

In this study, we will focus on the addition of other element which is rhodium for the purpose of improving the reduction behaviour of $Fe_2O_3$. Good performance of Rh on the reduction behaviour of iron oxide has also been studied by Seak et. al. [7] using $H_2$ as a reductant. Their study revealed that Rh additive can promote the reduction corresponding to the reduction of $Fe_2O_3$→$Fe_3O_4$ as the reduction temperature at this transition was obviously decreased. Thus, we will report the results of an attempt to understand the influence of Rh species on the reduction behavior of the iron oxide with CO as a reductant.

## Materials and Methods

### Materials

Iron(III) oxide (99%) and Rhodium(III) nitrate (99%) were obtained from Sigma Aldrich Chemical Company and the gas mixture of 10% CO in nitrogen was obtained from MOX.

### Catalyst preparation

The addition of 3% Rh (w/w, %) on $Fe_2O_3$ was prepared by impregnating $Fe_2O_3$ powder with aqueous solution containing rhodium cation additives. The $Fe_2O_3$ powder was directly impregnated into 50 ml distilled water corresponding metal cation additives in the above proportion and stirred vigorously for 4 hours at room temperature. The impregnated sample was dried at 110 °C overnight and subsequently calcined at 600 °C for 3 hours.

### Characterization

Temperature programmed reduction (TPR) measurements using a Micromeritic Autochem 2920 Chemisorption Analyzer apparatus; a feed of 10% CO in $N_2$ at a flow rate of 20 mL $min^{-1}$ (STP) was used as reducing gas. The 50 mg of samples were heated up to 900 °C, at a rate of 10 °C $min^{-1}$ were applied to the samples. The carbon monoxide consumption was monitored using a thermal conductivity detector (TCD). Phase characterization was carried out by X-ray diffraction (XRD) Bruker AXS D8 Advance type with X-ray radiation source of Cu Kα (40 kV, 40 mA) to record the 2θ diffraction angle from 10 – 80 degree at wavelength (λ = 0.154 nm) to observe the lattice of the structures and were matched with standard diffraction (JCPDS) files. Physical surface analysis (Brunauer–Emmett–Teller, BET) of nitrogen adsorption at 77 K (liquid nitrogen) was conducted using a Micromeritics ASAP 2010 instrument to obtain the adsorption isotherm of each sample. The calcined sample of Rh/$Fe_2O_3$ and $Fe_2O_3$ were degassed at 350 °C for 6 hours before the BET surface area analyses were done. The Brunauer–Emmett–Teller

(BET) surface areas were calculated from the isotherms. FESEM images were obtained using Merlin Ultra High Resolution FESEM operating with 3.0 kV.

## Results and Discussion

### Thermodynamic consideration data

Table 1 shows the thermodynamic data of iron oxide and rhodium oxide reduction process in CO atmosphere. Sequenced of three steps iron oxide reduction by using carbon monoxide are listed in the table as Eq. 1 to 3 together with the reduction process of rhodium oxide to rhodium metal as Eq. 4. The thermodynamic calculations based on the Gibbs free energy change due to the reactions below and the equilibrium composition of the oxides indicates all equations as written are favourable within the range that also has been mentioned by Svoboda and Bexter [8].

Table 1. Thermodynamics data of iron oxide reduction process in CO atmosphere

| Reactions | | ΔH ($kJmol^{-1}$) | ΔS ($Jmol^{-1}K^{-1}$) | ΔG ($kJmol^{-1}$) | T (°C) | Reaction Possibility |
|---|---|---|---|---|---|---|
| $3Fe_2O_3 + CO \rightarrow 2Fe_3O_4 + CO_2$ | (1) | -47 | +47 | -88 | 600 | Favourable |
| $Fe_3O_4 + CO \rightarrow 3FeO + CO_2$ | (2) | +19 | +53 | -26 | 600 | Favourable |
| $FeO + CO \rightarrow Fe + CO_2$ | (3) | -12 | -18 | +4 | 600 | Favourable |
| $Rh_2O_3 + 3CO \rightarrow 2Rh + 3CO_2$ | (4) | -564.5 | -9 | -556 | 600 | Favourable |

### Isotherm adsorption of $N_2$

The result indicates that the impregnation of $Fe_2O_3$ with rhodium nitrate (5.26 $m^2/g$) shows the BET surface area was larger than pure $Fe_2O_3$ (4.67 $m^2/g$). The higher BET surface area of $Rh/Fe_2O_3$ may contribute to the higher rate of reduction as mentioned by Hu et al. [9] as they mentioned that higher specific surface area was also an important factor which provide more unsaturated surface coordination sites exposed to the gas which may result in the increasing of the activity.

### Crystallinity studies

Figure 1 shows the X-ray diffraction patterns of prepared samples $Rh/Fe_2O_3$ and pure $Fe_2O_3$ before reduction with CO in nitrogen (10%, v/v). The characteristic peaks are consistent with the standard data of rhombohedral ($\alpha$-$Fe_2O_3$, JCPDS 33-0664) with the 2θ $Fe_2O_3$ main peaks revealed the presence of contribution at about 24.2, 33.2, 35.7, 40.9, 49.5, 53.5, 57.2, 62.4, 64.2, 72.4 and 75.7 with crystallite phases of (0,1,2), (1,0,4), (1,1,0), (1,1,3), (0,2,4), (1,1,6), (0,1,8), (2,1,4), (3,3,0), (10,1,0), (2,2,0), respectively. The diffraction peaks show improvement in the crystallinity when loading with Rh with no additional peak that can be explained by a high dispersion of the Rh particles, formation of non-crystalline compounds, compounds giving the same diffraction peaks as those of $Fe_2O_3$ or the amount of the Rh dopant may be too small to be detected significantly as suggested by Lorente et al. [10].

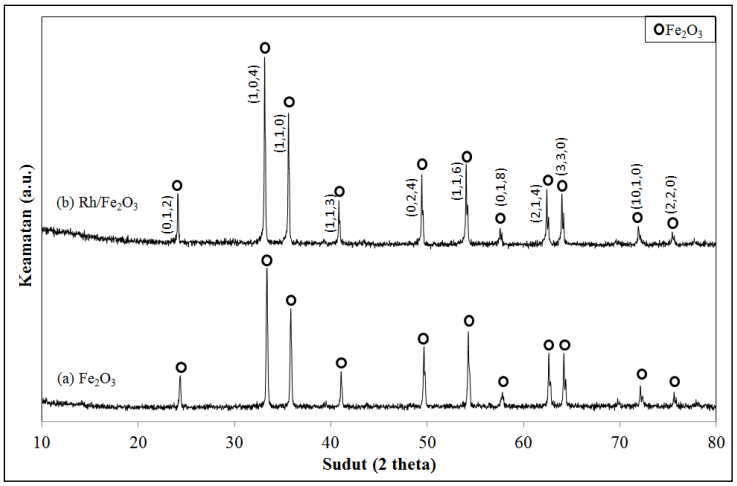

Figure 1. XRD diffractograms of (a) $Fe_2O_3$ and $Rh/Fe_2O_3$ after calcined at 600 °C

To investigate the role of Rh in the reduction behavior of $Fe_2O_3$ in CO atmosphere, all samples were collected according to the TPR pattern when the reduction of $Rh/Fe_2O_3$ in CO is assumed to be finished at 650 °C and also at 900 °C for comparison purposes. From the results display in Figure 2, $Rh/Fe_2O_3$ exhibit a complete reduction at temperature 650 °C with only metallic Fe diffraction peak observed (iron, JCPDS 65-4899). Meanwhile, for $Fe_2O_3$ the reduction accomplished only when the temperature reached 900 °C as it still exhibited a remaining unreduced $Fe_3O_4$ (magnetite, JCPDS 71-6336) and FeO (wustite, JCPDS 80-0686) at reduction temperature of 650 °C.

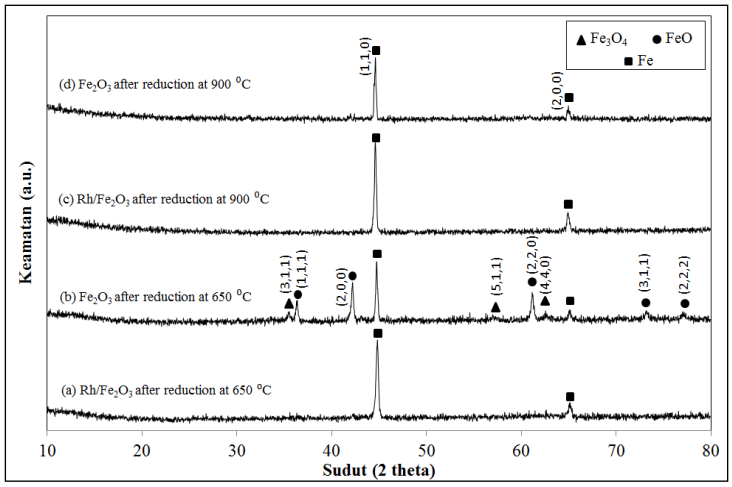

Figure 2. XRD diffractograms of $Rh/Fe_2O_3$ after reduction at (a) 650 °C and (c) 900 °C and $Fe_2O_3$ at (c) 650 °C and (d) 900 °C by CO

**Catalyst characterization by TPR**

The TPR pattern of non-isothermal CO reduction for $Rh/Fe_2O_3$ and $Fe_2O_3$ were shown in Figure 3. For $Fe_2O_3$, 3 reduction peaks were observed at temperature 361 °C, 509 °C and 807 °C which known to reflect the reduction reaction of iron oxides and proceeds the 3 steps reduction of $Fe_2O_3 \rightarrow Fe_3O_4 \rightarrow FeO \rightarrow Fe$. The results are in agreement with the XRD diffractogram as shown before. Meanwhile, $Rh/Fe_2O_3$ also showed one sharp peak at early reduction temperature represents the first stage reduction of $Fe_2O_3 \rightarrow Fe_3O_4$. Nevertheless, as the temperature increased, a broad reduction peak was observed at 565 °C which may represents the overlapping of several reduction steps

before completed to form metallic Fe. Based on the TPR profile together with the XRD diffractogram, $Rh/Fe_2O_3$ exhibited better reducibility compared to $Fe_2O_3$ as the reduction of $Rh/Fe_2O_3$ to metallic Fe completed at 650 °C compared to a much higher temperature (900 °C) of completion for $Fe_2O_3$ without Rh additive. According to Datta et al. [11], addition of other element as a dopant may activates the dissociation of CO and promotes the breaking of Fe-O and contribute to the enhancement of the reducibility process. Thus, the involvement of rhodium element in the structure of iron oxide inhibit the formation of FeO which is stable at higher temperature, thus promotes the direct reduction of $Fe_3O_4 \rightarrow$ Fe and accelerates the reduction process of $Fe_2O_3$. Moreover, Rh itself is favourable to react with CO as in agreement with the thermodynamic data of Eq. 4 as mentioned in Table 1 if compared to $Fe_2O_3$ alone.

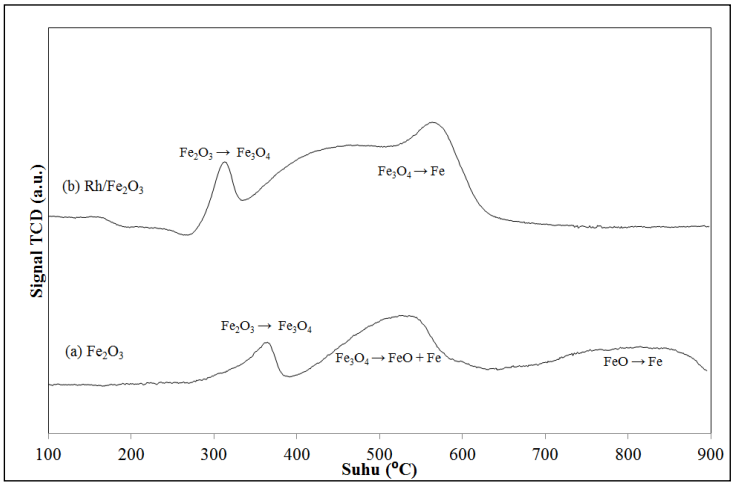

Figure 3. TPR profile of (a) $Fe_2O_3$ and (b) $Rh/Fe_2O_3$ in CO atmosphere

**Catalyst characterization by FESEM**

Figure 4 and Figure 5 show the FESEM images of $Fe_2O_3$ and $Rh/Fe_2O_3$ samples before and after the reduction process in 10% CO atmosphere as seen in magnification (20000x). It is clearly observed from the FESEM image that at reduction temperature of 650 °C, the particle size of $Fe_2O_3$ are slightly bigger that caused by sintering of iron oxide, while $Rh\text{-}Fe_2O_3$ sample showed no big changes in particles size compare with before and after the reduction process. Smaller in particles observed after reduction at 650 °C for $Rh/Fe_2O_3$ may contribute to better reducibility of $Fe_2O_3$.

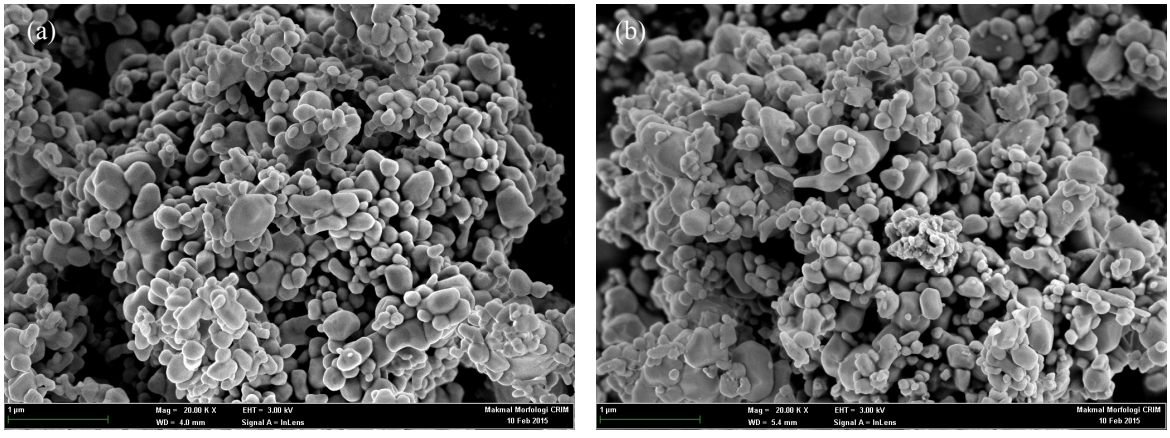

Figure 4. FESEM image of (a) prepared $Fe_2O_3$ and (b) prepared $Rh/Fe_2O_3$ calcined at 600 °C

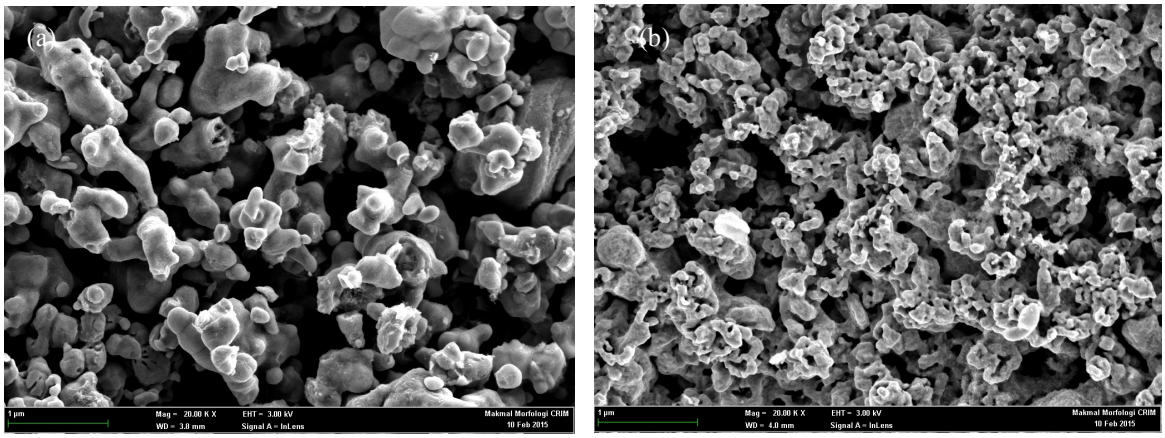

Figure 5. FESEM image of the surface of particle of (a) $Fe_2O_3$ and (b) Rh-$Fe_2O_3$ reduction at 650 °C in 10% CO atmosphere

## Conclusion

The reduction behaviour of Rh added to the $Fe_2O_3$ in CO as a reductant was investigated and compared using TPR and XRD. Addition of Rh to the iron oxide showed the effect on enhancing the reduction process in CO atmosphere. The reduction process completed 250 °C lower compared to $Fe_2O_3$ with XRD patterns showed only metallic Fe peak at 650 °C. Rhodium species played important role on lowering the reduction temperature due to well dispersed of the Rh particle, good interaction with CO as prove by the thermodynamic data and higher of surface area.

**Abstract**

$Cu_2O$ photocathode such as nanowire (NW) have shown to improve photoactivity than that nanoparticle thin film counterpart. This enhancement is attributed to enhanced photocatalytic reaction due to increase in surface active area and effective radial charge diffusion. However, the photoelectrochemical performance of reported work were rather low which need an improvement prior protection. In this study, $Cu_2O$ nanowire photocathode was fabricated using sequential wet chemical oxidation method and annealing under inert condition. Focusing on annealing step, the transformation of precursor $Cu(OH)_2$ nanowire to $Cu_2O$ nanowire undergone multistep annealing with a different ramping rate under inert condition. The highest photocurrent was then compared with photocurrent generated from $Cu_2O$ NW prepared with direct annealing strategy. With multistep annealing, the best photoelectrochemical performance was obtained from $Cu_2O$ NW prepared at the highest ramping rate which is 1.2 folds better than that obtained with single step annealing. The photocurrent enhancement obtained in this study was attributed to favourable morphology improving light trapping. Overall, the ampleness of material source, non-toxic, simple fabrication and excellent photocatalytic performance are the pre-requisite to realize solar hydrogen production.

**Keywords**: cuprous oxide nanowire, photocurrent, water-splitting, hydrogen production

**Abstrak**

Fotokatod $Cu_2O$ yang berstrukturkan nano wayar (NW) telah menunjukkan aktiviti foto yang lebih baik berbanding filem nipis. Prestasi fotomangkin yang baik ini disumbang oleh peningkatan luas permukaan yang aktif dan keberkesanan pengaliran cas. Walaubagaimanapun, prestasi fotoelektrokimia yang telah dilaporkan masih lagi rendah dan memerlukan penambahbaikan sebelum penyalutan sebagai perlindungan untuk kestabilan fotokatod. Dalam kajian ini, $Cu_2O$ NW fotokatod telah disintesis menggunakan oksidasi kimia dan pengkalsinan dalam keadaan lengai. Pada peringkat pengkalsinan, transformasi pemula $Cu(OH)_2$ nanowayar kepada $Cu_2O$ nanowayar telah melalui beberapa langkah pengkalsinan dengan kadar pengkalsinan yang berbeza. Fotoarus yang tertinggi akan dibandingkan dengan fotoarus yang terhasil daripada $Cu_2O$ nanowayar yang disediakan menggunakan pengkalsinan terus. Pada pengkalsinan berperingkat, prestasi fotoelektrokimia yang terbaik didapati daripada $Cu_2O$ NW yang disediakan pada kadar pengkalsinan yang paling tinggi iaitu 1.2 kali ganda lebih baik berbanding yang didapati daripada pengkalsinan terus. Peningkatan fotoarus yang terhasil daripada kajian ini telah disumbangkan oleh kesan morfologi bahan yang berkeupayaan menyerap cahaya secara efektif. Keseluruhannya, keberadaan sumber bahan yang mencukupi, tidak toksik, cara penyediaan yang mudah, serta prestasi fotomangkin yang bagus adalah keperluan untuk merealisasikan penghasilan hidrogen dari tenaga suria.

**Kata kunci**: nanowayar kuprous oksida, fotoarus, pembelahan air, penghasilan hidrogen

## Introduction

The photocatalytic performance of $Cu_2O$ photocathode for photoelectrochemical application can be enhanced by nanostructuring owing to its high surface area for photocatalytic reaction and alleviated issue of mismatch between the intrinsic carrier diffusion length [1, 2] and the light absorption depth near the band gap [3]. This single metal oxide was theoretically estimated to produce approximately -15 mA/cm$^2$ and photoconversion efficiency of 18% based on the AM 1.5 spectrum [4]. As photocathode, recent research trend has been attempts to fabricate the photocathode with nanowire (NW) arrays film [5-8] and stabilize it using facile technique and inexpensive protective material, respectively [4, 9-12]. Prior to stabilization, priority should be given to improve the photocurrent generation that can be tapped from the photoharvester of $Cu_2O$ film. This step is crucial to compensate photocurrent reduction which might be due to poor charge transportation between overlayers or any deleterious effect of the film after the coating treatment [9, 13-15]. $Cu_2O$ NW can be fabricated using sequential wet chemical oxidation method (WCOM) [1, 6, 11, 16] followed by annealing under inert condition as one of the method which promotes facility and high quality. This method is initiated with the fabrication of $Cu(OH)_2$ NW as precursor using WCOM [17] before transforming to $Cu_2O$ NW through annealing under inert condition. Focusing on the annealing process, the transformation of the precursor to $Cu_2O$ NW involved dehydration and deoxidization step [17, 18]. Therefore it needs a multistep of annealing to provide each step with a complete transformation from $Cu(OH)_2$ to CuO through dehydration and ultimately CuO to $Cu_2O$ through deoxidization.

Through literature survey on PEC application, there was only one single study which we know of following similar annealing strategy for $Cu_2O$ NW fabrication from $Cu(OH)_2$ NW precursor [19]. However, this study only managed to achieve photocurrent of -2.05 mA/cm$^2$ at 0.265 V vs. RHE which was produced from the sample annealed at 700 $^oC$ for 2 hours. The low photocurrent could be due to diminishing NW structure at high annealing temperature, thus decreased surface active area for photocatalytic reaction. Other reported studies with similar material and strategy deemed to practise a direct annealing since no details were mentioned on annealing step [5, 6, 8, 12, 16]. As far as photocurrent generation is concerned, the highest photocurrent ever reported for bare $Cu_2O$ from WCOM was -4.07 mA/cm$^2$ at 0V vs. RHE. This PEC performance was achieved using WCOM and direct annealing at 500 $^oC$ for 2 hours under Argon flow [10]. Based on the maximum theoretical measurement of photocurrent for $Cu_2O$ photocathode mentioned above, there is indeed more room for improvement.

Therefore, in this study, an annealing with multistep strategy was used to affect an improved $Cu_2O$ NW photocathode with excellent PEC performance. Since the effect of annealing temperature [5, 10], and holding time [8] were well studied, hence we investigated the effect of multistep ramping rate at 500 $^oC$ for 2 hours. For comparison, a direct annealing was conducted under similar annealing parameter that affect the highest photocurrent.

## Materials and Methods

### The fabrication of $Cu(OH)_2$ NW

In most recent studies, $Cu(OH)_2$ NW was prepared using an established method proposed by Zhang et. al. [17]. However, in this study, the growth solution was modified by the addition of $NH_3$. Briefly, a sheet of copper foil as substrate of 1 cm$^2$ was cleaned in acetone, ethanol, and double distilled water ($ddH_2O$) for 5 minutes each, consecutively. The wet Cu foils were then dried with nitrogen flow prior to immersion in growth solution. The growth solution composed of 2.67 M NaOH (Amreck), 0.133 M $(NH_4)_2S_2O_8$ (Sigma), and 4.26% $NH_3$ (Merck), were dissolved in $ddH_2O$ as reaction media. After 25 minutes of reaction, blue film appeared covering the substrate indicating the growth of $Cu(OH)_2$ NW. Then, the grown film was rinsed with $ddH_2O$ and dried in air.

### The conversion of $Cu(OH)_2$ NW to $Cu_2O$ NW

The as-prepared $Cu(OH)_2$ NW film was then subjected for annealing to be converted to $Cu_2O$ NW under $N_2$ flow. Three levels of ramping rate at 1, 3, and 5 $^oC$/min were carried out to reach final temperature of 500 $^oC$ for 2 hours. Routinely, the furnace was first evacuated with vacuum and followed by nitrogen sparging alternately for 3 cycles. Then, from room temperature, the furnace was first raised to 120 $^oC$ with 5 $^oC$/min ramping rate and held at 120 $^oC$

for 60 minutes before ramped up to 180 $^{o}$C for 1 hour and held for another 1 hour. With different ramping rate as mentioned, the temperature was finally raised to 500 $^{o}$C and held for another 2 hours before cooling down. For comparison on PEC performance, a direct annealing (without multistep) was conducted at the pre-determined ramping rate under similar annealing condition. For simplicity, hereafter, the $Cu_2O$ NW sample prepared with multistep annealing at 1, 3, and 5 $^{o}$C/min ramping rate were denoted as $Cu_2O$-(1 $^{o}$C/min), $Cu_2O$-(3$^{o}$C/min), and $Cu_2O$-(5$^{o}$C/min), respectively. Whereas sample labelled with $Cu_2O$-(5 $^{o}$C/min)(D.A) stands for $Cu_2O$ NW which prepared with direct annealing strategy at 5 $^{o}$C/min.

**Structural characterization**

The morphology of the samples was characterized using a Variable Pressure Scanning Electron Microscope (VPSEM). The crystallinity of the samples were determined by X-ray diffractometer (XRD) (Bruker D8 Advance), using Cu Kα radiation. Whereas, the UV-vis diffuse reflectance spectra were determined with a spectrophotometer (Perkin Elmer, Lambda 950).

**Photoelectrochemical measurement**

The photoresponse of the samples were measured using three electrodes configuration contained in a photocell with expose area of 0.196 cm$^2$. The fabricated photoelectrode was assigned as working electrode, Ag/AgCl as reference electrode, and platinum as counter electrode. Cu tape was connected to photoelectrode sample and clamped before it is filled with electrolyte. Those electrodes were immersed in 0.5 M $Na_2SO_4$ solution which was purged with Argon for 10 minutes prior to measurement. The photocurrent measurement was acquired under AM 1.5 Xenon light irradiation at 100 mW/cm$^2$. The photocurrent density was then determined as a result of subtraction between light and dark current and divided by the sample's exposed area.

## Results and Discussion

**Characterization of $Cu_2O$ NW film**

The transformation of $Cu(OH)_2$ NW to $Cu_2O$ NW depicts a morphology changes from a straight-standing $Cu(OH)_2$ NW to bendy and segmented $Cu_2O$ NW (Figure 1). The changes can be seen started at 180 $^{o}$C (Figure 1b) where a straight NW of $Cu(OH)_2$ NW was appeared bendy and the films turned black (insert (1b). As temperature increased to 500 $^{o}$C at different ramping rate and held for 2 hours, a dramatic change on the NW strand was noticed (Figure 1c, 1d, and 1e) indicating $Cu_2O$ NW was produced as evidenced from XRD analysis Figure 2. It was reported that the curly and bendy NW after annealing was due to the stress of phase changes resulted from oxygen separation from the lattice of CuO [8].

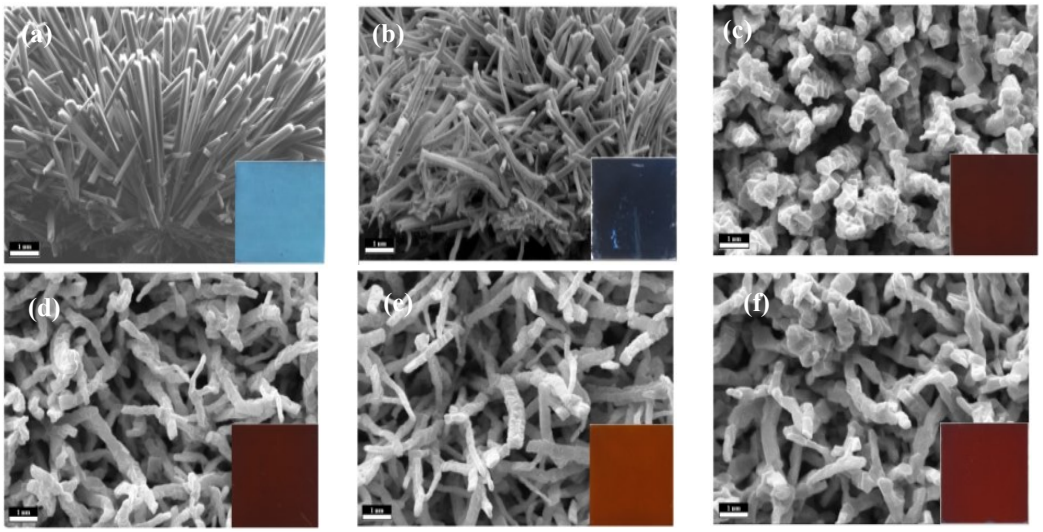

Figure 1. SEM images of a) $Cu(OH)_2$ NW, b) CuO NW, $Cu_2O$ NW prepared at multistep annealing with different ramping rate at c) 1 $^{o}$C/min, d) 3 $^{o}$C/min, e) 5 $^{o}$C/min, and f) without multistep $Cu_2O$ NW-(5 $^{o}$C/min) (D.A)

The phase transformation from CuO to $Cu_2O$ is explainable with deoxidization reaction where oxygen molecules was removed from the CuO lattice and reducing the ionic state from 2 to 1 becoming $Cu_2O$ [17]. Along with morphology changes, the NW dimension also changed accordingly as tabulated in Table 1.

Table 1. The dimension of nanowire before and after annealing measured using ImageJ software

| Samples | Length (µm) | Width (µm) |
|---|---|---|
| $Cu(OH)_2$ NW | 5.60 ± 0.20 | 0.40 ± 0.02 |
| $Cu_2O$-(1 $^oC$/min) | 2.72 ± 0.14 | 0.82 ± 0.14 |
| $Cu_2O$-(3 $^oC$/min) | 3.12 ± 0.09 | 0.45 ± 0.01 |
| $Cu_2O$-(5 $^oC$/min) | 4.07 ± 0.08 | 0.39 ± 0.08 |
| $Cu_2O$-(5 $^oC$/min)(D.A) | 3.33 ± 0.07 | 0.56 ± 0.04 |

The results obtained here can be concluded that, the length and width of NW arrays were shortened and widen as the ramping rate decreased. This observation is attributed to agglomeration of NW structure affected by long annealing time imposed by the lowest ramping rate. A long annealing time induced the increase in crystal size which is in agreement with reported study [8]. On the other hand, samples annealed at higher ramping rate has shorter annealing time and were not severely impacted by agglomeration, hence appeared to be the longest NW. Although $Cu_2O$-(5 $^oC$/min)(D.A) sample was prepared with the shortest annealing time, its NW length is shorter than that measured for $Cu_2O$-(5 $^oC$/min). This shows that during the multisteps annealing the different holding time at different temperatures affected the agglomeration rate differently than during direct annealing. Furthermore, it is reported that the curly and bendy NW after annealing was due to the stress of phase changes resulted from oxygen separation from the lattice of CuO [8].

In Figure 2, an overlayer of XRD pattern of the samples pre and post annealing are displayed. A distinct XRD pattern of each sample reflecting a complete transformation from Cu to $Cu(OH)_2$, CuO and subsequently to $Cu_2O$ after annealing. $Cu_2O$ is known with dominant peak of 111 phase which claimed to be responsible for good PEC performance [5, 20]. This particular peak has increased in intensity as the ramping rate decreased which remarked an improved crystallinity with longer annealing time (Figure 2). Contrastingly, the $Cu_2O$-(5 $^oC$/min)(D.A) has shown a higher peak intensity than that obtained by $Cu_2O$-(5 $^oC$/min). The peculiar results on NW dimension and crystallinity demonstrated by $Cu_2O$-(5 $^oC$/min)(D.A) sample might be clarified through the study of effect of annealing temperature on dominant peak intensity through direct annealing strategy.

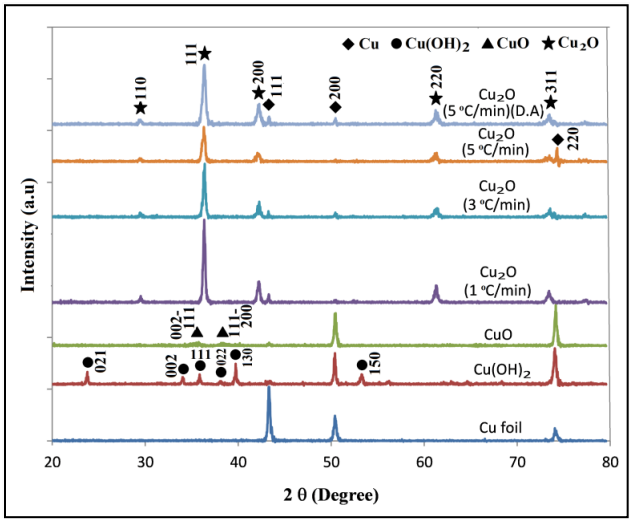

Figure 2. The overlayer of XRD pattern of samples pre and post annealing

The photoabsorption of the annealed samples were measured using diffuse reflectance spectrophotometry (Figure 3a). The higher reflectance indicates lower light absorption. Therefore, in this study, $Cu_2O$-(5 $^oC$/min) has the higher capacity in absorbing light than $Cu_2O$-(1 $^oC$/min) specifically within 300 – 500 nm light spectrum frame. This observation has the correlation with the morphology which structured at different ramping rate. As mentioned earlier, short and bulky NW arrays were made of large crystal which featured with low surface area to volume ratio. Dimensionally, it did not encourage high light absorption capacity. Long and slim NW arrays, on the other hand, were made of small crystal which structured at relatively shorter annealing time, thus enhancing light trapping efficiency. These observations are in line with the previous reported study with similar research material and strategy [8]. In order to determine the band gap of each $Cu_2O$ NW sample, Kubelka Munk-plotting function was used against band gap energy [21]. From the K-M plotting (Figure 3b), a very close band gap for all samples were extrapolated to be 2.05 ± 0.01 eV. The obtained band gap values are consistent with reported value and within the favourable band gap frame (1.8-2.1 eV) for PEC application as suggested by Murphy et al. [22].

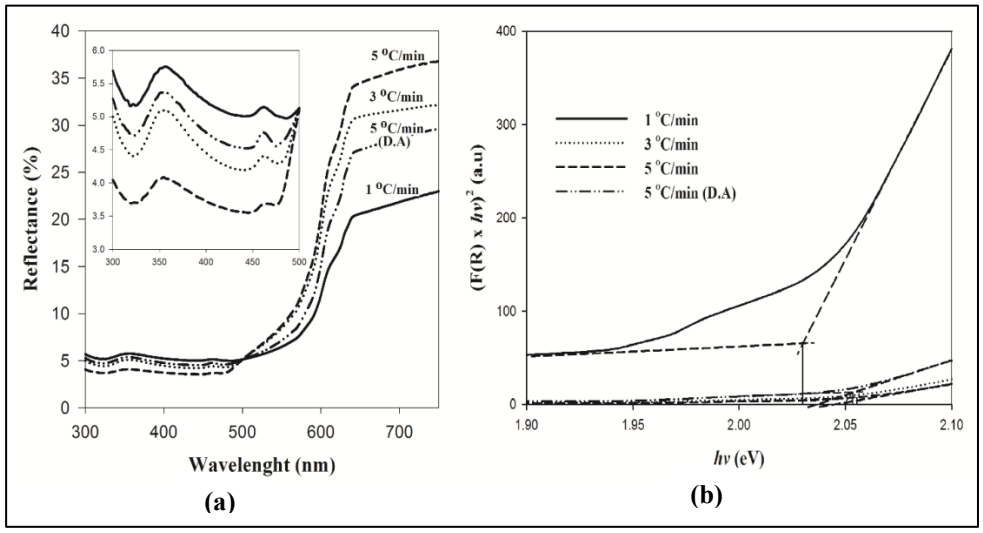

Figure 3. Diffuse reflectance spectra of a) $Cu_2O$ NW prepared at different ramping rate and annealing step; the insert shows the light reflectance value within a light spectrum frame, b) the corresponding Kubelka-Munk plot for the $Cu_2O$ NW-(1$^oC$/min), $Cu_2O$ NW-(3$^oC$/min), and $Cu_2O$ NW-(5$^oC$/min), and $Cu_2O$ NW-(5 $^oC$/min)(D.A)

**Photocurrent measurement**

The photocurrent appears to be influenced by the morphology of the NW which was affected by the ramping rate (Figure 2). A longer and thinner NW produced by a higher ramping rate (shorter time) enhanced photocurrent. Although the XRD peak intensity reduced with the higher ramping rate (shorter annealing time), this does not seem to reduce the photocurrent. Therefore, the NW morphology appears to have more effect on the photocurrent than the XRD peak intensity. This is shown by $Cu_2O$-(5 $^oC$/min) produced the highest photocurrent which benefitted from the long and slimmer NW which concomitantly provides high surface active area [23, 24], and improved radial charge diffusion for a better photocatalytic reaction [23, 25]. As the band gaps are very similar (Figure 3b), the photocurrent appears to be influenced solely by the morphology of the NW. Whereas, a lower ramping rate (longer annealing time) produced shorter and wider NW resulting in lower photocurrent. Even though the direct annealing strategy ($Cu_2O$-(5 $^oC$/min)(D.A)) has the shortest annealing time, but the photocurrent produced was significantly lower than that obtained by the sample $Cu_2O$-(5 $^oC$/min). This can also be observed from the NW morphology as well, where $Cu_2O$-(5 $^oC$/min)(D.A) has shorter and wider NW compared to$Cu_2O$-(5 $^oC$/min). Furthermore, $Cu_2O$-(5 $^oC$/min)(D.A) reflects light higher than $Cu_2O$-(5 $^oC$/min)(D.A) which explained the photocurrent reduction as shown in Figure 4. Eventhough $Cu_2O$-(5 $^oC$/min)(DA) was prepared at the shortest annealing time, however the multistep annealing used in the $Cu_2O$-(5 $^oC$/min) preparation improved the NW morphology which resulted in enhanced

photocurrent. This result suggested that multistep annealing is critical to affect complete phase transformation during the course of annealing.

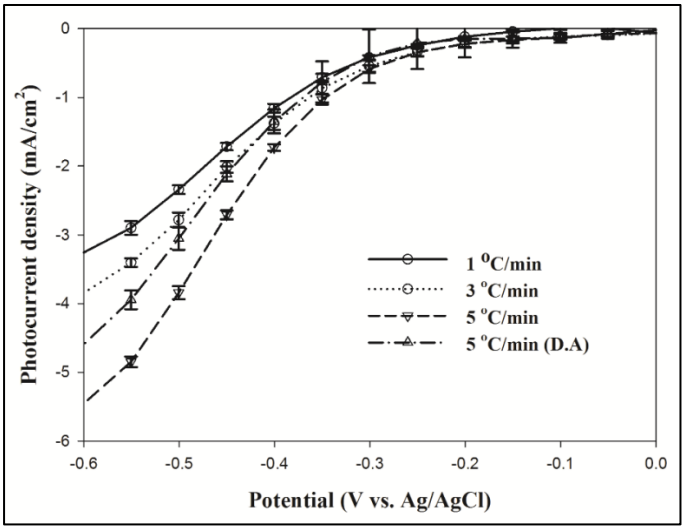

Figure 4. Photocurrent measurement generated from $Cu_2O$ annealed at different ramping rate and annealing step

## Conclusion

In this study, the photoactivity of $Cu_2O$ NW was markedly influenced by the effect of ramping rate which found to be analogous with the effect of annealing time. With longer and slimmer NW, $Cu_2O$-(5 $^o$C/min) sample exhibited the highest photoabsorption and photocatalytic activity, thus resulted with the highest photocurrent generation relative to the other $Cu_2O$ sample. This study also suggesting that a multistep annealing is necessary to prepare a good quality of $Cu_2O$ NW photocathode. Technically, this low cost and simple fabrication technique for $Cu_2O$ NW photocathode was adequate to produce a highly efficient photoelectrode for PEC system. The next step is to stabilize the $Cu_2O$ NW from photocorrosion problem which remain the biggest challenge.

**Abstract**

Carbon dioxide emissions generated from fossil fuel-based power plants and other industries has reached 400 ppm in atmosphere. This negatively impact the environment, infrastructures and wildlife in particular. A lot of efforts are needed to produce $CO_2$ gas sorbent in order to reduce high $CO_2$ concentration. Therefore, porous silica gel (SG) is modified with amine compound for carbon dioxide capture. Calcinated silica gel functionalized with tetradecylamine (TDA) using wet impregnation has been developed as a porous media. The prepared sorbents is characterized by $N_2$ physisorption technique Brunauer-Emmet-Teller analysis (BET). Significant changes in physical properties of the sorbents further ascertained the dispersion of TDA on the internal channels and external surface of the SG. Reactivity of porous sorbent towards $CO_2$ was evaluated using isothermal $CO_2$ adsorption desorption technique. This study shows 65TDA/SG enable to adsorb $CO_2$ in the highest capacity which is 23.22 $cm^3$ $CO_2$ per gram sorbent. Moreover, $CO_2$ capture consists of two type sorption which are physisorption and chemisorption. 55TDA/SG is the best sorbent in capturing $CO_2$ by chemisorption (19.62 $cm^3$ $CO_2$ per gram adsorbent).

**Abstrak**

Pembebasan karbon dioksida terhasil daripada plan penghasilan tenaga berasaskan bahan api fosil dan pelbagai industri telah mencecah kepekatan 400 ppm di atmosfera. Perkara ini memberi kesan negatif kepada alam sekitar, infrastruktur dan kehidupan liar khasnya. Pelbagai usaha diperlukan untuk menghasilkan penjerap gas $CO_2$ dalam usaha untuk merendahkan kepekatan $CO_2$ yang semakin meningkat ini. Oleh itu, silika gel berliang (SG) telah di ubahsuai dengan sebatian amina untuk pemerangkapan karbon dioksida. Silika gel yang telah dikalsin akan difungsikan dengan teteradesilamina (TDA) menggunakan kaedah impregnasi basah telah dibangunkan sebagai media berliang. Penjerap yang dihasilkan akan dicirikan dengan teknik jerapan fizikal $N_2$ iaitu analisis Brunauer-Emmet-Teller (BET). Perubahan ciri fizikal yang ketara pada penjerap mengukuhkan lagi sebaran TDA pada permukaan dalam liang dan juga permukaan luaran SG. Kereaktifan penjerap berliang terhadap $CO_2$ telah dinilai menggunakan teknik penjerapan dan penyahjerapan isoterma $CO_2$. Hasil kajian ini menunjukkan bahawa 65TDA/SG mampu menjerap $CO_2$ dalam kapasiti yang tertinggi sebanyak 23.22 $cm^3$ $CO_2$ per gram penjerap. Tambahan, pemerangkapan $CO_2$ terdiri daripada dua jenis serapan iaitu serapan fizikal dan jerapan kimia. Penjerap 55TDA/SG adalah penjerap terbaik dalam pemerangkapan $CO_2$ secara jerapan kimia (19.62 $cm^3$ $CO_2$ per gram penjerap).

## Introduction

In the era of globalization, carbon dioxide ($CO_2$) is well known as a main greenhouse gas. This gas is released into the atmosphere from human activities, industrial development including fossil fuel burning, chemical and petrochemical manufacturing [1]. Indoor air pollutants (IAPs) included that $CO_2$ is the representative pollutant of indoor air quality and its concentration is associated with the human activities while the outdoor concentrations of $CO_2$ range from 350 – 450 ppm. Therefore, studies have been done to collect $CO_2$ gas to be used as fuel feedstock and other chemicals. The great effort in reducing concentration of $CO_2$ in atmosphere is more important rather than lowering concentration of $CO_2$ gas emission [2]. The accumulated $CO_2$ traps the earth's heat, thus creating global warming which has already altered weather patterns and further increasing sea levels due to the melting of the polar iceberg. There were several works reported in reducing $CO_2$ concentration by capture and separate the $CO_2$ gas. There are different unit operations such as liquid absorption phenomena [3], solid adsorption [4-6], cryogenic techniques and selective diffusion through polymer, metallic or ceramic membranes [7].

Therefore, research in developing $CO_2$ sorbents must be taken in order to reduce the concentration of $CO_2$ in the atmosphere. Amines are the most widely used organic chemicals for $CO_2$ capture due to their basicity. This allows them to react with acidic $CO_2$ to form a carbamate compounds. This reaction known as chemisorption. Previous study, straight chain alkylamine with C18 known as octadecylamine was developed as $CO_2$ sorbent. Octadecylammonium octadecylcarbamate ion pairs (alkylammonium alkylcarbamate) was formed on contact with dry $CO_2$ [8]. Belmabkhout et al. [9] reported, under dry conditions, carbamate with $CO_2$/N stoichiometry ratio of 0.5 is formed. This means two amine groups are needed in interact with one $CO_2$ molecule on the adsorbent surfaces as reported by Gray et al. [10] (refer Equation 1).

$$\underset{\text{alkylamine}}{2\,RNH_2} + \underset{\text{carbon dioxide}}{CO_2} \longrightarrow \underset{\text{alkylacarbamate}}{RNHCO_2^-} + \underset{\text{alkylammonium}}{RNH_3^+} \quad (1)$$

Nowadays, porous materials are widely used as supporter such as silica dioxide, silica gel, activated carbon and many more [1, 2, 4, 6]. Supporter is important to improve stability of the amine compound. Besides, porous materials have an ability to interact with $CO_2$ gas through physical interaction (physisorption). In this study, physical and chemical modifications at the external surface or internal channels of the supporter (silica gel, SG) using organic functional groups (tetradecylamine, TDA, $C_{14}H_{31}N$) have drawn much attention. The synthesized sorbents were characterized by Brunauer-Emmet-Teller analysis (BET).

## Materials and Methods

Modification of silica gel (SG) by tetradecylamine (TDA) represented as TDA/SG was done through wet impregnation method with few modifications [11]. Silica gel powder (Fluka) was calcined at 600 °C for 3 hours before impregnation process with various percentage of TDA (ALDRICH®, 97%) and chloroform, $CHCl_3$ (SYSTERM®, 99 – 99.4%) as a solvent. After stirring for 4 hours in a closed system, the mixture was rested for 1 hour before sonication (S 4000-010 Sonicator 4000) and afterward evaporated in air for one night. The process followed by drying at 45 °C for 4 hours in a vacuum oven. Lastly, the adsorbents were physically characterized by $N_2$ adsorption desorption isothermal and reactivity towards $CO_2$ measured by $CO_2$ adsorption desorption isothermal at 30 °C using BET technique (Micrometiric ASAP 2020).

## Results and Discussion

The sorption capacity of $CO_2$ on prepared sorbents were measured by $CO_2$ isothermal adsorption desorption using BET technique at 30 °C. Referring to Figure 1 and 2, unmodified SG was able to captured 9.39 $cm^3$ $CO_2$ / g sorbent. This capacity is higher than another two modified SG, 5 and 15TDA/SG. Addition of 5-15 % TDA will prevent direct interaction of $CO_2$ towards SG due to formation of mono or multilayers TDA on SG surfaces. This happened during wet impregnation process in which mixture of TDA and chloroform were able to wet entire surface of SG including external and internal surfaces (small pores of SG). After drying process, chloroform was evaporated and TDA layers formed on the SG surfaces. It was clearly shown that pure SG is enable to adsorb $CO_2$. According to addition of 15 to 65 % TDA, the amount of $CO_2$ uptake increased proportional to the TDA percent loaded. The capacity of $CO_2$ gradually increased from 13.21 up to 23.22 $cm^3$ $CO_2$ / g sorbent. However, $CO_2$ uptake by the SG modified with 75 % TDA was reduced drastically and lower than 45TDA/SG sorbent.

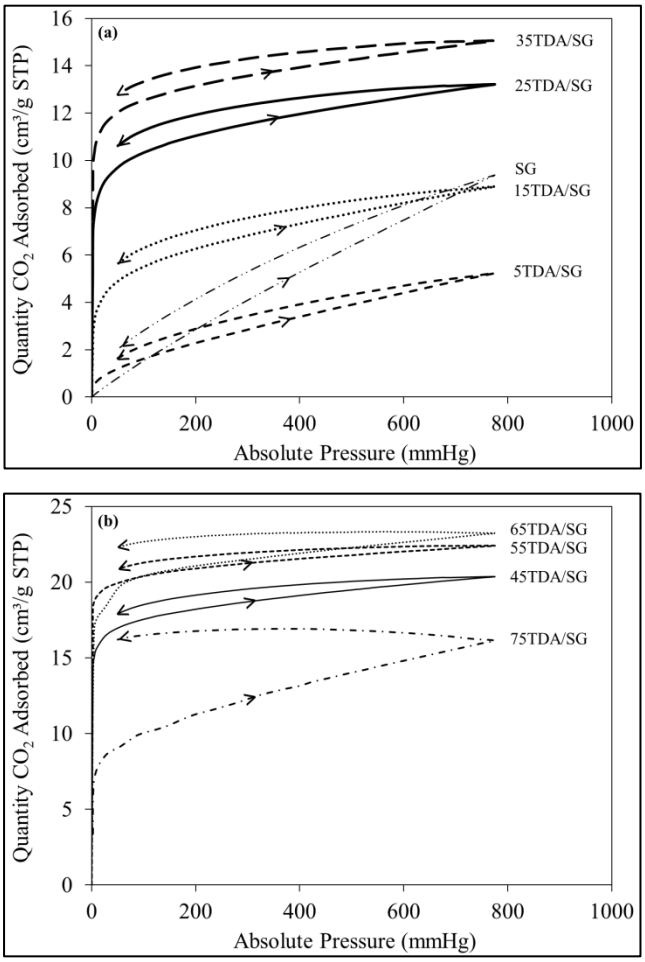

Figure 1. $CO_2$ adsorption-desorption isotherms of SG and modified SG with (a) SG, 5TDA/SG, 15TDA/SG, 25TDA/SG and 35TDA/SG and (b) 45TDA/SG, 55TDA/SG, 65TDA/SG and 75TDA/SG

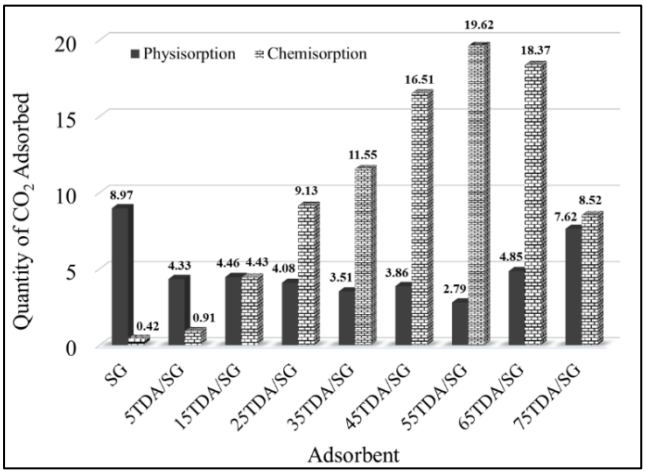

Figure 2. Quantity of $CO_2$ adsorbed physically and chemically measured by $CO_2$ adsorption desorption isothermal using BET technique

At a very low pressure, $CO_2$ sorption curve is very sharp and increased drastically around 0 – 20 mmHg. Formation of linear curve can be seen at higher pressure (more than 20 mmHg). This pattern is just applicable for modified SG whereas $CO_2$ sorption curve for unmodified SG sorbent was increased gradually without linear curve at the higher pressure. Shaw et al. [12] reported a very sharp sorption curve at the initial pressure showed that sorption of $N_2$ gas occurred in the small pores which known as micropores. Referring to Table 1, measured surface value t-$plot_{mic}$ for SG is 12.89 $m^2/g$ and this proved SG contained small pores in micro size known as micropores. In this research which involved $CO_2$ gas, the very sharp curve proved that the $CO_2$ gas were able to enter the micropores of SG. It happened due to strong interaction between internal SG channels (micropores surfaces) towards $CO_2$ gas. This interaction known as physical interaction or so called physisorption. However, drastically increased $CO_2$ uptake at the initial sorption also clarified chemical reaction that formed between $CO_2$ and TDA molecules. This chemical reaction also known as chemisorption and can produce another compounds such as alkylcarbamate and alkylammonium. Bacsik et al. [13] suggested highest amount of $CO_2$ uptake happened at highest pressure and lower temperature by modified silica with (3-aminopropyl) methyldiethoxysilane (APMDES) was referred to chemical adsorption of $CO_2$.

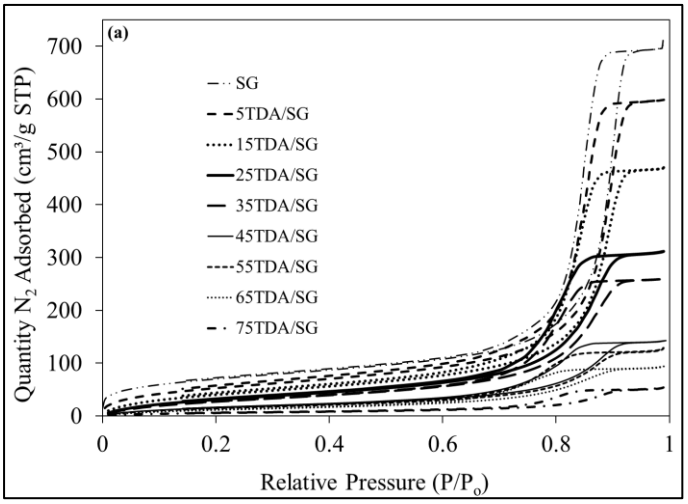
There are two lines on the sorption curve which refers to adsorption (->-) and desorption (-<-) line. Adsorption line starts from 0-760 mmHg whereas desorption line is vice versa (760 – 0 mmHg). Referring to the curve, we found desorption line is not converge with the adsorption line at lower pressure. This explained by changing pressure of the system was unable to fully desorp the captured $CO_2$ gas. Usually, this refers to $CO_2$ gas that entered micropores and chemically bonded with the TDA molecules. Energy (usually heat energy) is needed to break these chemical bonds. Therefore, captured $CO_2$ gas can be desorbed and sorbent can be used again in capturing $CO_2$.

Table 1. Effect of percent TDA loading towards SG surface properties

| **Adsorbent** | **$S_{BET}$ ($m^2/g$)** | **t-$plot_{mic}$ ($m^2/g$)** | **$V_t$ ($cm^3/g$)** | **$W_D$ (Å)** |
|---|---|---|---|---|
| SG | 246.17 | 12.89 | 1.2 | 174.9 |
| 5 TDA/SG | 194.7 | n.d | 0.9 | 121.8 |
| 15TDA/SG | 159.6 | n.d | 0.7 | 111.2 |
| 25TDA/SG | 128.8 | n.d | 0.5 | 91.5 |
| 35TDA/SG | 113.2 | n.d | 0.4 | 87.9 |
| 45TDA/SG | 81.4 | n.d | 0.2 | 81.0 |
| 55TDA/SG | 61.3 | n.d | 0.2 | 73.0 |
| 65TDA/SG | 48.8 | n.d | 0.1 | 71.0 |
| 75TDA/SG | 29.2 | n.d | 0.1 | 67.5 |

n.d = note detected

Figure 2 shows quantity of $CO_2$ adsorbed that measured by adsorption desorption of $CO_2$ using BET technique. As discussed earlier, $CO_2$ sorption at initial pressure (0 – 20 mmHg) was corresponded to chemisorption and physisorption in the micropores. Therefore, by subtracting capacity of $CO_2$ at the highest pressure (760 mmHg) to the value at lower pressure, the amount of $CO_2$ captured by physical interaction can be measured. $CO_2$ uptake by physisorption on SG was the highest compared to other sorbents with value 8.97 $cm^3$ $CO_2$/g sorbent. This value explained that SG is a porous material which able to attract and capture $CO_2$ gas in the SG pores through physical interaction. The absence of sharp sorption curve at the initial pressure proven physisorption was primarily occurred compared to chemisorption (0.42 $cm^3$ $CO_2$/g sorbent).



Addition of TDA from 5 to 55 % exhibited an increasing capacity of chemisorption from 0.91 to 19.62 $cm^3$ $CO_2$/g sorbent. Meanwhile, capacity of physisorption was reduced gradually with increasing percent of TDA. This clarified as amine was loaded onto SG, the pores of SG are filled with amine layers hence increasing the steric hindrance for

physisorption of $CO_2$ to occur and more $CO_2$ affinity sites were exposed for chemisorption to take place [14]. Thus, it is suggested that the higher sorption of $CO_2$ on modified SG also due to more chemisorption process occurred in the internal channels and external surfaces ($CO_2$–TDA chemical interaction/reaction).

However, capacity of $CO_2$ sorption by SG loaded with 5 and 15% TDA are not improve significantly compared to ability of pure SG since the presence of TDA layers on the internal SG pores have reduced the $CO_2$–SG physisorption and yet improved chemisorption. Conversely, $CO_2$ uptake by chemisorption on higher percent TDA loading (65 and 75TDA/SG) was declined to 8.52 $cm^3$ $CO_2$/g sorbent whereas capacity of physisorption was take place by increased up to 7.62 $cm^3$ $CO_2$/g sorbent. Hence, addition of high amount of amine (more than 55% TDA) is not require due to formation of amine double or multilayer on the SG surfaces which reducing amount of active sites and further dropping the ability of formation alkylammonium alkylcarbamate compounds [15].

Amine modified SG was further examined using physisorption analysis (Micrometiric ASAP 2020). BET surface area, micropore surface area (t-$plot_{mic}$), pore volume and pore width values was summarized in Table 1. Figure 3(a) shows $N_2$ adsorption and desorption isotherms of all adsorbents. According to IUPAC (1972), the hysteresis curve of all adsorbents is type A where the mesopores are cylindrical in shape [16]. At the earlier stage of the sorption, which is involving low pressure, the adsorption of a single/mono layer of $N_2$ happened inside pores and followed by adsorption of multiple layers at higher relative pressures. Based on the isotherms, as the TDA loading percentage increases, the quantity of $N_2$ sorbed will decreases. This is due to physical changes that occurred on the SG surface after the impregnation of TDA. According to rapid pore filling theory, the long chain molecules (TDA) can rapidly fill into the mesopores. Consequently, it creates pore blockage and resulted in the lowering of the quantity of $N_2$ adsorbed which is directly refers to the decreasing in BET surface area.

Referring to Figure 3(b), average pore diameter appeared as a peak for each sorbent. The highest peak was the SG without any loading while the lowest peak was the 75TDA/SG. The average pore width of SG is 174.9 Å, which refers to the aperture or diameter of the mesopores. When the SG was modified with 35% TDA, the average pore width shifted to a lower value (100.42 Å) since the formation of TDA layer on the inner wall of the mesopores. This result suggests that more molecules are able to get into the pores during modification even though TDA is a straight and long chain molecules. Moreover, the addition of 75% TDA shows drastically decreased in pore volume which is from 1.2 to 0.1 $cm^3$/g (Figure 3(c)). This explains the rapid entrance of amine molecules into the pores making the empty spaces to be filled with that amine molecules [17, 18]. Therefore, the decreasing values of average pore width are proportional with the total volume of the pores.

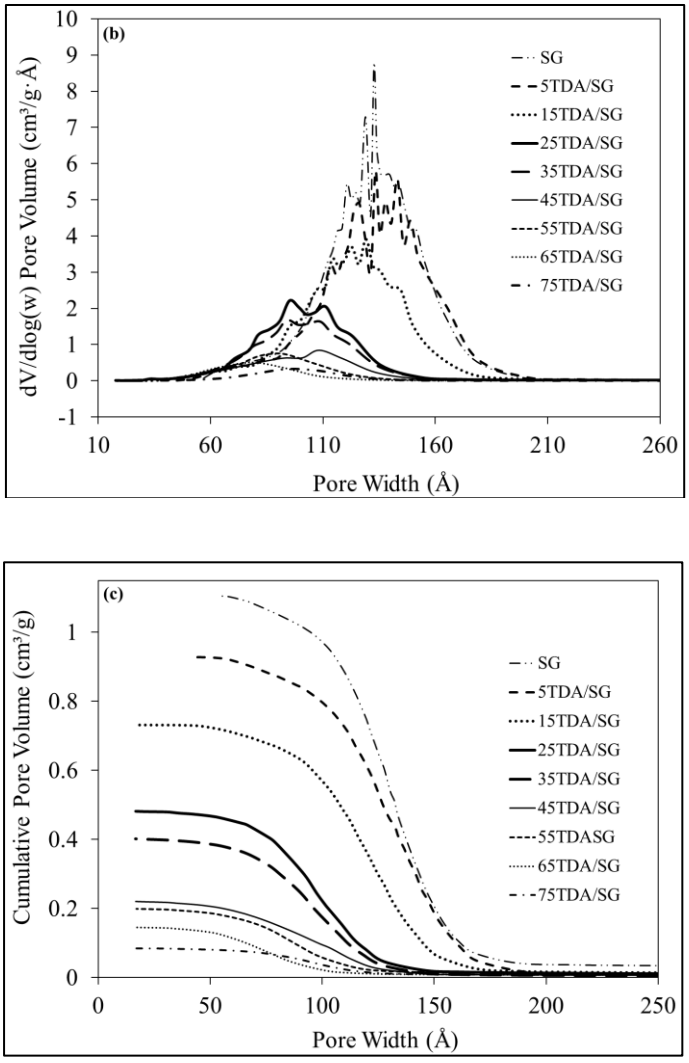


Figure 3. Surface properties of SG and modified SG (5TDA/SG, 15TDA/SG, 25TDA/SG, 35TDA/SG, 45TDA/SG, 55TDA/SG, 65TDA/SG and 75TDA/SG by BET technique with (a) $N_2$ adsorption desorption isotherms, (b) Pore size distributions and (c) Cumulative pore volume of sorbents.

## Conclusion

$CO_2$ gas can be captured by prepared sorbent which is SG modified with different percentage of TDA. $CO_2$ isothermal adsorption desorption analysis shows that capturing $CO_2$ gas involved two types of sorption (physisorption and chemisorption). SG is a porous material acts as supporter and able to physically capture $CO_2$ gas whereas modified SG are mainly undergo chemically capture $CO_2$ gas. Moreover, 55TDA/SG was the optimum sorbent due to its ability in capturing highest amount of $CO_2$ through chemisorption. It is very important in order to increase retention time of $CO_2$ on the sorbent before it finally being desorb at different time and place (good for transport purposes). Various amount of TDA loading resulted in great changes in physical properties of the adsorbents in term of BET surface area, average pore diameter and total pore volume of adsorbents. Therefore, all significant changes happened actually ascertained the existence of TDA on the SG surfaces by wet impregnation method.

**Abstract**

Dye-sensitized solar cell (DSSCs) is one of the photovoltaic cells that have attracted extensive research over decade. In this study, different weight percentage (wt.%) of graphene oxide (GO) was used with titanium dioxide ($TiO_2$) as photoelectrode in DSSCs. GO was synthesized by simplified Hummer's method at ambient temperature. The amount of GO in composite film are designed from 0.0 wt.%, 0.4 wt.%, 0.6 wt. % and 0.8 wt.%. The prepared samples were characterized by Field Emission Scanning Electron Microscopy (FESEM), X-ray Diffraction (XRD), Atomic Force Microscopy (AFM) and Incident Photon to Current Efficiency (IPCE). The photocurrent-voltage characteristics of the fabricated dye sensitized solar cells were examined using a solar simulator under 100 mW/cm$^2$ AM 1.5 xenon illumination. The results indicated that optimum the power conversion efficiency (PCE) was obtained for the device doped with 0.6 wt.% GO with the short circuit current density ($J_{sc}$), open circuit voltage ($V_{oc}$) and PCE of 9.8 mA/cm$^2$, 0.7 V and 3.7 %, respectively. It was observed that the introduction of 0.6 wt.% GO into $TiO_2$ photoelectrode has successfully increased the performance of DSSCs as much as 28% compared to the sample without GO. This is due to the increment in dye absorption and enhanced electron transportation as proven by IPCE analysis.

**Keywords**: dye sensitized solar cells, graphene oxide, photoelectrode, power conversion efficiency, titanium dioxide

**Abstrak**

Sel suria pemeka warna (DSSCs) adalah salah satu sel fotovolta yang telah menarik minat penyelidik sejak kebelakangan ini. Dalam kajian ini, peratusan berat grafin oksida (GO) yang berbeza telah digunakan bersama titanium dioksida ($TiO_2$) sebagai fotoelektrod di dalam DSSCs. GO telah disintesis dengan kaedah Hummer dipermudah pada suhu persekitaran. Jumlah GO dalam filem komposit telah ditetapkan dari 0.0 wt.%, 0.4 wt.%. 0.6 wt.% dan 0.8 wt.%. Sampel-sampel yang disediakan telah dicirikan dengan menggunakan analilsis Mikroskopi Imbasan Pancaran Medan Elektron (FESEM), Analisis Pembelauan sinar-X (XRD), Analisis Mikroskopi Daya Atom (AFM) dan analisis kejadian foton kepada keberkesanan pembawa arus (IPCE). Ciri – ciri fotoarus-voltan bagi sel suria pemeka warna telah diperiksa menggunakan simulator suria dengan intensiti dikawal pada 100 mW/cm$^2$ AM 1.5 pengcahayaan. Keputusan menunjukkan bahawa kecekapan penukaran kuasa (PCE) yang optimum telah dicatatkan oleh peranti DSSC yang ditambah 0.6 wt.% GO, dengan ketumpatan arus litar-pintas ($J_{sc}$), voltan litar-terbuka ($V_{oc}$) dan PCE masing-masing adalah 9.8 mA/cm$^2$, 0.7 V dan 3.7 %. Ini jelas menunjukkan bahawa penambahan 0.6 wt.% GO ke dalam $TiO_2$ fotoelektrod telah meningkatkan kecekapan prestasi bagi DSSCs sebanyak 28% berbanding dengan sampel tanpa GO. Peningkatan ini disebabkan oleh peningkatan penyerapan pewarna dan pengangkutan elektron seperti yang dibuktikan dalam analisis IPCE.

**Kata kunci**: sel suria pemeka warna, grafin oksida, fotoelektrod, kecekapan penukaran kuasa, titanium dioxide

## Introduction

Dye sensitized solar cells (DSSCs), the third generation of photovoltaic are currently proposed as the alternative to the conventional silicon solar cells. This is due to its low production cost, simple manufacturing procedures and practically under ambient condition with acceptable power conversion efficiency [1-3]. Generally, a monolayer of organic dye is attached to mesoporous metal oxide semiconductor with wide band-gap. The incident light is absorbed by the dyes and electrons are excited, and then injected into the conduction band of the metal oxide semiconductor. The electrons are then transported across the $TiO_2$ nanoparticles layer to the anode (current collector) and later, pass through the external circuit. The sensitizer is regenerated by the organic hole conductor which transport the positive charges to the counter electrode [4]. As a wide band gap semiconductor material, $TiO_2$ is commonly used as photoelectrode in DSSCs due to its abundances, low cost, good chemical stability, non-toxicity, and etc. [5]. It functions as a dye loader, electron acceptor and electron transporter in DSSCs. However, the particles sizes of $TiO_2$ in photoelectrode films are too small to support any space charge and form inner electric field, causing transportation of electrons in the $TiO_2$ porous film is a random process of electron diffusion and hopping [6]. These electron transportations modes encourage to electron recombination with oxidized states of dye or oxidized particles in electrolyte. The transportation of electrons was disturbed and thus decreased the photoelectric conversion efficiency (PCE) of DSSCs [7]. Currently, numerous ways are being explored by researchers to enhance the electron transportation in photoelectrodes and reduce the charge recombination in order to increase the performances of DSSCs. According to Yen et al. [8], both of the $V_{oc}$ and $J_{sc}$ can be enhanced by incorporating carbon nanotubes (CNTs) into $TiO_2$ to form compound photoelectrode. However, this enhancement is limited by poor contact between $TiO_2$ with CNT. In order to optimize the structure of photoelectrode in DSSCs, three different layers of TiO2 were designed by Hu et al. [9]. These layers including small pore size films, larger pore size films, and light-scattering particles. Their results show that DSSCs with optimized microstructures had better lightscattering effects and gaining a higher PCE compared to conventional DSSCs. Recently, a study was reported by Bai et al. [10] to enhance the electron transfer by introducing a new type of photoelectrode architecture. The photoelectrode was prepared by in situ direct growth of ZnO nanowires within a $TiO_2$ nanoparticle film through a hydrothermal process. The results show that by embedding an optimal amount of ZnO in $TiO_2$, it can enhance the PCE remarkably from 6.65% to 8.44%. Mane et al. [11] was reported the recombination between electron and oxidized dye as well as $I^{3-}$ in the electrolyte was reduced by introducing a core−shell structure by using the layer-by layer deposition to coat a 30 nm ZnO layer on $TiO_2$ film. The ZnO layer acts as an energy barrier to block electron transportation out of $TiO_2$, then reducing the recombination and increased the PCE from 3.31% to 4.51%.

Recently, the extensive investigation has been carried out on the graphene-based composite nanomaterials because of the synergistic effects of the different functional components in the composites. With excellent electron mobility and large specific area, graphene can be incorporated into $TiO_2$- based DSSCs photoelectrode as electron transport enhancer and support material for PCE improvement [12-14]. Numerous synthetic methods to produce graphene/$TiO_2$ composites as photoelectrode materials have been developed [15], and the positive effects of the incorporated graphene have been revealed and summarized in the following two main aspects: (1) increased dye adsorption and (2) significant longer exciton lifetime. The incorporation of graphene gives rise to the porosity of the anode films, which increases the surface area for more dye adsorption sites, therefore enhancing the dye loading and the light harvesting efficiency. Furthermore, graphene dispersed in $TiO_2$ matrix forms a continuous 2D conduction network. The photogenerated electrons in the network can be effectively transported across the $TiO_2$ matrix, which reduce the charge recombination, and extending the electron lifetime [13]. In this study, different amount of graphene oxide (GO) was doped with $TiO_2$ as the photoelectrode in DSSCs. The influences of different wt.% of GO on the photovoltaic parameters were studied. It exhibited that GO improved the $J_{sc}$, $V_{oc}$ and PCE of DSSCs in comparison to control device. The device with optimum doping concentration of 0.6 wt.% GO exhibited $J_{sc}$ = 9.80 mA/cm$^2$, $V_{oc}$ = 0.72 V and FF = 53.2 %, resulting in a PCE of 3.7 %.

## Materials and Methods

### Materials

Graphite nanopowder (400nm – 1.2µm, 99.9%) and titanium dioxide nanopowder ($TiO_2$, anatase, 99.5%, 15 nm) were purchased from US Research Nanomaterials. Potassium permanganate ($KMnO_4$, 99.9%), sulfuric acid ($H_2SO_4$, 98%), phosphoric acid ($H_3PO_4$, 85%), hydrogen peroxide ($H_2O_2$, 30 %), hydrogen chloride (HCl, 37%),

polyethylene glycol ($M_w$ =10,000) from Sigma Life Science, nitric acid ~70.0%, triton X-100 purchased from Sigma-Aldrich, iodolyte AN-50 from Solaronix and platinum paste PT-1 from Dyesol company.

**Synthesis of graphene oxide**

GO was synthesized using simplified Hummer's method at ambient temperature [16] as illustrated in Figure 1. Oxidation of graphite was carried out by mixing $H_2SO_4$:$H_3PO_4$ (72:8 mL), graphite nanopowder: $KMnO_4$ (0.72 g), and $KMnO_4$ (3 g) using a magnetic stirrer. After adding all the materials slowly, the one-pot mixture was left for stirring for 3 days at ambient temperature to allow the oxidation of graphite. The colour of the mixture changed from dark purplish green to dark brown. Several drop of $H_2O_2$ solution was added to stop the oxidation process, and the colour of the mixture changed to bright yellow, indicating a high oxidation level of graphite. The graphite oxide formed was washed three times with 1 M of HCl aqueous solution and repeated with deionized water until a pH 4 – 5 was achieved. The washing process was carried out using simple decantation of supernatant via a centrifugation technique with a centrifugation speed 10,000 rpm and 10 minutes. During the washing process with deionized water, the graphite oxide experienced exfoliation, which resulted in the thickening of the graphene solution, forming a GO paste.

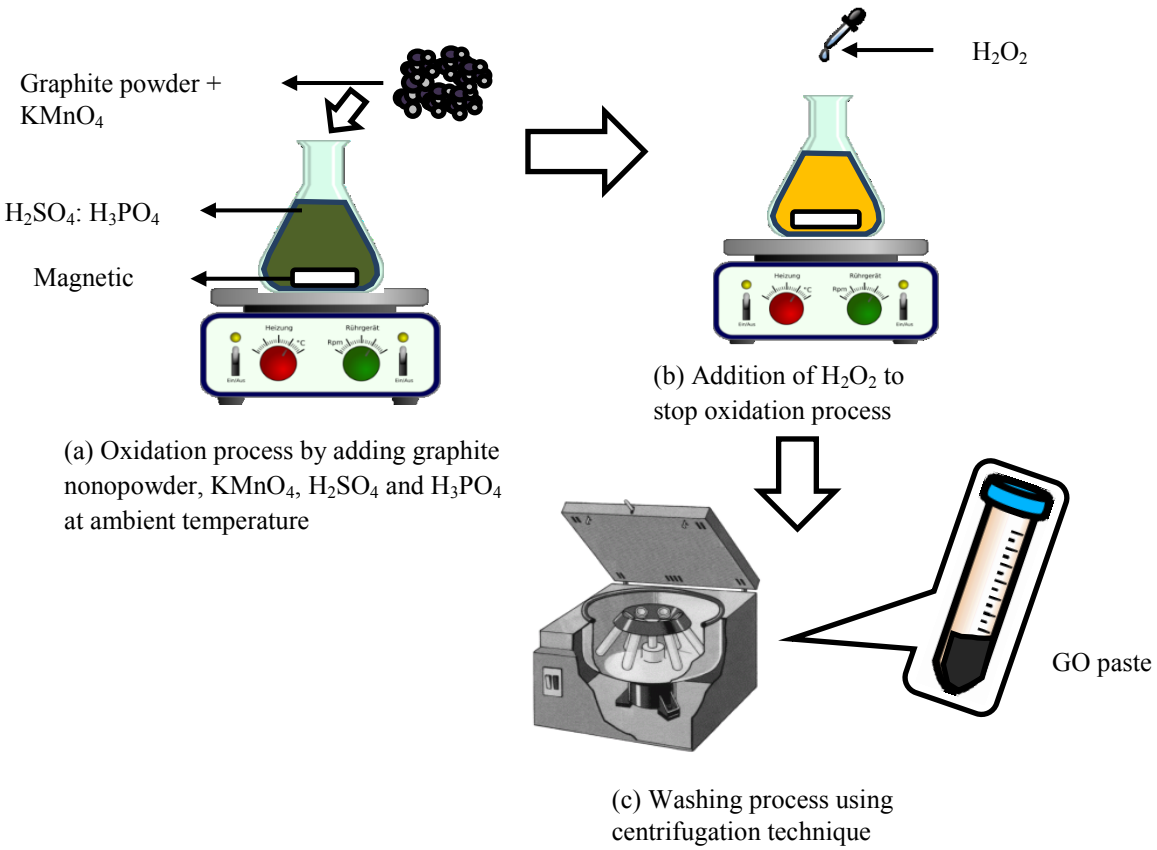

Figure 1. Synthesis of graphene oxide at ambient temperature

**Graphene oxide/$TiO_2$ preparation**

Graphene oxide paste was heated on hot plate at 70 °C for 15 minutes to remove the water. An amount 3 g of $TiO_2$ nanopowder, polyethylene glycol (PEG, $M_w$ =10,000), 0.13 ml nitric acid and 4ml distilled water were stirred well in the mortar for half an hour until a uniform paste formed. After that, several drops of Triton X-100 were added to

the paste and stirred another 30 minutes to get shiny and uniform paste. 0.4 wt.% of GO was put into the paste and the procedures were repeated by using 0.6 wt.% and 0.8 wt.% of GO. $TiO_2$ paste without GO also prepared as the control sample.

**Fabrication of DSSCs**

A complete DSSC device requires working electrode (photoelectrode) and the counter electrode (Figure 2). In the preparation of working electrode for DSSC, conductive substrate (FTO) (8 ohm/cm$^2$) was used. FTO substrate was cleaned by ultrasonic bath in acetone, ethanol and distilled water for 15 minutes each and was dried using nitrogen gas. GO/$TiO_2$ paste was deposited on FTO and form into a thin film using doctor blade technique. Single layer of magic tape was used to control the thickness and active area of GO/$TiO_2$. The active area of photoelectrode is 1.0 cm$^2$. The photoelectrode was annealed at 450 °C for 30 minutes, then was cooled down to 100 °C and followed by immersion in 0.03 mM N719 dye solution. After 24 hours immersion, photoelectrode was cleaned using ethanol to remove the excess dye in the GO/$TiO_2$ nanoparticle. In the preparation of counter electrode, platinum paste was deposited on the FTO substrates by doctor blade technique, and annealed at 450 °C for 30 minutes. The DSSC sample was assembled by sandwiching electrolyte layer between the GO/$TiO_2$ photoelectrode and Pt-coated conductive glass counter electrode. The electrodes were separated using U-shape Surlyn film and were pressed heated.

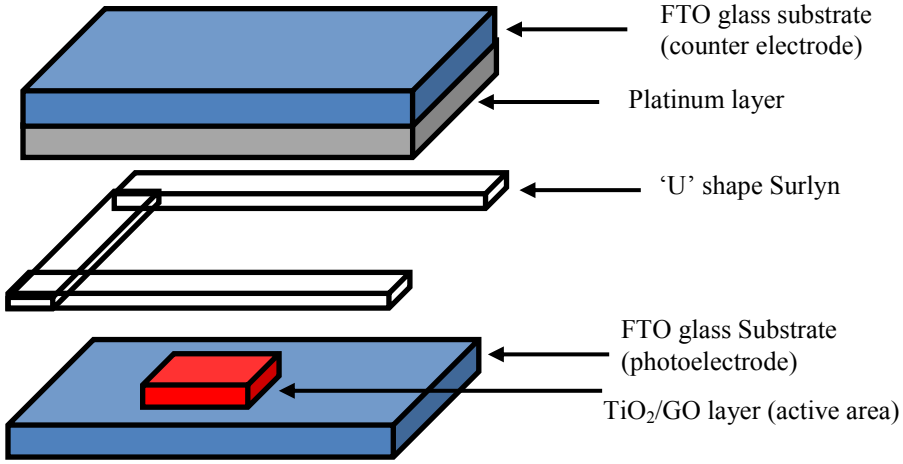

Figure 2. Fabrication of DSSC

**Characterization**

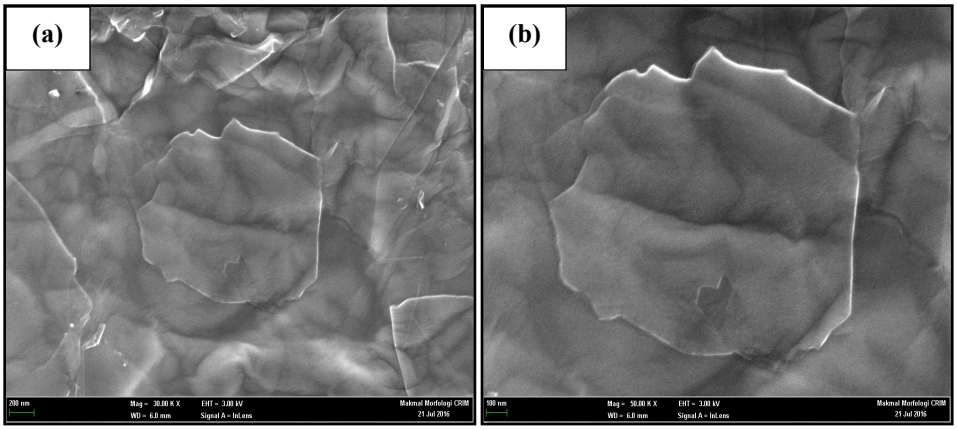
The micro-morphologies and energy-dispersive X-ray (EDX) of the GO and GO/$TiO_2$ was observed with field emission scanning electron microscope (FESEM) instrument (Zeisz Supra: 15 kV). The X-ray diffraction patterns of the samples were obtained by using X-ray diffractometer (Bruker D8 Advance). The average surface roughness of the thin film was determined by atomic force microscopy (AFM). Incident photon to current efficiency was analyzed using G300 instrument with simulated AM 1.5 xenon illumination. The current-voltage curves and power conversion efficiency of the cell was measured by light-current-voltage (LIV) Tester model Keithley 2400 with 100mW/cm$^2$ light output.

## Results and Discussion

**Morphology and structure analysis**

Figure 3 (a) and (b) show the field emission scanning electron microscopy (FESEM) images of synthesized GO at different magnification. Common process in chemical oxidation of graphite used ice bath during the initial addition of $KMnO_4$ and heating during the oxidation stage. But, the high temperature during the oxidation process reduces the size of GO produced [17]. In this study, the average lateral dimension of GO is obtained between about 600 –

900 nm, as shown in Figure 3 (b). According to Zhao et al. the electrical resistivity of GO sheets with large area is much lower compared to small GO sheets [18]. Figure 4 (a), (b) and (c) show the FESEM images of GO/$TiO_2$ thin films with different concentration of GO. As shown in Figure 4 (a), (b) and (c), GO/$TiO_2$, the porosity and specific surface area increased by increasing the concentration of GO in $TiO_2$. Several reports have shown that incorporation of GO into $TiO_2$ photoelectrode resulted in a coarse and porous surface, as a result of unique 2D structure of GO [19-21]. The evaporation of $H_2O$ in GO during the annealing process at 450 °C resulted in an increase of GO/$TiO_2$ thin film porosity from volume shrinkage [6]. The porous structure of thin film increase light scattering, dye absorptions and enhance the photovoltaic properties [6, 22]. However, previous study reported the optimal porosity for the photoelectrode was considered to be between 50% and 60% [23]. The compact structure will destruct the produced film that has many porous and crack at the surface of the film. The EDX analysis used to study the appearance elements of GO at 0.4 wt.%, 0.6 wt.% and 0.8 wt.% mixed with $TiO_2$. Based on the GO nanosheet film, the appearance peaks of C and O are 78.8% and 21.2% respectively, as shown in Figure 5(a) After annealed at 450 °C , the C element in 0.4%, 0.6% and 0.8% GO/$TiO_2$ samples were 2.7%, 4.0% and 4.3% respectively. The percentage of C element slightly increased due to the increment of GO percentage in $TiO_2$.



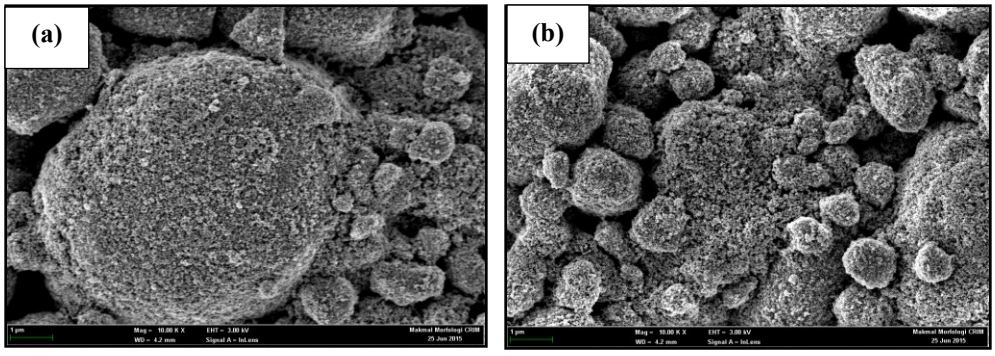


Figure 3. The FESEM images of synthesized (a) GO at low magnification and (b) GO at high magnification

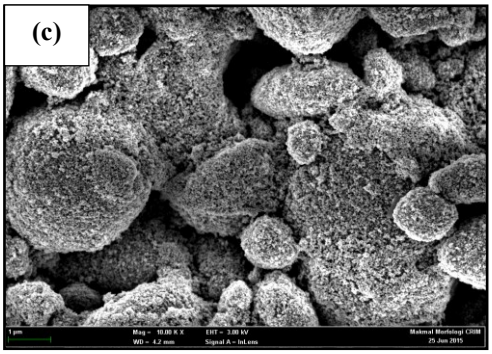

Figure 4. The FESEM images of GO/$TiO_2$ thin film with (a) 0.4, (b) 0.6 and (c) 0.8 wt.% of GO

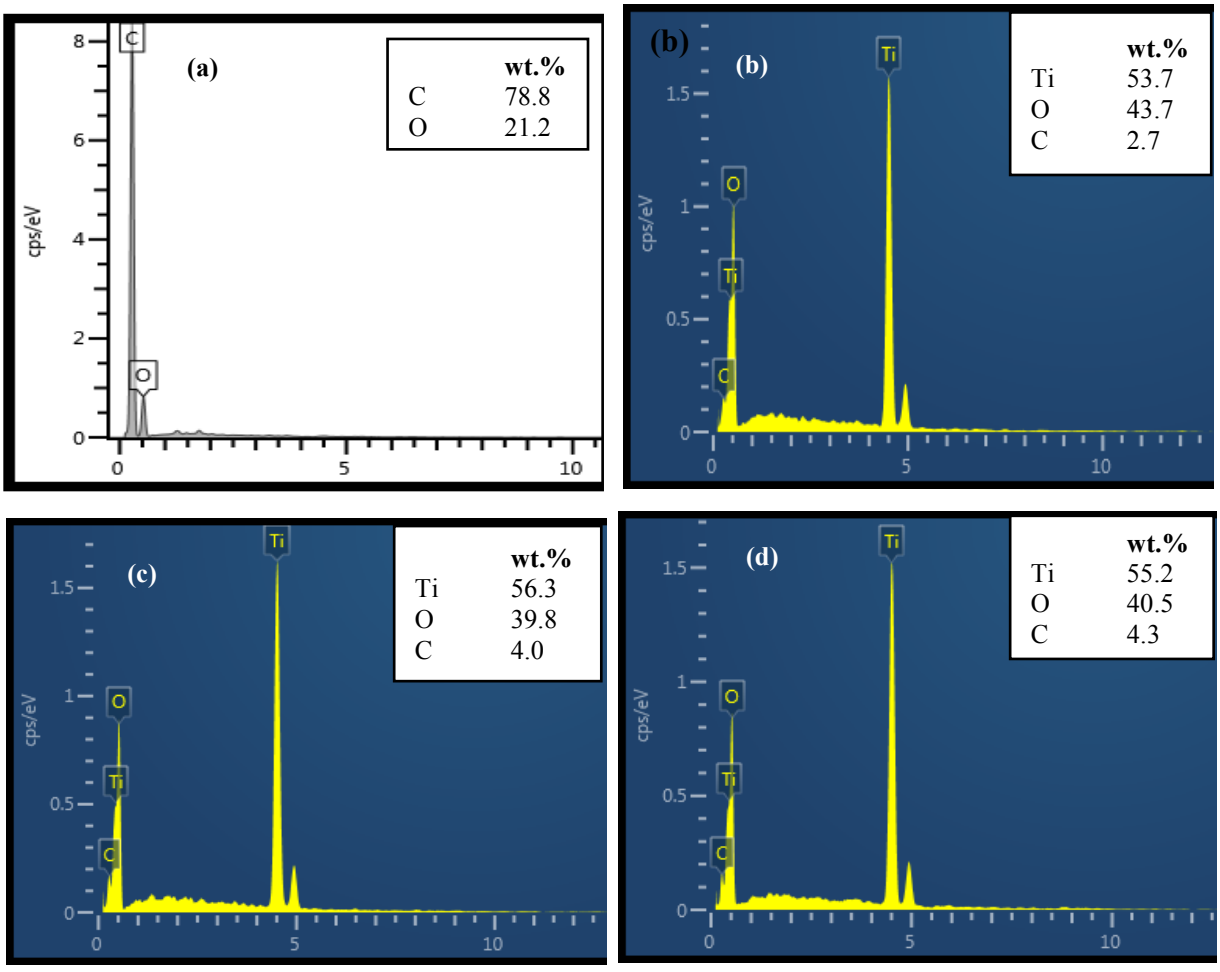

Figure 5. EDX analysis for (a) GO, GO/$TiO_2$ thin film with (b) 0.4 wt.%, (c) 0.6 wt.%, and (d) 0. 8 wt.% of GO

The morphology characterizations from AFM analysis are used to examine the surface roughness of the different percentage of GO doped in $TiO_2$ thin film. Figure 6(a), 6(b), and 6(c) and 6(d) show the three-dimensional surface morphology of the GO/$TiO_2$ thin films with 0.0 wt.%, 0.4 wt.%, 0.6 wt.% and 0.8 wt.% of GO, respectively. Based on the Table 1, the surface roughness values of 0.0 wt.%, 0.4 wt.%, 0.6 wt.% and 0.8 wt.% working electrode are 20.1 nm, 25.2 nm, 35.1 nm and 39.3 nm respectively. The high surface roughness indicates that GO/$TiO_2$ thin film exhibited high surface area, which in turn will give a greater absorption of the dye.

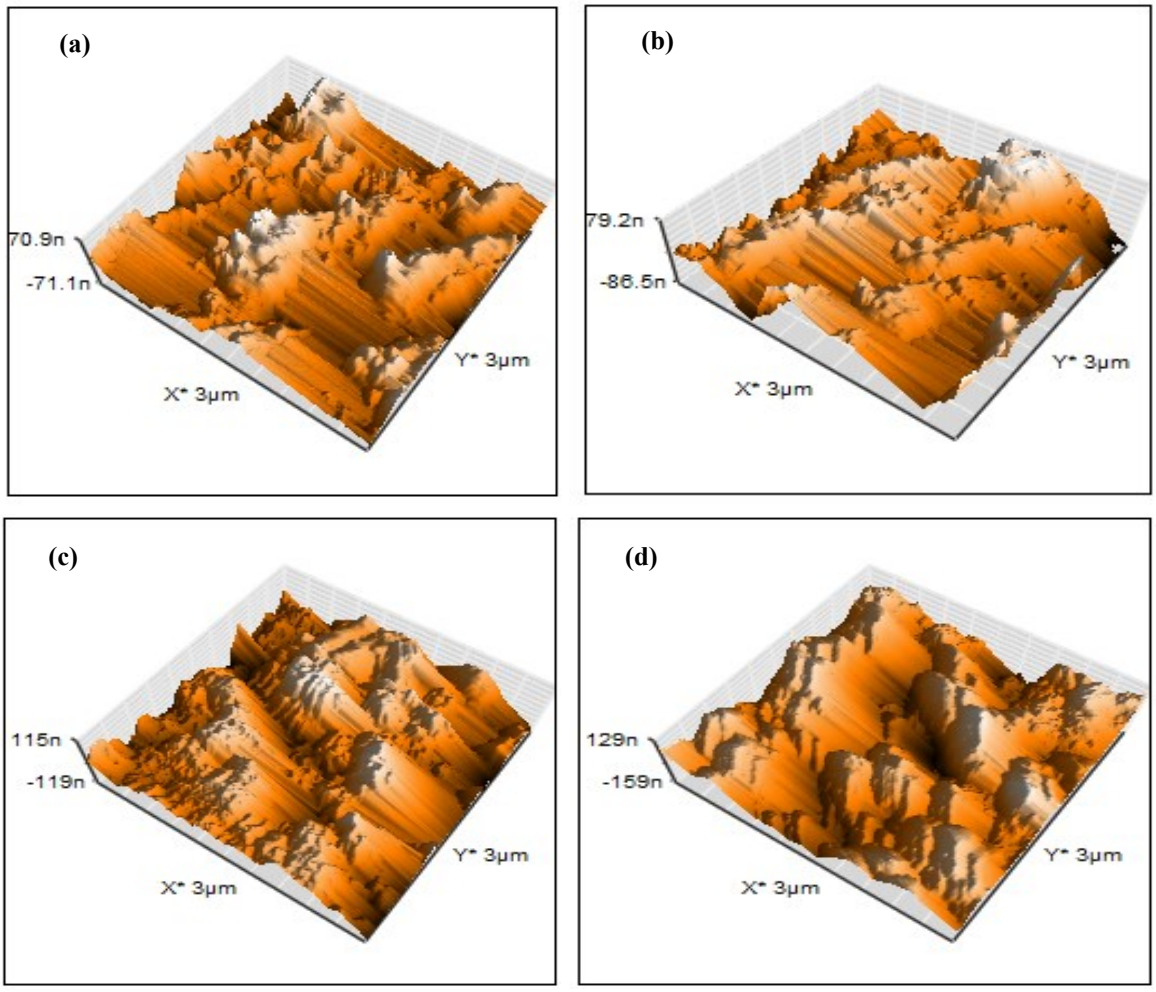

Figure 6. Topography AFM images of GO/$TiO_2$ film containing (a) 0.0 wt.%, (b) 0.4 wt.%, (c) 0.6 wt.% and 0.8 wt. % graphene oxide

Table 1. Roughness average parameter of thin films.

| Sample | Doping concentration of GO (wt.%) | Average Surface Roughness (nm) |
|---|---|---|
| (a) | 0.0 | 20.1 |
| (b) | 0.4 | 25.2 |
| (c) | 0.6 | 35.1 |
| (d) | 0.8 | 39.3 |

**X-ray diffraction analysis**

The results from XRD measurement are shown in Figure 7. The XRD pattern for $TiO_2$ shows obvious anatase phase with a characteristic peak of (1 0 1), (1 1 2), (2 0 0), (1 0 5), and (2 1 1). A small amount of rutile phase also are found in this pattern which assigned to (1 0 1) and (1 1 1) plane. The increasing of GO concentration in $TiO_2$ resulted in slight decrement of reflection peak intensity. However, due to its small content, the presence of GO in GO/$TiO_2$ sample were not detected. [24]**.** The Debye-Scherer formula was used to estimate the particle size as shown in formula equation 1.

$$D = \frac{k\,\lambda}{B\cos\theta} \tag{1}$$

where $\lambda$ is the wavelength of 1.492 nm, $B$ is the full width at half-maximum of the main peak and $\theta$ is the main peak position divided by 2 [6]. The results of crystallite size were shown in Table 2.

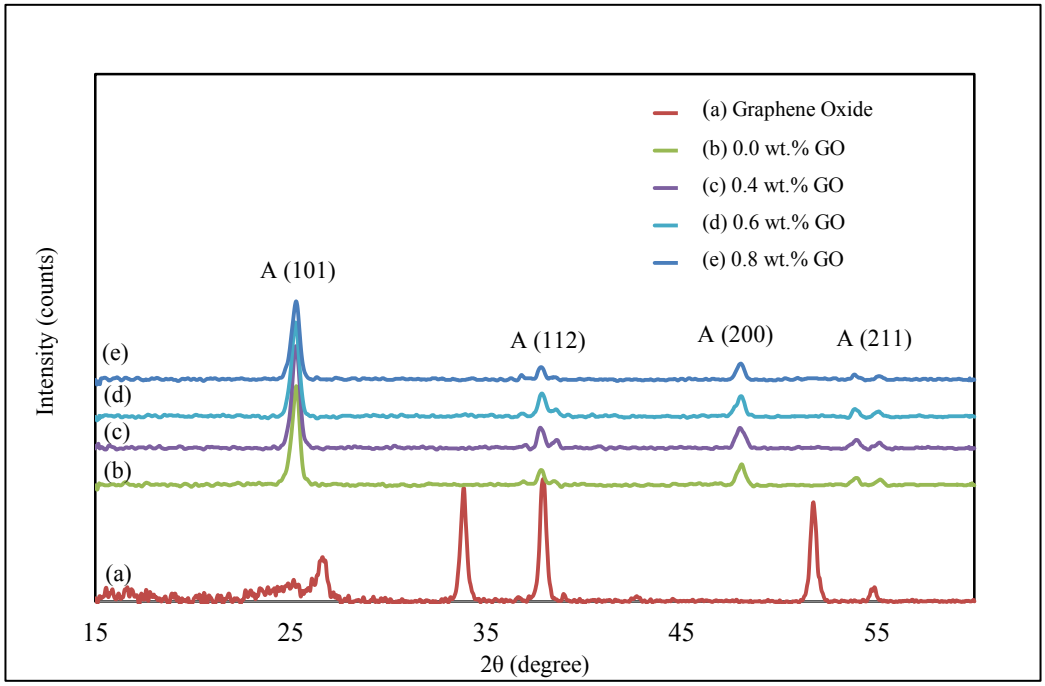

Figure 7. XRD pattern of GO and different concentration of GO/$TiO_2$ films

Table 2. The crystallite size for $TiO_2$ and GO/$TiO_2$ samples

| Samples | Doping Concentration of GO (wt.%) | Crystallite Size (nm) |
|---|---|---|
| (b) | 0.0 | 29.36 |
| (c) | 0.4 | 29.29 |
| (d) | 0.6 | 29.27 |
| (e) | 0.8 | 27.08 |

**DSSCs performance studies**

IPCE is the ratio of the number of electrons in the external circuit produced by an incident photon at a given wavelength [25]. The generation of IPCE is explained by three main factors: (1) the light-harvesting efficiency of dyes, (2) the efficiency of electron injection and (3) the efficiency of collecting photo injected electrons at the FTO substrate. In DSSC, it primarily responds to the wavelength of visible light in the 300 – 800 nm regions. Figure 8 shows the IPCE spectra of DSSC different concentration of GO doped $TiO_2$ photoelectrode. The dye that reacted at a wavelength of 500 – 600 nm had the highest quantum number, which is corresponding to the absorption peak of N719 dye [26]. The fabricated DSSCs exhibited a maximum absorption peak at ~515 nm, which mainly originated from the light-harvesting of the N719 dyes adsorbed by the photoelectrode films upon light illumination. The highest IPCE value of fabricated DSSCs was recorded by GO/$TiO_2$ 0.6 wt.%, with 51.49%, while the GO/$TiO_2$ 0.0 wt.%, 0.4 wt.%, and 0.8 wt.% showed low IPCE values of 42.89 %, 47.14 % and 48.89 %, respectively. The IPCE percentage increased by adding GO with concentration 0.4 wt.% and 0.6 wt.%, but slightly decreased by further adding GO with 0.8 wt.% concentration. The enhancement of IPCE value is caused by the increasing in specific surface areas of the GO/$TiO_2$ materials, which results in a considerably higher dye molecules loading and the ability to convert more photons to electrons. On the other hand, the lower IPCE value in GO/$TiO_2$ 0.8 wt.% indicates the electron-collection efficiency at the $TiO_2$/FTO substrate is poor due to too porous structure of photoelectrode. [27].

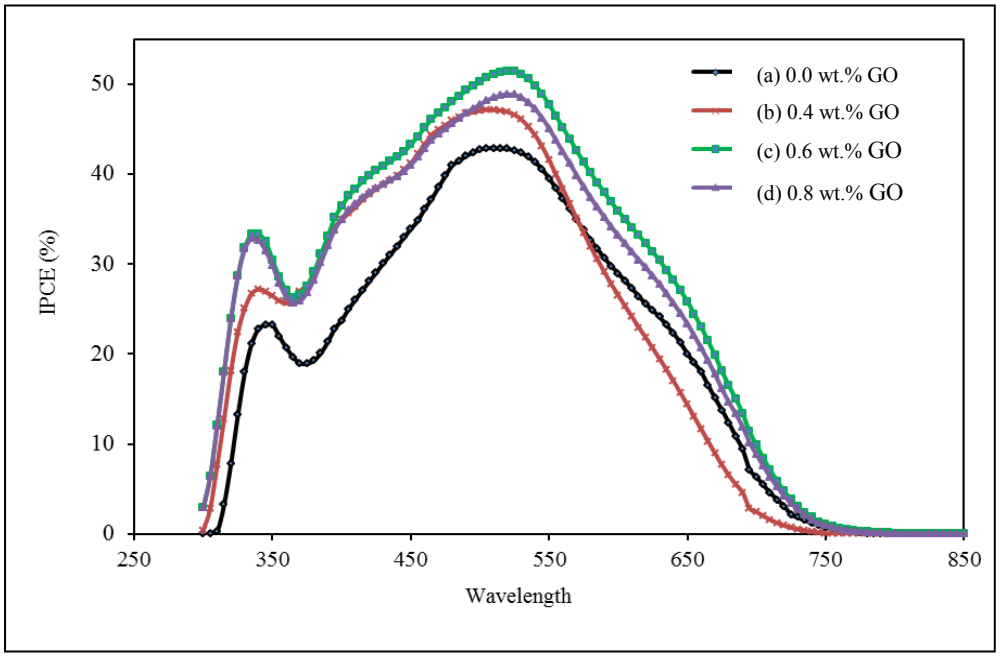

Figure 8. IPCE spectra of DSSC using different concentration of GO in $TiO_2$ photoelectrode

Table 3. IPCE parameter of DSSC

| Sample | Doping Concentration of GO (wt.%) | IPCE (%) |
|---|---|---|
| (a) | 0.0 | 42.89 |
| (b) | 0.4 | 47.14 |
| (c) | 0.6 | 51.49 |
| (d) | 0.8 | 48.89 |

Figure 9 shows the *J–V* curve of the DSSCs under varying illumination intensity of 100 mW $cm^{-1}$ (AM1.5G). The photovoltaic parameters of $TiO_2$ and GO/$TiO_2$ were summarized in Table 4. Based on the photovoltaic parameters in Table 4, the $J_{sc}$ and PCE of GO/$TiO_2$ DSSCs increased compared to the standard DSSC (without GO). This increment is similar to that reported in previous studies [28]. The highest $J_{sc}$ and PCE were obtained at 0.6 wt.% of GO in $TiO_2$ DSSC, with the value of 9.8 mA/$cm^2$ and 3.7%, respectively. $J_{sc}$ are mostly established by good charge injection from the excited state of dye into the GO/$TiO_2$ photoanode and great charge transport [29]. The $J_{sc}$ of GO/$TiO_2$ from 0.0 wt.% to 0.8 wt.% was recorded as 8.1, 8.6, 9.1 and 8.7mA/$cm^2$, respectively. The increasing of $J_{sc}$ and efficiency is due to following reasons: (a) improve the electron transfer efficiency from $TiO_2$ film to FTO substrate [30-32] and (b) reduce the charge recombination rate and resistance [33 – 37]. However, the value of $J_{sc}$ and PCE decrease with a further increase the percentage of GO up to 0.8 wt.%. This may be due to the porosity became too large to act as a kind of recombination center instead of providing an electron pathway that resulted in longer charge migration routes or electron contacting directly with FTO to form a dark current due to more graphene oxide surrounding $TiO_2$ nanoparticles [25].

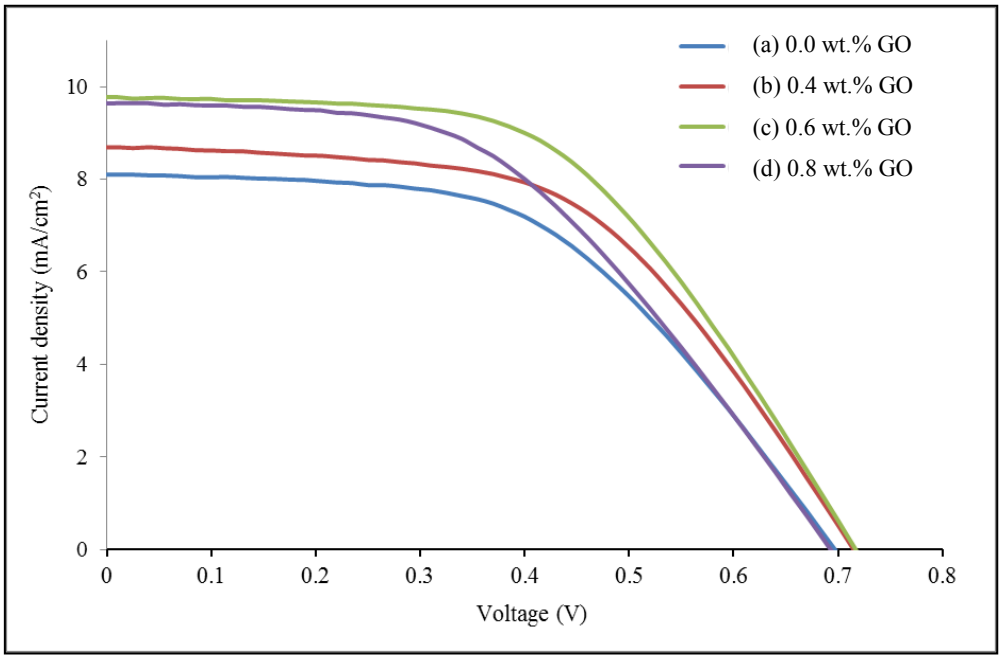

Figure 9. *J-V* curves of the DSSC with various wt.% of GO under illumination of simulated AM 1.5G sunlight at 100 mW/$cm^2$

Table 4. The photovoltaic parameter of DSSC for $TiO_2$ and GO/$TiO_2$

| **Doping Concentration of GO (wt.%)** | $V_{oc}$ **(V)** | $J_{sc}$ **(mA/cm²)** | **Fill Factor (%)** | **Efficiency, IPCE (%)** |
|---|---|---|---|---|
| 0.0 | 0.68 | 8.1 | 51.8 | 2.9 |
| 0.4 | 0.69 | 9.6 | 48.0 | 3.2 |
| 0.6 | 0.72 | 9.8 | 53.2 | 3.7 |
| 0.8 | 0.72 | 8.7 | 53.8 | 3.3 |

## Conclusion

Graphene oxide (GO) was successfully synthesized at ambient temperature and GO was doped with $TiO_2$ as photoelectrode. The results of DSSC showed that the doping of 0.6 wt.% graphene oxide into $TiO_2$ paste enhanced the photoelectric conversion efficiency (PCE) by 28% compared to standard DSSC. The increment is due to increase in dye absorption and enhanced electron transportation. However, further increase in GO concentration in $TiO_2$ can cause the decrease the efficiency of DSSC due to too porous structure of photoelectrode and lead to charge recombination.

# EFFECT OF VARIOUS POWER LEVEL AND DIFFERENT RATIO OF FRUIT TO WATER IN OIL PALM FRUITS MICROWAVE STERILIZER

## (Kesan Pelbagai Tahap Kuasa dan Nisbah Berlainan Buah terhadap Air dalam Pensterilan Gelombang Mikro Buah Kelapa Sawit)

**Abstract**

The aim of this paper is to investigate the effect of using various power level and different ratio of fruit to water in microwave sterilizer in order to acquire the shortest time of the fruit to be completely detached from the spikelet. Normally, the palm oil fruits processing uses steam heating for sterilization of oil palm fruit brunches. The conventional steam treatment of sterilization produces large amount of waste water from the palm oil mill process. Also, this process is classifying as crucial process with the intention of inactivate the lipolytic enzyme as prevention to the increase of free fatty acids (FFA) in oil. Therefore, microwave irradiation is used in this research for solving this problem and improving of palm oil fruit quality prior to extraction of crude palm oil (CPO). The optimal condition was 800W for 6 minutes of 100% strip of fruit from the spikelet with 1:0.5 ratio by means of 4.08% of FFA. It can be concluded that microwave radiation is suitable for quick detachment of the fruitlet from the spikelet and fruit loosening performed without kernels started to turn brown and appeared dehydrated. Throughout the trial, the quality of the oil extracted from the microwave sterilized spikelets in terms of the FFA percentage was acceptable. The quality of the oil is excellent, with free fatty acids of the crude oil generally below 5%.

**Keywords**: oil palm fruits, sterilisation, microwave, stripping, free fatty acids

**Abstrak**

Tujuan kertas ini adalah untuk mengkaji kesan menggunakan pelbagai tahap kuasa dan nisbah yang berbeza buah-buahan terhadap air dalam pensterilan gelombang mikro untuk memperoleh masa yang singkat buah-buahan terpisah lengkap daripada spikelet itu. Biasanya, pemprosesan buah kelapa sawit menggunakan pemanasan stim untuk tujuan pensterilan. Rawatan wap konvensional pensterilan menghasilkan sejumlah besar air sisa daripada proses kilang minyak sawit. Juga, proses ini diklasifikasikan proses sebagai penting dengan niat untuk menyahaktifkan enzim lipolitik sebagai pencegahan kepada peningkatan asid lemak bebas (FFA) dalam minyak. Oleh itu, penyinaran gelombang mikro digunakan dalam kajian ini untuk menyelesaikan masalah dan meningkatkan kualiti buah kelapa sawit sebelum pengekstrakan minyak sawit mentah (MSM). Keadaan optimum adalah 800W untuk 6 minit daripada 100% lerai buah dari spikelet dengan nisbah 1: 0.5 bagi 4.08% FFA. Dapat disimpulkan bahawa radiasi gelombang mikro adalah sesuai untuk peleraian cepat buah dari spikelet dan ia dapat dilakukan tanpa biji mula bertukar coklat dan kelihatan kering. Sepanjang ujikaji, kualiti minyak yang diekstrak daripada gelombang mikro disterilkan dari segi peratusan FFA boleh diterima. Kualiti minyak adalah yang baik, dengan asid lemak bebas minyak mentah biasanya di bawah 5%.

**Kata kunci:** buah kelapa sawit, pensterilan, gelombang mikro, pelucutan, asid lemak bebas

## Introduction

Malaysia is one of the countries that successfully beneficiaries of the oil palm industry and being responsible for uprising this industry globally through significant contributions and continuous commitment. In summary, oil palm processing in mill involves the receiving of fresh fruit bunches from the plantations, sterilizing and separating of the bunches to free the palm fruits, digesting and mashing of the fruits and pressing out the crude palm oil, clarification, purification, drying and storage[1, 2]. Pre-treatments are occasionally crucial with the purpose of overcome difficulties in material handling throughout subsequent processing steps. Sterilization process of oil palm fruits is categorize as the –first step in palm oil milling process prior to extract crude palm oil as well as identified steam treatment. At this moment, the conditions to apply sterilization is within range of 15 -45 psi of pressure, 70 – 90 min of cooking time and at temperature more than 100 °C [3, 4].

Crude palm oil (CPO) generated from this current process has good quality. Nonetheless, palm oil mill effluent (POME) known as hazardous to the surroundings has produced abundant waste water [5]. POME will be generated from three main sources for each tonne, sterilizer condensate, sludge separator and hydrocyclone waste with 27%, 44% and 29%, respectively [6, 7]. Even though POME is a non-toxic liquid waste with horrible smell and its chemical oxygen demand (COD) and biochemical oxygen demand (BOD) value are relatively high, thus the great cost of treatment was required to meet environmental standard [8]. To solve the problem of the generated POME, alternative methods may also be encountered throughout microwave oven to apply as a treatment to the oil palm fruits with the minimal water usage.

In the conventional milling process, fresh fruit bunches are loaded in cages and pushed into sterilizers where they are cooked. The process seizures oil quality deterioration due to enzymatic activity. Enzymatic lipolysis of the oil, which may result in a rise of free fatty acids (FFA) in the fruits, is halted immediately upon sterilization of the bunches. High amount of free fatty acids that the oil might become unfit for human consumption without appropriate refining. Sterilisation also facilitates the stripping of fruits from the bunch and the extraction of oil and kernel. At present, screw press and hydraulic presser technology has been carried out in palm oil mill processing [7, 9] that is completed after the fresh fruit bunches run through steam treatment. However, current method carried out in mill for oil extraction, generates residual oil or leftover oil about 3-7%, which is eventually gathered as POME and proven to be dangerous to the environment [10, 11]. Therefore, an effort is thus made in this study to look into the prospect of utilization of microwave heating for the first stage of the process.

Numerous experiments have established that the solventised fibres from soxhlet extraction were discovered to be very dry, brittle and completely decolourised, indicating complete exhaustion of oil [3, 12-15] . The clarification step in the conventional palm oil milling process which uses large amount of water, was fully omitted, bringing to cleaner and higher quality crude palm oil. Oil with higher content of vitamin E and carotenes produce from this solvent extraction method, will be more stable and having longer shelf life. The current pretreatment using microwave could also offer as an alternative route for phytonutrients recovery. It is also a clean technology due to minimal water effluent discharge. They also wrap up that milling would then be a process not only for the recovery of trapped crude palm oil in fibres after digesting process, but also for the recovery of high value added nutraceuticals too. This would enhance the economics of palm oil production.

To the best of our comprehension, the influence of microwave extraction *cum* sterilisation for the crude palm oil from oil palm fruits has not been reported yet. And also, less emphasis on stripping irradiation time of the sterilised oil palm bunch at various power levels, ratio and quality of the fruits after microwave sterilization is reported in published literature. Thus, the aims of the present research are: (1) to study the effect of using various power level to improve the stripping efficiency with shorter irradiating time or comparable to conventional method, (2) to discover effect of different ratio of fruit to water in microwave sterilizer in order to get the the shortest time of the fruit to be completely detached from the spikelet as well as good mesocarp and kernel condition. For this purpose, all parameters were individually investigated and then combined and optimized, finally (3) to analyse the quality of the oil extracted from the microwave sterilized oil palm spikelets in terms of the FFA percentage whether acceptable, below 5% [14, 15].

## Materials And Methods

### Materials

Fresh palm fruit was obtained from local oil palm plantation from open areas in Selangor, Malaysia. Fresh fruit bunch was chopped into fruit spikelets and 200g of each was weighed [12]. The sample was kept in a dry place ready for sterilization [16]. It is of utmost importance that the chopped fruits to be subjected to immediate sterilization in order to deactivate the lipase activity [17]. The FFA content from the fruit spikelets with major damage can reach above 5% if there was no pre- treatment process done immediately [13].

### Microwave sterilisation experiments

Only several spikelet of bunch were selected and weighed before undergoing microwave heating (microwave oven Panasonic Commercial, model: NN-ST651M, 1000 Watt frequency of 2450 MHz) for 2 minutes intervals time until 100% stripping reach. The trials were repeated 3 times for 100, 300, 400, 600 and 800W of microwave power level. The condition and appearance of the center of the kernel was noted. The fruits at the spikelets were detached with a slight push of a finger [12, 16] until the fruits were completely detached from the spikelet. The stripping efficiency was then determined according to Equation 1.

$$\%\ \text{Stripping Efficiency}, S_{\text{eff}} = \frac{F_l}{F_l + F_r} \text{x} 100\% \quad (1)$$

where $S_{eff}$, the percentage of stripping efficiency, $F_l$, the number of fruits loosened from the spikelet after stripping, and $F_r$, the number of fruits remained at the spikelet after stripping.

In addition, study is necessary on a combined system by using combination of moisture and heat in a microwave so that sterilisation can be conducted at shorter time with 100% fruits stripping efficiency. Effect of water ratio (m:v) at 1:0.5, 1:1 and 1:2 was also investigated for each batch of microwave revealing duration, where the ratio is fruits mass (gram) to water volume (ml). As the exposure duration of dry microwave was extended, there was significant increase in drying, cracking and browning effect on the mesocarp and kernel. This step on combination of moisture and heat in a microwave is essential to give them the initial moisture throughout sterilization process with very minimal water added [19 – 21]. The important benefit of a microwave is the 'time efficiency'. So, the energy and time are saved.

The percentage of free fatty acids was measured by means of Soxhlet extraction, where 20 g of mesocarp oil palm was weighed into a cellulose thimble(30mm x 77 mm, Whatman, Maidstone, UK) and placed in a Soxhlet device. Most mesocarp samples should be predried at 102 ± 2 °C for 1–2 hours to optimize the oil extraction. Water in the sample can decrease the efficiency of the solvent extraction, resulting in low fat recoveries. Two hundred milliliters of hexane (at 63 – 65 °C) were used as the solvent and the extraction was performed for 4 - 6 hours until the yellow color has disappeared [13, 18].

### Determination of free fatty acid content

The free fatty acid content was measured using the titration method as written in the MPOB Test Method [23] with some modification [13]. An amount 2 g of preheated oil (about 50 °C) was weighed in a clean beaker and mixed with 50 ml Isopropyl alcohol. The solution was neutralized by titration of 0.100 N sodium hydroxide (NaOH). The percentage of FFA content was calculated using this Eq. (2):

$$\%\text{FFA} = \frac{25.6 \text{x} V \text{x} N}{w} \quad (2)$$

where: $V$ = volume of sodium hydroxide used, $N$ = 0.1005 N Normality (concentration) of sodium hydroxide used, $w$ =Weight of oil used

## Results and Discussion

### Preliminary study: Optimization of microwave power level

Figures 1 shows effect on stripping efficiency of oil palm spikelet in relation various microwave power level of 100 to 800 Watt with fruit spikelets mass of 200 g. It can be observed that, the shortest time to reach completely fruits

detachment is at 800 Watt for only 4 minutes and the lengthiest irradiating time to reach 100% stripping is at 100 Watt. Immediate microwave sterilization is the ultimate importance in order to deactivate the lipase activity that later will increase the FFA percentage. In most of the microwave study, power and material always represent by power density which expressed number of power applies to the oil palm fruits sample per gram. High power density expressed effectiveness of moist microwave sterilization process due to maximum microwave energy being absorbed by small sample [24]. Overheating of the bunch portions will further deteriorate the stripping efficiency [18] as indicated by declining stripping trend as the heating time was prolonged after achieving highest stripping efficiency after 12 minutes for 2 kW, after 14 minutes for 1.5 kW and after 16 minutes for 1 kW. For microwave sterilization studied by [24], the stripping efficiency at elevated power level are 27%, 58.5% and 61%, after 16 minutes of exposure time.

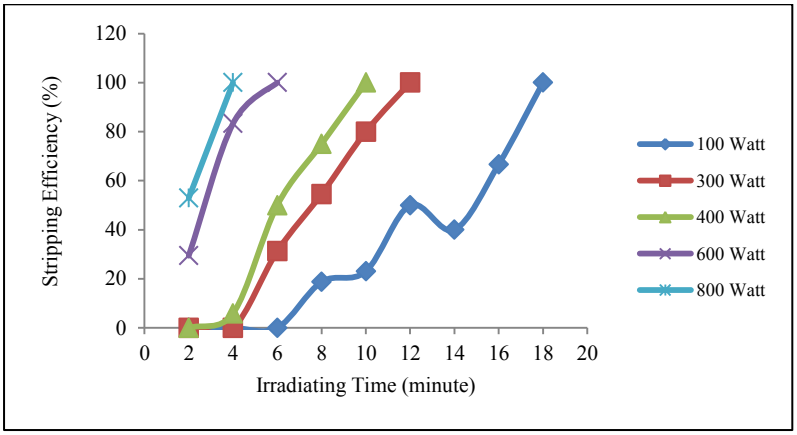

Figure 1. Effects on stripping efficiency of oil palm spikelet in relation various microwave power level of 100 to 800 Watt

Determination of microwave power level was decided after conducting several preliminary works, where researcher discovered that, the highest power level (1000 Watt) will contribute to low fruits quality, on the other hand at low power level (300 and 100 Watt) will be responsible for lengthy of time required for fruit detachments. As can be seen, power level workedin this study is medium level, within the range of 400, 600 and 800 Watt at irradiating time less than 10 minutes with oil palm fruits completely detached from the bunches.This results are similarly with previous work conducted by other researchers from[12, 21, 22]. These results also proved that microwave radiation is suitable to be used for fruit detachment from the bunch since the abscission region has higher dielectric properties [18] due to high moisture content as compared to other parts of the fruitlet. The high moisture content and conduction loss from ionic constituents were the two main contributing factors. Their results indicated that the ultimate of the moisture content is exactly positioned at the abscission region. Undeniably, the moisture content under a microwave treatment is important, since water is an excellent absorber of microwave energy [26]. This strong absorption provides the increase of the temperature inside the sample and then the break of the mesocarp positioned at pedicel by the *in-situ* water known as abscission zone [27], followed by the evaporation of water vapour. For that reason, the proposed microwave power level that will applicable in this research is medium range 400, 600 and 800 Watt.

**Effect of water ratio on stripping efficiency**

The purpose of addition of waterto fruits spikelet is to implement a combined system that using combinations moisture heat with microwave with the intention of sterilisation can be carried at shorter time with 100% fruits stripping efficiency and give good quality of CPO. Figure 2 exhibits effect on irradiating time in relation to fruit mass to water volume at with 1:0 , 1:1 and 1:2 (m:v). As can be observed, power level worked in this study is medium level, within the range of 400, 600 and 800 Watt. Obviously, at microwave power 400 Watt, it takes lengthy time to reach completely fruits detached with ratio of fruit mass to water volume at 1:2. Waves are absorbed

by the oil palm spikelets, some are reflected and the remaining unabsorbed power is dissipated into the water vessel, which is placed in a container in the microwave cavity. The microwave powers lower than 450 W were in favour of the best water retention capacities [28].

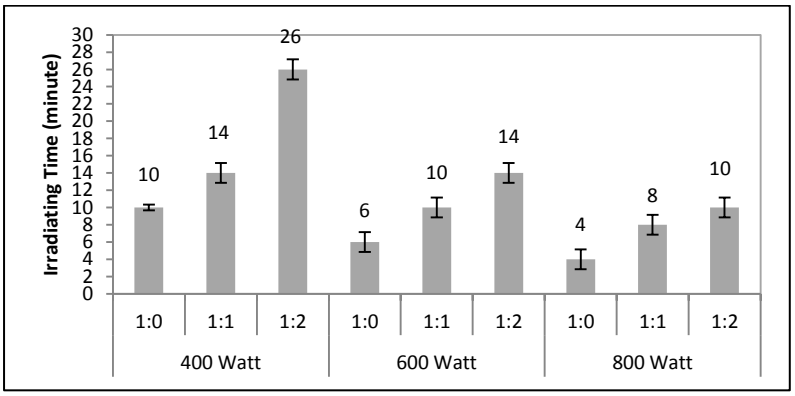

Figure 2. The irradiating time from medium power levels of microwave sterilization. Ratio fruit mass to water volume at with 1:0 , 1:1 and 1:2 (m:v)

Definitely, the moisture content under a microwave treatment is critical, since water is an outstanding absorber of microwave energy [26 - 29]. This strong absorption delivers the increase of the temperature inside the sample and then the rupture of the mesocarp and kernel cells by the *in situ* water, followed by the evaporation of water vapour. However, huge water adding in the vessel will interfere the stripping process time the oil palm fruits. To the best of our knowledge, implementation a combined system that using combinations moisture heat with microwave technique has never been applied for the oil palm fruits sterilisation. For that reason, through adding water will improve the kernel condition and mesocarp as well.

**Effect of microwave exposure on quality of palm oil**

The quality of crude palm oil (CPO) can be indicated from chemical properties such as free fatty acids content. Figure 3 presented FFA percentage with medium range power level microwave and ratio. CPO normally contains free fatty acids which need to be eliminated as part of the refining process. Obviously, Figure 3 summarizes at power 600 W and 800 W the maximum free fatty acids percentage are 4.04 and 4.08, respectively with ratio 1:0. As can be seen also in the Figure 3, the trend of FFA percentage increased at 400 Watt. However, after increasing microwave power the FFA trend percentage was decreased. Throughout the trial, the quality of the oil extracted from the oil palm fruit spikelets in terms of the free fatty acid percentage was acceptable i.e below 5%, varying from 1.02 to 4.08%. However it should be kept as low as possible for nicer oil quality of palm oil and lower refining cost [28 – 30]. It is also important in oil extraction to have an suitable microwave irradiation power setting as high power can degrade volatile compounds and the plant material itself [30, 31]. The fruits consequently need to be heated immediately after harvest to inactivate the lipase and to prevent an unacceptable level of free fatty acids in the oil. The enzyme is activated upon abscission of the fruit and also when the fruit is bruised.

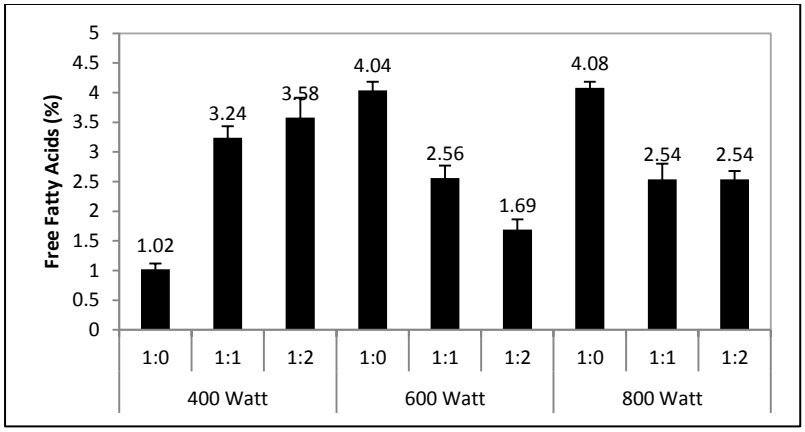

Figure 3. Effects of different fruit mass to water volume ratio on free fatty acids percentage. Microwave sterilised process was performed at different: irradiation power in medium range 400, 600 and 800 Watt

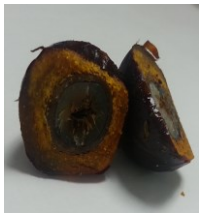

**Physical appearance of microwave treated palm fruits**

Table 1 indicates the physical appearance of oil palm spikelet in relation to microwave heating period at water ratio 1:0 and 1:0.5. The extension of microwave exposure with fruit to water ratio (m:v) of 1:0.5 was not discovered to burn kernel and mesocarp as observed in Table 1 even though at 800 Watt. The purpose of studying minimal water to the oil palm fruit spikelets is to distinguish the kernel condition once microwave irradiation. Production of water vapour and caramel-like aroma was also recognised for all microwavable exposure conditions. The removal of water was part of the heating process [32, 21]. Indeed, the moisture content under a microwave treatment is critical, since water is an excellent absorber of microwave energy [36]. This mechanism is led to the drying effect and justifiable for the cracked, hardened and desiccated mesocarp [3].

Table 1. Physical appearance of oil palm fruits after microwave sterilisation by: (a) 1:0, (b) 1:0.5 ratio

| **Power (W)** | **Ratio (m:v) (g:ml) (fruit mass: water volume)** | | | |

Table 1 (cont'd). Physical appearance of oil palm fruits after microwave sterilisation by: (a) 1:0, (b) 1:0.5 ratio

| Power (W) | Ratio (m:v) (g:ml) (fruit mass: water volume) | | | |
|---|---|---|---|---|
| | (a) 1:0 | | (b) 1:0.5 | |
| | Empty Spikelet and Mesocarp | Kernel | Empty Spikelet and Mesocarp | Kernel |
| 800 |  |  |  |  |

The mesocarp of fresh palm fruits has a fibrous-like texture which is yellowish- orange, hard and possesses a sweet fragrant. The seed or kernel is a single, hard and white in colour. As the exposure duration was extended with water ratio 1:0, there was significant increase in drying, cracking and browning effect on the mesocarp and kernel especially. It was observed that microwave exposure has greater effect on the kernel than mesocarp [25, 37]. There was almost slight drying and browning effect upon 2 min exposure with various power level and fruit mass to water ratio (m:v). Although kernels started to turn brown and appeared drier after several minute of exposure with fruit to water ratio of 1:0.5, 1:1 and 1:2, the mesocarp undergoes negligible browning. Therefore, thecondition and appearance of microwave exposed oil palm fruits after reaching 100% strip from the spikelets at 800 Watt and ratio 1:0.5 were denoted in Table 1(b). It shows good quality of white in colour kernel as compared to kernel in Table 1(a) at same power level.

## Conclusion

In this research paper, the effect of using various power leveland ratio of fruit to water as well as analyze the quality of extracted oil have been presented and discussed. It has been shown that, medium power range of 400, 600 and 800 Watt enhance the stripping efficiency with shorter irradiating time. The optimum condition of this research was 6 min of irradiating time at 800 Watt and 1:0.5 ratio to reach completely fruit loosening and exhibits good quality of white in colour kernel with 4.08% of FFA. It was found that the microwave sterilisation can be completed at shorter time with 100% fruits stripping efficiency supplementary with minimum water ratio and this suggests further works especially on the understanding of the microwave interaction with the spikelet during irradiation with the intention ofextraction the oil. During the experimental, the quality of the oil extracted in terms of the free fatty acid percentage was acceptable, varying from 1.02 to 4.08%. With the help of microwave mechanism, in future clean crude palm oil extraction can be done completed without toxic organic solvents in minutes instead of hours with various advantages.

**Abstract**

Polyaniline (PANI) doped with various concentration of dedocylbenzene sulfonate acid (DBSA) were prepared by oxidative polymerization with presence of ammonium persulfate. Emerald green PANI powder obtained were characterized by Fourier transform infrared spectroscopy (FTIR), differential scanning calorimetry (DSC), and carried out electrical conductivity test. In this research, the conductivity and thermal properties of PANI has been changed with the effect of doping. With increasing concentration of DBSA, the conductivity raises up to certain concentration (1.65 mmol of DBSA), afterwards with further increase of DBSA concentration, conductivity value declines and reaches to a value lower than that of pristine PANI. The similar trend is also observed for enthalpy values (ΔH) determined by DSC of pristine PANI and DBSA doped PANIs' which may attribute the effect of concentration of DBSA on molecular arrangement in PANI. Results from polymeric structure obtained from FTIR clearly indicate the disruption in bond when PANI doped with DBSA and it may indicate that the DBSA changes molecule structure of PANI in term of segmented local structure of polymer.

**Abstrak**

Polianilin (PANI) didopkan dengan pelbagai kepekatan asid sulfonat dodekilbenzena (DBSA) telah disediakan dengan kaedah pempolimeran oksidatif dengan kehadiran ammonium persulfat. Serbuk hijau zamrud PANI yang diperolehi dicirikan oleh spektroskopi inframerah Fourier (FTIR), kalorimeter imbasan pembeza (DSC), dan ukuran kekonduksian. Dalam kajian ini, didapati bahawa kekonduksian haba dan sifat – sifat PANI telah ditukar sebagai kesan daripada pendopan. Dengan peningkatan kepekatan DBSA, kekonduksian juga meningkat sehingga kepekatan tertentu (1.65 mmol daripada DBSA). Kemudian, kekonduksian berkurangan dengan peningkatan kepekatan DBSA selanjutnya. Keputusan PANI daripada DSC, yang mengandungi nilai entalpi yang berbeza (ΔH) menunjukkan bahawa DBSA tidak mengubah struktur molekul PANI dari segi segmen struktur tempatan polimer dan ΔH juga menunjukkan ke arah kesan kepekatan DBSA pada susunan molekul dalam PANI.

## Introduction

Now days, conductive polymers are widely used in electric and electronic devices. Among the conductive polymers, polyaniline (PANI) conquers a place of special interest in alternative to metal and semiconducting material [1].

Through the past 20 years, a variety of different conducting polymers have been found and studied [2]. From the commercial viewpoint, these polymers show promise for the invention of materials for numerous applications; they be able to replace metals and semiconductors, because their feature in conductivity, low density, and easy processability. Polyaniline (PANI) a representatives from the family of conducting polymers is well-known by easy synthesis and high environmental stability. Interest about PANI (Figure 1) is evidenced by the fact that the field of conducting polymers has concerned scientists from such varied areas of interest as electrochemistry, materials science, synthetic chemistry, polymer science, solid state physics, electrical and electronics engineering.

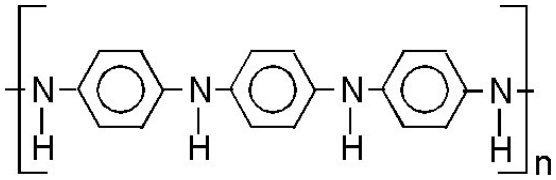

Figure 1. Polyaniline molecule structure

The attention has been paid in studying conducting polymers because these polymers have aromatic rings - and nitrogen-substituted derivatives which can be readily synthesized. Rings and derivatives can exist in several different oxidation states these in principle can be doped by various dopants through non-redox processes or by partial chemical or electrochemical oxidation. DBSA has been widely used as dopant which also acts as a surfactant and a protonating agent [3], especially in emulsion polymerizations [4] where the PANI performs as a semiconductor. Preparation of PANI–DBSA colloids [5] to polymerize PANI is a doping process for adding impurities to intrinsic semiconductors (PANI) to change their electrical properties. However, the doping process sometime will affect directly or indirectly to the conductivity of PANI. Hence, the concentration of dopant also have maximum limit that will contribute to lower in conductivity because of the restricted electron delocalization. The study of polymeric materials by thermal analysis has become increasingly popular in today's analytical laboratory because it will give more information about molecule arrangement and defect in crystal structure.

Therefore, in this research focusing more on the DBSA effect without using strong acid to alter the acidic condition of PANI during polymerization. DBSA doped PANI were characterized using four point probe method for conductivity, differential scanning calorimeter (DSC) for thermal analysis and Fourier Transforms Infrared spectrometer (FTIR).

## Materials and Methods

### Materials

Aniline chloride and hydrochloric acid (HCl) (37%) were collected from Merck, Ammonium peroxydisulfate and dodecylbenzene sulfonic acid ($C_{18}H_{30}NaO_3S$) were collected from Sigma-Aldrich.

### Synthesis of PANI

The pristine PANI was synthesized (direct oxidation) by the polymerization of aniline hydrochloride and ammonium peroxydisulfate without addition of dodecylbenzene sulfonic acid (DBSA). The aniline hydrochloride and ammonium peroxydisulphate ($(NH_4)_2S_2O_8$) was dissolved in 100 mL of distilled water separately. Both solutions were precooled at 9 °C for 12 hours and were mixed in a beaker, briefly stirred and left at rest to polymerize in a refrigerator at 9 °C for 24 hours. While for DBSA doped PANI was synthesized by the polymerization of aniline hydrochloride in different concentrations of aqueous DBS acid solutions. Aniline hydrochloride (purum; 5.18 g, 40 mmol) was added in aqueous DBS acids (0.8, 1.65, 2.0, and 2.5 mmol) of 100 mL solution. The reaction conditions for synthesis of PANI-DBSA are given in Table 1. Ammonium peroxydisulphate (purum; 11.42 g, 50 mmol) was dissolved in distilled water to prepare another 100 mL of solution. Both solutions were precooled (9 °C, 12 hours) and were mixed in a beaker, briefly stirred, and left at rest to polymerize in refrigerator at 9 °C for 24 hours. Afterwards the PANI precipitate (emeraldine salt) was collected on a filter, washed three times with 100 ml of 0.2 M HCl acid followed by 100 mL of acetone. Later salt was dried in vacuum at 60 °C for 24 hours.

Table 1. Reaction conditions for synthesis of PANI-DBSA

| Code | Monomer | Oxidant | Dopant | Volume of Dopant (mmol) | Temperature |
|---|---|---|---|---|---|
| $DBSA_1$ | | | | 0.8 | |
| $DBSA_2$ | | | | 1.2 | |
| $DBSA_3$ | Aniline | $(NH_4)_2S_2O_8$ | $C_{18}H_{30}NaO_3S$ | 1.6 | 9 °C |
| $DBSA_4$ | | | | 2.0 | |
| $DBSA_5$ | | | | 2.5 | |

**Characterization: Fourier Transformation Infrared analysis**
FTIR (FT/IR-6100; JASCO) analysis was conducted to confirm the presence of functional group in pristine PANI and PANI-DBSA. PANI granules powder was grounded to obtain fine particles. All spectra were recorded at ambient temperature and the analysis was performed at wavelength range from 400 $cm^{-1}$ to 4000 $cm^{-1}$ at scanning speed of 2 mm $s^{-1}$ with aperture size of 7.1 mm.

**Conductivity**
For conductivity measurement, PANI powders are firstly press into a pellet form by using hydraulic presser to make less than 1mm samples. Then, conductivity measurements, using the four-point probe technique (ASTM D-991-89) were performed upon pressed pellets of the starting material. The measurements were made using a Jandel four-point probe.

**Thermal scanning**
Differential Scanning Calorimetry (Perkin Elmer model DSC 7) were conducted in nitrogen atmosphere at a temperature range of 30-300 $^{\circ}C$ with a heating rate of 20 $^{\circ}C$/min

## Results and Discussion

**Fourier transforms infrared spectroscopy**
FTIR is used to observe the changes in PANI bonding structure. From Figure 2, the strong peak observed at ~1600 $cm^{-1}$ is related to C=C conjugate. This peaks are shown in pristine PANI, PANI-$DBSA_3$ and PANI-$DBSA_5$ at 1608, 1617 and 1612 $cm^{-1}$, respectively. The adsorption band at around 1380 $cm^{-1}$ (blue circle) corresponds to group of sulphoamide formed after doping with DBSA, for that reason only PANI-$DBSA_3$ AND PANI-$DBSA_5$ spectra shows slightly broad peaks base on sulphoamide structure present in their molecule. The major peaks at 1360 –1250 $cm^{-1}$ correspond to quinone and benzene ring stretching deformations as correspond to aromatic amide in PANI structure. The adsorption band at 1306 $cm^{-1}$ corresponds to $\pi$-electron delocalization induced in polymer via protonation. The PANI-$DBSA_3$ and PANI-$DBSA_5$ spectra also show the adsorption band correspond to covalent sulphonates at 1095 and 1084 $cm^{-1}$ as shown in the red circle. The main functional group of PANI is 1,4-disubstituded benzene which found at 820,814, and 810 $cm^{-1}$ for pristine PANI, PANI-$DBSA_3$ and PANI-$DBSA_5$, respectively. The various peaks in the range of 700 to 500 $cm^{-1}$ are correspond to main aromatic component of PANI's. Table 2, shows the absorption FTIR peaks collected from pristine PANI, PANI-$DBSA_3$ and PANI-$DBSA_5$ as compare to reference values [6].

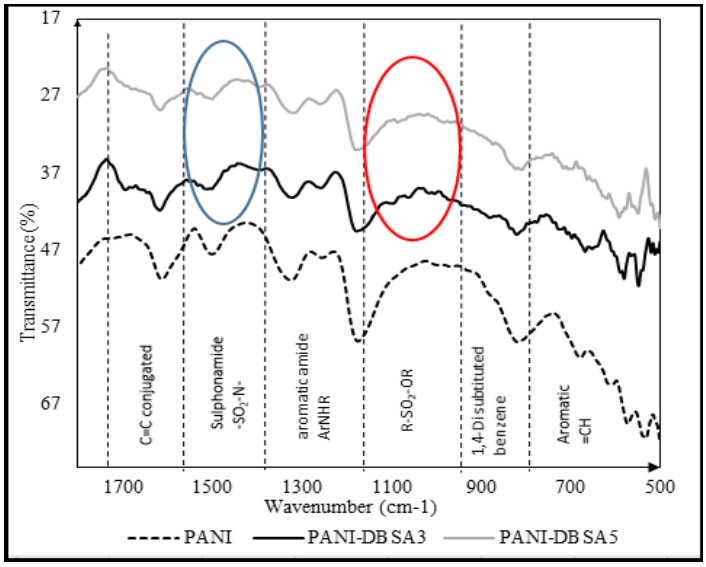

Figure 2. FTIR specra of Pristine PANI, PANI-DBSA$_3$, and PANI-DBSA$_5$.

| 1,4-Disubstituded benzene | 860-780 | 814 | 820 | 810 |

**Conductivity**

Electrical conductivity of PANI doped with various concentration of DBSA were determined by using four point probe analysis and their values are shown in Figure 3. The highest conductivity after doping with DBSA is 13. 37S/cm. The graph shows conductivity of pristine PANI decrease when DBSA$_1$ is introduce to the polymerization system. It is may be due to the polymerization of PANI are disturbed and segmental molecule structure not properly arranged. Furthermore, after addition of 1.2 and 1.65 mmol of DBSA, the trend shows by increasing of amount of DBSA, the conductivity is increased. Moreover, PANI-DBSA$_3$ AND PANI-DBSA$_4$ shows almost similar value of conductivity before the conductivity decreases at PANI-DBSA$_5$. PANI itself is consisting of benzoid and oxidized quinoid units [7]. The conduction of electricity in PANI is due to conjugation in the backbone of the polymer in the benzoid and quinoid units. Due to overlapping of conjugated π-electrons, there develops valance and conduction bands throughout the backbone of the PANI.

This can be explained as the presence of DBSA in polymerization, as "holder" to hold the aniline micelles monomer in aqueous medium as schematic representation shown in Figure 4. Aniline ion (phenyl-$NH_3^+$) resides between the individual sodium dodecyl sulphate (SDS) near the shell of micelle complexes with sulfate ion. The aniline molecule are oriented with phenyl substitution (hydrophobic nature of DBSA) to be the core of micelle and the $NH_3^+$ to the outer side of micelle. During the polymerization process, the aniline ion is polymerized into the micelle

together with DBSA after being oxidized by APS. Therefore, the increasing of amount of DBSA will increase the aniline ion attached together to formed a large size of micelle, hence enlargement of polymer chain. The longer chains of PANI formed, the higher conductivity of PANI as the present of large amount of the conjugated ion in the polymer chains. The formed chains also arranged in a segment, and the segmental local structure of polymer are shorten.

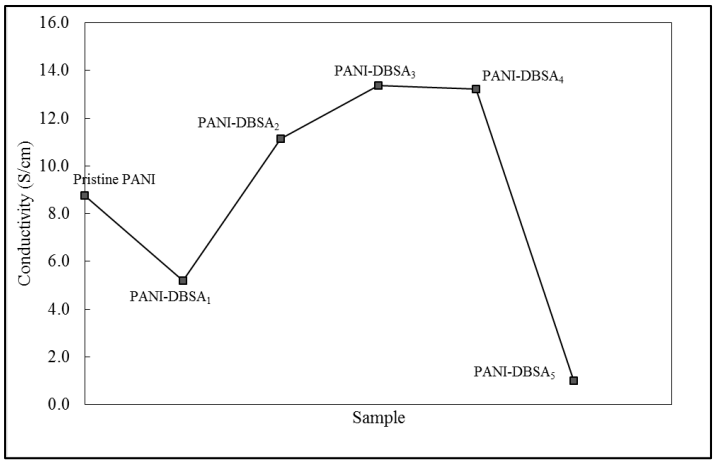

Figure 3. Conductivity of PANI-DBSA

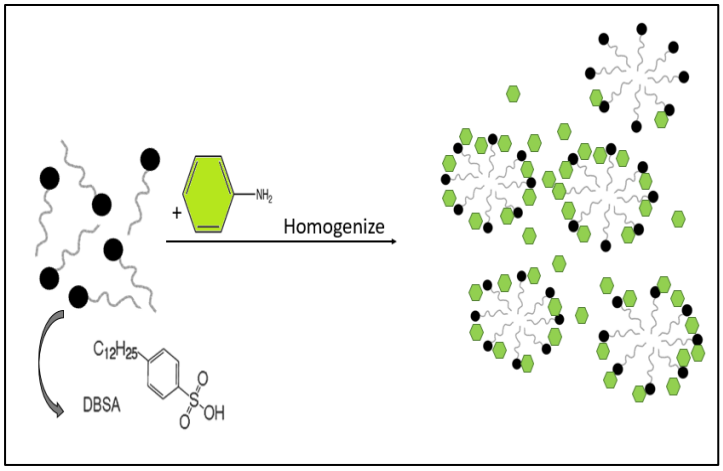

Figure 4. Probable reaction mechanism of micelles SDS and aniline during polymerization

On the other hand, the excessive amount of DBSA (as increased to 2.0 and 2.5 mmol of DBSA) shows the decreasing in conductivity. It can be inferred that the DBSA also act as surfactant in the system. The excessive amount of sodium dodecyl sulphate (SDS) ion, will capture more aniline ion to be in one large micelle before oxidation occurs.

After addition of APS, the longer chains formed during oxidative polymerization process. However, as stated by Khohklov in 1981, the longer chains formed during polymerization, the higher possibility the polymer chains will collapse [8]. The collapse polymer chains or a Gaussian coil starts to aggregate, resulting in a homogeneously dense sausage-like shape. After several times, the minimization of interfacial area drives this sausage-like shape to

condense and shorten until, at the final stage, a globule is formed [9]. The collapse phenomena creates chains disordered (globule) and resulting in dislocated of conjugated π-electrons hence lower the conductivity. The decrease in conductivity also could be assigned to the dominating role of ion association over free ion formation which decreases the number of charge carriers for conduction [10].

**Differential scanning calorimetry**

From DSC thermogram in Figure 5, we can determined the onset temperature of melting point, peak temperature that represent the melting point of the polymer, and the enthalpy of fusion, ΔH by calculating area under the graph. Table 3 shows the DSC thermogram data for Pristine PANI and PANI-DBSA.

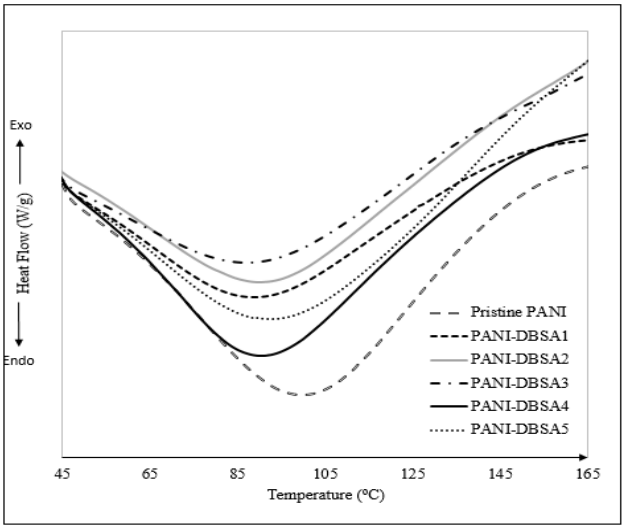

Figure 5. DSC thermogram of Pristine PANI and PANI-DBSAs

Table 3. DSC thermogram data for Pristine PANI and PANI-DBSA

| Sample | Onset Temperature ($T_o$), $^oC$ | Melting temperature ($T_m$), $^oC$ | Enthalpy of Fusion (ΔH), J/g |
|---|---|---|---|
| Pristine PANI | 50.31 | 97.77 | 210.2908 |
| PANI-$DBSA_1$ | 42.31 | 87.22 | 219.7509 |
| PANI-$DBSA_2$ | 41.60 | 86.85 | 158.4879 |
| PANI-$DBSA_3$ | 41.56 | 84.16 | 136.6957 |
| PANI-$DBSA_4$ | 40.34 | 88.27 | 157.8515 |
| PANI-$DBSA_5$ | 40.73 | 89.15 | 187.4384 |

In semi-crystalline polymer like PANI, a broad melting curve is the normal DSC thermogram, thus make separating melting from simultaneous crystallization or crystalline reorganization can be difficult [10]. The onset temperature usually indicates the starting point PANI's molecules start to change their state from solid to rubbery state. The PANI's molecules become soften and crystalline portions start to move transitionally [11]. As increasing in amount of DBSA during polymerization of PANI, the onset temperature is decreasing shows the presence of DBSA has altered the chains length make it easily to adsorbed heat to disturb ordered molecule regions. Though, sample PANI-$DBSA_5$, shows the onset temperature increase slightly compare to PANI-$DBSA_4$, it shows insignificant value because the differences is too small. The melting point of the pristine PANI and PANI-DBSAs shows the same trend as onset temperature. In addition of DBSA, the melting point slightly decreased compare to pristine PANI.

In Figure 6, the enthalpy of fusion shows indirectly proportional to the value of conductivity. It can be enlightened that the amount of DBSA doped PANI affect the conductivity and thermal properties of PANI. The value enthalpy of fusion (ΔH) corresponds to the normalized peak area in joules per gram (J/g) and a result of crystal imperfection [12]. The increase in conductivity with ΔH is interpreted in terms of hopping mechanism between co-ordination sites, local structural relaxation and segmental motion of polymer [13]. Thus the segmental local structures of polymer are shorten with increasing in amount of DBSA in polymerization of PANI. This can be assure as the ΔH are decreasing as increasing in amount of DBSA. However, as concentration of DBSA is increase up to 2.0 mmol, the ΔH shows slightly increased. This is may be due to the PANI local structure has been increased and the segmental motion are stiffer thus increase heat required to vibrate the PANI structure.

Moreover, increasing amount of DBSA shows no independent influence to melting point of PANI. This may be due to the amount of DBSA are very small to influence the melting point even though the ΔH shows a great significant value.

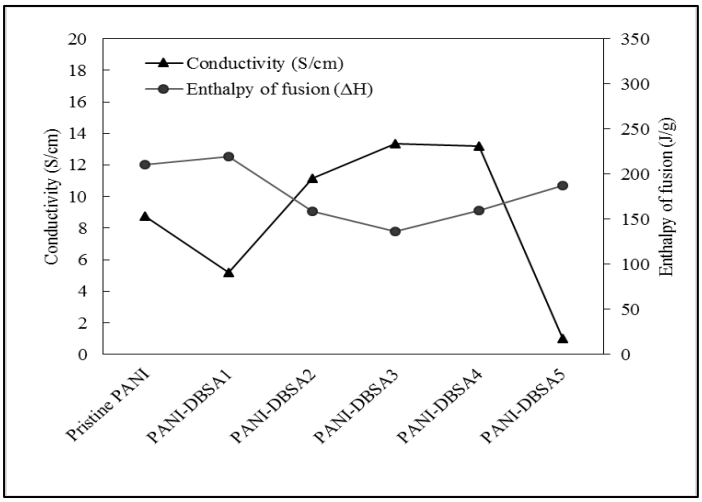

Figure 6. Graph of enthalpy and conductivity versus amount of DBSA in PANI

## Conclusion

Polyaniline was prepared by chemical synthesis using DBSA as the surfactant. The spectra of PANI-DBSA has the important significant peaks of DBSA after doping procedure. For synthesized PANI-DBSA, FTIR spectra shows the dopant peaks as the interaction with PANI structure. The electrical conductivity measurement has shown that electrical conductivity of pristine PANI is 8.77 S/cm and addition of DBSA as dopant in PANI polymerization has increased the conductivity up to 13.37 S/m. Based on DSC results, DBSA has a strong effect as it can lowered the ΔH values of PANI-DBSA$_1$ to PANI-DBSA$_3$ but increases at PANI-DBSA$_4$ and PANI-DBSA$_5$ as the doping give an effect on PANI molecular arrangement.

**Abstract**

Recombinant bromelain is a cysteine protease that can be exploited for its protease activity in food and pharmaceutical applications. The aim of this study was to compare different purification methods aqueous two-phase system (ATPS), ammonium sulphate precipitation, ion exchange, affinity, and gel filtration chromatography) for the recombinant bromelain purification from *Escherichia coli* BL21-A1. From the SDS-PAGE analysis, all methods produced band with molecular weight between 50 to 55 kDa. Among the methods used, the ATPS purification consisting of 13% (w/w) of PEG6000 and 11% (w/w) potassium phosphate at pH 7.0 was chosen as the best purification method. The method produced 16.39 ± 0.03 % of yield, purification fold of 5.35 ± 0.11, and specific activity of 3.47 ± 0.11 unit/mg of recombinant bromelain. This proposed study can be used as a platform for large-scale downstream processing of recombinant bromelain in industry.

**Keywords**: recombinant bromelain, purification, chromatography, aqueous two-phase system

**Abstrak**

Rekombinan bromelain adalah sisteina protease yang boleh dieksploitasi dalam aplikasi makanan dan farmaseutikal. Tujuan kajian ini adalah untuk membandingkan kaedah penulenan yang berbeza dengan menggunakan sistem akueus dua fasa (ATPS), pemendakan amonium sulfat, pertukaran ion, afiniti dan gel penapisan kromatografi untuk penulenan rekombinan bromelain daripada *Escherichia coli* BL21-A1. Daripada analisis SDS-PAGE, semua kaedah menghasilkan jalur dengan berat molekul antara 50 hingga 55 kDa. Antara kaedah yang digunakan, sistem akueus dua fasa (ATPS) yang terdiri daripada 13% (w/w) PEG6000 dan 11% (w/w) kalium fosfat pada pH 7.0 telah dipilih sebagai kaedah penulenan yang terbaik. Kaedah ini mendapat 16.39 ± 0.03% hasil, kadar penulenan 5.35 ± 0.11, dan aktiviti rekombinan bromelain sebanyak 3.47 ± 0.11 unit/mg. Kajian ini dicadangkan boleh digunakan sebagai platform untuk pemprosesan hiliran rekombinan bromelain secara besar-besaran dalam industri.

**Kata kunci:** rekombinan bromelain, penulenan, kromatografi, sistem akueus dua fasa

## Introduction

Bromelain is a plant protease that is commercially obtained from stem, fruit, and waste of pineapple plant [1]. Bromelain is notable for being used in multitude industrial applications such as meat tenderization, food, beverages, and pharmaceuticals, hence increases its market demand [2]. However, there is a rising argument whether pineapple

crop should be selected for food or bromelain extraction. Besides, the processing of pineapple crop to produce bromelain generates bulk waste that eventually leads to environmental issues. Considering the significance of economic, efficient production and downstream processing of bromelain, recombinant bromelain was successfully expressed in various hosts, including *Escherichia coli* BL21-A1 [3], *E.coli* BL21 DE3pLysS [4] and *Brassica rapa* [5]. Our research group has successfully cloned the stem bromelain from *Ananas comosus* into the pENTR/TEV/D-TOPO vector and subcloned it into the pDEST17 expression vector. Later, *E. coli* BL21-A1 was transformed with the expression vector [3] and was cultivated in a batch process using auto-induction media [6]. The recombinant bromelain is an intracellular enzyme and remains abundantly in the cytoplasm of the *E. coli* cells. Therefore it is vital to develop a reliable, efficient, and cost-effective purification process to purify the recombinant bromelain after cell disruption process using ultrasonication method [7].

Commonly, recombinant bromelain was purified using affinity chromatography under native condition [3, 8]. An instrument such as AKTA prime plus® (GE Healthcare, USA) provides a quick design to facilitate affinity chromatography purification as the plasmid vector of recombinant bromelain has a unique polyhistidine (His6) tag [3]. It was reported that, the recombinant bromelain purified from *E. coli* BL21-A1 has a molecular weight of 50 – 55 kDa and exhibited optimum proteolytic activity at pH 4.6 [3]. In the majority of food industry, the enzyme is added in bulk quantity. The enzyme purified by Amid et al. [3] was only produced in a small amount (~200 µl) and could not be used for large scale food-related processes. Therefore, there is a need to develop a purification protocol that accompanies higher recovery, lower cost, and shorter processing time. Aqueous two-phase system (ATPS) is one of the alternative purification methods which involves a mixing of two polymers or one polymer and one salt under specific condition to form a phase separation. Due to its low cost and high recovery, ATPS purification method has been addressed previously by other researchers for the purification of recombinant protein [9, 10] and bromelain from pineapple plant [1].

To date, recombinant bromelain has not been extracted by aqueous two-phase technique, which could be promising in the bromelain research. In this paper, we compare the purification efficiency of ammonium sulfate precipitation, aqueous two-phase system, ion exchange chromatography, affinity chromatography, and gel filtration chromatography. Purified recombinant bromelain was further evaluated using SDS-PAGE analysis and enzyme assay with Nα-CBZ-L-lysine *ρ*-nitrophenyl ester (LNPE) as substrate.

## Materials and Methods

### Media and culture condition

The cultivation of *E. coli* BL21-A1 [3] was conducted in a batch fermentation using auto-induction method [6]. Approximately 10 ml of starter medium supplemented with 100 µg/ml ampicillin was inoculated with single colony of *E. coli* BL21-A1 harbouring the bromelain gene and incubated for 16 hours at 37 °C with shaking at 300 rpm in an incubator shaker (CERTOMAT® IS, Sartorius, Germany). 1 L of ZYM medium [11], supplemented with 100 µg/ml ampicillin, was inoculated with 10 ml of starter culture and incubated in an incubator shaker (CERTOMAT® IS, Sartorius, Germany) for 12 hours at 37 °C with shaking at 250 rpm until the $OD_{600nm}$ reached 0.6-1.0. After 12 hours, the cells were harvested by centrifugation (4 °C, 16000 x g, and 15 min) (Heraeus Multifuge X1R, Thermo Scientific, USA), and the cell pellet was stored at -20 °C until further used. The cell pellet was suspended in lysis buffer at a ratio of 1 g to 5 ml of lysis buffer before cell disruption by sonication technique (20% amplitude and first cycle for 130 ml/min) [7]. The lysate was then centrifuged at 16000 x g for 45 min (Heraeus Multifuge X1R, Thermo Scientific, USA) to obtain a clear supernatant for further analysis.

### Enzyme activity assay

The enzymatic assay was based on continuous spectrophotometric rate determination method. The proteolytic activity of recombinant bromelain was measured using Nα-CBZ-L-lysine *ρ*-nitrophenyl ester (LNPE) as a substrate at 44 °C and pH 4.6. Initially, 2.60 ml of LNPE buffer was mixed and incubated with 100 µl of enzyme solution for approximately 3 min. Then, 100 µl of 50 mM LNPE substrate was added and mixed by inversion. The absorbance measurement of enzymatic reaction was measured spectrophotometrically for 5 min at 340 nm using a microplate reader (Thermo Scientific, USA). One unit of enzyme activity corresponds to the release of 1.0 µmole of ρ-nitrophenyl ester from the LNPE substrate per min after reaction with bromelain [12]. The hydrolysis of substrate was monitored at the selected wavelength starting 50 sec after the addition of enzyme in order to allow enough time

for the assay medium to reach 44 °C. Initial velocity measurements were obtained from the data recorded over the next 300 sec (5 min), where linearity was maintained. The results were plotted as ΔAbs per min versus amount of enzyme. The slope of this line, together with the molar absorption coefficient obtained as described in equation 1, allowed us to calculate enzyme activity in terms of units/mg protein as below:

$$\frac{\left(\frac{\Delta A_{340nm}}{\text{min Test}} - \frac{\Delta A_{340nm}}{\text{min Blank}}\right) \times 2.8 \times DF}{6.32 \times 0.1} \quad (1)$$

where the values of 2.8, 6.32, 0.1 and DF denote the assay volume in milliliters, the millimolar extinction coefficient of ρ-nitrophenol at 340 nm, the volume of enzyme used in milliliters, and the dilution factor, respectively. Assays were carried out in triplicate.

**Protein assay**
Protein content was measured based on the Bradford method using Bio-Rad Protein Assay (Bio Rad, Germany). Absorbance was measured at a wavelength of 595 nm using a microplate reader. (Thermo Scientific, USA). Bovine serum albumin was used as a standard for the protein assay [13]. Assays were carried out in triplicate.

**Sodium dodecyl sulfate-polyacrylamide gel electrophoresis**
Purified samples from ATPS were analyzed by using sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) [14]. The ATPS samples were diluted two times before applying to 12% resolving gel and 4% stacking gel. After electrophoresis was performed at 200 V, 700 mA for 37 min, the gels were stained using silver stain or Coomassie blue.

**Ammonium sulfate precipitation**
Protocol for ammonium sulfate precipitation was adopted from Grodzki et al. [15]. The precipitation of the recombinant bromelain was performed by slow addition of ammonium sulfate to the crude cell lysate at 4 °C. Initially, solid ammonium sulfate was slowly added to achieve a final concentration of 30% (w/v). The mixture was incubated for 30 minutes with continuous stirring. After the ammonium sulfate was completely dissolved, the mixture was centrifuged at 4 °C and 16000 x g for 15 minutes (Heraeus Multifuge X1R, Thermo Scientific, USA). Precipitate was discarded, and the recombinant bromelain in supernatant was collected. The supernatant was subjected to further precipitation by slowly adding ammonium sulfate to achieve a final concentration of 60% (w/v). The solution was stirred and incubated overnight at 4 °C to reach equilibrium. The precipitated protein was collected for chromatography analysis after centrifugation at 16000 x g for 15 minutes. The weight of saturated ammonium sulfate in gram that was required for salting out the protein is given in Equation 2.0 [15] as follows:

$$g = Volume\ of\ sample\ (ml) \times 0.515 \frac{g}{ml} \times \frac{(S_2 - S_1)}{1 - S_2} \quad (2)$$

where $S_2$ and $S_1$ are final saturation (%) and initial saturation (%), respectively. The value of 0.515 g/ml denotes the solubility of ammonium at 4 °C. The ammonium sulfate has a molecular weight of 131.14 g/mol, and 100% saturation of ammonium salt at 4 °C corresponds to 3.93 M, therefore the solubility of ammonium sulfate at 4 °C is 0.515 g/ml.

**Ion-exchange chromatography**
Ion exchange chromatography using AKTA Prime Plus® (GE Healthcare, UK) was performed to purify recombinant bromelain. A glass column connected to AKTA Prime Plus® (GE Healthcare, UK) with an inner diameter of 1 cm and the length of 10 cm was packed with DEAE-Sepharose FF® with 5.5 $cm^3$ column volume and equilibrated with 100 mM of Tris at pH 9.0 followed by 5 ml sample loading from 0.16 g recombinant bromelain produced from 60% ammonium sulfate precipitation process at a flow rate of 1 ml/min. After that, the column was washed with the same buffer. A stepwise elution experiment was performed with elution buffer of 100 mM of Tris and 700 mM NaCl at pH 9.0. Finally, the eluates were analyzed for their enzyme activity, specific activity, total protein content and purification fold.

**Affinity chromatography**

Affinity purification was conducted using AKTA Prime Plus® (GE Healthcare, UK). A glass column connected to AKTA Prime Plus® (GE Healthcare, UK) with an inner diameter of 1 cm and 10 cm length was packed with 5.5 $cm^3$ column volume of Ni-NTA agarose and equilibrated with equilibration buffer (50 mM of $NaH_2PO_4$, 300 mM NaCl and 10 mM of imidazole) at pH 8.0. The protein precipitate (0.16 g) from 60% of ammonium sulfate precipitation process was suspended in 5 ml equilibration buffer and was loaded into the packed column at a flow rate of 1 ml/min. After the unbound protein was washed with washing buffer (50 mM of $NaH_2PO_4$, 300 mM NaCl and 20 mM of imidazole, pH 8.0), the desired protein was eluted with a stepwise elution using elution buffer (50 mM of $NaH_2PO_4$, 300 mM NaCI and 250 mM of imidazole, pH 8.0). Collected fractions were analyzed by enzyme activity, specific activity, total protein content, and purification fold.

**Gel filtration chromatography**

A glass column connected to AKTA Prime Plus® (GE Healthcare, UK) with an inner diameter of 2.5 cm and 100 cm length was packed with 375.57 $cm^3$ column volume of Sephacryl S-200® and equilibrated with two column volumes of 100 mM Tris buffer, pH 7.0. Recombinant bromelain sample (0.16 g) from 60% of ammonium sulfate precipitation was applied to the packed column at a flow rate of 1 ml/min and washed with two column volumes of the same buffer until no other proteins were eluted. Purified proteins were analyzed for enzyme activity, specific activity, total protein, and purification fold.

**Aqueous two-phase system**

Stock solution of PEG 1500, 2000, 4000, 6000, 8000 and potassium phosphate was prepared with 50% (w/w) concentration. Potassium phosphate solution was prepared using specified ratios of $K_2HPO_4$ and $KH_2PO_4$ to achieve pH 7.0. ATPS was prepared in a graduated tube by adding 20% (w/w) of recombinant bromelain lysate, known weight of the PEG stock solution, potassium phosphate stock solution at definite pH, and deionized water to reach a total of 50% (w/w) concentration of ATPS. The mixture was mixed thoroughly for 3 minutes using a Vortex mixer. Phase separation was achieved by centrifugation at 1000 × g for 10 minutes at 25 ºC. Then, the top and bottom phases were collected for assay analysis. In order to evaluate the purification process, a purification factor (PF) and partition coefficient ($K_E$) recovered in the bottom and top phases were calculated according to the equation below:

$$PF = \frac{SA_e}{SA_i} \tag{3}$$

where $SA_e$ is a specific activity of each phase and $SA_i$ is an initial specific activity of crude lysate. The partition coefficient ($K_E$), was defined as follows:

$$K_E = \frac{A_T}{A_B} \tag{4}$$

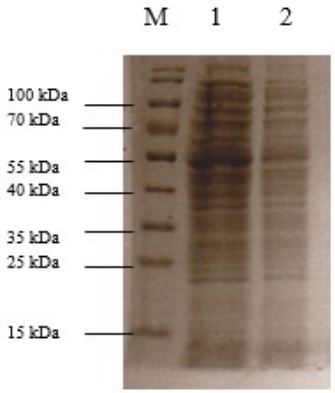
where $A_T$ and $A_B$ are the enzyme activity in the top and the bottom phase, respectively.

## Results and Discussion

**Ammonium sulfate precipitation**

In many cases, ammonium sulfate precipitation is often used as a preliminary purification of crude cell lysates to remove unwanted proteins prior to use of expensive columns in chromatography technique for its easy operation and economic practicality. Crude lysate of recombinant bromelain obtained after cell lysis was subjected to ammonium sulfate precipitation. It was hypothesized that most of the recombinant bromelain would be susceptible to precipitate from crude cell lysate in the presence of between 30% to 60% ammonium sulfate. The percentages were relative to a saturated solution (100%), which was equal to 3.93 M at 4 °C. Hence, the concentration was between 1.179 M and 2.358 M. The recombinant bromelain was found to precipitate at 60% of saturation with specific activity and purification fold of 0.03 ± 0.03 unit/mg and 0.05-fold, respectively. SDS-PAGE analysis shown in Figure 1 indicates the size of precipitated recombinant bromelain is approximately 50 – 55 kDa [3]. From Figure 1, we could see that most of the unwanted proteins have been removed after ammonium sulfate precipitation process.

This finding was in conformity with the previous works by Devakate et al. [16], stating that the bromelain from the pineapple fruit plant was precipitated at a saturation level of 40 – 60% with 2.81-fold purity. Soares et al. [17] also recovered bromelain at saturation range of 20 to 40% with purification fold of 4.4 using ammonium sulfate and ethanol precipitation. However, the purification fold of precipitated recombinant bromelain in the current work was lower than those of the native precipitated bromelains obtained by Devakate et al. [16] and Soares et al. [17]. The presence of more than one contaminant proteins precipitated with recombinant bromelain at saturation level of 40 – 60% (Figure 1) decrease the purification fold. Therefore, further purification steps such as chromatography purification were needed to obtain a pure protein sample with high purification fold. Besides, there was an absence of carbohydrate moiety in recombinant proteins produced in *E. coli* and folding anomalies might occur due to the inability of *E. coli* to perform post-translational modifications, therefore potentially resulted in modification of enzyme activity [18].



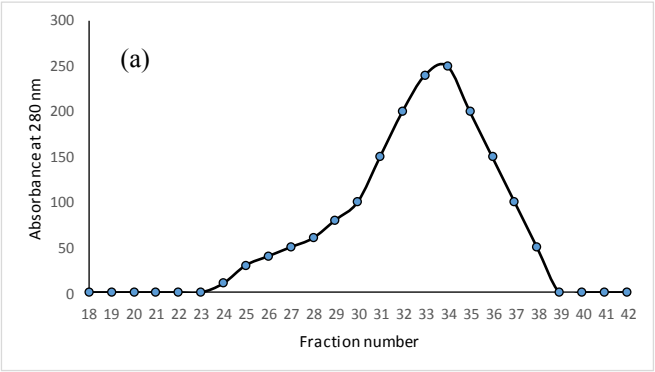


Figure 1. SDS-PAGE of purified recombinant bromelain using ammonium sulfate precipitation. Lane M: the standard molecular weight. Lane 1: crude cell lysate containing recombinant bromelain. Lane 2: 60 % ammonium sulfate precipitation. The position of recombinant bromelain is at estimated size of 50-55 kDa [3].

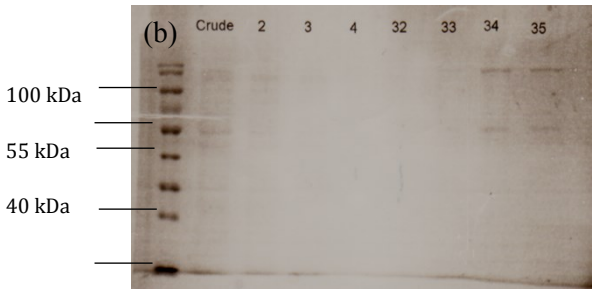
**Ion-exchange chromatography**

Ion-exchange chromatography was employed to purify the recombinant bromelain. A stepwise elution experiment was performed using binding buffer containing 100 mM of Tris at pH 9.0 and elution buffer containing 100 mM of Tris with 700 mM NaCl at pH 9.0. A chromatogram of recombinant bromelain purified using DEAE Sepharose is shown in Figure 2. From the elution profile shown in Figure 2, a prominent peak appears at fraction 33. All fractions under the peak were pooled and assayed for protein content and enzyme activity. The pooled fractions exhibited specific activity and purification fold of 0.094 unit/mg and 0.14, respectively. The fractions were analyzed by SDS-PAGE (Figure 2).



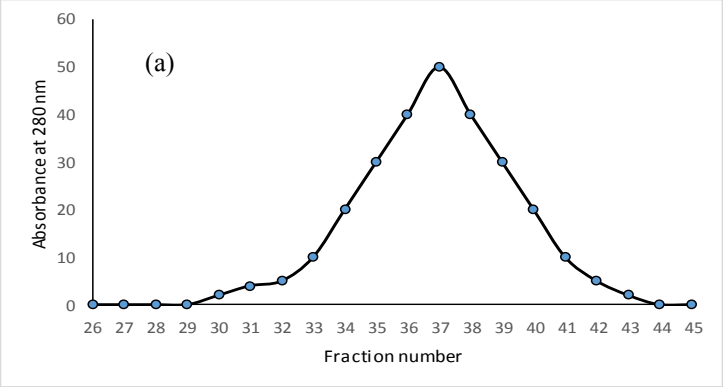


Figure 2. Chromatogram of the purified bromelain from ion exchange chromatography using DEAE Sepharose resin (a). The SDS-PAGE analysis of recombinant bromelain from ion exchange chromatography (b). 1 ml fraction was collected at a flow rate of 1 ml/min. The position of recombinant bromelain is at estimated size of 50-55 kDa [3]

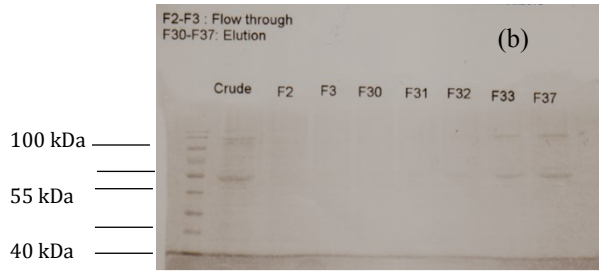
**Affinity chromatography**

Affinity chromatography was conducted for purification of recombinant bromelain using AKTA prime plus® system. Equilibrium buffer used contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 10 mM imidazole at pH 8.0. Washing buffer contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 20 mM of imidazole buffer, pH 8.0. Elution buffer contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 250 mM imidazole at pH 8.0. A chromatogram of recombinant bromelain purified using Ni-NTA agarose resin is shown in Figure 3. The recombinant bromelain pooled from fractions 33 to 37 exhibited specific activity and purification fold of 1.77 ± 0.02 unit/mg and 2.72-fold, respectively and appeared on the SDS-PAGE at the expected size of 50 – 55 kDa (Figure 3). The purification conditions are in accordance with the research presented by Amid et al. [3] and Bala et al. [8].



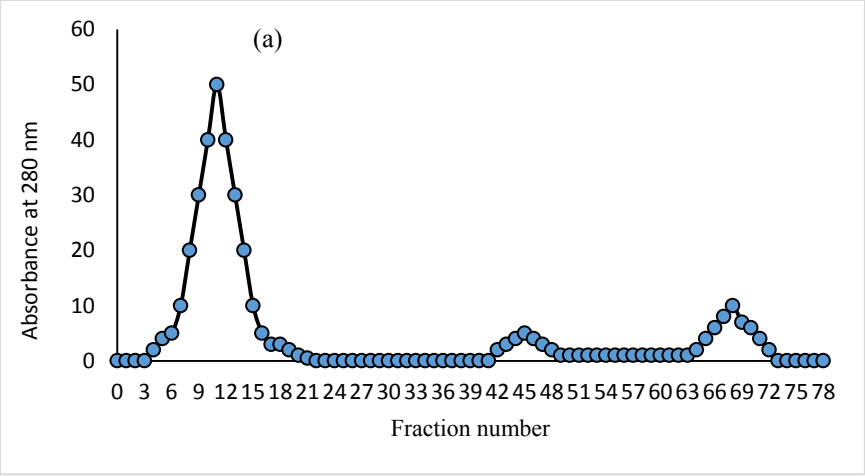


Figure 3. Chromatogram (a) and SDS-PAGE analysis (b) of the purified samples from affinity chromatography using Ni-NTA agarose resin. Equilibrium buffer contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 10 mM imidazole at pH 8.0. Washing buffer contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 20 mM of imidazole buffer, pH 8.0. Elution buffer contained 50 mM of $NaH_2PO_4$, 300 mM NaCl, and 250 mM imidazole at pH 8.0. 1 ml fraction was collected at a flow rate of 1 ml/min. The position of recombinant bromelain is at estimated size of 50 – 55 kDa [3].

**Gel filtration chromatography**

Gel filtration chromatography is a separation technique based on the size of the protein. The protein precipitated from the 60% of ammonium sulfate precipitation process was subjected to gel filtration chromatography using Sephacryl S-200® resin and a total of 78 fractions were collected (Figure 4). From the chromatogram, it can be seen that there was a high peak after washing step from fractions 9 to 20, followed by a broad absorbance peak from fractions 42 to 72 (Figure 4). The ammonium sulfate precipitation step removed the majority of protein contaminants and the remaining unwanted proteins were separated based on size by gel filtration beads. Thus, recombinant bromelain with 55 kDa was eluted first. The specific activity and purification fold obtained after gel filtration purification were 2.00 ± 0.51 unit/mg and 3.08 ± 0.79-fold, respectively. The SDS-PAGE analysis from Figure 4 shows that the recombinant bromelain pooled from fractions of 11 to 14 has an apparent molecular weight of 50 – 55 kDa.

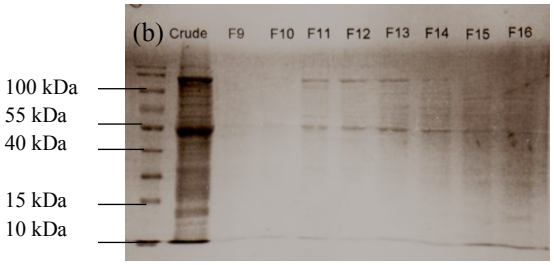

Figure 4. Chromatogram (a) and SDS-PAGE (b) analysis of the purified samples from gel filtration chromatography using Sephacryl S-200® resin. Equilibrium, washing and elution buffers contained 100 mM Tris buffer, pH 7.0. 5 ml fractions were collected at a flow rate of 1 ml/min. The position of recombinant bromelain is at estimated size of 50-55 kDa [3]

The SDS-PAGE analysis was also performed for the remaining peak from fractions 27 to 78, however, no protein band was visible, indicating that no impurities present in the sample. Costa et al. [19] performed ion exchange chromatography prior to gel filtration chromatography to purify bromelain with a molecular weight of 30 kDa from pineapple stem residue. The gel-filtration resin used was Sephadex®G-50. Suh et al. [20] employed gel filtration chromatography to estimate the molecular weight of bromelain as 32.5 and 37 kDa from pineapple fruit and stem, respectively using Sephadex G-200 resin. Hence, it can be concluded that the combination of low-resolution (ammonium sulfate precipitation) and high-resolution (chromatography) methods are most likely provide a higher purity of desired protein.

**Aqueous two-phase system**

In order to determine the best ATPS extraction conditions for the recovery and purification of recombinant bromelain, different molecular weight of PEG was used. The influence of PEG with different molecular weights (1500, 2000, 4000, 6000, and 8000) at constant volume ratio of 1.0 was investigated for the purification of recombinant bromelain. Most recombinant bromelain partitioned in all two phase systems to PEG-rich top phase and salt rich bottom phase. It is because, in a PEG-salt system, phase separation is caused by the volume exclusion effect of the polymer and salting-out effect of salt [21].

Table 1 shows the partition coefficient ($K_E$), purification fold (PF), and enzyme activity recovery of recombinant bromelain in the PEG-rich top phase. The PEG1500/phosphate and PEG2000/phosphate systems exhibited relatively small partition coefficient, purification fold and enzyme activity recovery of recombinant bromelain compared to other three systems investigated (PEG4000, PEG6000 and PEG8000). One explanation for this observation is that high molecular weight of PEG has high hydrophobicity and thus increases the salting-out characters that drive the partition of recombinant bromelain to the upper phase [22]. Conversely, low molecular weight of polymer attracts the migration of contaminant proteins to the top phase and causes a decrease in remaining free volume available for the recombinant bromelain to occupy [23]. Thus, the $K_E$, PF, and enzyme activity recovery values at the top phase were significantly reduced. Bekale et al. [24] had proved by using molecular modelling technique that PEG6000 was strongly adsorbed on bovine serum albumin (BSA) and human serum albumin (HSA) through hydrophobic binding compared with PEG3000. The interaction of polymer-enzyme in ATPS has led to the equilibration between polymer hydrophobicity and salting-out force that explains the preference of recombinant bromelain to migrate to the upper segment [25].

The highest $K_E$ (1.63), PF (5.35), and enzyme activity recovery (53.25%) were obtained in a system consisting of 11% (w/w) of potassium phosphate and 13% (w/w) of PEG6000. Even though the system with the composition of 11% (w/w) PEG8000 and 12% (w/w) potassium phosphate has a high partition coefficient, its purification fold and enzyme activity recovery were found to be low. The purification fold represents the specific activity of purified protein over the specific activity of crude lysate. Thus, high purification fold for the ATPS of 11% (w/w) of potassium phosphate and 13% (w/w) of PEG6000 indicated high specific activity and purity. The molecular weight of partitioned protein may influence the composition of polymer and salt. Ketnawa et al. [1] had successfully

partitioned bromelain from pineapple peels using the system containing 18% (w/w) PEG6000 and 17% (w/w) $MgSO_4$. Ramakrishnan et al. [26] observed that the enzyme recovery of lipase from *Enterococcus faecium* MTCC5695 was increased with the increase of PEG molecular weight from 1000 to 8000. The purified sample from the top phase (PEG-rich) was subjected to SDS-PAGE analysis. All of the purified samples were run on SDS-PAGE under reducing conditions (Figure 5). The protein bands observed at 50-55 kDa represent the molecular weight of recombinant bromelain.

Table 1. The effect of molecular weight to the partition coefficient ($K_E$) and purification fold (PF). (Note: PP: potassium phosphate, PEG: polyethylene glycol)

Lane M corresponds to protein marker, lane 1 is the top phase (PEG-rich), lane 2 is the bottom phase (salt-rich), and lane 3 is the crude cell lysate containing recombinant bromelain. The position of recombinant bromelain is at estimated size of 50 – 55 kDa [3].

**Comparison of purification by ATPS and chromatographic techniques**

The purification efficiency of the recombinant bromelain from various purification methods is summarized in Table 2. The chromatography process for the purification of recombinant bromelain has been well explained by Amid et al. [3]. In chromatography purification, the crude extract from cell lysis process was subjected to ammonium sulfate precipitation to concentrate and precipitate the recombinant bromelain. Later, the precipitated protein was dissolved in equilibrium buffer, depending on the type of chromatography (affinity, ion exchange, and gel filtration) used. In contrast, ATPS purification was performed directly after centrifugation in which the crude extract from cell lysis was applied to the PEG6000-potassium phosphate extraction stage.

Table 2. Purification efficiency of recombinant bromelain by different purification methods.

| Purification Methods | Volume (ml) | Total Protein (mg) | Total Activity (units) | Specific Activity (units/mg) | Purification Folds | Yield (%) |
|---|---|---|---|---|---|---|
| Crude | 200 | 304.96 ± 0.00 | 197.49 ± 0.00 | 0.65 ± 0.00 | 1.00 ± 0.00 | 100 ± 0.00 |
| Ammonium sulphate precipitation | 50 | 36.05 ± 0.00 | 1.16 ± 0.00 | 0.03 ± 0.03 | 0.05 ± 0.00 | 0.59 ± 0.02 |
| Affinity (Ni-NTA agarose) chromatography | 3 | 0.13 ± 0.00 | 0.23 ± 0.00 | 1.77 ± 0.02 | 2.72 ± 0.00 | 0.12 ± 0.00 |
| Ion-exchange (DEAE Sepharose) chromatography | 11 | 5.29 ± 0.01 | 0.49 ± 0.01 | 0.09 ± 0.00 | 0.14 ± 0.00 | 0.25 ± 0.00 |

Table 2 (cont'd). Purification efficiency of recombinant bromelain by different purification methods.

| Purification Methods | Volume (ml) | Total Protein (mg) | Total Activity (units) | Specific Activity (units/mg) | Purification Folds | Yield (%) |
|---|---|---|---|---|---|---|
| Gel filtration (Sephacryl S-200®) chromatography | 20 | 0.05 ± 0.00 | 0.10 ± 0.00 | 2.00 ± 0.51 | 3.08 ± 0.79 | 0.05 ± 0.01 |
| Aqueous two-phase system | 20 | 3.02 ± 0.00 | 10.50 ± 0.00 | 3.47 ± 0.11 | 5.35 ± 0.11 | 16.39 ± 0.03 |

In this study, Ni-NTA agarose chromatography (affinity) resulted in purity and specific activity of 2.72-fold and 1.77 ± 0.02 unit/mg, respectively. Meanwhile, DEAE Sepharose chromatography (ion exchange) achieved 0.09 unit/mg and 0.14-fold, respectively. The Sephacryl S-200® chromatography produced specific activity of 2.00 ± 0.51 unit/mg with 3.08 ± 0.79-fold. However, the ATPS purification (13% (w/w) of PEG6000 and 11% (w/w) potassium phosphate, pH 7.0) produced favourable value of purification fold (5.35±0.11-fold) compared with that produced after Ni-NTA agarose chromatography (2.72-fold) and Sephacryl S-200® chromatography (3.08 ± 0.79 fold). With respect to yield percentage, ATPS process exhibited higher yield (16.39 ± 0.03%) compared to ammonium sulphate precipitation (0.59 ± 0.02%), DEAE Sepharose chromatography (0.25%), Ni-NTA agarose chromatography (0.12%), and Sephacryl S-200® chromatography (0.05 ± 0.01%). The yield is defined as the amount of purified protein (total units) divided by the initial amount of protein (defined as 100%).

From economic analysis point of view as stated in Table 3, it can be summarized that ATPS method exhibited the second lowest operating cost with shorter operating time (30 minutes) over chromatographic methods. Among the chromatography methods used, gel filtration chromatography appeared to exhibit higher operating cost due to long separation time (72 hours), causing an increment of buffer usage. Affinity chromatography was positioned as the second most costly method owing to the expensive resin and chemicals used within 1 hour operation time. In terms of reusability, the resin can be re-used up to 100 times only, with an additional cost of using sodium hydroxide, sodium chloride, nickel sulphate, and EDTA for stripping and regenerating the resin after each run. In the case of ATPS, the polymer and salt cannot be recycled as they were part of the final purified enzyme [23]. Such economic and operation analysis provides understanding for further research, and the ATPS process is proven to be a cost-effective, time-saving, and a higher recovery method that may be scaled up for industrial purpose. The purification method should be selected based on the complexity and the application of the recombinant bromelain. In many cases, it is not necessary to have the protease preparation in high purity form, especially for the commercial use such as in food, cosmetics, and textile industries [2]. Therefore, the purification method is aimed to obtain an active protease preparation in high recovery and high yield for industrial purpose. However, for some pharmaceutical uses, the protease must be highly purified. High purity protease is almost invariably expensive due to the purification intricacy to get rid of undesirable contaminating substances. For that reason, this study enables producers and researchers to choose the desired level of protease purity, thereby further reducing the cost of the production process.

Table 3. Direct comparison between chromatography and ATPS methods for the downstream processing of recombinant bromelain

| **Parameter** | **Ammonium Sulfate** | **Ion Exchange** | **Affinity** | **Gel Filtration** | **ATPS** |
|---|---|---|---|---|---|
| Operation | Batch | Batch and semi-batch | Batch and semi-batch | Batch and semi-batch | batch |
| Processing time | 24 hours | 1 hour | 1 hour | 72 hours | 30 minutes |
| Cost of the resin | - | DEAE Sepharose: USD 7.84/7ml | Ni-NTA: USD 121.03/7 ml | Sephacryl S-200®: USD 184/200 ml | - |
| Cost of the column | | Flow Adaptor (1.0 cm): USD 191.99 Econo Column (1 cm x 10 cm): USD 69.82 | Flow Adaptor (1.0 cm): USD 191.99 Econo Column (1 cm x 10 cm): USD 69.82 | Flow Adaptor (1.5cm): USD 191.99 Econo Column (2.5 x 100 cm): USD 71.26 | - |
| Cost of the chemicals (per kg) | Ammonium sulfate: USD 151.24 | Tris: USD 197.85 NaCl: USD 118.15 | Imidazole: USD 614.55 NaCl: USD 118.15 $NaH_2PO4$: USD 280.98 | Tris: USD 197.85 | $K_2HPO_4$: USD 173.45 $KH_2PO_4$: USD 210.21 PEG6000: USD 42.42 |
| Cost of the operation per system | USD 151.24 | USD 585.65 | USD 1396.52 | USD 645.10 | USD 426.08 |

## Conclusion

The ATPS, ammonium sulfate precipitation, and chromatographic procedures for downstream processing of recombinant bromelain were investigated. Our study clearly demonstrated that ATPS process was proven to be a cost-effective (USD 426.08), time-saving (30 min), and high-recovery method (16.39 ± 0.03%) that may be scaled up for industrial purpose. The optimum conditions of ATPS system comprised of 13% (w/w) of PEG6000 and 11% (w/w) potassium phosphate at pH 7.0 which resulted 3.47 ± 0.11 unit/mg, and 5.35 ± 0.11-fold for the specific activity, and purification fold, respectively. Herein, ATPS can be a potential technique for the purification of single step separation and avoid multistep purification like ammonium sulfate precipitation and chromatography process.

**Abstract**

Nanoparticle with its nanoscale can be used as a data collector in every part of the development of the petroleum field. By having a hydrophilic condition for the nanoparticles, it can move to the targeted area in the water zone. The hydrophilic condition will differentiate between oil zone and water zone. The objective of the study is to use the hydrophilic nanoparticles to detect the oil and water zones using sand-pack displacement test. An experiment using the sand-pack method was done to show that the hydrophilic nanoparticles can be used to collect data. The nanoparticles used were aluminum oxide ($Al_2O_3$) and nickel zinc ferrite oxide (NiZnFeO). The results showed that for NiZnFeO, at 3-inch distance from the injection point, the percentage difference increased from 15% to 25%, while for $Al_2O_3$, the nanoparticles also showed the same increment but different in values, which were from 6% to 15%. This is shown by the significant change of resistivity percentage at the 3-inch distance. To conclude, the use of both types of nanoparticles that have hydrophilic nanoparticles can show the significant changes for resistivity at internal short front face of well reservoir with oil zone only.

**Keywords**: nanoparticles, formation characterization, sand-pack displacement, resistivity

**Abstrak**

Nanopartikel dengan skala nano boleh digunakan sebagai pengumpul data di setiap bahagian pembangunan bidang petroleum. Dengan adanya keadaan hidrofilik untuk nanopartikel, ia boleh bergerak ke kawasan yang disasarkan di zon air. Keadaan hidrofilik akan membezakan antara zon minyak dan zon air. Objektif kajian ini adalah untuk menggunakan nanopartikel hidrofilik untuk mengesan zon minyak dan air menggunakan ujian pek pasir. Satu eksperimen menggunakan kaedah pek pasir dilakukan untuk menunjukkan bahawa nanopartikel hidrofilik boleh digunakan dalam mengumpul data. Nanopartikel yang digunakan adalah aluminium oksida ($Al_2O_3$) dan nikel zink ferit oksida (NiZnFeO). Hasil kajian menunjukkan bahawa untuk NiZnFeO, pada jarak 3 inci dari sudut suntikan, perbezaan peratusan meningkat daripada 15% kepada 25%, manakala bagi $Al_2O_3$, nanopartikel juga menunjukkan kenaikan yang sama tetapi berbeza dalam nilai iaitu dari 6% kepada 15%. Ini ditunjukkan oleh perubahan yang ketara peratusan kerintangan pada jarak 3 inci. Kesimpulannya, penggunaan kedua-dua jenis nanopartikel yang mempunyai nanopartikel hidrofilik boleh menunjukkan perubahan signifikan bagi kerintangan muka depan pendek dalaman takungan baik dengan zon minyak sahaja.

**Kata kunci:** nanopartikel, penentuan formasi, pengaliran pek pasir, kerintangan

## Introduction

In the oil and gas industry, nanotechnology has been applied for approximately more than 50 years in many branches like exploration, drilling, production, Enhanced Oil Recovery (EOR), as well as refining and processing [1]. There are many tools used in well logging and one of the most important logging tools is resistivity logging. Resistivity logging has been widely used in well logging. It is one of the useful induction logging combination tools that have been enhanced by replacing the short normal quantitative interpretation [2]. It is also known as electric logging tool. The resistivity logging consists of two types of logging systems, which are dual lateral log and induction log. At present, resistivity logging uses both types of logs but the most commonly used logging is the induction logging. Besides that, the dual lateral log is used as a combination with the induction log for resistivity logging. Therefore, the quality of resistivity measurements is increased for the logging [3].

Research that focuses on nanoparticles used in well logging has not been attempted so far. Nevertheless, excellent works have been carried out on the Enhanced Oil Recovery (EOR). The nano particles are used to increase oil recovery via the EOR method [4]. Injected nanoparticles in the formation will somehow push the leftover oil in the formation to the wellbore for recovery and it has been proven in some recent studies. The idea is by mixing the nanoparticles with water and they will increase the electrical properties of the water. Furthermore, it is known that metal oxide nanoparticles do have good electrical properties that can change the electrical properties of the water. Therefore, the resistivity of water is altered by adding nanoparticles into it. Hence, the motivation for the use of nanoparticles in well logging becomes a more interesting study to be conducted. The low resistivity condition for oil and brine water can be solved by conducting the current research.

The conditions of low resistivity and low contrast pay on the resistivity are also termed as wet condition [5, 6] and it is considered as a limitation in logging tool resolution that has to be looked into. Although low resistivity and low contrast pay can be grouped together, they are actually different. Low resistivity pay is a deep resistivity log curves of approximately 1 to 10 ohm. They are also known as the mixing combination of shale content, mineralogy, macro and micro-porosity, and bed thickness. On the other hand, low contrast pay lacks resistivity contrast between pay zones or good area or best formation with oil zones and flanking shale or wet zones. It is a problem when a logging tool passes through a zone that contains fresh water or water in an area of low salinity. As salinity decreases, the conductivity becomes lower and the path for movement of electrical properties becomes weaker and it will attribute to more resistance. Therefore, the resistivity of the water leg should be high enough to record the data for resistivity between pay zone and wet zone, which is difficult to differentiate [5, 7, 8].

Furthermore, there are also some other factors, for example, the geological aspect factor. They are laminated clean sand with shales, silts or shale sands, clay-couted sand, gloucanite sand, sands with interstitial disperse clay, sand with disseminated pyrite, or other conductive minerals [8]. The geological factor has become a big factor with a combination of bed thickness, grain size, mineralogy, structure of formation, clay distribution, and water salinity. Thus, the conventional logging tool shows poor resolution [8, 9] as the formation or the sand is shown as shale due to the lower value of its cut-off zones. With that, the formation is grouped as low contrast and low resistivity reservoir [7].

On finding the resistivity of formation in the reservoir, a resistivity tool is used. There are two types of resistivity package tools, which are Dual Lateral log (DLL) and Induction log. They respond to real rock and all petro-physical analysis to find water saturation, hence, they follow the Archie's Law [12-16]. In fresh water, there is no conductive medium due to the non-ionic solution of the fresh water. So, when resistivity logging is done in fresh water, very high resistivity data are recorded. Therefore, it can be said that the fresh water is poor in conducting electrical current flow. On the other hand, water with saline and rich in mineral is more conductive due to the ionic materials contained in the water and the salinity of the water itself contributes to the conductive liquid. With this principle, the resistivity is conducted to measure the conductive formation in finding the best reservoir with high pay. Basically, most of the sedimentary rocks are very poor in conductive flow [14]. So, most of the conductivity fluid is brine water with ionic salt minerals.

Hence, the condition of low resistivity with low contrast pay needs to be altered, and one of the ways is by introducing nanoparticles. This is because nanoparticles are materials that are nano in size and the use of nanoparticles has become an interesting method to be incorporated within the research. Besides that, the size of pore and grain in nanoparticles makes it a good injector for formation. The size of pore and grain in a formation is minute, thus, only small particles with good permeability can penetrate the formation [17]. A study conducted by Yu et al. [17] showed that the size of pore and grain is a vital factor and it depends on the coating material for the nanoparticles. In selecting the nanoparticles, it needs to be based on polar and non-polar conditions of the nanoparticles because the nanoparticles need to be hydrophilic so that they can be immiscible into the brine, while oleophilic to be immiscible into the hydrocarbon oil. The main reason for the increasing interest within the industry is due to the numerous advantages that the nanotechnology brings. Known success of implementation of nanoparticles has been documented since its inception. Matteo et al. [18] reported that nanoparticles, when combined with smart fluids, can be deployed as very sensitive downhole sensors for extreme pressure, stress, and temperature. Innovative corrosion-resistant material solution can also be processed with the help of nanotechnology. It extends the lifespan and efficiency of drilling systems and when applied as a corrosion inhibitor for pipelines, nano-layer can act through the creation of permanent molecular layer, thus, can help to reduce HCl or $H_2S$ corrosion.

## Materials and Methods

### Materials

The nanoparticles used were metal oxide nanoparticles with the purity of 99% and purchased from the US Research Nanomaterials, Inc. USA. The nanoparticles are nickel zinc ferrite oxide (NiZnFeO) and aluminum oxide ($Al_2O_3$). Meanwhile, the crude oil sample for the crude oil injection was taken from the Malacca Petronas Refinery plant and the crude oil sample was collected upon receiving it from shipment. The properties of the crude oil are shown in Table 1 below. The sand-pack was fabricated with a cylindrical column prospexglass with 3 points interval distance to measure the resistivity as shown in Table 2 below. The sand-pack fabrication model is also shown in Table 2 below. The resistivity measurements were made using the Keithley Multimeter from the Keithley Instrument, Inc. Cleveland, Ohio USA and recorded using ExceLINX software by the Keithley Instrument. The unit for resistivity will be in ohm.

Table 1. Crude oil Properties

| Crude Oil type | Properties | Value | Unit |
|---|---|---|---|

**Preparation of nanoparticles**

Preparation of nanoparticles with concentration of 1000ppm. The nanoparticles, NiZnFeO and $Al_2O_3$, were prepared using a 100 mL beaker. The nanoparticles were weighted before being mixed with 100 mL of distilled water to produce nano-fluid. In order to make the nanoparticles suspended in the distilled water, the nano-fluid produced needs to control its pH value of 8.

Before the nanoparticles were injected into the sand-pack, the sand-pack needs to be pre-prepared first. The cylindrical column that is being fabricated need to be packed with sand. The collected sand needs to be washed with distilled water and dried a few times to make sure that there are no salt contaminations present in the sand. The sand-pack needs to be packed uniformly. After packing, the sand-pack experimental setup was prepared. The setup is shown in Figure 1.

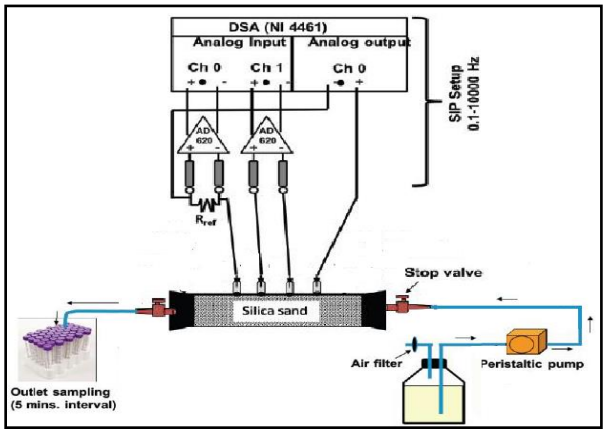

Figure 1. Experimental setup for the sand-pack

Once the process complete, the sand-pack was saturated with 7000 ppm of brine. A fully saturated sand-pack with brine is achieved when there are no more bubbles present in the outlet. After that, the first measurement of resistivity was taken in order to record the resistivity measurement before the injection of nanoparticles.

The injections of nanoparticles were done for 0.25, 0.50, 0.75, and 1.00 pore volume of injection. Each injection's volume was 60 mL and the resistivity measurement was taken after 5 minutes of each injection to make sure that the fluid movement inside the sand-pack was in a static condition without any outlet at the outlet stream.

## Results and Discussion

The 7000 ppm brine is a typical low salinity water in the Malay Basin [7]. The concentration of nanoparticles is 1000 ppm. Properties of the sand-pack are shown in Table 1 and results of the effects of NiZnFeO and $Al_2O_3$ nanoparticles are given in Table 3 and 4, respectively. As proposed, the resistivity of the brine/water phase showed a reduction from the initial values for NiZnFeO nanoparticles injection by 14.59, 3.94, and 1.82% at 3, 6, and 9-inch range, respectively, at the 0.25 pore volume injection of the sand-pack in Table 3 and Figure 2(A). When the experiments were conducted with different pore volumes, the resistivity readings agreed with our expected results. The nanoparticles moved along the interval distance causing a reduction in resistivity and at the pore volume of 1, the changes increased because the nanoparticles were suspended between the 3 to 9-inch ranges. It was proven from the measurement of outlet from the test that the amount got it only 0.01 ppm in the outlet collected.

Table 3. Resistivity change in sand pack after injection of 1000 ppm NiZnFeO nanoparticles (measurement taken every 5 minutes of injection finish)

| **Pore Volumes Injected** | **0.25** | | | **0.50** | | | **0.75** | | | **1.00** | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Interval distance from inlet (inch) | 3 | 6 | 9 | 3 | 6 | 9 | 3 | 6 | 9 | 3 | 6 | 9 |
| % Change in resistivity of water zone | 14.59 | 3.94 | 1.82 | 12.72 | 3.93 | 3.96 | 12.47 | 3.98 | 1.98 | 2.43 | 10.93 | 14.04 |

On the other hand, for the $Al_2O_3$ nanoparticles, as shown in Table 4 and Figure 2(b), the initial values of the injected nanoparticles were 5.7, 1.94, and 1.62 % at 3, 6, and 9-inch range, respectively, at the 0.25 pore volume injection of the sand-pack. When it went to all of the interval distances, it showed the same patent of decreasing value in terms of percentage difference. It proved that the $Al_2O_3$ had good hydrophilic nanoparticles for the movement of nanoparticles in the brine/water. The difference can be used to differentiate the oil and water zones for log measurements. Within the water zone, the reduction in resistivity indicated that the nanoparticles and traveled along the core, but the heterogeneity in the sand-pack had resulted in uneven resistivity drops.

Table 4. Resistivity change in sand pack after injection of 1000 ppm $Al_2O_3$ nanoparticles (measurement taken every 5 minutes of injection finish)

| **Pore Volumes Injected** | **0.25** | | | **0.50** | | | **0.75** | | | **1.00** | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Interval distance from inlet (inch) | 3 | 6 | 9 | 3 | 6 | 9 | 3 | 6 | 9 | 3 | 6 | 9 |
| % Change in resistivity of water zone | 5.7 | 1.94 | 1.62 | 9.53 | 2.24 | 1.58 | 11.20 | 4.83 | 1.35 | 15.26 | 5.26 | 2.88 |

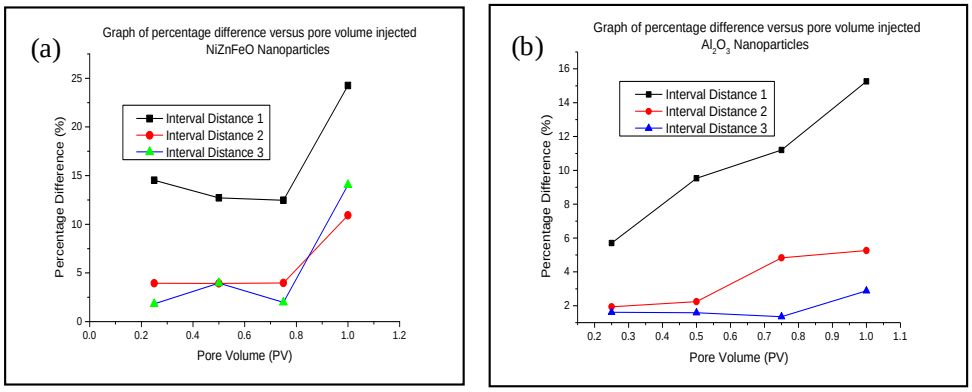

Figure 2. Percentage difference of resistivity value with difference pore volume for a) NiZnFeO and b) $Al_2O_3$ nanoparticles injection

Both nanoparticles in the experiments showed interests in the water zone. Therefore, the use of both nanoparticles has made it possible to differentiate between the oil and water zones. The results also showed that only a small pore volume was needed to determine the changes. For example, the NiZnFeO nanoparticles with only 0.5 pore volume of injected nanoparticles can detect the difference in the targeted zone. The same goes for the $Al_2O_3$ nanoparticles. Other than that, a 6-inch traveling distance for the nanoparticles was good enough to show the changes that happened. This condition is suitable for both NiZnFeO and $Al_2O_3$ nanoparticles.

## Conclusion

It can be concluded that oil zone can be determined using nanoparticles. It is proven by looking at the penetrations done by the NiZnFeO and $Al_2O_3$ nanoparticles in the sand-pack at 0.25 and 0.50 pore volume. The NiZnFeO and $Al_2O_3$ nanoparticles were injected and resistivity changes were recorded at the interval distance stated. NiZnFeO and $Al_2O_3$ nanoparticles showed the same patent for the percentage difference of resistivity at 3 and 6-inch injections. It can be seen from the percentage difference at 0.25 and 0.50 pore volume of injection. Both nanoparticles favored hydrophilic nanoparticles that went to water zone. Therefore, by having a system with oil water system that is low in contrast during log determination, the nanoparticles will choose the water zone and expose the oil zone. In this case, the oil zone can be determined while making changes for the water zone only. The targeted production zone for oil zone can be clearly stated and determined.

## Acknowledgement

The research was funded by the E-science programme of the Malaysian Ministry of Science, Technology, and Innovation. M. Zulkifli M. Noor's study is made possible by Universiti Malaysia Pahang. We would like to thank Universiti Teknologi PETRONAS for the full access to the excellent laboratory facilities and the staff of the Centre of Research in Enhanced Oil Recovery (COREOR) for providing other support services.

**Abstract**

Film of carrageenan and glyoxylic acid has been produced with an aim for hard capsule application through manipulation of physical crosslink. In this paper, the computational calculation has been used through utilization of density functional theory to predict the possible location of the physical crosslink in the conjugate complex between carrageenan and glyoxylic acid (film of carrageenan and glyoxylic acid). The calculations for pure kappa carrageenan (k-carrageenan), glyoxylic acid and conjugate complex were carried out using Gaussian 09W; and analysis of molecular electrostatic potential (MESP) was carried out using Gaussview 5. The molecular electrostatic surface potential (MESP) for optimized structure for k-carrageenan and glyoxylic acid have been generated with the red region represents the most negative electrostatic potential which can be found around oxygen and sulphur atoms for the carrageenan molecule. While the blue region that represents the most positive electrostatic potential which can be found around the hydrogen atom far from the double bond oxygen atoms in glyoxylic acid. Therefore, both of this regions may interact and form physical crosslink via hydrogen bond interaction.

**Keywords**: computational analysis, hard capsule, Gaussian 09W, molecular electrostatic potential, hydrogen bond

**Abstrak**

Filem karagenan dan asid glioksilik telah dihasilkan untuk aplikasi kapsul keras melalui manipulasi kaedah ikatan sambung silang fizikal. Di dalam kertas penyelidikan ini, pengiraan komputer menggunakan teori fungsi ketumpatan telah digunakan untuk mengenalpasti lokasi ikatan sambung silang fizikal yang terbentuk di dalam kompleks kappa-karagenan dan asid glioksilik. Penggiraan teori telah dilakukan untuk struktur kappa-karagenan, asid glioksilik dan kompleks kappa-karagenan-asid glioksilik menggunakan perisian Gassian 09W; dan analisis keupayaan elektrostatik molekul (MESP) dilakukan menggunakan perisian Gaussview 5. Ikatan sambung silang dapat ditentukan berdasarkan gambar-gambar MESP yang dihasilkan. Ikatan sambung silang tersebut dapat dilihat melalui interaksi antara keupayaan elektrostatik negatif (atom oksigen, dan sulfur di dalam karagenan) dan keupayaan elektrostatik positif (atom hydrogen di dalam asid glioksilik). Maka, kedua – dua bahagian ini mempunyai interaksi dan membentuk sambung silang fizikal melalui interaksi ikatan hidrogen

## Introduction

Kappa carrageenan (k-carrageenan) is an anionic sulphate polysaccharide with interesting pharmacology properties such as ability to inhibit hepatitis A viruses [1]. It has been used by in various studies to produce drug delivery carrier such as hydrogel [2, 3, 4], shell of microcapsules [5], and beads [6] which normally has prolonged drug release properties. This prolonged drug release properties is due to the swelling capability of k-carrageenan film such as been reported by Hezaveh and Muhammad [2] that non-crosslink k-carrageenan hydrogel can swelled up to 16% after soaked for 35 hours in pH 7 solution. While, this study aims to produce the hard capsule using k-carrageenan which require to disintegrate in less than 15 minutes. Therefore to achieve this aim, the crosslink method has been used with physical crosslink establishment as a main target. This physical crosslink can promote rapid swelling of k-carrageenan hard capsule and ensure its ability to disintegrate as required by US pharmacopeia [7]. According to Hiemstra et al. [8], physical crosslink is a mild crosslink or interaction such as hydrogen bond interaction in which its network can be easily disrupted due to changes in the external environment. At present, the interaction studies Adam et al. [9] and Karavas et al. [10] used the computational chemistry to simulate and calculate the establishment of the interaction through calculation of radial diffusion function (RDF) and interaction energy for hydrogen bond established in the system.

In this paper, the computational study using quantum mechanics concept will be presented. The quantum mechanics calculation was carried out to determine the particular atoms involved in the physical crosslink establishment between k-carrageenan and glyoxylic acid. The electron and proton donor site can be determine and conjugate complex k-carrageenan – glyoxylic acid was set at the selected site. This then may indicate the suitability of physical cross-linked carrageen to be developed as hard capsule application. In addition the effect of physical crosslink to the k-carrageenan molecule may further investigate.

## Materials and Methods

### Quantum Mechanics Calculation

The density functional theory (DFT) calculations have been carried out using Gaussian 09W software at B3LYP (Becke's three-parameter functional [11] and nonlocal correlation of LYP expression [12]) level of theory; with basis set of 6-31G. The geometry optimization and frequency calculations for pure k-carrageenan, glyoxylic acid and physical crosslink conjugate complex of k-carrageenan-glyoxylic acid (GaSc) were executed with the selected functional and correlation function. The molecule electronic surface potential (MESP) of k-carrageenan and glyoxylic acid has been generated from the geometry optimization calculation. Through this MESP, determination of the physical crosslink conjugate complex has been drawn and calculated for it optimum geometry. The crosslink point between k-carrageenan and glyoxylic acid was measured to ensure its can be categorized as hydrogen bond through calculation of interaction energy produced using Equation 1 below. While the absolute difference in muliken charges of optimized conjugate complex k-carrageenan-glyoxylic acid and k-carrageenan may indicate the probability of scission of chains. This scission effect may promote mechanical fracture (crack) of film. Figure 1 illustrates the quantum mechanics calculations steps that were carried out in this study.

$$\text{Interaction energy} = \text{ESCF complex} - \{\text{ESCF polysaccharide} + \text{ESCF crosslinker agent}\} \quad (1)$$

## Results and Discussion

The IR spectrum (Figure 2) for optimized k-carrageenan and glyoxylic acid molecules were generated from the frequency calculation. The frequency calculation was carried out after the molecules has been optimized. The positive value of vibration produced and for k-carrageenan and glyoxylic acid may indicate that the molecules geometry optimize calculation has managed to found the stationary point of the local minima on the potential energy surface. This validation technique has been suggested by Kumar et al. [13] in their quantum study of azelaic acid.

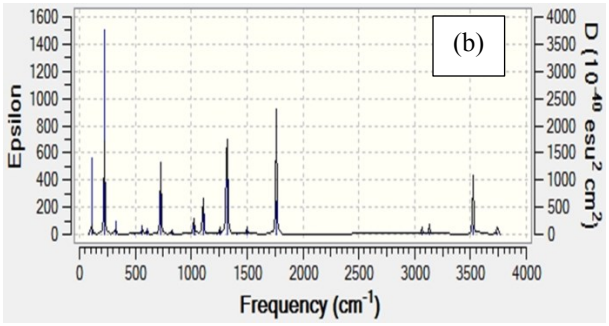

Figure 2. IR spectrum generated for optimized (a) kappa carrageenan molecule, and (b) glyoxylic acid molecule

In Figure 3 (a) and (b), the molecule electronic surface potential (MESP) for optimized k-carrageenan and glyoxylic acid illustrate the charge distributions of molecule with different values of the electrostatic surface potential at the surface. The potential increases (electron rich) in the order blue<green<yellow<orange<red. Knowledge of the charge distribution of the molecule which illustrated by electrostatic surface potential of molecule can be used to predict how molecule react to the other molecule such as suggested by Rawat and Singh [14]. Figure 4(a) shows that the negative regions in k-carrageenan are mainly localized on the oxygen and sulphur atoms which agreed with suggestion by Kumar et al. [13]. They suggested that the shapes of the electrostatic potential surface is influenced by the structure and charge density distributions in the molecule with sites close to the oxygen atom, showing region of most negative electrostatic potential. While in the glyoxylic acid, the positive regions are localized at the hydrogen atoms from hydroxyl functional group. Therefore, the physical crosslink may establish between the red region of k-carrageenan and blue region of glyoxylic acid or vice versa. The k-carrageenan will serve as an electron donor with glyoxylic acid will serve as a proton donor to establish the hydrogen bond. Tanak [15] also found negative potential site generated around Sulphur molecule using the BL3YP calculation for 4,5-bis(tert-butylsulfanyl)phthalonitrile and may serve as electron donor.

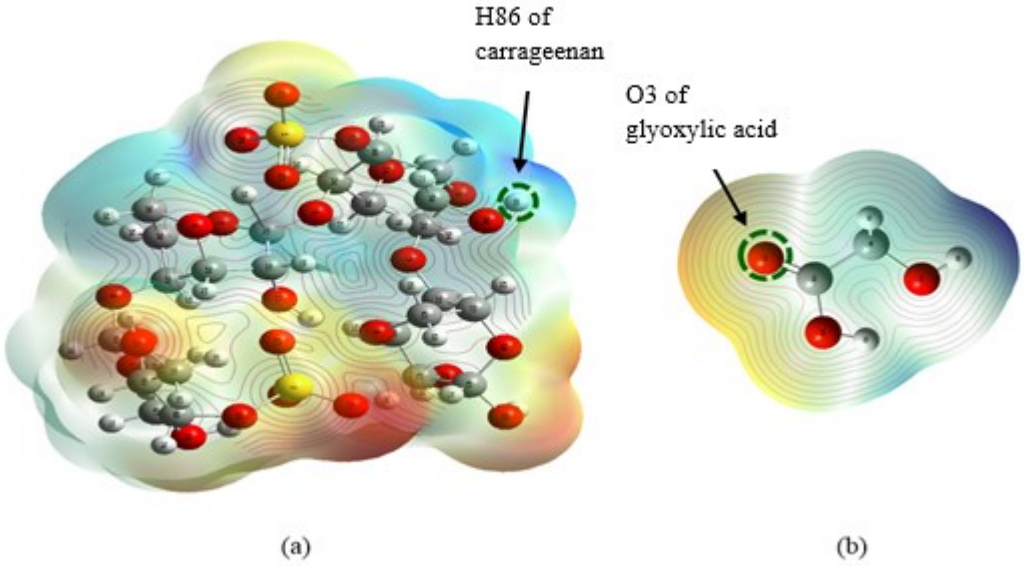

Figure 3. The molecular electrostatic potential (MESP) analysis for optimized molecule structure of (a) k-carrageenan and (b) glyoxylic acid

In this calculation the interaction between H86 of k-carrageenan and O3 of glyoxylic acid has been set up at the length of 2.2 Å at the beginning of calculation. The hydrogen bond has been established between H86 --- O3 with bond length of 1.90 Å (Figure 4) after optimization step completed for conjugate complex k-carrageenan-glyoxylic acid. According to Karavas et al. [10] the hydrogen bond length established in their Gaussian calculation for k-carrageenan and fluvastatin is around 1.897 Å. While Adam et al. [9] calculated hydrogen bond length of 1.75 Å for interaction between ethanol and patchouli in their molecular dynamic simulation. Therefore, the hydrogen bond established in this calculation is around the acceptable ranged. The hydrogen bond is the strongest intermolecular interaction [16, 17], which as physical crosslink, it may produce stable hard capsule shell that may promote disintegration.

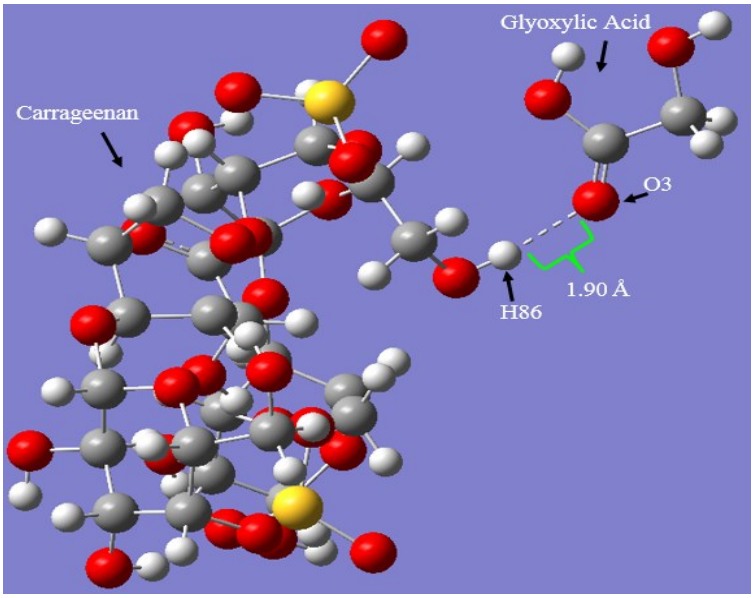

Figure 4. Hydrogen bond point between H86 --- O3 generated from the optimization calculation

The self-consistent field (SCF) energy values for optimized k-carrageenan, glyoxylic acid and conjugate complex k-carrageenan-glyoxylic acid were tabulated in Table 1. This study calculated -75.735 kJ $mol^{-1}$ for interaction energy of hydrogen bond between k-carrageenan and glyoxylic acid using 6-31G basis set. While Karavas et al. [10] calculated -318 kJ $mol^{-1}$ for the interaction energy of hydrogen bonding between iota carrageenan and (API) fluvastatin using basis set of 6-31G **(d.p) with ** as diffusion function and (d,p) as polarization function. This additional functionals may produce better result however due to computer constraint, this study only use basis set of 6-31G without additional functions. Meanwhile Reichardt and Welton [18] reported that a strong hydrogen bond interaction energy for hydrofluoric acid (HF---HF) is -155 kJ $mol^{-1}$. Thus the interaction energy calculated in this study may indicate that hydrogen bond established in the conjugate complex of k-carrageenan-glyoxylic acid weaker and can promote disintegration as well.

Table 1. SCF energy value for optimized k-carrageenan, glyoxylic acid and conjugate complex k-carrageenan-glyoxylic acid

| **Component** | **SCF energy for optimized molecule (kJ $mol^{-1}$)** |
|---|---|
| k-Carrageenan | -938 9839.095 |
| Glyoxylic acid | -798 961.796 |
| k-Carrageenan – glyoxylic acid | -1 018 876.626 |
| Interaction energy (ΔSCF energy) | -75.735 |

Another parameter that generated from this DFT calculations is the muliken charges of the molecule (Table 2). Sakaguchi et al. [19] reported that absolute ΔMulliken atomic charge can be used to predict the ionic degree of the covalent bond comprising polymer main chain. They concluded that the higher absolute ΔMulliken atomic charge, the higher ionic degree or ionic yield. While Gao et al. [20] suggest that the ionic degree indicates the hardness of covalent bond. Lower ionic degree may induce the scission of polymer chains. Therefore the absolute ΔMulliken atomic charge of 0.492 may induce the scission that promote further disintegration of hard capsule at C32 – O5 (Figure 5).

Table 2. Mulliken atomic charges, and absolute Mulliken atomic charges (ΔMC) obtained for optimized k-carrageenan and conjugate complex of k-carrageenan-glyoxylic acid.

| Component | C32 | O5 | C34 | ΔMC C32 – O5 | ΔMC O5 – C34 |
|---|---|---|---|---|---|
| k-Carrageenan | -1.850 | 0.180 | 0.617 | 2.030 | 0.437 |
| k-Carrageenan - glyoxylic acid | 0.054 | -0.442 | 0.691 | 0.492 | 1.133 |

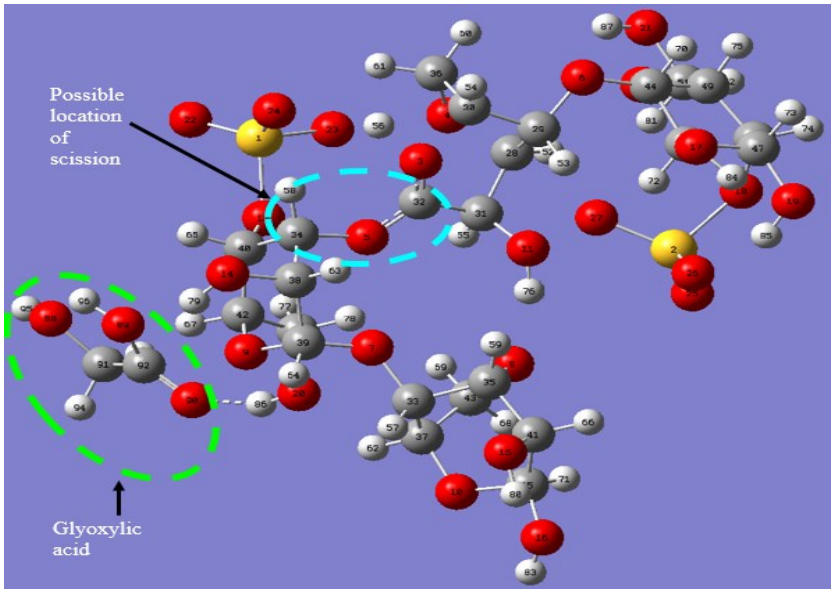

Figure 5. Probability of scission effect in conjugate complex k-carrageenan-glyoxylic chains

## Conclusion

The DFT calculations to determine the physical crosslink establishment has been successfully carried out and generated positive value of vibrations indicate calculations are at the global minima. The calculated interaction energy for established hydrogen bond is -75.735 kJ $mol^{-1}$. While generated MESP for k-carrageenan and glyoxylic acid indicate that both molecules have the electron and proton donor site which can establish the hydrogen bond as physical crosslink. Furthermore the absolute ΔMulliken atomic charge of may suggest scission effect toward main covalent bond in k-carrageenan and thus further promote disintegration of hard capsule. It is recommended that a higher accuracy calculations should be carried out through addition of diffusion and polarization functions to the basis set used in this work.

**Abstract**

*Alchemilla vulgaris* (AV) and *Filipendula ulmaria* (FU) are European medicinal plants possess bioactive compounds that exhibit many pharmacological benefits in human. The present work aims to assess two plants ethanolic extract; AV and FU of their antioxidant activities as natural preservative in beef patties. All plant samples were analysed using total polyphenol content (TPC), their antioxidant activities using Trolox Equivalent Antioxidant Capacity (TEAC), Ferric Reducing Antioxidant Power (FRAP), color and TBARS (Thiobarbituric acid reactive substances) analysis to measure their potential as synthetic preservative in muscle food. The antioxidant activity of FU and AV extracts measured with TEAC were 88.46 and 68.21 mmol of Trolox (TE)/g Dry Weight (DW) respectively. Whereas, FRAP assay were 44.6 and 40.12 mmol of TE/g DW for FU and AV extracts. The effect of lipid oxidation of beef patties were measured with adding 0.1% (w/w) of lyophilise FU and AV and Butylated hydroxytoluene (BHT) packed in modified atmosphere (MAP) (80% v/v $O_2$ and 20% v/v $CO_2$) for 14 days storages. FU and AV treated samples showed no significant different compared with BHT ($p>0.05$). Beef patties treated with 0.1% (w/w) FU showed minimum changes in red color and formation of metmyoglobin throughout storages ($p<0.05$). These results indicate that these edible plants extract are promising sources of natural antioxidants and can potentially be used as functional preservatives in meat products.

**Keyword**: *Alchemilla vulgaris*, *Filipendula ulmaria*, antioxidant, free radicals, polyphenol

**Abstrak**

*Alchemilla vulgaris* (AV) dan *Filipendula ulmaria* (FU) merupakan tumbuhan perubatan Eropah mempunyai sebatian bioaktif yang boleh memberi kesan positif farmakologi terhadap manusia. Kajian ini bertujuan menganalisa kedua-dua tumbuhan; AV dan FU terhadap aktiviti antioksidan dan sebagai pengawet semula jadi dalam model makanan. Aktiviti antioksidan di dalam FU dan AV ekstrak menggunakan analisis keupayaan antioksidan setara Trolox (TEAC) masing-masing adalah 88.46 dan 68.21 mmol Trolox/g bahan kering. Sebaliknya, aktiviti antioksidan oleh ujian kuasa antioksidan penurunan ferik (FRAP) adalah 44.6 dan 40.12 mmol Trolox/g bahan kering bagi ekstrak FU dan AV. Kesan aktiviti antioksidan disukat dalam burger daging yang mempunyai 0.1% (w/w) lyophilise FU dan AV tidak menunjukkan perbezaan yang ketara berbanding dengan 0.1% BHT apabila disimpan dalam pembungkusan MAP (80% $O_2$ dan 20% $CO_2$ v/v) selama 14 hari ($p> 0.05$). Burger daging yang dirawat dengan 0.1% (w/w) FU menunjukkan perubahan minimum pada warna merah dan pembentukan metmyoglobin sepanjang penyimpanannya ($p <0.05$). Keputusan ini menunjukkan bahawa ekstrak tumbuhan yang boleh dimakan ini menjanjikan satu sumber antioksidan semulajadi yang berpotensi untuk digunakan sebagai bahan pengawet di dalam produk daging.

## Introduction

Over the last decades, the development of ready-to-serve foods products posed new challenges from modern consumer to satisfy and optimized the food cost, appearance and most importantly about the food safety and nutritional values. Moreover, customers recently have been gaining interest in formulation of foodstuff that are healthy and functional, least chemical additives and preferably with natural ingredient [1].Therefore, the food manufacturing industries nowadays are very keen to venture in the variety of healthy food products innovation as new market demand and stimulate purchasing. The use of synthetic antioxidant such as butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT) and tert-butylhydroquinone (TBHQ) in food formulation developed health concern by public due their possible toxicological effects that may contribute too many diseases [2].

Lipid oxidation occurs in meat product affects the sensory characteristics such as colour, flavour, odour and texture, also causes the loss of nutritional value and the generation of toxic reaction products such as malonaldehyde (MDA) [3]. Alternatively, partial substitution of meat preservatives using natural preservatives had been studied in past years [4 – 8]. Soltanizadeh et al. [9] demonstrated the use of 3% (w/w) of Aloe Vera improved most quality characteristic that satisfy consumer acceptability. Soya, rosemary, thyme, oregano, broccoli and *Gentiana lutea* are among healthy substitute in the meat patties role as natural preservatives [10 –14]. Hence, it conclude that the natural edible plants responsible to many antioxidant actions may linked to the various type of actives ingredients including polyphenol.

*Alchemilla vulgaris* (AV) and *Filipendula ulmaria* (FU) are perennial herbs in the family Rosaceae, widely spread around Europe and Western Asia. They displayed excellent antioxidant activity and many pharmacological benefits in human [15]. AV is well known for their antioxidant activities probably due to the high phenolic contents (rutin, tannins, antocianidins, flavonoids, flavonol, phenolic acid and kempherol) [15 –18]. The plant extract exhibited different pharmacological roles, such as astringent, antidiarrheal, diuretic, depurative, intestinal antiseptic, bacteriostatic and bactericidal, tonic, anti-arthritic and cancer deterrent [19]. Moreover, FU showed relevant biological activity as astringent, antacid, anti-ulcer, anti-rheumatic, immunomodulatory and cytotoxic properties with various polyphenol compositions [15, 20, 21]. Many authors demonstrated the present of numbers of phenolic constituent including derivatives salicylates, flavonols and ellagitannins that contributed to the biological activities in the plant extract [22, 23]. Moreover, both these plants could act as antioxidants and antimicrobials in food, acting as natural additives that increased food shelf life as well as adding health benefits to potential consumers.

However, the antioxidant activity of AV and FU leaves extract towards lipid oxidation has not been fully determined. Thus, our goals were (1) to quantify the phenolic compounds in AV and FU leaves extract (2) to evaluate the antioxidant activity of AV and FU leaves extract using in Trolox equivalent antioxidant capacity (TEAC) assays and Ferric Reducing Antioxidant Power (FRAP) (3) to demonstrate the ability of AV and FU leaves extract to inhibit lipid deterioration and their effect toward red color changes in meat patties.

## Materials and Methods

### Materials

Commercial dried AV and FU was kindly supplied by Pàmies Hortícoles (Balaguer, Spain), a registered herbal company. All reagents and solvents used were of analytical grade and obtained from Panreac (Barcelona, Spain) and Sigma Aldrich (Gillingham, England).

### Extraction of plants extract

Dried roots of AV and FU were finely ground using a standard kitchen food processor. Ground plants were extracted with 50:50 (v/v) ethanol: water in the ratio 1:10 (w/v). The extractions were performed at 60 ± 1°C for 24 hours, in the dark with constant stirring. The plants extract solutions were recovered by filtration using Whatman Filter paper, 0.45 µm. Part of the supernatant were taken for subsequent use to determine the antioxidant activities. The volume of the remaining supernatant was measured and the excess of ethanol was removed under vacuum using

a rotary evaporator (Buchi Re111, Switzerland) and kept frozen at -80°C for 24 hours. All extracts were dried in a freeze dryer (Unicryo MC2L -60 b°C, Germany) under vacuum at -60 °C for 3 days to remove moisture.

**Determination of the total phenolic content**

The Folin-Ciocalteu method was used to determine the total phenolic content (TPC) as reported by Santas et al. [23]. Mixtures of 7.7% sample, 4% Folin reagent and 30.8% of saturated sodium carbonate solution final concentrations were diluted with the sample with 1:25 (v/v). Finally, final mixture was diluted with Milli-Q water, shaken and incubated in the dark for 1 hour. Absorbance at 765 nm was measured using a microplate reader (Fluostar Omega, BMG Labtech, Ortenberg, Germany) against water as a blank. Gallic acid was used to prepare a standard calibration, and the results were expressed as mg of Gallic acid equivalents/g dry weight (mg GAE/g DW).

**Determination of the Trolox equivalent antioxidant capacity assay**

The antioxidant activities against $ABTS^{\bullet+}$ radical of plants extract were measured by using a modified TEAC assay, as described by Azman et al. [14]. $ABTS^{\bullet+}$ radical cation (7 mM, final concentration) was dissolved before adding potassium sulphate (2.45 mM, final concentration) and allowing the mixture to stand in the dark up to 16 hours. Phosphate Buffer Solution (PBS, 10 mM) with the $ABTS^{\bullet+}$ radical cation were incubated at room temperature for 30 minutes before used. Then, the mixture of the $ABTS^{\bullet+}$ radical cation was adjusted to an absorbance of 0.73 ± 0.2 nm, using a microplate reader (Fluostar Omega, BMG Labtech, Ortenberg, Germany). The TEAC values for the different concentrations of each compound were interpolated from the Trolox calibration curve and expressed as milligrams of Trolox equivalent per gram of dry weight sample (mg TE/g DW sample).

**Determination of the ferric reducing antioxidant power**

The FRAP method was introduced by Benzie et al. [24] and implemented with some modifications. The FRAP solution was prepared in proportions of 10:1:1 of 300 mmol/L acetate buffer (pH 3.6), 10 mmol/L, 2,4,6-tripyridyl-s-triazine (TPTZ) in 40 mmol/L hydrochloric acid (HCl) and 20 mmol/L iron(III) chloride ($FeCl_3$), respectively. FRAP solution was incubated at 37 °C for 20 minutes before it was mixed with the adequate dilution of the extract. The absorbance was measured at 593 nm using a microplate reader. Results were compared with the Trolox calibration curve, and concentrations were expressed as micromoles of Trolox equivalents per gram dried weight of sample (mmol of TE/g DW).

**Determination of antioxidant activity in food model: Preparation of beef patties**

The lean meat of male cows slaughtered in accordance with approved guidelines of the Animal Ethics Committee was supplied by local market. The meat was collected 7 days after slaughter to allow it to mature and was kept at approximately -20 °C for further treatment. Fat and joint tissues from lean meat were trimmed off lean meat (2000 g) and the meat was minced through 8 mm industrial plates. Then, the minced meat was divided into 4 batches (w/w) and were mixed with 1.5% of sodium chloride (NaCl) and either i) control (no addition), ii) 0.1% butylated hydroxytoluene (BHT), iii) 0.1% FU lyophilise, iv) 0.1% AV lyophilise. All batches were mixed vigorously for 2 minutes to attain an even distribution of additives throughout the meat. Each sample was moulded into smaller portions (about 20 g each), stuffed and packed with polystyrene B5-37 (Aerpack) trays and placed in BB4L bags (Cryovac) of low gas permeability (8–12 $cm^3$ $m^{-2}$ over 24 hours). The air in the trays was flushed with 80:20 (v/v) oxygen: carbon dioxide ($O_2$:$CO_2$) by EAP20 mixture (Carburos Metalicos, Barcelona) using packaging. Samples were stored in the dark at 4 ± 2 $^oC$ for 2 weeks to analyse the oxidation for thiobarbituric acid reactive substances (TBARS) method. Every measurement was carried out in triplicate each day.

**TBARS assay**

TBARS measurement was used to measure the extent of lipid oxidation over the storage period as described by Grau et al. [25]. The samples (1 g) were weighed in a tube and mixed with 3 g/L aqueous ethylenediamine-tetraacetic acid (EDTA) in ratio 1:1 (w/v). Then, the sample was immediately mixed with 5 mL of thiobarbituric acid reagent using an Ultra-Turrax (IKA, Germany); 32000 rpm speed, for 2 min. All procedures were carried out in the dark and all samples were kept in ice. The mixture was incubated at 97 ± 1 $^oC$ in hot water for 10 minutes and shaken for 1 minute during the process to form a homogeneous mixture. The liquid sample was recovered by filtration (Whatman Filter paper, 0.45 μm) after the sample was cooled for 10 minutes. The absorbance value for each sample was measured at 531 nm using a spectrophotometer. The TBARS value was calculated from a

malonaldehyde (MDA) standard curve prepared with 1,1,3,3 tetraethoxypropane and analysed by linear regression. All results were reported in mg malonaldehyde per kg of sample (mg MDA /kg sample).

**Percentage of metmyoglobin**

The metmyoglobin method was based on the method developed by Xu et al. [26]. An amount 5 g beef patties were homogenized with 25mL of ice-cold 0.04 M phosphate buffer (pH 6.8) for 15 second using homogenizer (Ultra-Turrax, IKA, Germany), which was set at speed setting 2 (18000 rpm). The homogenate was allowed to stand in 4 $^{o}$C for 1 hourr and centrifuged at 4500 g for 20 minutes at 4 $^{o}$C using a high-speed freezing centrifuge (GI-20G, Anke, Shanghai, China). The absorbance of the filtered supernatant was read at 572, 565, 545, and 525 nm with a spectrometer (Fluostar Omega, BMG Labtech, Germany). The percentage of metmyoglobin was determined using the formula; MetMb (%) = [-2.514(A572/A525) + 0.777(A565/A525) + 0.8(A545/A525) + 1.098] x 100

**Statistical analysis**

A one-way analysis of variance (ANOVA) was performed using Minitab 16 software program ($\alpha$=0.05). The results were presented as mean values (n $\geq$3).

## Results and Discussion

**Extraction yield, total polyphenols and antioxidant activity assays**

The European herbs were tested for their polyphenol content and antioxidant ability. Ethanol is used as extraction solvent because is recognized as a GRAS (Generally Recognized as Safe) component that safely used in the food industry application [27]. Rababah et al. [28] reported temperature of 60 $^{o}$C found to be the best for extracting phenolic compounds in most common herbs including oregano, thyme and terebinth. In addition, 70% (w/w) ethanol extract is used to extract the bioactive compound of AV and FU for acetylcholinesterase and tyrosinase inhibitory assay for treatment of neurodegenerative disorder in human [15].

Table 1 illustrated the extraction yield, phenolic compound and antioxidant activity of AV and FU in 50% (w/w) aqueous solvent extract. Generally, AV showed higher yield, phenol content and antioxidant activity than FU extract. The phenolic content value of the AV and FU extracts showed positive correlation to the antioxidant activity value in TEAC and FRAP assays. The total phenolic content of AV and FU extracts allowed the estimation of all phenolic acids, flavonoids, anthocyanin, non-flavonoids and many classes of polyphenol compounds present in the samples. The obtained results are in agreement with Neagu et al. [15] which found phenolic content of AV and FU are 112.33 µg/mL and 103.00 µg/mL using 70% ethanol solvent. The authors also identified amount of proanotcyanidins and flavonoes in the plants extract. Previous research finding correlates the total phenolic content with antioxidant activity which may contributes many pharmacological actions in plants extract [23].

Table 1. Extraction yield, TPC and antioxidant activity of AV and FU extracts in ethanol aqueous

| **Activities Plant extract** | **Extraction solvent 50:50 (v/v) EtOH:$H_2O$** | |
|---|---|---|
| | **FU** | **AV** |
| Extraction yield (%) | 32.1 ± 0.03 | 30.4 ± 0.01 |
| Total phenolic content (mg GAE/g DW) | 122.11 ± 0.12 | 96.43 ± 0.2 |
| TEAC (mmol of TE /g DW) | 88.46 ± 0.83 | 68.21 ± 0.33 |
| FRAP (mmol of TE/g DW) | 44.6 ± 0.19 | 40.12 ± 0.11 |

*Mean value n = 3 and the standard deviation for each assay is less than 5%. Gallic Acid Equivalent (GAE), Trolox Equivalent (TE), Dry Weight (DW)

Nevertheless the *in-vitro* antioxidant activity of TEAC assay gave higher antioxidant activity values of compared to the FRAP assay in both plant extracts. The assay value indicated the extracts potency to scavenge the long-life radical cation ABTS•+ generated in the assay [29]. Research finding from Kiselova et al. [17] showed the antioxidant activity of AV extract in TEAC assay that has strong correlation with the polyphenol content ($r^2$ = 0.92). Moreover, Barros et al. [20] observed FU extract using acetone showed highest value in TEAC assay compare with

methanol and water. Meanwhile, FRAP assay showed the antioxidant ability of polysaccharides in the plant extracts react with a colorless Fe(III) to generate a colored Fe(II)–tripyridyltriazine form which can measured at 593 nm absorbance. A number of *in-vitro* antioxidant studies has been carried out including TEAC, Oxygen Radical Absorbance Capacity (ORAC) and 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging shown antioxidant activity potential in the AV and FU extracts [15, 30, 31]. However, to the best of our knowledge this is the first report of antioxidant activity extract from AV and FU assessed using FRAP method. Sufficient amount of studies have reported the antioxidant activities of AV and FU due to the various polyphenol compositions such as rutin quercetin, synaptic acid and chlorogenic acid. These compounds exert radical scavenging behavior towards free radical mainly reactive radical species (ROS) that could be explain in the FRAP and TEAC value during this study.

**Antioxidant activity in food model**

Many strategies on laboratory scale have been developed to improve the stability of shelf life in food models including adding amount of natural extracts that have similar effect as synthetic preservative. The effect of AV and FU on inhibiting lipid oxidation in muscle food has not been described. The oxidation in meat patties was measured in second stage of oxidation, secondary oxidation products (TBARS). In addition the change in color and % metmyoglobin were measured as physically resemble the freshness of the meat.

**TBARS analysis in beef patties**

The study carried out using modified atmosphere packaging for beef patties that was similar to the real packaging in the market. Hence, higher oxygen concentrations in MAP mixtures of 60 – 80% $O_2$ and 20 – 40% $CO_2$ are commonly used in beef product packaging for retail display in the market. Figure 1 shows lipid oxidation in different burger samples during the 2 weeks of storage. Thiobarbituric acid reactive substances (TBARS) as an indicator of secondary phase of lipid oxidation occurs in the sample are measured based on mg of malondialdehyde per kg of the sample. The secondary lipid oxidation is responsible for the alteration of flavor, rancid odor and the undesirable taste in foods [42]. The initial amount of malonaldehyde on day 0 to day 3 varied in the range of 0.1 – 0.2 mg/kg of the sample and no significant differences were observed among the burger samples. Starting day 3 onwards control sample showed the highest TBARS value among samples treated antioxidant ($p > 0.05$). During the 14 days of storage, lipid oxidation proceeded in the control sample and reached 3.90 mg malonaldehyde/kg sample.

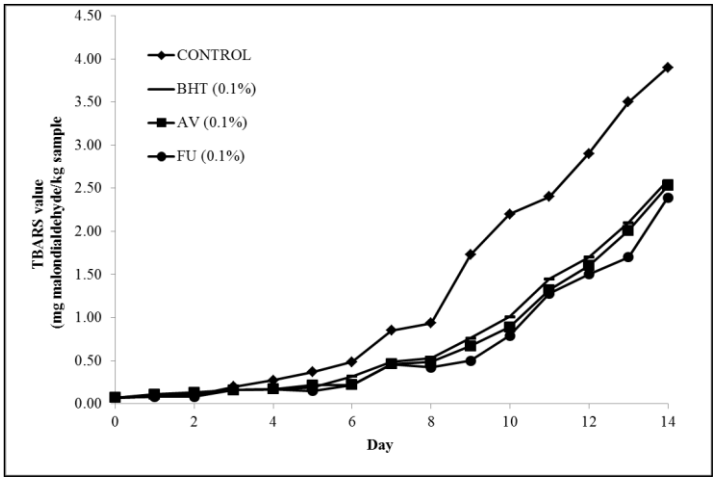

Figure 1. Changes in TBARS values (mg malodialdehyde/kg sample) of control and sample containing different concentrations (0.1% w/w) of AV and FU extract and BHT extract in MAP atmosphere during 14 days storages at 4 ± 1 °C without light. Each sample was measured in triplicate and the average standard deviation for each sample was less than 5%.

In general, the levels of lipid oxidation in beef patties increased over time and followed the order: 0.5% FU < 0.5% AV < 0.5% BHT < Control. The presence of control atmosphere with high oxygen packaging (MAP) resulted in higher TBARS and increased the oxidation rate in muscle food [29, 32, 33]. No statistical difference was observed between sample treated with antioxidant throughout the 14 days storages, however the TBARS value of both samples showed significant difference compared to control samples($p<0.05$). From Figure 1, the antioxidant potential of AV and FU extract at different storages days showed that the plants have activity equivalent to synthetic antioxidant, BHT ($p>0.05$). 0.1% BHT was added as comparison with natural antioxidant beside the FDA guidelines for using BHT is ≥ 200 ppm in meat product [29].

The effect of AV and FU extract on the lipid oxidation in meat has never been reported before. The active properties of AV and FU attributed to various phenolic acid including flavonols, flavonoids-glucosides, isoflavones, ellagitannins and sinapic acid which prevent propagation of lipid oxidation [15]. The antioxidant activity of phenolic compound is closely related to the hydroxyl group linked to the aromatic ring which is capable donating hydrogen atoms with electrons and neutralizing free radicals. This mechanism blocks further degradation of active oxidizing from such as MDA, which can be measured by TBARS method [34]. The study confirmed the potential of AV and FU extract to inhibit the lipid degradation in beef patties.

**Colour and % Metmyoglobin**

Figure 2 illustrated the color changes in meat patties were significantly affected by two plant extracts and BHT. The change of meat color is an important factor that impacts visual attraction in consumers. Normally, the colour analysis parameters collected using Minolta Chroma Meter CR-400 represent the lightness (L*), redness (a*), yellowness (b*) of the meat surface. However, only a* value are shown in this study due to red color is important color parameter in evaluating meat oxidation. The decrease in redness color makes meat product unacceptable to consumer [35]. In all samples, the a*value decreased as storage time progressed and the red color of control faded very rapidly. The natural color of the plant extract influenced the a*value of the meat at the first 3 days showed significant different from BHT and control ($p <0.05$). At the end of storages, the redness value of control sample was significantly lower than the antioxidant treated sample. 0.1% BHT displayed highest value of a* until 5 days storages and declined gradually onwards ($p <0.05$). This finding was expected as BHT role as synthetic antioxidant which used to retain colour and delaying lipid oxidation in the meat. Sample treated with 0.1% AV exhibited the redness color at the highest value after 14 days storages ($p <0.05$), whereas FU sample showed no significant different of a* value with BHT sample. Therefore, the AV and FU at 0.1% (w/w) extracts as natural preservatives potentially preserved the redness color of the meat and displayed the potentially useful in prolonging the shelf life of the meat product.

Meanwhile Figure 3 presents the effect of natural plants extract and BHT on relative metmyoglobin percentage in beef patties. A significant correlation between metmyoglobin (MetMb) percentage and the redness color features were analysed previously [29, 36]. The MetMb percentage increased as the storage time increased throughout the 14 days refrigeration, whereas the control showed the highest MetMb value compared to all samples. Initial mean MetMb percentage was 23.9 ± 0.17 on 0 day and gradually increase until 7 days with no significant different for all samples ($p >0.05$). After 7 days onwards MetMb percentage increased progressively and sample treated with AV exhibited the lowest value significantly at 14 days storages ($p <0.05$). FU and BHT samples showed no significant different throughout the storage period, whereas the AV sample showed even superior to such synthetic antioxidant as BHT. According to Kim et al. [33], the MetMb percentage should not exceed 40%, especially when considering consumer acceptance and AV meat sample was satisfied this limit until day 7.

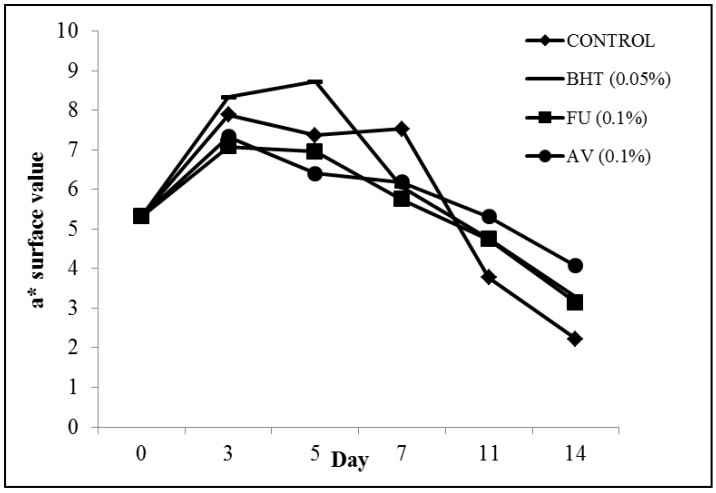

Figure 2. Changes in a* values of control and sample containing different concentrations (0.1% w/w) of AV and FU extract and BHT extract in MAP atmosphere during 14 days storages at 4 ± 1 °C without light. Each sample was measured in triplicate and the average standard deviation for each sample was less than 5%

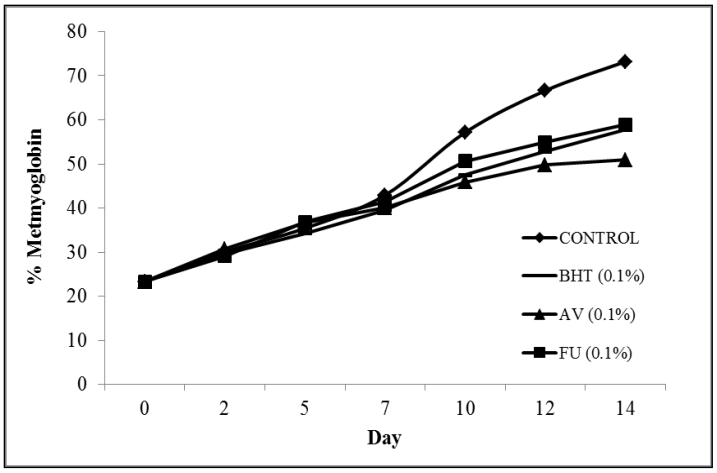

Figure 3. Changes in metmyoglobin percentage of control and sample containing different concentrations (0.1% w/w) of AV and FU extract and BHT extract in MAP atmosphere during 14 days storages at 4 ± 1°C without light. Each sample was measured in triplicate and the average standard deviation for each sample was less than 5%

A number of studies examined the effect of different antioxidant on the meat color and demonstrated the lipid oxidation decrease the redness color of the meat [8, 14, 37]. Xu et al. [26] have proposed that the chemical reaction influences discoloration act as a catalyst of lipid oxidation. Free radicals produced by lipid oxidation in meat are susceptible to initiating the reaction of oxidizing oxymyoglobin (red colour, measured by a*value in Figure 2) to metmyoglobin (brown colour, analysed by relatively formation of metmyoglobin in Figure 3) which results in the discolouration of meat. Hence, the overall changes of % metmyoglobin were inversely proportional to the value of redness (a*). The scavenging ability of samples treated with antioxidant can reduce the oxidation of metmyoglobin acting as scavengers of hydroxyl radicals produced from oxidation of oxymyoglobin. The 0.1% of FU extract displayed the lowest metmyoglobin percentage and capable to preserve redness color specifically compared to

synthetic antioxidant, BHT. However, color deterioration and lipid oxidation very dependent on the test system, including the influenced of salt, sample preparation, temperature, oxygen composition, storage time and packaging condition. Thus, modified atmosphere (MAP) at control gas composition of the meat packaging is important to reduce the variable that affect the meat shelf life.

The present study investigates the antioxidant activity potential of two medicinal plants –AV and FU – as inhibitor of lipid oxidation in muscle foods, which there is no data in the literature with this regard. The most bio active composition of the plants are the same may due to the same family of Rosaceae, however, the activity values tested are different. Numerous researches founds high content of polyphenol compounds in both FU and AV ethanolic extract, could be explained as antioxidant activity role in preventing lipid deterioration similar as BHT [15,38,39]. The plants contain polyphenol compounds that showed close behavior of antioxidant activity relevant in the study, which are rutin, quercetin, chlorogenic acid and synaptic acid. Rutin and quercetin are responsible exhibit significant pharmacological actives including anti-oxidation, whereas quercetin exert radical scavenging behavior that benefits in many neurodegenerative diseases by mitigating cellular damage induces by radical oxygen species (ROS)[40]. While, Chlorogenic acid (CGA) is a polyphenolic components associate to free radical scavenging and antioxidant activities towards hydrogen peroxide and amyloid beta [41]. The present of synapic acid present has also radical scavenging properties beside the behavior or anti-apotopic and anti-inflammatory [42].

## Conclusion

The aqueous extract of FU and AV plants exhibited different levels of phenolic content and antioxidant activity measured by TEAC and FRAP assays. Therefore, the antioxidant activity of FU and AV extract in the Trolox Equivalent Antioxidant Capacity (TEAC) were 88.46 and 68.21 mmol of TE/g DW respectively while the ferric reducing antioxidant power (FRAP) antioxidant activity for FU and AV extracts were 44.6 and 40.12 mmol of TE/g DW respectively. This study revealed the first time of radical scavenging activity has been evaluated in FU and AV extract using FRAP method. Addition of 0.1% (w/w) lyophilise FU and AV as an antioxidant in beef patties inhibited lipid oxidation during 14 days of storage in MAP atmosphere at 4 ± 1 °C without light. 0.1% (w/w) FU and AV decreased the discoloration of meat after 14 days of storage ($p < 0.05$) while FU showed no significant different of color changes in beef patties with BHT (synthetic antioxidant) sample. Thus, this study showed that the AV and FU as a potential antioxidant sources for natural preservatives in prolonging the shelf life of the food products.

# PERFORMANCE OF SOLAR PHOTOCATALYSIS AND PHOTO-FENTON DEGRADATION OF PALM OIL MILL EFFLUENT

## (Prestasi Fotopemangkinan dan Degradasi Foto-Fenton Menggunakan Sinar Suria ke atas Efluen Kilang Minyak Kelapa Sawit)

**Abstract**

Palm oil mill effluent (POME) contains significant amounts of organic matter, solids, and grease or oil, which requires appropriate treatment prior to being discharged into the environment. In this study, solar radiation was investigated as a possible source of photon in the solar $TiO_2$ and ZnO photocatalysis, and solar photo-Fenton treatments to reduce the chemical oxygen demand (COD) in POME. The results indicated that solar photo-Fenton was more efficient in reducing COD levels compared to dark Fenton and indoor photo-Fenton. The highest removal was recorded at 89% in the presence of 1:30 ratio of $Fe^{2+}$:$H_2O_2$ under acidic pH (~2.8) after 3 hours of solar exposure. Increased concentrations of $H_2O_2$ have greatly influenced the COD removal. Additionally, solar $TiO_2$ photocatalysis (pH~3.7; $TiO_2$ = 0.1 g/L) has outperformed solar photolysis and solar ZnO photocatalysis in reducing COD levels in POME. With successive increase of $TiO_2$ from 0.02 to 0.1 g/L, the removal of COD had linearly increased from 54.3% to 88.5% after 5 hours of solar exposure. Based on the investigated conditions, the optimum $TiO_2$ concentration of 0.1 g/L was concluded. In conclusion, solar $TiO_2$ photocatalysis and solar photo-Fenton can be applied as possible means to reduce the organic loads in POME.

**Keywords:** advanced oxidation process, organic matter, reduction, solar, titanium dioxide

**Abstrak**

Efluen kilang minyak kelapa sawit (POME) mengandungi jumlah bahan organik, pepejal dan gris atau minyak yang ketara yang memerlukan rawatan sesuai sebelum ia boleh disalurkan ke persekitaran. Dalam kajian ini, sinar suria dikaji sebagai salah satu sumber foton dalam fotopemangkinan $TiO_2$ dan ZnO sinar suria dan rawatan foto-Fenton menggunakan sinar suria untuk mengurangkan keperluan oksigen kimia (COD) dalam POME. Keputusan kajian menunjukkan foto-Fenton menggunakan sinar suria adalah lebih berkesan dalam menurunkan COD berbanding dengan Fenton bercahaya dalam dan Fenton tanpa cahaya. Penyingkiran tertinggi yang dicatatkan ialah 89% menggunakan nisbah $Fe^{2+}$:$H_2O_2$ sebanyak 1:30 dalam pH berasid (~2.8) selepas pendedahan kepada sinar suria selama 3 jam. Peningkatan kepekatan $H_2O_2$ sangat mempengaruhi penyingkiran COD. Tambahan pula, fotopemangkinan $TiO_2$ menggunakan sinar suria (pH~3.7; $TiO_2$ = 0.1 g/L) menunjukkan prestasi yang lebih baik berbanding dengan fotolisis dan fotopemangkinan ZnO menggunakan sinar suria dalam mengurangkan kandungan COD dalam POME. Peningkatan $TiO_2$ secara berturutan dari 0.02 ke 0.1 g/L meningkatkan penyingkiran COD secara linear daripada 54.3% ke 88.5% selepas pendedahan kepada sinar suria selama 5 jam. Berdasarkan keadaan eksperimen yang dikaji dapat dirumuskan bahawa kepekatan optimum $TiO_2$ ialah sebanyak 0.1 g/L. Kesimpulannya, teknik fotopemangkinan $TiO_2$ sinar suria dan Fenton sinar suria boleh digunakan untuk mengurangkan kandungan organik dalam POME.

**Kata kunci**: proses pengoksidaan termaju, bahan organik, penurunan, sinar suria, titanium dioksida

## Introduction

Malaysia is known as the world's largest palm oil exporter. The palm oil industry has made significant contribution to the country's economic revenue. The global demand for palm oil, particularly for crude palm oil and its related products, such as palm oil and palm kernel oil, is rapidly growing. Consequently, the palm oil industry is generating a significant amount of waste, namely palm oil mill effluents (POME). Approximately 44 million tons of POME was generated in 2008 in Malaysia [1]. Typically, raw POME is brownish in colour and contains elevated levels of organic matter, such as total solids (405,000 mg/L) and grease/oil (6000 mg/L), as well as high biochemical oxygen demand (BOD) (25,000 mg/L) and chemical oxygen demand (COD) (50,000 mg/L) [2, 3]. POME is also known to be highly acidic (pH 3.8 – 4.5) and biodegradable in nature. The open ponding system is currently used by 85% of palm oil mill operators, as the potential method to treat POME [1], due to its biodegradable nature. A ponding system comprises of a series of anaerobic, facultative and aerobic treatments. This type of system demands vast area of lands, requires lengthy treatment periods (up to 40 – 60 days) for effective treatments to be achieved, and it releases bad odour, despite its ease of operation [4, 5]. A previous study has reported that this biological treatment process is rather inefficient in treating POME [2]. It contributes to various environmental issues due to the high loadings of BOD and COD, while a low pH of POME renders the conventional treatment technique inefficient.

In recent times, advanced oxidation processes (AOPs) have been considered as suitable methods to treat effluents in various wastewaters. AOPs are based on short-lived hydroxyl radicals (HO•), which are powerful oxidizing agents that can decompose organic compounds in water [6]. AOPs, such as photocatalysis, ozonation, wet oxidation, and photo-Fenton have been documented to efficiently eliminate or mineralize organic pollutants in different types of wastewaters such as textile wastewater [7], pharmaceutical wastewater [8, 9], and pulp mill wastewater [10]. In this study, titanium dioxide ($TiO_2$) and zinc oxide (ZnO) photocatalysis, and photo-Fenton oxidation have been narrowed down as suitable methods to reduce the organic loads in POME. The photo-Fenton process uses Fenton reagents ($H_2O_2$ and $Fe^{2+}$) in the presence of light to produce HO• radicals. This process involves the oxidation of ferrous ions ($Fe^{2+}$) to ferric ions ($Fe^{3+}$) in an acidic aqueous solution to produce HO• radicals, which will trigger the oxidation of organic compounds. It is important to keep the solution at pH 3 because the Fenton reaction works best in an acidic condition [11].

In the case of $TiO_2$ and ZnO photocatalysis, photon illumination ($\lambda$<400 nm) onto the $TiO_2$ and ZnO surfaces, of greater than or equal to the band gap energy, will result in the formation of electron-hole pairs. These pairs will be involved in the oxidative and reductive reactions with molecules present at/or near the surface of the semiconductor [12]. Both $TiO_2$ and ZnO have similar band gap energy of 3.2 eV [13]. Nonetheless, $TiO_2$ is the most applied photocatalyst in various environmental applications, primarily due to its non-toxicity, low cost, and photostability. ZnO, despite being highly photosensitive and absorbs a larger portion of the solar spectrum compared to $TiO_2$, suffers from photocorrosion in acidic aqueous solution and the formation of $Zn(OH)_2$ on its surface due to dissolution [13]. Thus, photocatalysis is of special interest since sunlight can be used as a photon source. Solar ZnO and $TiO_2$ photocatalysis can be activated by sunlight of lower than 390 nm, while photo-Fenton oxidation requires sunlight of up to 500 nm. The degradation of organic pollutants using AOPs with sunlight as the energy source is advantageous in lowering costs. Previous studies on solar photo-Fenton [14], and solar ZnO and $TiO_2$ photocatalysis [15,16] have recognized the roles of these mechanisms in reducing or degrading organic compounds in wastewater effluents. Nonetheless, there remains a paucity of knowledge regarding the feasibility of these treatments on POME. Aris et al. [17] reported that solar photo-Fenton has resulted in a better COD and colour from biologically treated POME compared to ambient photo-Fenton. On the other hand, $TiO_2$ photocatalysis was able to reduce the COD level of POME to 78% within 20 hours of irradiation [18].

This study aims to assess the efficiency of solar ZnO photocatalysis, solar $TiO_2$ photocatalysis, and solar photo-Fenton in reducing the COD level of POME. The dependence of solar photodegradation rate on intrinsic parameters, such as ZnO and $TiO_2$ concentrations, and the ratio of $Fe^{2+}$:$H_2O_2$ was investigated.

## Materials and Methods

### Sample collection

The POME samples used in this study were collected during the month of November 2014, from SALCRA Palm Oil Mill Plant located in Bau, Sarawak, Malaysia. The POME samples were collected from the cooling ponds of the palm oil mill, and stored in polyethylene bottles. The air-tight bottles were transported to the laboratory and kept refrigerated at 4 °C until further analysis. Characterization and solar photocatalytic oxidation treatments were performed using diluted POME.

### Characterization of palm oil mill effluents

Diluted POME was used for water quality analysis. Distilled water was used to dilute 1 mL of POME effluent to 1000 mL. The levels of biological oxygen demand ($BOD_5$), chemical oxygen demand (COD), total suspended solids (TSS), and dissolve oxygen (DO) were determined. All analyses were performed according to the Standard Methods of Water and Wastewater Treatment [19].

### Solar photodegradation of palm oil mill effluents

POME solar photodegradation study was conducted on the ground floor of the Faculty of Resource Science and Technology, Universiti Malaysia Sarawak, Malaysia. All solar treatments were performed for 2 – 5 hours on sunny days. Beakers filled with diluted POME and the required quantities of reagents were exposed to sunlight under continuous magnetic stirring. The beaker used for solar study was covered with a polyethylene wrap to avoid evaporation. A portable digital Lux meter (TEX 1335) was used to measure the intensity of sunlight. Temperature, pH, and solar intensity were periodically measured during periods of solar exposure. The recorded sunlight intensity and temperature during all solar experiments had ranged from 30 to 180 Klux and 30 to 38 °C, respectively. The temperatures recorded during the solar photo-Fenton and solar ZnO and $TiO_2$ photocatalysis had varied from 28 to 38 °C. In the case of indoor photo-Fenton experiments, the recorded temperatures had varied from 23 to 24.5 °C. All experiments were performed in duplicate. COD reduction was calculated using Equation 1:

$$\text{COD reduction } (\%) = \frac{\text{COD}_{\text{initial}} - \text{COD}_{\text{final}}}{\text{COD}_{\text{initial}}} \text{x } 100 \quad (1)$$

### Palm oil mill effluent concentration for treatment

As the concentration of POME in the photocatalytic treatments would affect the overall COD removal efficiency, three dilution ratios (POME: water) were considered: 1:10, 1:100 and 1:1000. Diluted POME sample of 1:10 ratio (Figure 1a) appeared to be more brownish, thicker, and murkier compared to the other diluted samples (Figure 1b and 1c). To ensure the maximum performance of the photocatalysts or reagents in these treatments, and to ensure adequate light penetration, the dilution ratio of 1:1000 was used. At high pollutant initial concentrations, all catalytic sites are occupied [20].

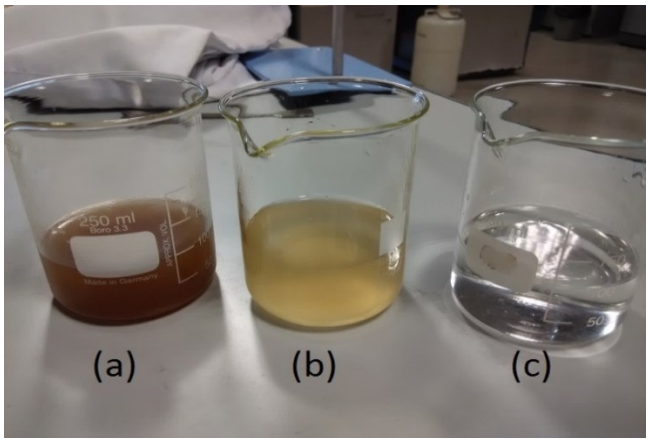

Figure 1. Photograph of diluted POME solutions (POME: water) (a) 1:10, (b) 1:100, and (c) 1:1000

**Treatment of palm oil mill effluent using solar photocatalysis**

Solar ZnO and $TiO_2$ photocatalysis were conducted by varying the concentrations of $TiO_2$ and ZnO from 0.02 to 0.2 g/L and 0.5 to 4 g/L, respectively in 150 mL of diluted POME (1:1000). The mixture of POME and photocatalyst (either ZnO or $TiO_2$) was magnetically stirred for 30 minutes in a dark environment (covered with polyethylene wrap) to establish equilibrium between the two substances. Then, the reaction slurry in the beaker was uncovered before being exposed to direct sunlight. The beaker was magnetically stirred during solar exposure and sample collection was done at pre-determined intervals using a syringe. A parallel control experiment (without photocatalyst) was also conducted. Supernatant obtained *via* filtration was used for COD analysis.

**Treatment of palm oil mill effluent using solar photo-Fenton**

Indoor photo-Fenton (laboratory) treatments with ambient light and solar photo-Fenton treatments were performed to compare their efficiency in reducing COD levels in POME. The concentration of $Fe^{2+}$ was kept constant, while the concentration of $H_2O_2$ was varied in the photo-Fenton experiments. Similar ratios of Fenton reagents, $Fe^{2+}$:$H_2O_2$, which include 1:10, 1:20, 1:30, and 1:40, were investigated for both treatments. The pH of the solution mixture was kept in the range of pH 2 to 3 by adding $H_2SO_4$ accordingly. Then, the mixture was continuous stirred in the laboratory to ensure homogeneity. It was subsequently exposed to sunlight. Samples were collected at fixed intervals. At the end of the solar exposure period, the pH of the sample was adjusted to range between pH 11 and 12 by adding NaOH pellets. The sample was stirred again for 15 minutes before being left overnight to ensure the decomposition of $H_2O_2$. After the sample has stood overnight, filtration was performed, which was followed by COD analysis. A blank sample (POME only) was also exposed to sunlight alongside the photo-Fenton treatment. Similar procedures were applied for photo-Fenton treatments in the laboratory. In this case, the source of photon was from the visible light in the laboratory. The beaker used for dark Fenton treatment was wrapped with aluminium foil to prevent any form of light from penetrating the reaction mixture.

**Characterization**

Analytical grade $TiO_2$ photocatalysts (99.8% trace metals basis, anatase) and ZnO were supplied by Sigma-Aldrich and Bendosen, respectively. The crystal phase of the $TiO_2$ and ZnO samples were determined using the X-ray Diffraction (XRD, PaNalytical X'pert Pro) method with Cu Kα radiation ($\lambda = 0.154$ nm) in the scanning range of $2\theta$ between 10° and 80°, at a rate of 0.04° per second. The accelerating voltage and applied current were 45 kV and 40 mA, respectively. Field emission scanning electron microscopy (FESEM) was performed using the Carl Zeiss, SUPRA 40VP Scanning Microscope to analyse the surface morphology of the samples. A low electron beam voltage of 5 kV was used. Therefore, no coating was required prior to imaging.

## Results and Discussion

**Characteristics of palm oil mill effluent**

Table 1 lists the results of pH, $BOD_5$, COD, and TSS. POME is a thick brownish colloidal mixture of water, oil, and fine suspended solids. The pH of POME was found to be acidic, resulting from the organic acids produced during the fermentation process [5]. This indicates that raw POME is unsuitable to be directly discharged into water bodies as the permissible level set by DOE falls between 5 and 9 (Table 1). The BOD and COD values obtained in this study implied the elevated levels of organic matters in POME. A comparison between the obtained values and those outlined by the effluent discharge standard of the Environmental Quality Act 1974 [5], showed that these values had exceeded the permissible levels. The ratio of $BOD_5$/COD, which is normally used to express the biodegradability of wastewater, was calculated to determine whether POME could be biodegraded using biological treatments [21]. Clearly, the obtained $BOD_5$/COD ratio of 0.10 (Table 1) implied that POME was not suitable to be biodegraded using biological treatments. The characterization of POME suggested that the open ponding system, as practiced by palm oil mill operators, has failed to reduce these parameters to comply with the discharge limits set by the Environmental Quality Act 1974. Based on the obtained $BOD_5$/COD ratio, this method is inefficient to improve the water qualities of POME to an acceptable level. Therefore, other treatments must be sought.

Table 1. Characteristics of POME

| Parameter | Mean ± SD | Effluent discharged standard for crude palm oil (Environmental Quality Act 1974)* |
|---|---|---|
| pH | 4.85 ± 0.05 | 5-9 |
| $BOD_3$, 30°C (mg/L) | 7600 ± 15.2 | 100 |
| COD (mg/L) | 73 150 ± 124.5 | 1000 |
| $BOD_5$/COD | 0.10 | NA |
| TSS (mg/L) | 18 000 ± 5000 | 400 |

*Parameters Limit of Environmental Quality (Prescribed Premises) (Crude Palm Oil) (Amendment) Regulation 1997, and NA: Not applicable

**Reducing chemical oxygen demand using solar heterogeneous photocatalysis**

Two types of photocatalyst, $TiO_2$ and ZnO were applied during the solar heterogeneous photocatalytic treatment of POME. The effect of photolysis (without photocatalyst) was studied for two reasons: (i) to act as a control, and (ii) to confirm the contribution of solar heterogeneous photocatalysis towards reducing COD level. COD reduction, by means of photolysis, has ranged between 7 to 29%, thus indicating that the presence of $TiO_2$ or ZnO is crucial to reduce the COD level in POME.

An optimum concentration of photocatalyst under studied experimental conditions is an important factor towards achieving efficient removal of COD. Thus, the effect of $TiO_2$ (0.02 to 0.2 g/L) and ZnO (0.5 to 2.0 g/L) concentrations on the reduction of COD was studied. The same experimental conditions were applied for both photocatalytic treatments, where 150 mL of diluted 1:1000 POME was exposed under sunlight for 5 hours. The optimum concentration of photocatalyst was then fixed for other parameters studied. Figure 2 shows the percentage of COD reduction after 5 hours of solar $TiO_2$ photocatalysis. As expected, the percentage of COD reduction was increased from 54.3 to 88.5% concomitantly with the increased amount of $TiO_2$ from 0.02 to 0.1 g/L. However, further increase of $TiO_2$ to 0.2 g/L has yielded only 40% of COD reduction. Under the studied experimental conditions, 0.1 g/L of $TiO_2$ has led to a maximum reduction of 88.5% of COD (Figure 2). $TiO_2$ concentrations of higher than the optimum value (0.1 g/L) could increase the opacity of the suspension due to the excess amount of photocatalyst. Furthermore, penetration of solar radiation could have been impeded by the excess catalysts [22], contributing to the retardation of COD reduction. With 0.1 g/L of $TiO_2$, COD was reduced from 73,150 mg/L to 8,000 mg/L after 5 hours of solar exposure (Figure 3).

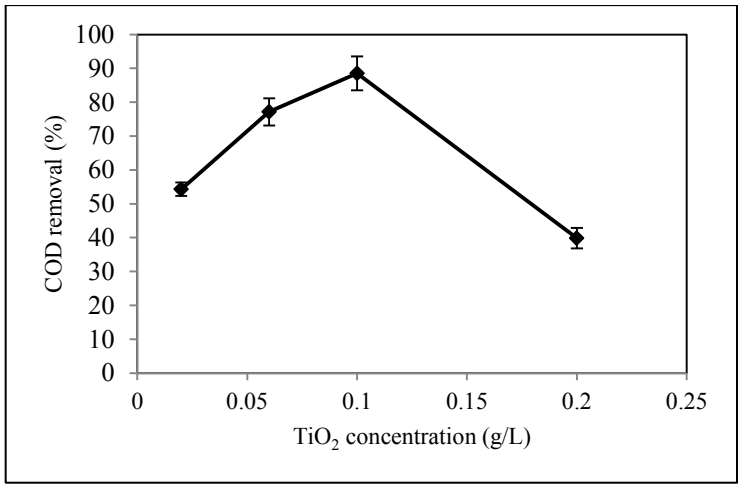

Figure 2. Effect of $TiO_2$ concentration on COD reduction efficiency using solar $TiO_2$ photocatalysis (error bars indicate standard deviation)

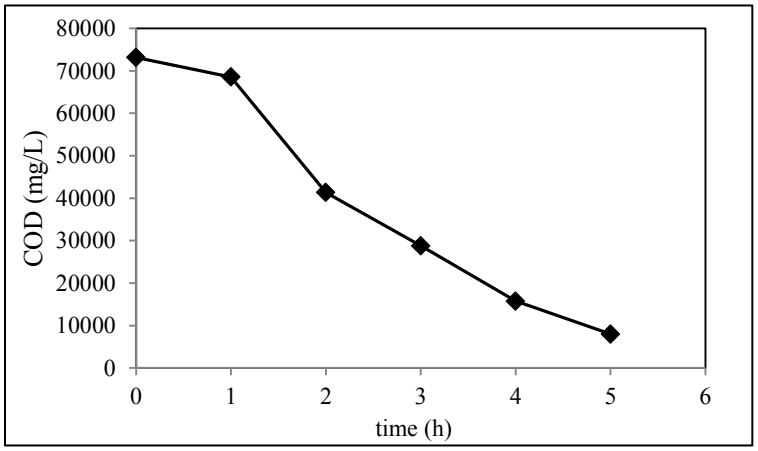

Figure 3. Reduction of COD with the optimum concentration of $TiO_2$ (0.1 g/L) using solar $TiO_2$ photocatalysis

In the case of ZnO, the percentage of COD reduction has increased from 26.3 to 60.5% with increased ZnO concentration, from 0.5 to 2 g/L (Figure 4). Further increase of ZnO concentration to 4 g/L has resulted in the declining percentage of COD reduction to 36.6%. The reasons elucidated for $TiO_2$ photocatalysis could also be applied to the phenomenon observed during the ZnO photocatalysis. When the performances of ZnO and $TiO_2$ photocatalysis were compared based on the effect of photocatalyst concentration on COD reduction, the latter has demonstrated better reduction efficiency under the investigated experimental conditions. The higher percentage of COD reduction of 88.5% was achieved with a low $TiO_2$ concentration (0.1 g/L). In contrast, 2 g/L of ZnO was required to obtain the maximum percentage of COD reduction of 60.5%. Several studies have reported that ZnO photocatalysis had performed better than $TiO_2$ photocatalysis for pollutant degradation [16, 23] because ZnO can absorb a larger fraction of the solar spectrum compared to $TiO_2$. However, in this study, the performance of $TiO_2$ was superior to ZnO.

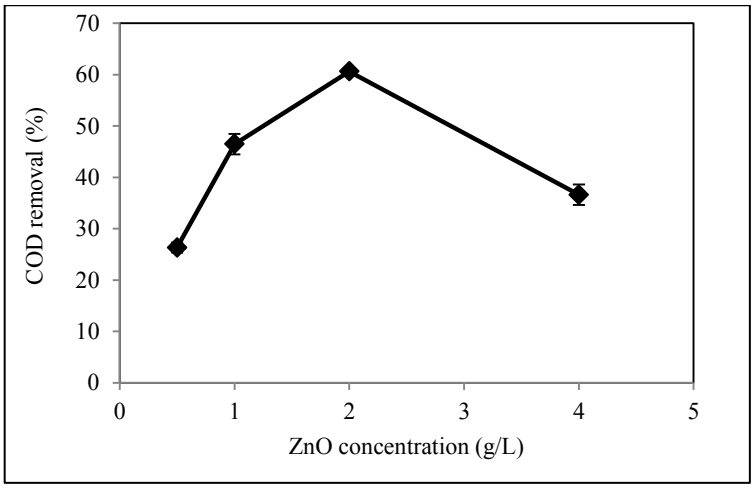

Figure 4. Effect of ZnO concentration on COD reduction efficiency using solar ZnO photocatalysis (error bars indicate standard deviation)

The performance of photocatalysts in degrading organic matter is known to be closely linked to their synthetic nature. The XRD patterns in Figure 5 clearly corresponded to the typical pure anatase $TiO_2$. The existence of strong crystalline peaks at $2\theta$ values of 25.3°, 37.6°, 48.0°, 53.9°, and 54.9°, which corresponded to the crystal planes of

(101), (004), (200), (105), and (211), respectively, were indicative of pure anatase $TiO_2$ (Figure 5a). As for ZnO, the crystalline peaks at $2\theta$ values of 31.8°, 34.4°, 36.2°, and 47.5° corresponded to the crystal planes of (100), (002), (101), and (102), respectively. These peaks were indicative of the predominant crystalline phase of ZnO (Figure 5b). FESEM images were also acquired for the commercial $TiO_2$ and ZnO, as shown in Figure 6. Figure 6a shows the surface of $TiO_2$ to be smooth and spherical in shape, with slightly varied particle sizes. Meanwhile, ZnO particles were predominantly rod-shaped (Figure 6b). Irregular sizes of ZnO particles in spherical and rectangular shapes can also be observed.

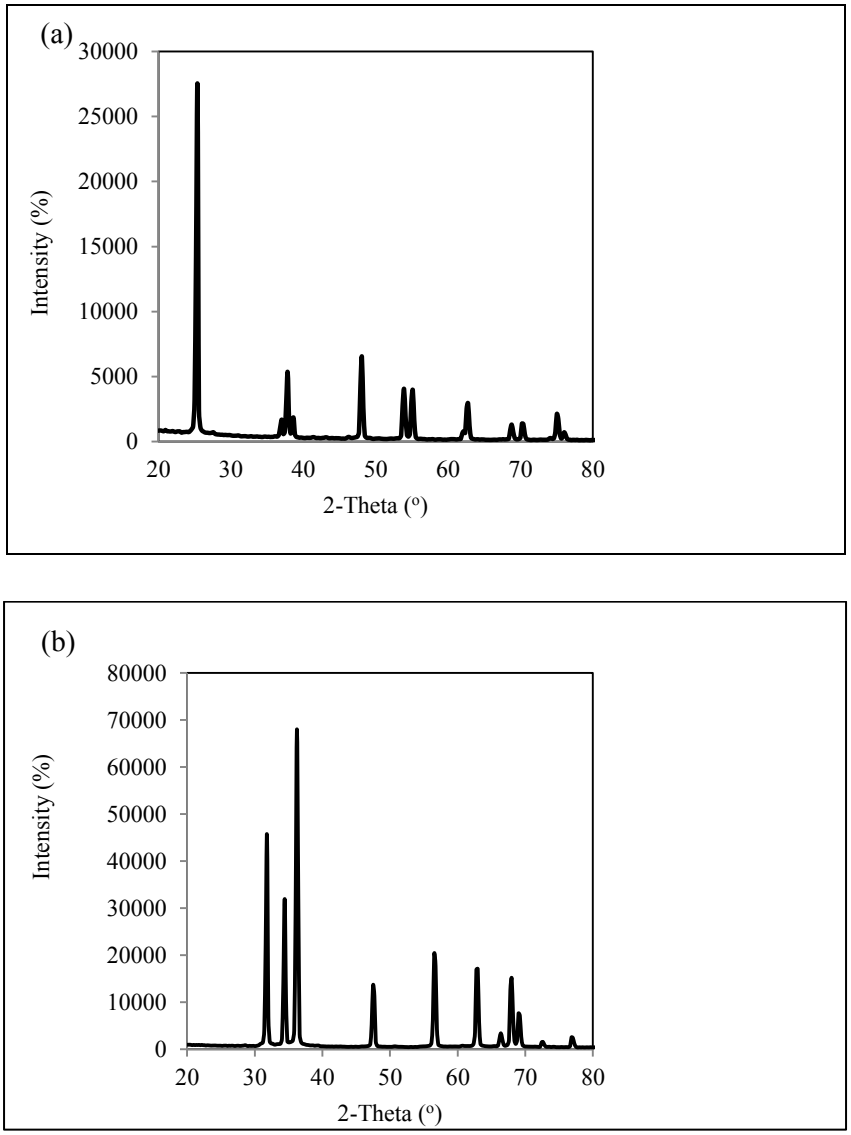

Figure 5. Comparison of XRD patterns between commercial: (a) $TiO_2$, and (b) ZnO

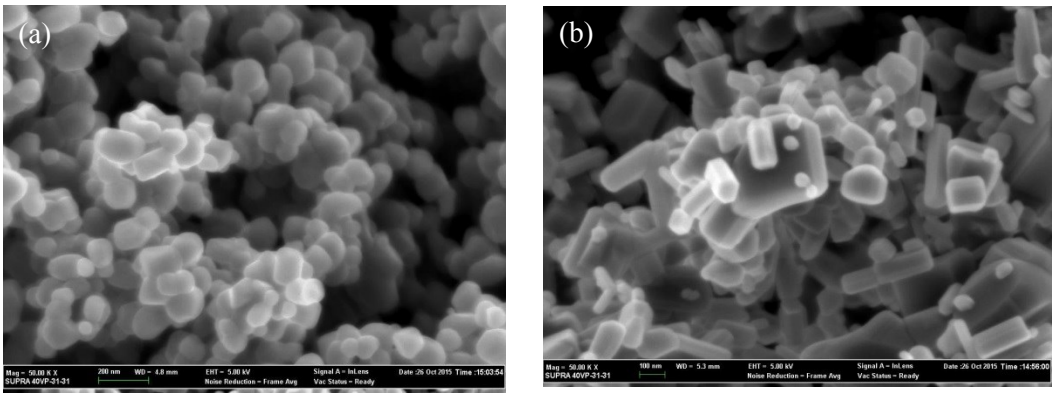

Figure 6. FESEM images of commercial: (a) $TiO_2$, and (b) ZnO

High crystallinity and non-porosity of both ZnO and $TiO_2$ could have contributed to the oxidation or mineralization of the organic matter in POME. The Brunauer-Emmett-Teller specific surface areas ($S_{BET}$) for $TiO_2$ and ZnO were 55 $m^2/g$ and 25 $m^2/g$, respectively. The average particle size of $TiO_2$ could also be estimated from the $S_{BET}$ by assuming that all particles have the same spherical size and shape. The particle size, $D$ is given by Equation 2 [24]:

$$D = \frac{6000}{S_{BET} \times \rho} \quad (2)$$

where $\rho$ is the true density for $TiO_2$, which in this study, was 4.2 g/mL and the estimated particle size was 26 nm. However, estimating the particle size of ZnO from Equation 2 would be inaccurate as ZnO has distinct irregular shapes, ranging from rod to rectangular. By using the Image J software, the particle size of ZnO was estimated to be 300 – 400 nm, with some 46 – 50 nm spherical particles. In this study, COD removal efficiencies could largely be attributed to fine spherical nanoparticles that have higher surface areas compared to the larger particles. With its smaller particle size, $TiO_2$ could absorb more photon and subsequently, more active sites were created, where more hydroxyl radicals were induced to enhance COD removal. In contrast, ZnO has lower absorption potential due to its relatively larger particle size. A similar observation was also made by Rojviroon et al. [25] and Vineetha et al. [26].

The performance of solar photocatalytic reaction is greatly influenced by pH and the concentration of catalyst [27]. In this study, solar ZnO and $TiO_2$ photocatalysis were performed without any pH adjustment. POME is known to be very acidic in nature. In this study, pH adjustment was not considered as it will increase the cost of treatment. Nonetheless, pH readings were recorded during sample collection to investigate whether there was any direct relationship between the pH of the suspension and COD reduction. The pH values of the collected samples during this treatment ranged between 1.2 and 4.9. The recorded mean pH for the highest percentage of COD reduction, which was attained using 0.1 g/L $TiO_2$, was at 3.68. Higher $TiO_2$ loading of 0.2 g/L had not only resulted in a very acidic pH (~1.2), it had also produced the lowest percentage of COD reduction. The aggregation of $TiO_2$ particles at 0.2 g/L could have reduced the ability of the suspension to absorb light [24], thus affecting the percentage reduction of COD. In addition, $TiO_2$ photocatalytic oxidation of POME may also produce other intermediary or degradation products, which could also have been acidic in nature, and directly affected COD reduction. Hence, this study has shown that COD reduction in POME is possible by means of solar $TiO_2$ photocatalysis without any prior pH adjustments and a small amount of $TiO_2$.

**Reduction of chemical oxygen demand by solar photo-Fenton**

Solar photo-Fenton treatment was conducted by varying the $Fe^{2+}$: $H_2O_2$ ratio to investigate its effect on COD reduction efficiency. Experiments were conducted by varying the concentrations of $H_2O_2$ in difference ratios of $Fe^{2+}$:$H_2O_2$ (1:10, 1:20, 1:30, and 1:40). A predetermined volume of NaOH was added to the samples at the end of the photo-Fenton treatments. The NaOH will lead to the formation of iron precipitate, $(Fe(OH)_3)$, which could accelerate the decomposition of $H_2O_2$. The precipitation of $Fe(OH)_3$ was observed to be slightly reduced in samples treated *via* photo-Fenton. To avoid the interference of excess $H_2O_2$ in the COD analysis, titration with potassium

permanganate was conducted to ensure the complete decomposition of excess $H_2O_2$. In the presence of $H_2O_2$, manganese(VII) was reduced to colourless manganese(II), as shown in Equation 3.

$$2KMnO_4 + 5H_2O + 3H_2SO_4 \leftrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2 \quad (3)$$

Blank diluted POME (1:1000) was added with $FeSO_4 \bullet 7H_2O$ and $H_2O_2$ separately (without both reacting simultaneously) to determine the effect of the addition of these reagents on COD reduction. POME samples that contained $H_2O_2$ had turned bright red immediately after the addition of Ferroin indicator, thus no titration was performed on these samples. POME samples with $FeSO_4 \bullet 7H_2O$ had required similar amount of ferrous ammonium sulphate as the blank sample during titration. This observation implies that the addition of these reagents did not affect the experimental results of COD reduction in the photo-Fenton treatment.

The amount of Fe(II) catalyst was fixed, while the amount of $H_2O_2$ was varied to determine its optimum ratio. Ferrous ions react rapidly with $H_2O_2$ to produce a large amount of HO• radicals (Equation 4). Based on the properties of this catalyst, only a small amount was required to speed up the reaction. Higher loadings of ferrous ions may only contribute to the waste of chemical.

$$H_2O + Fe^{3+} + h\nu \rightarrow HO\bullet + H^+ + Fe^{2+} \quad (4)$$

Figure 7 shows the reduction of COD using dark Fenton, indoor photo-Fenton and solar photo-Fenton after 3 h of reaction time. Dark Fenton oxidation has contributed to COD reduction percentage that ranged between 20 to 45%. The COD reduction efficiency was increased when the ratio of $H_2O_2$ concentration was increased from 1:10 to 1:30 for both indoor (50 – 78%) and solar photo-Fenton (62 – 89%) treatments. When the ratio was increased to 1:40, COD reduction efficiency had declined to 40% for indoor photo-Fenton and 56% for solar photo-Fenton. The excessive $H_2O_2$ loading could have resulted in the production of $HO_2\bullet$ radicals, which are less productive, compared to HO• radicals (Equation 5). $HO_2\bullet$ radicals could also have formed with the incorporation of HO• radicals in $H_2O_2$ (Equation 6). In addition, the HO• radicals could have recombined to form $H_2O_2$, without favouring any reactions (Equation 7). Based on Figure 7, the reaction was concluded to be optimized when the $Fe^{2+}$:$H_2O_2$ ratio was 1:30. With this ratio, the maximum percentages of COD reduction of 78% (from 73,000 to 16,000 mg/L) and 89% (from 73,400 to 7,855 mg/L) were obtained with indoor photo-Fenton and solar photo-Fenton treatments, respectively after 3 h of reaction time (Figure 8). A comparison of COD reductions between dark Fenton oxidation, solar photo-Fenton, and indoor photo-Fenton has shown that photon is necessary to activate the Fenton reagents. COD reduction using dark Fenton oxidation was rather low, although the trend was similar to those observed in the photo-Fenton treatments (indoor and solar).

$$H_2O_2 + HO\bullet \rightarrow HO_2\bullet + H_2O \quad (5)$$

$$HO\bullet + H_2O_2 \rightarrow HO_2\bullet + H_2O \quad (6)$$

$$HO\bullet + HO\bullet \rightarrow H_2O_2 \quad (7)$$

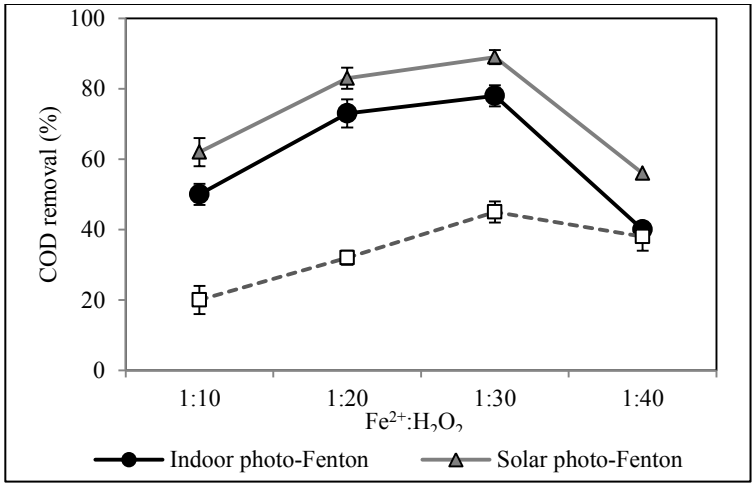

Figure 7. Reduction of COD by dark Fenton, solar photo-Fenton, and indoor photo-Fenton processes

In a Fenton treatment, pH plays an important role. The optimal pH condition in a Fenton reaction system is between 2.8 and 3.0 [28]. Therefore, the pH of POME solutions during each treatment was kept between 2.8 and 2.9. The purpose of the acidic pH is to avoid the precipitation of iron, which might interfere with the absorption of solar irradiation by the exposed medium. Prevention of iron precipitation will lead to the continuous photoreduction of ferric iron complexes at a longer wavelength.

In this study, solar photo-Fenton was found to be more efficient than indoor photo-Fenton. This result was in agreement with the findings reported by Aris et al. [17]. Several other studies have also concluded that solar photo-Fenton had performed better than other AOPs in various conditions, such as for textile effluent [29] and pharmaceutical wastewater [30]. The findings from the present study suggested that solar photo-Fenton should be considered as a valuable option for the reduction of COD in POME.

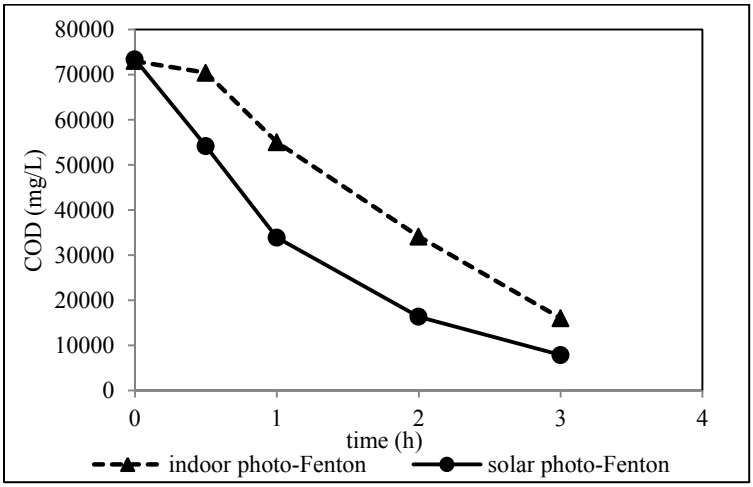

Figure 8. Reduction of COD by solar photo-Fenton and indoor photo-Fenton using the optimum $Fe^{2+}$:$H_2O_2$ ratio (1:30)

## Conclusion

A higher percentage of COD reduction was accomplished with solar photo-Fenton compared to indoor photo-Fenton and dark Fenton under similar solar exposure time. The reduction of COD in POME was found to be governed by the concentration of the photocatalyst in solar ZnO and $TiO_2$ photocatalysis. On the other hand, $H_2O_2$ concentration was the determinant for better solar photo-Fenton and indoor photo-Fenton treatments. In addition, the pH value in photo-Fenton systems has also played an important role, where the optimum pH value was found to be between 2.8 and 2.9. Decreasing the pH to 1.2 or increasing the pH to an alkaline level may result in poor COD reduction. Both solar photo-Fenton and solar $TiO_2$ photocatalysis were able to produce up to 89% of COD reduction. Nevertheless, solar photo-Fenton took only 3h of exposure time to achieve the highest reduction compared to solar $TiO_2$ photocatalysis that took up to 5h to achieve a similar level. This study has shown that the reduction of COD in POME generated from palm oil milling activities can be performed using solar photo-Fenton and $TiO_2$ photocatalysis. Thus, solar photo-Fenton and $TiO_2$ photocatalysis can be considered as pre-treatment steps prior to the biological treatment.

**Abstract**

Two pyridine-2,6-dicarboxylates each containing butynyl and pentynyl at position 2 and 6 were synthesized by esterification of 2,6-pyridinedicarbonyl dichloride with *N*-alkyne alcohol. All compounds were characterized by using nuclear magnetic resonance spectroscopy (NMR), infrared spectroscopy (IR) and mass spectrometry (MS) techniques. Crystallographic studies showed that both compounds, 3-dibutynyl pyridine-2,6-dicarboxylate **(3a)** and 4-dipentynyl pyridine-2,6-dicarboxylate **(3b)** crystallized in monoclinic system with same space group of C 2/c.

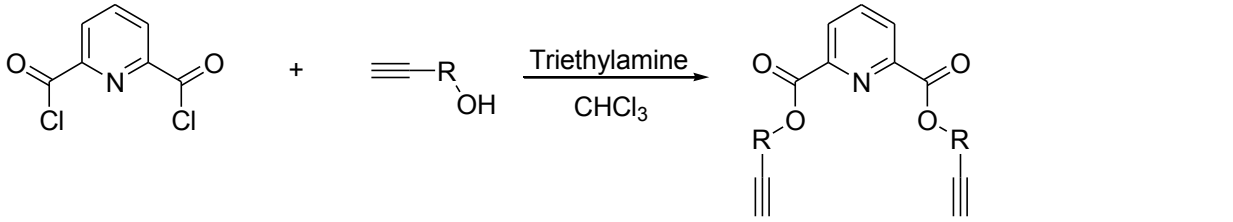
**Keywords**: diester macrocyclic, esterification, X-Ray structural study

**Abstrak**

Dua sebatian piridina dikarboksilat, 3-dibutinil dan 4-dipentinil pada kedudukan 2 dan 6 telah berjaya disintesiskan dengan tindak balas pengesteran di antara 2,6-piridinadikarbonil diklorida dengan *N*-alkuna alkohol. Setiap sebatian berjaya dicirikan dengan teknik spektroskopi resonans magnetik nuklear (RMN), infra merah (IR) dan spektrometri jisim (MS). Kajian kristalografi menunjukkan sebatian 3-dibutinil piridina-2,6-dikarboksilat **(3a)** dan 4-dipentinil piridina-2,6-dikarboksilat **(3b)** terhablur dalam sistem monoklinik dengan kumpulan ruang C 2/c.

**Kata kunci:** makrosiklik diester, tindak balas pengesteran, kajian struktur sinar-X

## Introduction



The synthesis study of macrocyclic has been rapidly developed for almost 40 years [1]. The design of this compound can be varies depending on the linker being used such as pyridine, benzene or aliphatic chain. The side chain can be functional group of ester, ether, thiourea, alkyne and alkene [2-7]. Various derivatives have been reported due to straightforward preparation and potential in biological activities and medicine.

Macrocyclic compound is an important reference compound in chemistry studies such as complexation to metal due to existence electron donating atom in the ligand [8-9]. Some of macrocyclic derivatives have been reported showing great capability in antibacterial, anticancer and HIV treatment [10-14]. Besides that, macrocyclic compounds contained alkene or alkyne ligands have been studied in recent trend of metathesis reaction. This

reaction has been shown to facilitate several complicated reaction steps especially in natural product synthesis such as lactones and marine alkaloid nakadomarin A [15].

Esters are commonly synthesized from the condensation reaction between carboxylic acid and alcohol with the loss of water. The esters can also be prepared by other reactions using acid anhydrides, acid chloride, unsaturated hydrocarbon, amides, nitriles, ethers, aldehydes, ketones, alcohols, and ester itself. The synthesis of these macrocyclic were carried out by esterification reaction with acyl chloride and alkyne alcohol in the presence of triethylamine as a base. The nitrogen's lone pair of triethylamine assisted the deprotonation of hydrogen at hydroxyl to initiate the esterification reaction.

This is demonstrated in the present work where pyridine acyl chloride was reacted with alkyne alcohol to form pyridine bridged diester macrocyclic followed by 3- and 4-dialkyne to form 3-dibutynyl pyridine-2,6-dicarboxylate **3a** and 4-dipentynyl pyridine-2,6-dicarboxylate **3b**, respectively (Scheme 1). With the help of X-ray structure, we could see either the presence of lone pair of nitrogen pyridine, position of the ester on ring or the *sp* hybridization of alkyne would give effect on geometry of the isomers. Following this, the designing of next product for future study, especially in complexation or metathesis reaction become facile. Thus, the synthesis, characterization and X-ray structures of the isomers are presented.

## Materials and Methods

### Materials

2,6-pyridinedicarbonyl dichloride, 3-butyn-1-ol, 4-pentyn-1-ol, triethylamine, chloroform, cyclohexane and ethyl acetate were purchased from Sigma Aldrich. Other chemicals were analytical grades and used as received.

### Instruments

The reactions were monitored by thin-layer chromatography (TLC) using 0.25 mm silica gel plates (Merck Kieselgel $60F_{254}$ UV indicator). Column chromatography was performed using silica gel Merck Kieselgel (230-400 mesh). The NMR spectra were recorded by Bruker spectrometer at 400 MHz for $^1$H NMR using tetramethylsilane (TMS) as internal standard and 100 MHz for $^{13}$C NMR. The coupling constant (*J*) are given in Hz. IR spectra were recorded in the range of 4000-370 $cm^{-1}$ using a Perkin Elmer Spectrum GX with samples prepared as KBr pellets. The melting point was determined by using Barnstead Electrothermal IA9000 Series Melting Point Apparatus with oven temperature range ambient to 400 °C. The Mass spectrometry was recorded by Bruker MicroToF Q with method of direct infuse and source type electro-spray ionization (ESI).

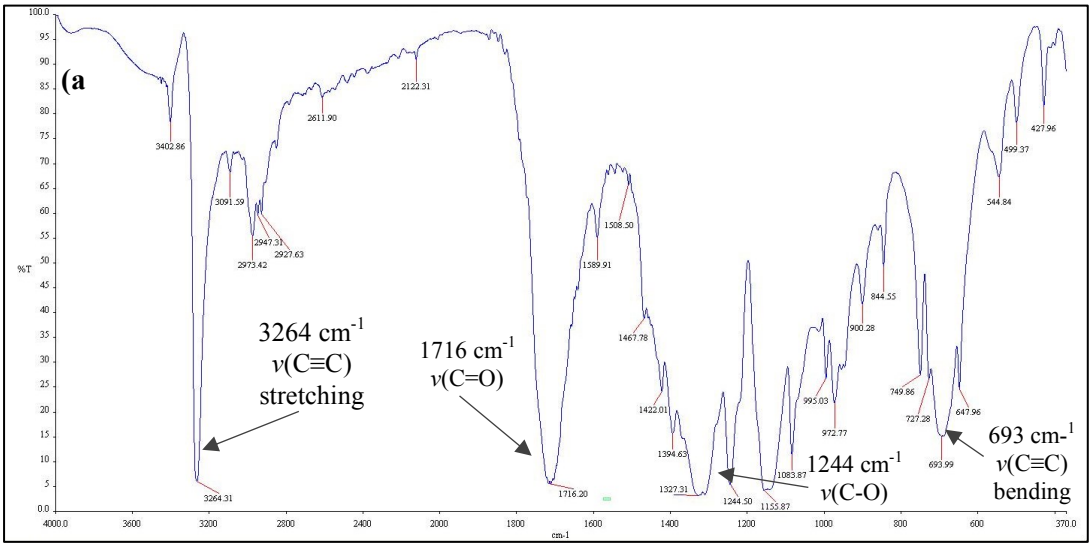
### Synthesis of *N*-dialkyne pyridine-2,6-dicarboxylate

2,6-pyridinedicarbonyl dichloride (4.9 mmol, 1g) was dissolved in 25 mL chloroform inside the one-neck round bottom flask. Alkyne alcohol solution (9.8 mmol) is added into the mixture followed with 2.1 mL of triethylamine. The mixture was stirred at 0 °C for 10 minutes and continued stir at room temperature for 18 hours. The mixture

then dried under vacuum and the residue purified by flash chromatography (cyclohexane/ethyl acetate) to give colorless crystal upon evaporation. The crystals are suitable for X-ray study.

## Results and Discussion

**Representative data for synthesis 3-dibutynyl pyridine-2,6-dicarboxylate, 3a**



The compound was obtained as colorless crystal in 76% yield after recrystallization. Mp 86 - 87 °C. IR (KBr pellets) υ/cm$^{-1}$: 3264 (stretching C≡C), 1716 (C=O), 1327 (Ar-N), 1244 (C-O), 693 (bending C≡C).; $^{1}$H NMR (400 MHz; $CDCl_3$) $\delta_{H\ 2.06}$ (2H, s, C≡CH), 2.73 (4H, t, J= 6.8, 2xC$H_2$C≡C*H*), 4.52 (4H, t, J= 7.2, 2xO$CH_2CH_2$C≡CH), 8.02 (1H, t, J=7.6, ArH), 8.30 (2H, d, J=7.6, 2xArH). $^{13}$C NMR (100 MHz; $CDCl_3$) $\delta_C$ 18.9 ($CH_2$C≡CH), 63.6 (O-*C*$H_2$), 70.3 (*C*≡CH), 79.5 (*C*≡CH), 128.2 (Ar*C*H), 138.4 (Ar*C*H), 148.1 (Ar*C*), 164.1 (*C*=O). HRMS (ES$^+$) m/z calculated for $C_{15}H_{13}NO_4Na$ $[M+Na]^+$ 294.2578, found 294.0740.

**Representative data for synthesis 4-dipentynyl pyridine-2,6-dicarboxylate, 3b**

The compound was obtained as colorless crystalline in 63% yield after recrystallization. Mp 80 - 82 °C. IR (KBr pellets) υ/cm$^{-1}$: 3278 (stretching C≡C), 1736 (C=O), 1288 (Ar-N), 1237 (C-O), 693 (bending C≡C). $^{1}$H NMR (400 MHz; $CDCl_3$) $\delta_{H\ 2.01}$ (2H, s, C≡CH), 2.09 (4H, **t**, J= 8, 2xC$H_2$C≡C*H*), 2.41 (4H, q, J= 4, 2x$CH_2CH_2$C≡CH), 4.54 (4H, t, J=8, 2xO-$CH_2CH_2CH_2$C≡CH), 8.02 (1H, t, J=8, ArH), 8.27 (2H, d, J=8, 2xArH). $^{13}$C NMR (100 MHz; $CDCl_3$) $\delta_C$ 15.27 ($CH_2$C≡CH), 27.45 (O-$CH_2$-$CH_2$)64.70 (O-$CH_2$), 69.26 (C≡CH), 82.87 (C≡CH), 127.90 (ArCH), 138.25 (ArCH), 148.44 (ArC), 164.51 (C=O). HRMS (ES+) m/z calculated for $C_{17}H_{17}NO_4Na$ $[M+Na]^+$ 322.3109, found 322.1158.

**Characterization**

The infrared spectra for both ester macrocyclic isomers, **3a** and **3b** showed the presence of the stretching frequency at 3264 and 3278 cm$^{-1}$ due to the existence of terminal alkyne. The peak at 1716 and 1740 cm$^{-1}$ are the stretching frequencies for the *v* (C=O). For the peak at 1327 and 1288 cm$^{-1}$ are referred to aromatic amine of the pyridine and peak at 1244 and 1237 cm$^{-1}$ are for the ether group. Sharp peak at 693 and 654 cm$^{-1}$ are referring to bending mode of the terminal alkyne. Figure 1(a) display the IR spectrum of **3a** and (b) for compound **3b**.

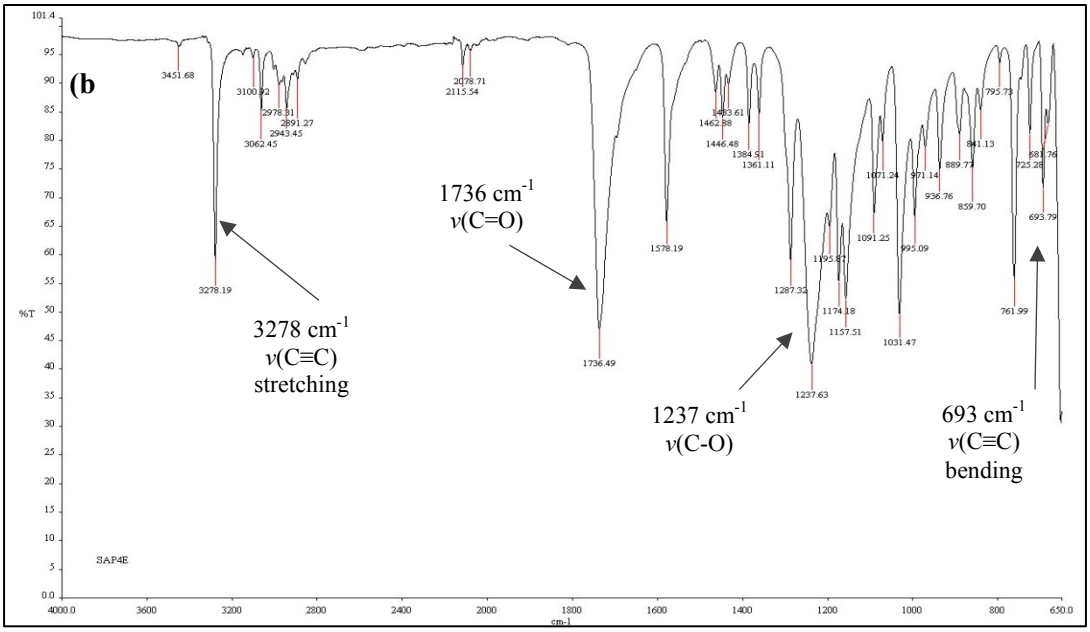


Figure 1. The IR spectrum of (a) **3a** and (b) **3b**

The chemical shifts of the pyridine rings protons for the both isomers are similar and appeared as a dublet at 12.0 and a triplet at 11.0 ppm, respectively. The terminal alkynes protons for the compounds **3a** and **3b** were found in the range of 1.0-2.0 ppm. The chemical shifts of the methylene protons near the alkyne ($-CH_2C\equiv CH$) appeared at the range of 2.07-5.02 ppm while the methylene protons's chemical shifts are found at 4.50 ppm. In the $^{13}C$ NMR spectra, the carbon chemical shifts of C=O is found at 174.0 ppm, respectively for the both isomers. The aromatic pyridine carbon chemical shifts of the isomers appeared in the range of 124.5-136.0 ppm. The chemical shift for the terminal alkyne observed at the range of 21.1-43.8 ppm. The value of molecular ion peak found in mass spectrometry for **3a** and **3b** are agreed with the expected molecular weight, respectively.

**X-ray crystallographic study**

The colorless crystals of **3a** and **3b** are crystallized in monoclinic system with same space group of C 2/c. The crystallographic data are summarized in Table 1.

Figure 2 shows the structure molecular with labels of the molecules **3a** and **3b**. Both molecules with the pyridine linker and both side chains groups, respectively adopt a cis-cis against the C=O bond. The two molecules have asymmetric unit of ½ independence molecule generated since they are centrosymmetric across the N1/C8 and N1/C9 atoms.

**3a** **3b**

Figure 2. ORTEP diagrams of compund 3a and 3b drawn at 50% probability displacement ellipsoids

Compound **3a** possess a planar geometry by its pyridine ring N1/(C6-C8)/C6a-C7a) with the ester C4-C5/O1-O2 and C4a-C5a/O1a-O2a with maximum deviation of 0.016 Å for atom C4. The pyridine and ester groups are

perpendicular with the alkyne side chain with dihedral angle to the ester at C5/O1/C4/C3 with -139.8(4)°. As for compound **3b**, all atoms are in planar with maximum deviation at C8 with 0.052(4) Å. The bond lengths and angles are in normal ranges for both compounds (Table 2).

In the crystal structure, the **3a** molecule is linked by C1—H1···O2 intermolecular hydrogen bond. In contrast with molecule **3b**, linked by nitrogen of pyridine with the hydrogen methine of C9 pyridine, N1···H9—C9 and oxygen carbonyl and hydrogen methine of C8 pyridine, C8—H8···O1 (Table 3). The intermolecular hydrogen bond for molecule **3a** and **3b** formed a network of polymorph at b-axis and c-axis (Figure 3).

## Conclusion

The ester macrocyclic 3-dibutynyl-2,6-pyridine dicarboxylate and 4-dipentynyl-2,6-dicarboxylate were successfully synthesized by condensation reaction and fully characterized using spectroscopic techniques. Both compounds were crystallized in the solvent system of cyclohexane and ethyl acetate for purification and afforded colorless and needle-liked crystals. The observation on CCDC data has no record on these compounds. Both compounds have monoclinic system with space group of C 2/c but different geometry as **3b** showed fully geometry planar. The intermolecular hydrogen bond gave the compounds a polymorph network in the crystal structure. The terminal alkynes on both compounds are suitable metathesis reaction. Thus, further study on the metathesis reaction and optimization to obtain cyclic compounds are in progress.

**Abstract**

Breakdown of hydrogen sulfide ($H_2S$) in seawater is highly dependent on both the concentration of dissolved $H_2S$ and dissolved oxygen (DO). A simple correlation was found in the $H_2S$ dissociation and ratio of [DO/$H_2S$]. When the [DO/$H_2S$] ratio is more than one, $H_2S$ breakdown rapidly, resulting in a short half-life of $H_2S$ in the seawater (in a time scale of minute). When the dissolved oxygen is not a limiting factor, $H_2S$ breakdown in a first order reaction. Nevertheless, when [DO/$H_2S$] ratio is less than 1, $H_2S$ breakdown in the seawater becomes slower, resulting in a longer $H_2S$ half-life (in a time scale up to hours). In this case, the $H_2S$ breakdown in a pseudo-second order reaction. This pseudo-second order reaction is commonly reported by other investigators. This study also investigated the relation between the concentration of dissolved $H_2S$ and pH changes during $H_2S$ dissociation in the seawater. The pH is lowered with increasing concentration of initial $H_2S$ in the seawater but appears to reach an asymptotic low value of about 4 as the dissolved $H_2S$ approaches its saturation limit in the seawater at about 2,500 mg $L^{-1}$.

**Keywords:** hydrogen sulfide, dissolved oxygen, oxidation, seawater, $H_2S$ dissociation

**Abstrak**

Penguraian hidrogen sulfida ($H_2S$) dalam air laut sangat bergantung kepada kepekatan kedua-dua $H_2S$ terlarut dan oksigen terlarut (DO). Satu kolerasi mudah telah ditemui antara penguraian $H_2S$ dan nisbah [DO/$H_2S$]. Apabila nisbah [DO/$H_2S$] melebihi satu, penguraian $H_2S$ adalah cepat, menyebabkan separuh hayat $H_2S$ yang pendek dalam air laut (dalam skala masa minit). Dalam keadaan yang mana oksigen terlarut bukan faktor penghad, penguraian $H_2S$ merupakan tindak balas tertib pertama. Namun, apabila nisbah [DO/$H_2S$] kurang daripada satu, penguraian $H_2S$ dalam air laut menjadi lambat, menyebabkan separuh hayat $H_2S$ yang lebih lama (dalam skala masa jam). Dalam kes ini, penguraian $H_2S$ adalah tindak balas pseudo tertib kedua. Tindak balas pseudo tertib kedua ini biasa dilaporkan oleh ramai penyelidik. Kajian ini turut menyiasat hubung kait antara kepekatan $H_2S$ terlarut dan perubahan pH semasa penguraian $H_2S$ dalam air laut. Nilai pH jadi rendah dengan peningkatan kepekatan awal $H_2S$ dalam air laut tapi ia mencapai nilai asimptot yang rendah dalam lingkungan 4 apabila kepekatan $H_2S$ terlarut menghampiri had ketepuannya dalam air laut pada kepekatan 2,500 mg $L^{-1}$.

**Kata kunci:** hidrogen sulfida, oksigen terlarut, pengoksidaan, air laut, penguraian $H_2S$

## Introduction

Hydrogen Sulfide ($H_2S$) gas is one of the potential contaminant found in oil and gas production. $H_2S$ is normally formed in oil and/or gas reservoirs through the decomposition of organic matter under anaerobic condition by microbes. Typically, such $H_2S$ will be removed from the main hydrocarbon stream and disposed off to increase the sales value of the sweetened hydrocarbon. In the ocean, $H_2S$ is mainly formed through geochemical processes during deep sea volcanic activities including hydrothermal vents [1]. When $H_2S$ is present in the seawater in dissolved form, it dissociates into hydrosulfide ($HS^-$), which is the product of the first dissociation equilibrium ($K_{a1}$). The second dissociation equilibrium ($K_{a2}$) produces the sulfide ion ($S^{2-}$). $H_2S$ is a weak acid, with $pK_{a1}$ being reported by various investigators in the order of 7.0 [2-5] and $pK_{a2}$ in the order of 12.5 [6]. Due to the first dissociation of $H_2S$ to $HS^-$, the concentration of aqueous $H_2S$ will decrease with increasing pH in water. At pH 7.0, the concentration ratio of the aqueous $H_2S$ to $HS^-$ is approximately 1:1. As the pH increases beyond 7.0, the ratio of the concentration of $HS^-$ to aqueous $H_2S$ increases. Sulfide ion ($S^{2-}$), which is the product of the second dissociation becomes significant, only when pH is above 12.

The hydrosulfide ion is susceptible to oxygenation reactions under aerobic condition in seawater. The oxygenation of $HS^-$ is rather complex, involving a multitude of chemical reactions, producing various intermediate and final products, amongst others, the following possible reactions 1 – 3 [7, 8]:

$$2HS^- + 3O_2 \rightarrow 2SO_3^{2-} + 2H^+ \quad (1)$$

$$HS^- + 2O_2 \rightarrow SO_4^{2-} + H^+ \quad (2)$$

$$2HS^- + 2O_2 \rightarrow S_2O_3^{2-} + H_2O \quad (3)$$

In the presence of relatively high concentration of dissolved oxygen (DO), the ion species of sulfite ($SO_3^{2-}$) is stable. Even so, some of the $SO_3^{2-}$ species would also be oxidized to sulfates ($SO_4^{2-}$) [7, 9]. Hence, it is apparent that the actual overall oxidation rate of $H_2S$ in seawater varies depending on the conditions studied. A simplified gross measure of the overall breakdown of $H_2S$ in seawater due to various reactions shown above can be depicted by the $H_2S$ half-life; which is a measure of the time taken to lower the $H_2S$ concentration from its initial value to half the initial value. Various publications have provided different $H_2S$ half-life values, depending on the reaction conditions investigated. Göte and Alexander [10] reported that the $H_2S$ half-life of about 17 minutes at constant dissolved oxygen concentration of 5.4 mg $L^{-1}$ and 25 °C in seawater. Sharma and Yuan [11] reported $H_2S$ half-life of 25 minutes for treated domestic wastewater initially containing about 6 mg $L^{-1}$ of $H_2S$ and 8 mg $L^{-1}$ DO, while Asaoka et al. [12] reported an *in-situ* half-life of approximately 50 minutes in the Etajima Bay, which contains about 28 mg $L^{-1}$ of sulfide.

Decomposition of the $H_2S$ becomes more complicated when microbial degradation is also taking place [13] or when catalytic metals are present [14]. Oxidized metals such as Fe(III), Mn(III) and Mn(IV), for example, are efficient catalysts to overcome the kinetic barrier for the chemical oxidation of sulfides [15]. The interaction of all these factors in the seawater leads to unpredictable outputs in the tropical marine environment. It is apparent that the half-life of $H_2S$ dissociation in such waters is quite complex and dependent on the physical chemical properties as well as biological assemblage of the seawater. Thus, whenever the rate of $H_2S$ decomposition is the intended subject, invariably there is a need to conduct *in-situ* verification using the actual seawater source. Understanding the rate of $H_2S$ breakdown in seawater is important in environmental management as it plays an important role in toxicity and ecological footprint of the toxic gas in the marine environment. Hence, this paper describes the experiments undertaken to determine the rate of $H_2S$ breakdown in seawater obtained from the Terengganu offshore, as representative of the offshore water of Peninsular Malaysia. The study includes analysis to derive appropriate rate equations and rate constant(s) for the $H_2S$ breakdown in seawater as well as estimations of the dissociation half-life. In addition, the effect of $H_2S$ dissociation on the pH of the resultant solution is of particular interest. In freshwater, the dissolution of $H_2S$ into $HS^-$ ions generate protons, which effectively lowers the pH of the solution. However, in seawater, the natural alkalinity of the seawater tends to counteract the lowering of the pH through various carbonaceous compounds in the seawater carbonate equilibrium. This can result in a complex, non-linear pH correlation with concentration of $H_2S$ dissolution. In this study, it is desired to establish an empirical relationship between the effect of $H_2S$ dissolution and resultant pH of the seawater solution.

## Materials and Methods

### Materials

Seawater used in this experiment was collected from the South China Sea off Terengganu. The seawater was then filtered and acclimatized for one week before use. 1 L Kipps apparatus was used to produce the hydrogen sulfide ($H_2S$) gas used in this study. In the Kipps apparatus, excess pyrite ($Fe_2S$) was allowed to react with hydrochloric acid (20%) to generate $H_2S$ gas. The gas was bubbled into 1 L oxygen-free deionized water for 24 hours to produce an approximately 2000 mg $L^{-1}$ $H_2S$ aliquot for the subsequent experiments. Oxygen free water was prepared by purging deionized water with pure nitrogen at 30 mL $s^{-1}$ for 40 minutes. High Purity oxygen and nitrogen (> 99 %) gases were used in this study. All the chemicals used in the study were of analytical grade and supplied by Merck Co.

### Determination of hydrogen sulfide in seawater

Hydrogen sulfide ($H_2S$) probe (MS-AQUA) was used to monitor $H_2S$ concentration in the experiments. Analysentechnik GmbH develops the amperometric MS-AQUA $H_2S$ micro sensor for *in-situ* determination of dissolved $H_2S$ or Total sulfide in aqueous solution within a pH range of 0 to 8. Other than the ion sensitive electrode (ISE), the MS-AQUA is the only method for *in-situ* [$H_2S$/ Total Sulfide] measurement. MS-AQUA is more relevant as compared to the other ISEs because the workable pH range of MS-AQUA is more relevant to the study undertaken. The accuracy and the concentration of the MS-AQUA below 3 mg $L^{-1}$ is essentially better than the other ISEs. Table 1 shows the technical data extracted from the technical manual of the sensor. The $H_2S$ probe was pre-calibrated by the manufacturer and was validated with standard solutions by comparing the concentration obtained from the probe and the standard methods (APHA 4500-$S^{2-}$F., Iodometric method and APHA 4500-$S^{2-}$H, calculation of unionized $H_2S$) [16]. Dissolved oxygen and pH were determined by using YSI 550a and the pH probe of the MS-AQUA respectively.

Table 1. Technical specification of MS-AQUA $H_2S$ probes used in the study

| Technical Specification | Range |
|---|---|
| Measurement range | |
| • Type I* | • 10 µg $L^{-1}$ – 3 mg $L^{-1}$ $H_2S$ |
| • Type II | • 50 µg $L^{-1}$ – 10 mg $L^{-1}$ $H_2S$ |
| • Type III* | • 500 µg $L^{-1}$ – 50 mg $L^{-1}$ $H_2S$ |
| Accuracy of the sensor | 2 % |
| Temperature range | 0°C – 30°C |
| pH range | 0 – 8 |
| Salinity range | < 40 ppt (g $L^{-1}$) |
| Signal Interference | |
| • Carbon dioxide | Up to 25.38% |
| • Methane | Up to 5.78% |
| • Hydrogen | Up to 0.544% |
| • Ammonia | Up to 1000 ppm |
| • Carbon monoxide | Up to 92 ppm |
| • Carbon disulfide | Up to 5% |
| • Acetic acid | Up to 1 mol $L^{-1}$ |
| • Dimethyl sulfide | Up to 10% |
| • Ethanol | Up to 10% |

* Sensors used in this study

APHA Method 4500–$S^2$-F [16] was also used to validate the reading from the probe as well as to determine those concentration that fell beyond the measurement range of the MS-AQUA. In the case where the $H_2S$ level exceeded the measurement range, water sample was collected from the experimental chamber by using syringe acted as a

piston to drive water sample out of the vessel. Samples drawn out from the experiment was analyzed for its pH and $H_2S$ level right after sampling. Briefly, 20 mL of iodine solution (0.025 N) followed by 2 mL 6N HCl was poured into a 500 mL flask. An amount 200 mL sample was discharged under the solution surface into the flask. More iodine solution was added if the color of the iodine disappeared. The sample was then back-titrated with standard sodium thiosulfate solution (0.025 N). A few drops of starch solution were added as indicator for the end point (disappearance of blue color). The concentration of total sulfide was then calculated, taking into account the dilution factor during titration. The concentration of unionized $H_2S$ is then calculated by multiplying the dissociation factor at the measured pH with the total sulfides as stipulated in APHA Method 4500–$S^2$-H [16].

**Breakdown of hydrogen sulfide in seawater**

Experimental chamber as shown in Figure 1 was used in this study. The chamber consists four major components; 1. $H_2S$, temperature and pH probes, 2. Aliquot injection port, 3. Dissolved oxygen probes, and 4. Magnetic bar and stirrer. The experimental chamber was incubated in a 20 L water bath. The reactor vessel was first filled with 2 L of seawater. Pure oxygen and nitrogen from gas cylinders were used to adjust the level of dissolved oxygen in the seawater. 50 mL syringe was used to inject concentrated $H_2S$ aliquot through the injection port into the reactor. The volume of concentrated $H_2S$ solution injected into the reactor was obtained based on dilution equation ($M_1V_1 = M_2V_2$) to make up the desired $H_2S$ concentration. The volume of injection was limited to less than 2% of the total reactor volume. No head space was permitted in the chamber throughout the experiment. In order to avoid leakages, all ports were sealed with silicon glue. Magnetic bar and stirrer (300 rpm) were used to homogenize the aliquot and seawater in the experimental vessel. The experiments were conducted in the laboratory at 28°C, pH 8.0 and 30 ppt. Experiment started one minute after injection of the $H_2S$ aliquot. This is to ensure sample homogeneity in the vessel. Readings were recorded continuously by using a camcorder and then manually transferred into excel spreadsheet. The data were then used to determine the reaction order, rate and constant. All the experiments were conducted in triplicate.

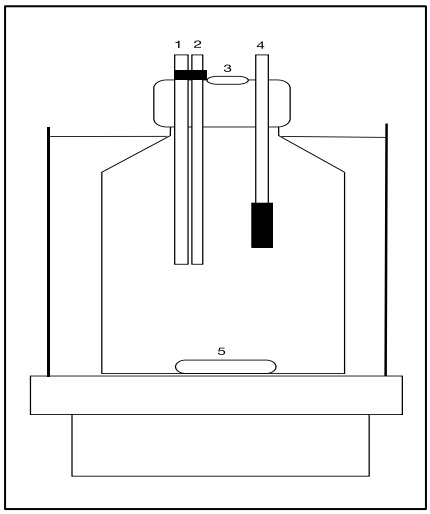

Figure 1. Experimental setup for investigation of $H_2S$ removal in seawater. 1. $H_2S$, temperature and pH probes, 2. Aliquot injection port, 3. Dissolved oxygen probe, 4. Magnetic bar and stirrer

**$H_2S$ solubility and pH changes in seawater**

Prior to the main $H_2S$ breakdown rate experiments, solubility of the $H_2S$ in seawater was tested using the experimental setup as shown in Figure 2. In the experiment, $H_2S$ gas generated from Kipps apparatus was bubbled through the seawater at 28°C, 30 ppt and pH 8.0 in a 2 L vessel through port 2. Port 4 is the vent for excess gas. During sample withdrawal, port 4 was clipped and the syringe (5) was used as a piston to drive water sample out of the vessel through port 3. The concentration of the $H_2S$, temperature, pH and dissolved oxygen were determined

immediately. The experiments were conducted in a 20 L water bath for consistent temperature at 28 °C (±0.5 °C). All the experiments were conducted in three replicates.

**Determination of reaction order, rate constant and half-life**

Data obtained from $H_2S$ breakdown experiments were used to determine the reaction order, rate constant and half-life of the $H_2S$ removal. Reaction kinetics were studied based on computation procedure of Han et al. [17]. The reaction orders, rate constants and half-life were obtained by using graphical method. In the case where the dissolved oxygen is in excess, the reaction constant and the breakdown rate of the $H_2S$ would resemble the pseudo-first order ($K_1$) reaction as (4):

$$\frac{d[H_2S]}{dt} = -K_1[H_2S]_t \quad (4)$$

Where, $[H_2S]_t$ is define as concentration of hydrogen sulfide at time t and $K_1$ is define as rate constant.

While, the reaction constant and the breakdown rate of the $H_2S$ resemble a second order reaction, it represented as (5):

$$\frac{d[H_2S]}{dt} = -K_2[H_2S]_t[O_2]_t \quad (5)$$

where, $[H_2S]_t$ is define as concentration of hydrogen sulfide at time t, $[O_2]_t$ is define as concentration of dissolved oxygen at time t and $K_2$ is rate constant.

The reaction constant for second order reaction, $K_2$, can be assessed by dividing $K_1$ with $[O_2]_t$. $K_1$ can also be derived from the concentration graphs by computing the gradient of the $H_2S$ concentration over the linear portion of the decline and dividing by the average concentration of $H_2S$ over the considered range. Comparing equations (4) and (5), $K_2$ can be estimated from $K_1/[O_2]$. Since the DO concentration in the seawater for the case of lower DO/ $H_2S$ concentration ratio is expected to decline in tandem with the breakdown of $H_2S$, estimation of $K_2$ in this case, is applicable only over a narrow time range where the DO concentration within that time range does not resulted in a significant differences in $K_2$ and $K_1$. In this study, such approximations are restricted to the first few minutes of the experiments, where the $H_2S$ concentration decline is still linear and the DO has not declined more than 50% of its

initial concentration. Integrating equation (5) provides a mathematical estimate of the $H_2S$ dissociation half-life for the experiments (equation 6 - 8):

$$\int \frac{\mathrm{d[H2S]}}{\mathrm{[H2S]}}\mathrm{dt} = -1 \int K_2 [O_2]$$
$$\frac{1}{[O_2]_o - [H_2S]_o} \ln \frac{[O_2]_t [H_2S]_o}{[O_2]_o [H_2S]_t} = K_2 t \quad (6)$$

When $[O_2]_o$ is much higher than $[H_2S]_o$, $[O_2]_o \sim [O_2]_t$, equation (6) become (7)

$$\frac{1}{[O_2]_t} \ln \frac{[H_2S]_o}{[H_2S]_t} = K_2 t$$

$$[H_2S]_t = [H_2S]_o e^{-[O_2]_t K_2 t} \quad (7)$$

Half-life can be determined based on equation (7), as $[H_2S]_t = 0.5[H_2S]_o$, thus

$$t_{1/2} = \frac{ln0.5}{-K_2[O_2]_o} \quad (8)$$

**Statistical analysis**

Paired t-test was performed to compare if there is significant different in the reading obtained from $H_2S$ probe (MS-AQUA) and the standard methods [16]. The statistical analysis was performed by using open source software, R statistics version 3.3.2.

## Results and Discussion

**Validation of $H_2S$ probe**

Data obtained by using the $H_2S$ probe (MS-AQUA) was cross checked with APHA 4500-$S^{2-}$F standard method. Experiments and analysis on different concentration of $H_2S$ standard solution was conducted to validate the corresponding measurement on the sensor. Results obtained from the probe were not significantly different (paired t-test, $p>0.05$) from those obtained by using APHA standard method and there is a correlation between the data values. (Pearson, $P < 0.05$, $R^2 = 0.9974$). Figure 3 shows the correlation of $H_2S$ concentration obtained by using probe and the standard method. Validation of the $H_2S$ probe is important because the probe is considered new in the market and there are only few reports on its efficiency in measurement. The probe is responsive towards $H_2S$ even it exceeded the measurement range recommended by the manufacturer although the last two points in the validation curve (Figure 3) starts showing deviation from the proportionality.

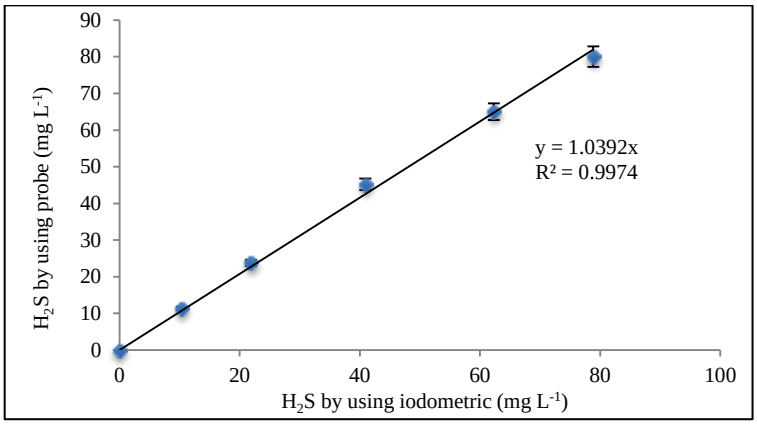

Figure 3. $H_2S$ Probe (MS-AQUA) measurement correlated with concentration determined by using APHA standard methods (4500-$S^{2-}$F and APHA 4500-$S^{2-}$H)

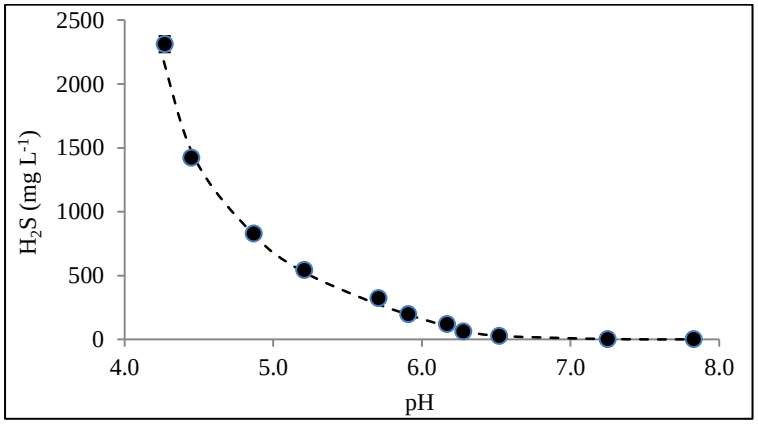
**$H_2S$ solubility and pH changes in seawater**

When $H_2S$ was continuously bubbled into the seawater, the seawater pH dropped from an initial value of pH 8.01 down to pH 4.27 as the $H_2S$ concentration was approaching 2312 mg $L^{-1}$ (Figure 4). At 28 °C, the concentration of $H_2S$ was saturated at about 2500 mg $L^{-1}$ in 30 ppt seawater in the experiments. It is anticipated that $H_2S$ would equilibrate and evolve into the vapor space at the saturation state. Hence, the $H_2S$ concentration used in this study was limited to 1500 mg $L^{-1}$ to reduce experimental errors and in terms of safety consideration.



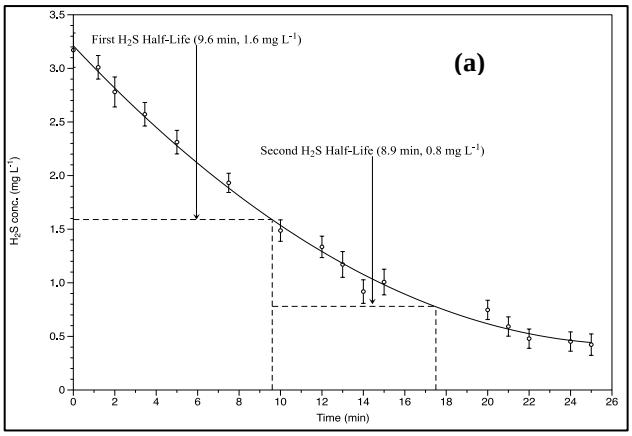


Figure 4. Effect of hydrogen sulfide concentration on seawater pH

**Hydrogen sulfide breakdown in seawater at different [DO]/[$H_2S$] ratio**

In the presence of excess dissolved oxygen in seawater, dissolved hydrogen sulfide ($H_2S$) is oxidized rapidly in the seawater. Figure 5 shows the $H_2S$ breakdown against time in seawater under aerobic condition. At an initial dissolved oxygen of 10.2 mg $O_2$ $L^{-1}$ (Figure 5a), the $H_2S$ decomposed from initial 3.2 mg $L^{-1}$ into half of its initial concentration at 1.6 mg $L^{-1}$ in about 10 minutes when the ratio of [DO/$H_2S$] is 3.4 (Figure 5a). The $H_2S$ concentration was further decomposed in the seawater. The subsequent half-life of the $H_2S$ concentration 1.6 to 0.79 mg $L^{-1}$ was about 9 minute. We repeated the experiment by introduced an initial concentration of 5.2 mg$L^{-1}$ $H_2S$ under a [DO/$H_2S$] ratio of 3.2 (Figure 5b) at an initial dissolved oxygen of 17.4 mg $O_2$ $L^{-1}$, after 10.6 minutes, the $H_2S$ concentration dropped to half of its initial concentration. The $H_2S$ concentration in this experiment further decomposed to 1.3 mg$L^{-1}$ after 10.4 minutes. In both experiments, the dissolved oxygen remained above 4 mg$L^{-1}$ at the end of the experiments. On average, $H_2S$ breakdown at 9.9 ± 0.8 minute in the seawater when dissolved oxygen is in excess. The $H_2S$ breakdown reaction appears to be a first order reaction, when the dissolved oxygen is not a limiting factor.

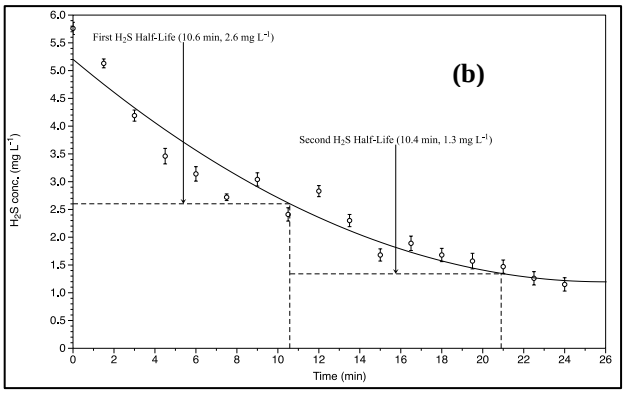

Figure 5. Hydrogen sulfide breakdown in the seawater at (a) initial dissolved oxygen of 10.2 mg $L^{-1}$, [$DO/H_2S$] ratio 3.4 (b) initial dissolved oxygen of 17.4 mg $L^{-1}$, [$DO/H_2S$] ratio 3.2

**Hydrogen sulfide breakdown in seawater at low [$DO/H_2S$] molarity ratio**

Under low [$DO/H_2S$] molarity ratio, as the hydrogen sulfide ($H_2S$) is oxidized, the concentration of DO in the seawater decreased in tandem with the decrease in $H_2S$ concentration. In this case, $H_2S$ breakdown no longer resemble a first order reaction due to the dissolved oxygen depletion in the seawater. The $H_2S$ breakdown is rather regulated by the availability of the dissolved oxygen. Figure 6 shows a typical $H_2S$ concentration decline as it is reacted with DO under a low [$DO/H_2S$] concentration ratio. The $H_2S$ half-life at initial conditions of the experiment was estimated based on equation (4) provided earlier. Further experiments were conducted at low [$DO/H_2S$] ratios to derive the correlations of $H_2S$ breakdown in seawater and determine the approximate $H_2S$ half-life under those conditions. The experiments were conducted such that the [$DO/H_2S$] molarity ratio range spanned from less than 0.1 to above 10. This would provide adequate evidence of any correlation between the concentration ratio and the dissociation half-life. Table 3 below provides the measured $H_2S$ half-life for various [$DO/H_2S$] ratio.

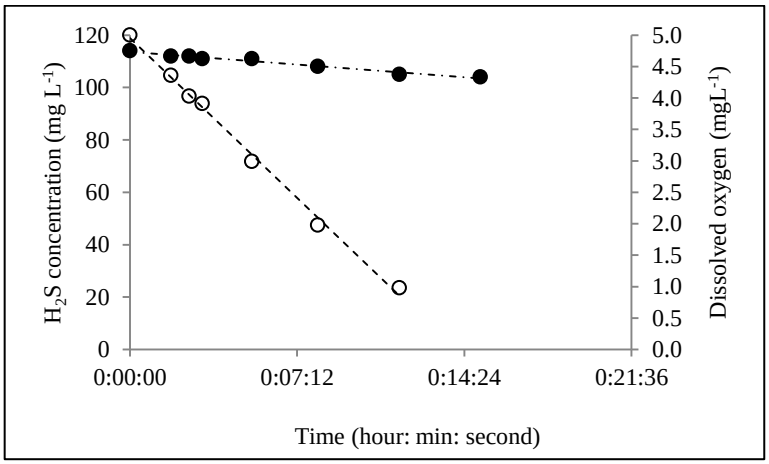

Figure 6. Typical hydrogen sulfide breakdown in seawater at low [$DO/H_2S$] concentration ratio [$H_2S$ initial concentration = 114 mg $L^{-1}$; DO initial concentration = 5 mg $L^{-1}$]. Open blank circle indicates dissolved oxygen while filled circle indicates concentration of hydrogen sulfide in seawater

Table 3. $H_2S$ Half-life at various [DO/$H_2S$] ratio

| [DO/$H_2S$] Ratio | $H_2S$ Initial Conc. (mg $L^{-1}$) | DO Initial Conc. (mg $L^{-1}$) | $H_2S$ Half-life (min) |
|---|---|---|---|
| 0.05 | 114.0 | 5.0 | 82.1 |
| 0.16 | 92.7 | 14.0 | 35.7 |
| 0.49 | 43.2 | 20.0 | 17.3 |
| 3.41 | 3.2 | 10.2 | 10.3 |
| 12.02 | 1.5 | 16.4 | 3.3 |

As can be seen from Table 3 and Figure 7, the $H_2S$ half-life versus [DO/$H_2S$] concentration ratio reveal a non-linear regression. The log transformed half-life and [DO/$H_2S$] ratio showed a significant regression ($P < 0.05$, $y = -0.54x + 1.16$, $R^2 = 0.9687$). Figure 7 shows the $H_2S$ half-life plotted against the molarity ratio of [DO/$H_2S$] in a log-log plot. The relationship between the [DO/$H_2S$] versus $H_2S$ half-life resembles an inverse relationship, where decomposition of $H_2S$ is very much dependent on the presence of dissolved oxygen in the seawater. Based on Figure 7, when [DO/$H_2S$] concentration ratio is lower than 0.07, the $H_2S$ half-life will extend beyond hour. When the [DO/$H_2S$] ratio is higher than 1.1, the $H_2S$ half-life will fall within 10 minutes.

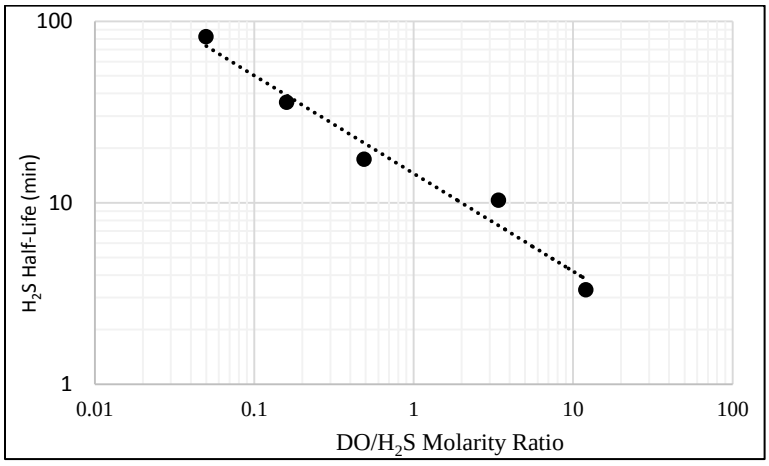

Figure 7. Hydrogen sulfide half-life versus the molarity ratio of [DO/$H_2S$] in a log-log plot

Table 4 shows a compilation of $H_2S$ half-life reported in various reports. The $H_2S$ half-life reported ranged from 17 minutes up to 55 days. Our current finding is consistent with the previous reports which reported that oxidation of $H_2S$ resembles a first order reaction in seawater when the dissolved oxygen is high and unlimited and becomes a second order reaction when dissolved oxygen is depleting [7, 8]. Nevertheless, both group of researchers reported that oxidation of $H_2S$ in seawater involved a series of complicated processes that are dependent on the composition and conditions of seawater. Different seawater conditions; which include physical, chemical and biological parameters is interacting and will influent $H_2S$ breakdown in the seawater.

Pos et al. [18] reported $H_2S$ in seawater subjects to photo-oxidation that had a half-life of 45 ± 15 minutes in Biscayne Bay water and 147 ± 15 minutes in the Gulf stream while Heitmann and Blodau [19] reported oxidation and incorporation of $H_2S$ by dissolved organic matter in seawater. Luther et al. [20] reported a complicated inorganic and biological mediated processes in the fate of $H_2S$ in the seawater environment. To the best of our survey, we have not encounter any comprehensive report that reveals the total interaction of physical, chemical and

biological factors into the $H_2S$ breakdown in seawater and the complicated interaction is probably the reasons that lead to various $H_2S$ half-life reported in the seawater.

## Conclusion

Hydrogen sulfide ($H_2S$) breakdown in seawater is highly dependent on the concentration of dissolved $H_2S$ and the concentration of dissolved oxygen (DO). The rate of $H_2S$ breakdown can be generally estimated based on the molarity ratio of [DO/$H_2S$]. At high [DO/$H_2S$] ratio (> 1), the $H_2S$ breakdown rate can be rapid, resulting in short half-life of $H_2S$ dissociation (within 10 minutes). Under this circumstance where the dissolved oxygen is not a limiting factor in the $H_2S$ oxidation, the breakdown rate appears as a first order reaction. However, when the ratio of [DO/$H_2S$] ratio is lower than 0.07, the breakdown rate became slower, resulting in longer half-life of $H_2S$ breakdown (more than an hour's). In this case, the breakdown rate displays a second order reaction form, which concurred with reports from other investigators. This study also investigated relation between the dissolved $H_2S$ content and pH changes in the seawater. The pH of seawater became lowered with increasing initial $H_2S$ concentration in the seawater. It reached an asymptotic low value of about 4 as the dissolved $H_2S$ content approaches its saturation limit in the seawater at about 2,500 mg $L^{-1}$.

# ANTI-PROLIFERATIVE EFFECT OF *Aerva javanica* EXTRACTS ON MCF7 AND MDA-MB-231 BREAST CANCER CELL LINES

## (Kesan Anti-proliferatif Ekstrak *Aerva Javanica* Ke Atas Titisan Sel Kanser Payudara MCF7 dan MDA-MB-231)

**Abstract**

In this study, the medicinal plant *Aerva javanica* was sequentially extracted with n-hexane, chloroform and 80% methanol using maceration technique. The anti-proliferative effect of the three extracts was assessed on two different breast cancer cell lines, MDA-MB-231 and MCF7, using MTT assay. 1, 1-diphenyl-2-picryl-hydrazyl (DPPH) scavenging activity assay was used to assess the antioxidant activity of the three extracts. The result showed that the chloroform extract exerted an inhibitory effect in a concentration dependent manner on both cancer cell lines with $IC_{50}$ values of 32.7 ± 0.7 µg/ml and 40.9 ± 2 µg/ml on MDA-MD-321 and MCF7 respectively. 80% methanol extract exhibited cytotoxic effect on MCF7 with $IC_{50}$ value of 96.6 ± 2.9 µg/ml, whereas had no cytotoxic effect on MDA-MB-231 cell line ($IC_{50}$ > 200 µg/ml). n-hexane extract found to be less cytotoxic against both cancer cell lines with $IC_{50}$ values of 178.3 ± 3.7 and 196.9 ± 2.8 µg/ml on MDA-MB-231 and MCF7, respectively. The highest $IC_{50}$ value for scavenging activity was shown by 80% methanol extract (46.5 ± 2.2 µg/ml) followed by chloroform extract (78.3 ± 3.6 µg/ml). On the other hand, the extract prepared in n-hexane showed no scavenging activity effect ($IC_{50}$ > 1000 µg/ml). *Aerva javanica* possesses moderate anti-proliferative activity against human breast cancer cell lines with some cytoselectivity towards MDA-MB-231 compare to MCF7 cells. Further studies are needed to identify the potential anticancer component (s) from *Aerva javanica*.

**Keywords**: MTT assay, *Aerva javanica*, MCF7, MDA-MB-231

**Abstrak**

Dalam kajian ini, tumbuhan ubatan *Aerva javanica* telah diekstrak secara berturutan dengan n-heksana, kloroform dan 80% metanol menggunakan teknik pemaseratan. Kesan anti-proliferatif daripada tiga ekstrak dinilai pada dua titisan sel kanser payudara yang berbeza iaitu MDA-MB-231 dan MCF7, menggunakan ujian MTT. Ujian aktiviti hapus sisa DPPH telah digunakan untuk menilai aktiviti antioksidan daripada tiga ekstrak. Keputusan menunjukkan bahawa ekstrak kloroform memberikan kesan perencatan bergantung kepekatan ke atas kedua-dua jenis sel kanser dengan nilai-nilai $IC_{50}$ 32.7 ± 0.7 µg/ml dan 40.9 ± 2 µg/ml pada MDA-MD-321 dan MCF7 masing-masing. Ekstrak 80% metanol menunjukkan kesan sitotoksik ke atas MCF7 dengan nilai $IC_{50}$ 96.6 ± 2.9 µg/ml, tetapi tidak memberikan kesan sitotoksik ke atas MDA-MB-231 ($IC_{50}$ > 200 µg/ml). Ekstrak n-heksana didapati kurang sitotoksik terhadap kedua-dua titisan sel kanser dengan nilai-nilai $IC_{50}$ 178.3 ± 3.7 dan 196.9 ± 2.8 µg/ml masing-masing ke atas MDA-MB-231 dan MCF7. Aktiviti hapus sisa yang tertinggi ditunjukkan oleh ekstrak 80% metanol ($IC_{50}$ 46.5 ± 2.2 µg/ml ) diikuti dengan ekstrak kloroform ($IC_{50}$ 78.3 ± 3.6 µg/ml). Berbeza dengan ekstrak n-heksana yang tidak menunjukkan kesan aktiviti hapus sisa ($IC_{50}$ > 1000 µg/ml). *Aerva javanica* mempunyai aktiviti anti-proliferatif

sederhana terhadap titisan sel kanser payudara manusia dan lebih selektif terhadap sel-sel MDA-MB-231 berbanding MCF7. Kajian lanjut diperlukan untuk nengenalpasti komponen yang berpotensi sebagai anti-kanser daripada *Aerva javanica*.

**Kata kunci**: Ujian MTT, *Aerva javanica*, MCF7, MDA-MB-23

## Introduction

Breast cancer is the most common type of cancer and the main cause of cancer death among women in both developed and developing countries. It accounts for 25% of all cancer diagnosed cases and 15% of all cancer female deaths [1]. New advances in research have produced medications for treating different stages of breast cancer. These chemically synthesized agents while being effective, often have some major side effects such as loss of appetite, muscle and joint pain, weakness, dizziness, vaginal bleeding, hair thinning and weight loss. The huge demand for herbal medicines is due to their wide biological activities, higher safety and lower costs [2]. Plants have shown an important role in the development of cancer therapy. Vincristine and vinblastine from *Catharanthus roseus* and paclitaxel from the bark of the Pacific yew tree, *Taxus brevifolia* are well known examples of plant-based anti-cancer drugs [3]. Investigating medicinal plants to explore traditional medicines could lead to the development of novel drugs.

*Aerva javanica* is a medicinal plant belongs to Amaranthaceae family [4]. It is a perennial herb extensively found in various regions of the tropical world. It is native to Africa, but can also be found in some Asian countries [5]. In Sudan, *A. javanica* plant or *Ras Elshaieb* as locally known has been used in traditional medicine in different parts of the country. In North Kordofan Province the plant is used for treating ulcers, wounds, abdominal pain and as anti-plasmodial. In the White Nile province, the plant is used against snake bites, breast cancer and rheumatism [6].

Phytochemical analysis studies of *A. javanica* revealed the presence of different important phytochemical constituents which include flavonoids, alkaloids, triterpenes anthraquinones, coumarins, diterpenes, triterpenes, sterol, saponins, carbohydrates, tannins and polyphenols [7, 8, 9].

In Sudan, *A. javanica,* is considered as an important traditional medicinal plant and has been used for treating various diseases, including cancer; however, its anti-cancer properties have not been investigated yet. The main objective of this study was to screen three *A. javanica* extracts for their cytotoxic effects on MCF7 (estrogen-receptor positive) and MDA-MB-231 (estrogen- receptor negative) breast cancer cell lines and to assess the antioxidant activities of the different extracts.

## Materials and Methods

### Reagents and chemicals

Dulbecco's modified eagle medium (DMEM), fetal bovine serum (FBS), penicillin/streptomycin and trypsin-EDTA were purchased from Gibco, USA. 3-(4,5-Dimethylthiazol-2-yl)- 2,5diphenyl tetrazolium bromide (MTT) reagent, phosphate buffered saline tablets, dimethyl sulfoxide (DMSO) and 1,1-diphenyl-2-picryl-hydrazyl (DPPH) were obtained from Sigma-Aldrich, Germany.

### Plant sample collection and identification

The whole plant of *Aerva javanica* was collected from Nile river banks, state of Khartoum, Sudan, in November 2015. The plant was authenticated by the plant taxonomist Yahya Suliman Mohamed and voucher specimen was deposited in the herbarium of Medicinal and Aromatic Plants Research Institute (MAPRI) – National Center for Research, Khartoum, Sudan.

### Plant extraction

The whole plant was dried under shade for two weeks and then was grounded to make a fine powder. Powdered whole plant (500 g) was macerated sequentially with n-hexane, chloroform and 80% methanol for 3 days at 50 °C. The ratio of raw material to solvent was 1:10. The extracts were filtered through Whatmann No. 1 filter paper and concentrated using rotary evaporator at 50 °C, and then all the extracts were put in oven at 50 °C until complete dryness. The stock solutions of the extract were prepared at 10 mg/ml and kept at 4 °C until use.

**Cell culture**
Human breast adenocarcinoma cell lines MCF7 and MDA-MB-231 were originally obtained from American Type Culture Collection (ATCC, Rockville, MD, USA). MCF7 and MDA-MB-231 cells were grown in DMEM supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin. All cell lines were incubated in a humidified incubator at 37 °C under an atmosphere containing 5% $CO_2$. The cells were sub cultured when nearly confluent using 0.25% trypsin-EDTA.

**Cell viability assay**
Cell viability and proliferation were assessed by MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyltetrazolium bromide) dye reduction assay. In brief, the cells were seeded in a 96-well plate ($3 \times 10^3$ cell/well for MCF7 and $5 \times 10^3$ cell/well for MDA-MB-231) and treated with different concentrations of the extracts (6.25 – 200 µg/ml) for 48 hours. MTT solution (5 mg/ml in PBS) was added (20 µl/well) and incubated for 3 hours. The formazan crystals formed by the viable cells were dissolved by adding 200 µl/well DMSO. Optical density was measured at 570 nm wavelength (reference filter 630 nm) using an ELISA plate reader (TECAN, sunrise). Cell survival rates were expressed as the percentage of untreated controls, and the 50% inhibitory concentrations ($IC_{50}$) of the extracts were calculated.

**1, 1-diphenyl-2-picryl-hydrazyl (DPPH) free radical analysis**
1,1-diphenyl-2-picrylhydrazyl (DPPH) assay was carried out to evaluate the scavenging activity of the extracts. The stock solution of DPPH was prepared at a concentration of 200 µM in absolute methanol while stock solutions of the extracts were prepared at a concentration of 10 mg/ml. 100 µl of DPPH was dispensed in 96-well plate and immediately, 100 µl of samples were added at final concentrations of 12.5, 25, 50, 100, 200 and 400 µg/ml. Ascorbic acid was used as positive control. Methanol alone and methanol with DPPH were used as blank and negative control, respectively. The mixtures were incubated for 30 minutes in the dark and then the absorbance was measured at 517 nm using TECAN microplate reader (Tecan sunrise). The dose response curves were obtained and then used to calculate the median inhibitory concentration ($IC_{50}$). The results were expressed as mean ± SEM (n = 6).

**Statistical analysis**
All of the cytotoxic and antioxidant experiments in the study were carried out for at least three times in triplicate and results were expressed as mean ± standard deviation (SD). One-way analysis of variance (ANOVA) and Dunnet's Multiple Comparison Test were used to assess $IC_{50}$ values and cytotoxicity data. $P < 0.05$ was considered as statistically significant.

## Results and Discussion

**Extraction**
Extraction efficiencies (% yield) of the three solvents, n-hexane, chloroform and 80% methanol showed significant differences ($P < 0.05$). The maximum extraction yield was shown by 80% methanol (2.8 %) followed by n-hexane (1.1 %) and chloroform (0.6%). Figure 1 shows the extraction yields of the different solvents.

**(4,5-dimethylthiazole-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) assay**
The three extracts exhibited variations in their cytotoxic effect on the two examined breast cancer cell lines with different $IC_{50}$ values. The chloroform extract showed the lowest $IC_{50}$ values of 32.7 ± 0.7 and 40.9 ± 2 µg/ml on MDA-MB-231 and MCF7, respectively. 80% methanol extract exhibited cytotoxic effect on MCF7 with $IC_{50}$ value of 96.6 ± 2.9 µg/ml, while had no cytotoxic effect on MDA-MB-231 cell line ($IC_{50}$ > 200 µg/ml). The n-hexane extract showed high $IC_{50}$ concentrations for both cancer cell lines (Table 1).

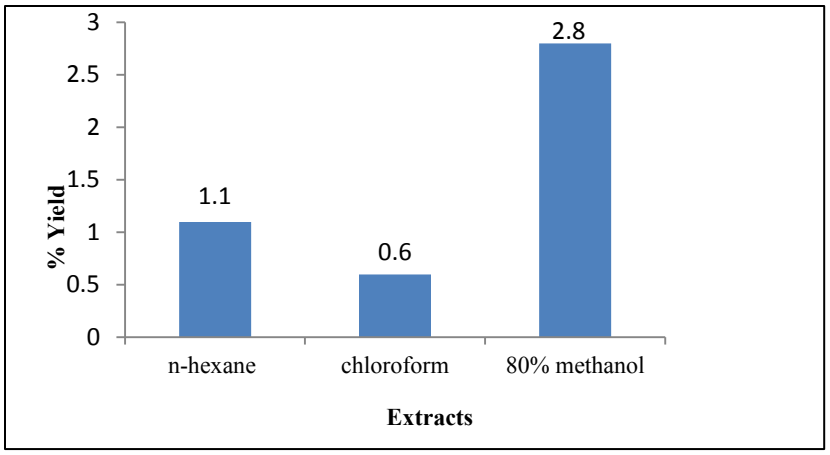

Figure 1. Extraction yields of *Aerva javanica* using the three different solvents

Table 1. $IC_{50}$ (µg/ml) values of the three extracts against the two cancer cell lines

| Extracts | IC $_{50}$ value (µg/ml) | |

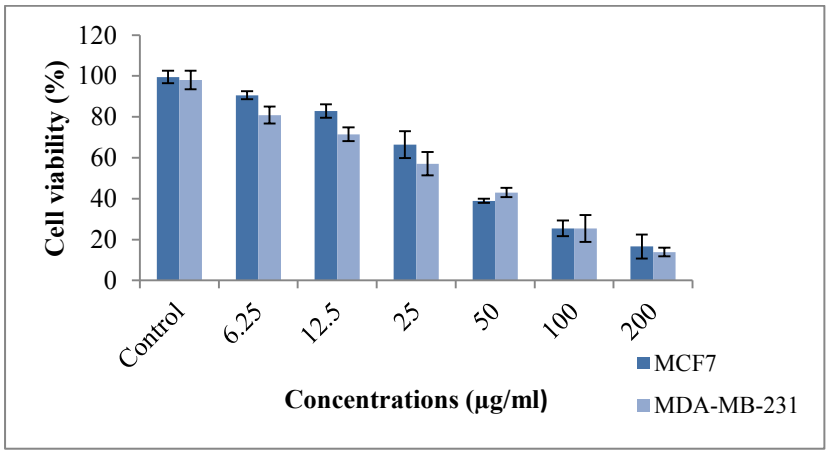
| | MCF7 | MDA-MB-231 |
| n-Hexane | 196.9 ± 2.8 | 178.3 ± 3.7 |
| Chloroform | 40.9 ± 2.3 | 32.7 ± 0.7 |
| 80% Methanol | 96.6 ± 2.9 | > 200 |

The results are presented as mean ± SEM. Each experiment was repeated three times; (n =3)

The chloroform extract exerted moderate cytotoxic activity in a concentration dependent manner on both cancer cell lines MDA-MB-231 and MCF7 cell line (Figure 2). Unexpectedly, the cytotoxic effect of the extract was more potent in the highly invasive breast cancer cell line; MDA-MB-231.



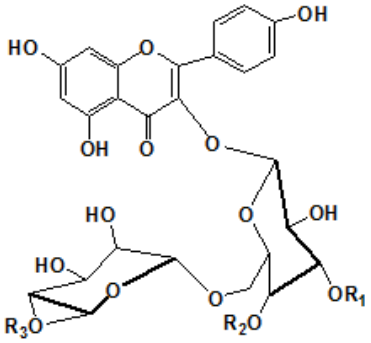


Figure 2. Effect of *A. javanica* chloroform extract on MDA-MB-231 and MCF7 cell viability. The cells were treated with different concentrations and DMSO as a control for 48 h and the cell viability was tested using MTT assay

The pharmacological effects of medicinal plants can be attributed to their main constituents such as alkaloids, flavonoids, coumarins, lignans, saponins and saccharides. Flavonoids are considered as an important phytochemical, with various anti-cancer activities. It has been reported that many flavonoids significantly decrease cancer cell viability via the upregulation of caspase activity [10]. The flavonols, kaempferols and kaempferol glycosides are found in a variety of plants and plant-derived foods [11, 12, 13]. Several reports have shown that kaempferol and/or some kaempferol glycosides induce cell death in a variety of cancer cells from different tissues, including human leukemia cell lines [14] and breast cancer cell lines [15 – 18]. Many flavonol glycosides have been isolated from *A. javanica* as major phytoconstituents [9].

Recently, three kaempferol glycosides have been isolated from *A. javanica* flowers, namely, kaempferol-3-O-b-D-[4000-E-p-coumaroyl-a-L-rhamnosyl(1→6)]-galactoside (1), kaempferol-3-O-b-D-[4000-E-p-coumaroyl-a-L-rhamnosyl(1→6)]-(300-E-p-coumaroyl)-galactoside (2), and kaempferol-3-O-b-D-[4000-E-p-coumaroyl-a-L-rhamnosyl(1→6)]-(400-E-p-coumaroyl)- galactoside (3) [19]. Figure 3 shows the structure of the three acylated flavonoid glycoside compounds isolated from *A. javanica*.

1: R1 = R2 = H, R3 = *E*-*p*-coumaroyl
2: R1 = *E*-*p*-coumaroyl, R2 = H, R3 = *E*-*p*-coumaroyl
3: R1 = H, R2 = R3 = *E*-*p*-coumaroyl

Figure 3. Structure of the three acylated flavonoid glycoside compounds isolated from *A. javanica*

Coumarins are an important medicinal phytochemicals present in different medicinal plants. Coumarins have a wide range of biological activities including anticancer properties [20]. Both natural and synthetic coumarins exhibited potent anticancer activity against various types of cancer, including breast cancer with low toxicity and good selectivity [20]. Figure 4 shows the coumarin structure. Previous study revealed the presence of coumarins in *A. javanica* chloroform fraction; however, no coumarin compounds have been isolated from the plant yet [8].

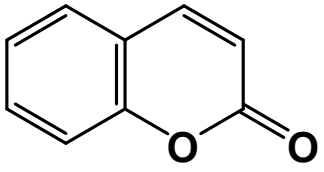

Figure 4. The structure of coumarin

The anti-proliferative effect exhibited by the chloroform extract in this study could be due to the presence of one or both of these important phytochemicals. Further studies are needed to identify the bioactive compounds that present in *A. javanica* chloroform extract and to elucidate the mechanism of action for these compounds. Our results showed that *A. javanica* chloroform extract was more cytotoxic to MDA-MB-231 than MCF7 cell line. The

differences in susceptibility of different tumor cell lines have been shown by several research groups [21, 22, 23]. The differential response of these two cancer cell lines could be due to the differences in their signaling pathway responsible for the cytotoxic effect [23]. It should be noted that the MDA-MB-231 cell line does not express the estrogen receptor [24] and the fact that the extract showed cytotoxic effect on this cell line indicates that estrogen-receptor signaling pathway is not required in its mode of action. This is very interesting since many conventional drugs that are used in the treatment of breast cancer, such as tamoxifen, raloxifene and toremifene require estrogen-receptor to exert their cytotoxic effect [25]. Furthermore, the response of estrogen-receptor negative subtype of breast cancer to conventional drugs is very poor [24, 26]. The possible molecular mechanisms underlying the differential responses of MCF-7 and MDA-MB-231 cells to the cytotoxic effects of *A. javanica* need to be further investigated.

**Antioxidant activity**

The results obtained from DPPH free radical scavenging activity assay in this study showed that the 80% methanol extract demonstrated the most potent antioxidant activity (46.5 ± 3 µg/ml) followed by chloroform extract (78.3 ± 4 µg/ml), whereas the extract prepared from n-hexane showed poor DPPH scavenging activity as the $IC_{50}$ value estimated to be more than 1000 µg/ml (Table 2).

Table 2. $IC_{50}$ values of the three extracts of *Aerva javanica* evaluated for DPPH scavenging activity

| Extract | DPPH ($IC_{50}$ µg/ml) |
|---|---|
| n-Hexane | > 1000 |
| Chloroform | 78.3 ± 3.6 |
| 80% Methanol | 46.5 ± 2.2 |
| Ascorbic acid | 3.3 ± 3.9 |

The 80% methanol extract contains significantly high free radical scavenging activity. Thus, it was found that free radical scavenging activity increased with the increase of the solvent polarity. This observation strongly supports previous results [27] as the methanol extract contains the highest amount of phenolic compounds. Phenolic compounds are known to be powerful antioxidants; they possess scavenging ability due to their hydroxyl groups [28]. So, in the present study, the antioxidant activity of the hydroalchoholic extract was possibly due to its high phenolic content.

## Conclusion

The result of the present study concludes that *Aerva javanica* shows moderate cytotoxic effect on two different breast cancer cell lines with some cytoselectivity towards MDA-MB-231 compare to MCF7 breast cancer cell line. The plant also exerts moderate free radical scavenging activity. Further studies are needed to identify the potential anticancer component(s) from this medicinal plant and to determine the mechanism(s) of action underlying its cytotoxicity.

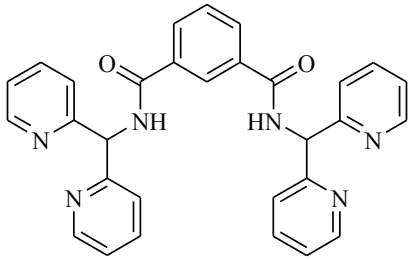
**Abstract**

Chelating ligands play a prominent role as organic linker in the construction of multinuclear complexes due to their strong binding to metal ions. Thus, in this study, two new bridging ligands with chelating arms, namely 1,3-*N,N'*-[bis(di(pyridin-2-yl)methyl)]isophthalamide (L1) and 1,4-*N,N'*-bis[(di(pyridin-2-yl)methyl)]terephthalamide (L2) were successfully synthesized and characterized using Fourier Transform Infrared (FTIR), $^{1}$H and $^{13}$C Nuclear Magnetic Resonances ($^{1}$H and $^{13}$C NMR) and X-ray crystallography. Reaction of L1 and L2 with metal salts gave two multinuclear cadmium complexes, with formula molecules $[\{CdCl_2(CH_3OH)(L1)CdCl_2\}_2]$ and $[(CdBr_2)_2(L_2)(CH_3OH)_2]$, respectively. X-ray crystallography reveals that ligands L1 and L2 used all four nitrogen donors from di-2-pyridylmethaneamine units to chelate with cadmium ions in forming stable multinuclear complexes. The complexes are also stabilized by supramolecular interactions such as hydrogen bonding and pi-pi stacking, as observed in the crystal packing.

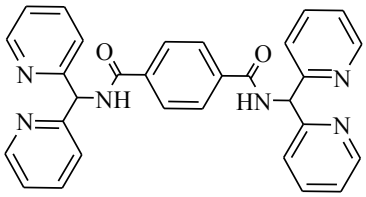
**Keywords**: crystal, chelating ligands, synthesis, pi stacking, supramolecular

**Abstrak**



Ligan pengkelat memainkan peranan penting sebagai penghubung organik dalam pembentukan kompleks multinuklear kerana ikatan yang kuat terhadap ion logam. Oleh itu, dalam kajian ini, dua ligan penghubung baharu yang mempunyai kumpulan pengkelat, iaitu 1,3-*N,N'*-[bis(di(piyridin-2-il)metil)]isoptalamida (L1) dan 1,4-*N,N'*-bis[(di(piridin-2-il)metil)]tereptalamida (L2) telah berjaya disintesis dan dicirikan menggunakan analisis Inframerah Transformasi Fourier (FTIR), $^{1}$H dan $^{13}$C Resonan Magnetik Nuklear ($^{1}$H dan $^{13}$C RMN) dan kristalografi sinar-X. Kajian kimia koordinatan ligan L1 dan L2 dengan garam logam menghasilkan dua kompleks multinuklear kadmium dengan formula molekul masing-masing adalah $[\{CdCl_2(CH_3OH)(L1)CdCl_2\}_2]$ dan $[(CdBr_2)_2(L_2)(CH_3OH)_2]$. Kajian hablur kristalografi sinar-X menunjukkan bahawa ligan L1 dan L2 menggunakan empat atom penderma nitrogen dari di-2-piridilmetanaamina unit untuk berikatan pada ion kadmium dalam menghasilkan kompleks multinuklear yang lebih stabil. Kompleks ini turut distabilkan oleh interaksi supramolekul seperti ikatan hidrogen dan interaksi pertindihan pi-pi sebagaimana yang dilihat dalam padatan hablur.

**Kata kunci:** hablur, ligan pengkelat, sintesis, pertindihan pi, supramolekular



## Introduction

The use of bridging ligands that have the capacity to chelate each metal centre bridged by the ligand is important to improve the stability of multinuclear complexes or enhance metal–metal interactions [1-4]. Steel and co-workers for instance, have reported many complexes derived from the bridging ligands containing di-2-pyridyl chelating motifs such as di-2-pyridylamine (dpa) based bridging heterocyclic ligands with silver(I), copper(II) and palladium(II) [2-5]. On reaction with silver salts, the ligands act as divergent bridging unit, with only two of the four pyridine rings involved in the coordination to form 1-D coordination polymers. Conversely, on reaction with copper(II) and palladium(II), the ligand uses all four nitrogen donors to coordinate with the metal centres and form stable discrete dinuclear complexes [5]. Along with this interest, significant efforts have been paid to generate bridging ligands with flexible di-2-pyridyl chelating moieties [6-9]. The additional spacer at di-2-pyridyl chelating moieties is important not only to confer flexibility but also to minimise the potential for hydrolysis that plagues other related compounds described in the literature [2,4,5]. Also, by using flexible bridging ligands, a diverse range of complexes and crystal packing can be obtained.

Di-2-pyridylmethaneamine (dpma), is the example of flexible chelating ligand that consists of methylene spacer between di-2-pyridyl rings and amine. (Figure 1). Dpma compound has been studied by Trilla and co-workers in 2006 and has shown potential as recyclable catalyst in Suzuki cross coupling reactions [10]. Before that, it was synthesized and the coordination chemistry with ruthenium salts was investigated by Chang et al. [11]. However, it was a little surprise to discover that this chelating compound is less explored particularly as bridging ligands unit, and the reason behind this little attention was not mentioned in any reports. Therefore, in line with our interest to expand the repertoire of bridging ligands containing flexible pyridyl moieties available for studies [12-13] and to explore their coordination chemistry of the type of ligands, we have produced another two new doubly bidentate bridging ligands with dpma units appended to isophthalamide (L1) and terephthalamide (L2) core, as shown in Figure 1.

L1

L2

Figure 1. The structure of two new doubly bidentate bridging ligands L1 and L2 described in this study

Basically, di-2-pyridylmethane chelating unit can coordinate to metal centres through three coordination modes, which are chelating, monodentate or bridging. Between the three modes, predominant coordination mode of the di-2-pyridyl motif is to chelate to particular metal centre through the two nitrogen donor atoms (Figure 2). Therefore, this study is carried out to further investigate the chelating potential of the bridging ligands and identify the chelating modes preferred by compounds L1 and L2, respectively.

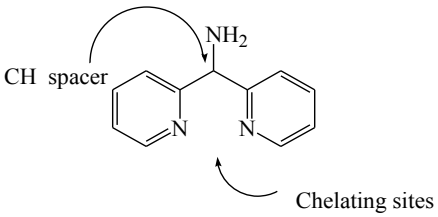


Figure 2. Molecular structure of di-2-pyridylmethaneamine (dpma) with CH spacer and metal ion chelating sites

## Materials and Methods

### Instrumentations

Elemental analyses were performed by the Campbell Microanalytical Laboratory at the University of Otago, Dunedin, New Zealand. Infrared spectra were collected on a Perkin Elmer Spectrum BX Infrared spectrometer as KBr disks. Nuclear Magnetic Resonances (NMR) spectra were recorded on Varian Gemini 300MHz NMR spectrometer at 23 ºC using a 5 mm probe. $^{1}$H NMR spectra recorded in deuterated chloroform ($CDCl_3$-$d_6$); $^{1}$H NMR spectra recorded in $CDCl_3$-$d_6$ which was referenced to the solvent peak: 7.24 ppm. $^{13}$C NMR spectra were all referenced to their solvent peaks: $CDCl_3$, 77.23 ppm. Electrospray (ES) mass spectra were recorded using a Finnigan LCQ mass spectrometer by preparing serial dilutions of a 1 mg/mL solution of the compound. Crystals were analyzed by single crystal X-ray crystallography using Oxford Diffraction X-calibur at 150(2) K.

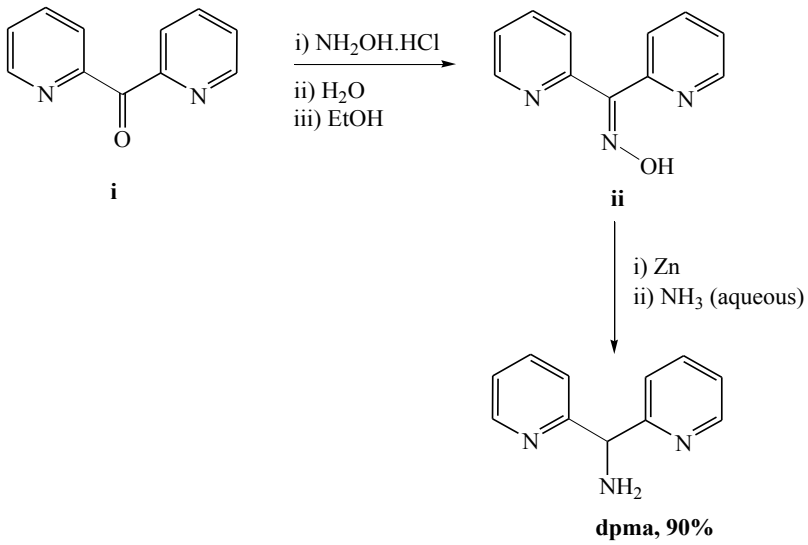
### Syntheses of the ligands: 1,3-*N,N'*-[bis(di-(pyridin-2-yl)methyl)]isophthalamide (L1)

Isophthaloyl chloride (0.55 g, 2.8 mmol) was dissolved in dichloromethane (40 mL). Then, di-(2-pyridyl)methylamine (1.01 g, 5.5 mmol) and triethylamine (0.76 mL, 5.5 mmol) were added to the solution and heated at reflux for 72 hours. The solvent was removed in vacuo to give a brown solid which was collected, washed with diethyl ether, dried and recrystallized from ethanol to give **L1** as a light brown solid (0.90 g, 63%).

### 1,4-*N,N'*-bis[(di(pyridin-2-yl)methyl)]terephthalamide(L2)

Terephthaloyl chloride (0.30 g, 1.5 mmol) was dissolved in dichloromethane (40 mL). Then, di-(2-pyridyl)methylamine (0.55 g, 3.0 mmol) and triethylamine (0.41 mL, 3.0 mmol) were added to the solution and heated at reflux for 72 hours. The solvent was removed in vacuo to give a brown solid of **L2**. The solid was washed with diethyl ether, dried and recrystallized from ethanol to give **L2** as a fine brown solid (0.43 g, 57%).

### Syntheses of the cadmium complexes: [{$CdCl_2(CH_3OH)(L1)CdCl_2$}$_2$]



A solution of $CdCl_2$ (0.037 g, 0.20 mmol) was dissolved in methanol (5 mL), heated for 20 minutes, before being added dropwise to a solution of L1 (0.051 g, 0.10 mmol) which was dissolved in methanol (10 mL). The colourless solution was further heated for 45 minutes before being left to evaporate at room temperature. After three weeks, the solution afforded [{$CdCl_2(CH_3OH)(L1)CdCl_2$}$_2$] as colourless crystals in low yield (0.015 g, 16%).

### [$(CdBr_2)_2(L_2)(CH_3OH)_2$]

A solution of $CdBr_2$ (0.0195 g, 0.072 mmol) was dissolved in water (5 mL), heated for 20 minutes, before being added dropwise to a solution of L2 (0.0180 g, 0.036 mmol) in methanol-acetonitrile (15 mL). The colourless solution was heated for 45 minutes and left to evaporate at room temperature. After a week, the solution afforded [$(CdBr_2)_2(L2)(CH_3OH)_2$] as colourless crystals in good yield (0.012 g, 75%).

## Results and Discussion

Di-2-pyridylmethaneamine (dpma) was synthesized by using reductive amination methods which requires two steps of reactions as described in the literature procedures [14]. In the first step of the method, di-2-pyridyl ketone (i) was treated with hydroxylamine to produce di-2-pyridyl ketone oxime (ii) and reduced by zinc powder in aqueous ammonia to give di-2-pyridylmethaneamine (dpma) in 90% yield (Scheme 1).

Scheme 1. Synthesis of dpma from di-2-pyridyl ketone

After the dpma compound was obtained, it was further reacted with isopthalolyl chloride and terephthaloyl chloride in dry dichloromethane to give two new doubly bidentate bridging ligands, namely 1,3-*N,N'*-[bis(di(pyridin-2-yl)methyl)]isophthalamide (L1) and 1,4-*N,N'*-bis[(di(pyridin-2-yl)methyl)]terephthalamide (L2), respectively. The products were subjected for elemental analysis and the results obtained (Table 1) show good agreement between theoretical and experimental data of L1 and L2, as proposed earlier in Figure 1.

Table 1. Elemental analysis data for compounds L1 and L2

| Compounds | C(%) | | H(%) | | N(%) | |
|---|---|---|---|---|---|---|
| | Calcd. | Found | Calcd. | Found | Calcd. | Found |
| L1 | 71.98 | 70.13 | 4.83 | 4.98 | 16.79 | 15.63 |
| L2 | 71.98 | 71.83 | 4.83 | 4.08 | 16.79 | 16.05 |

In the IR spectra of the ligands, strong absorbance bands which were indicated at 1650 – 1652 $cm^{-1}$ were assigned to C=O stretching of the amide moieties. Strong bands of NH stretches which were observed at range 3211 – 3217 $cm^{-1}$ confirmed the formation of amide coupling that generate the respective bridging ligands. In similar to the IR spectra, the $^{1}H$ NMR of compound L1 and L2 also showed all resonances that were consistent with the expected 2-fold symmetric disubstituted compound. The NH peaks were observed at range 8.87 – 8.96 ppm, respectively. The difference in chemical shift in either IR and NMR spectra of L1 and L2 was due to the different conformations of the amides about the 1,3 and 1,4-phenyl cores. This different was also reported in our previous study using terephathaloyl and isophthaloyl based moieties [13]. The electrospray mass spectrum showed peaks at m/z 501.1 and 522.4, which corresponded to $[L1+H]^+$ and $[L1+Na]^+$. Meanwhile, a peak at m/z 501.2 which corresponding to $[L2+H]^+$ and $[L2+Na]^+$ was observed at m/z 523.2 in a low relative abundance.

In order to determine the molecular structure of the ligands, compounds L1 and L2 were dissolved in hot ethanol and left to evaporate at room temperature. Crystals of L2 were obtained in two weeks and subjected for X-ray crystallography while L1 remain as brown powder. Compound L2 crystallizes in the triclinic space group *P*-1, with one molecule of ligand L2 in the asymmetric unit. The phenyl core is planar, although the amide groups are twisted

slightly out of the plane of the ring (torsion angles 119.60 and 117.05°). The two di-2-pyridyl units are further twisted relative to the phenyl, as shown in Figure 3.

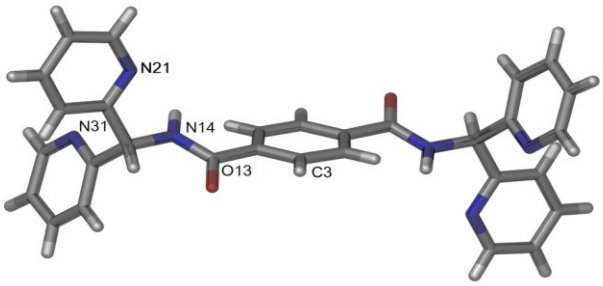


Figure 3. The perspective view of the asymmetric unit of L2

As observed in the crystal structure, the two pyridyl rings are not co-planar. The rings are arranged in *trans* conformations which brought the nitrogen atoms from the two pyridyl rings closer. This conformation has been observed in a crystal structure of a related chelating ligand, namely 1,2-bis(di-pyridylaminomethyl)benzene [2]. The packing of L2 is stabilized by supramolecular interaction (C-H···π) between the hydrogen atom from the phenyl ring and the pendant pyridine with H-centroid distance of 2.788 Å (Figure 4). This distance is closed to other edge-on C-H···π interaction distances reported for other compounds [15].

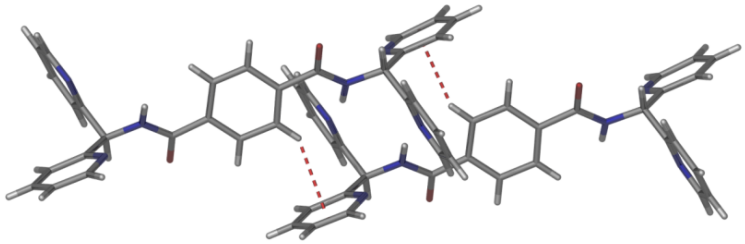

Figure 4. The extended view of compound L2 with a C-H···π interaction showing by dashed line

To further understand the types of structures and coordination chemistry of L1 and L2, these ligands were reacted with a range of metal salts to provide variety geometries and coordination numbers for the metal component. Reaction with selected metal salts such as copper, cobalt, palladium and zinc chloride produced only oils or oily solids that were not further characterized or could not be crystallized. Further attempts at these reactions using different ratios (1:1 and 1:2 metal-to-ligand ratios) and different solvent mixtures generally failed to give cleanly isolatable products. Fortunately, reaction of L1 and L2 with cadmium chloride and cadmium bromide gave products in crystals form, highly suitable for X-ray crystallography.

**X-ray crystallography of cadmium complexes**

Complex of L1, with formula molecule $[\{CdCl_2(CH_3OH)(L1)CdCl_2\}_2]$ crystallizes in the triclinic space group *P*-1, with one molecule of L1, two cadmium atoms, four coordinated chloride anions and one coordinated methanol molecule in the asymmetric unit (Figure 5). The Cd-N bond lengths are in the range 2.318(5) - 2.371(5)Å which are similar to many previous literature studies [15-20]. This complex has two cadmium atoms with trigonal bipyramidal geometries, although the cadmium atoms have quite different donor sets. Cd(1) is coordinated by two nitrogen atoms from the pendant pyridyl rings of L1, two chloride atoms (one bridging and one monodentate), while the second cadmium atom Cd(2) is coordinated by two nitrogen atoms from the pyridyl rings of L1, two chloride atoms and one methanol molecule. In similar manner to related ligands, [17] ligand L1 uses all four nitrogen donors to

coordinate with the cadmium atoms. The distance between Cd1-Cd2 is 6.40 Å, while the distance between the two cadmium atoms bridged by the chloride anions is much shorter at 3.68 Å. The coordination mode of L1 in this complex has quite a different motif compared with complexes incorporating other ligands based on a 1,3-phenyl core, such as 1,3-bis(di-2-pyridylaminomethyl)benzene [2]. In previous work, reaction of this ligand with silver nitrate gave discrete [1+1] metallo-macrocycle complex, while reaction with silver perchlorate and silver hexafluorophosphate gave 1-D coordination polymers [17]. The previous study revealed that ligand 1,3-bis(di-2-pyridylaminomethyl)benzene acted as a divergent bridging unit, with only two of the four pyridine rings involved in the coordination to form the complexes.

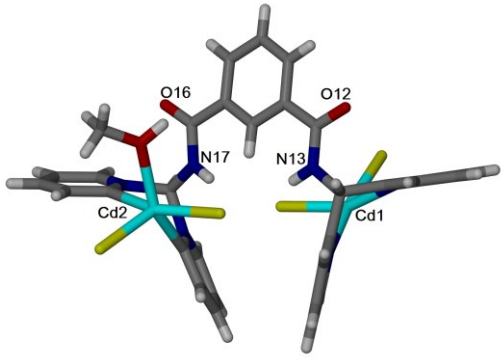

Figure 5. A perspective view of the asymmetric unit of complex [{$CdCl_2(CH_3OH)(L1)CdCl_2$}$_2$]

The extended view of complex L1 shows that the bridging chloride atoms connect the two dinuclear units to form a dimer as shown in Figure 6.

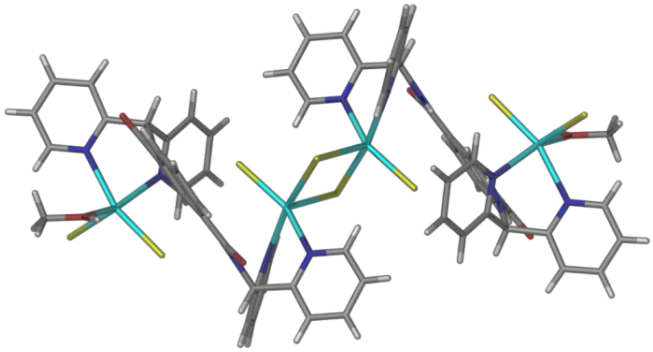

Figure 6. An exended view of complex [{$CdCl_2(CH_3OH)(L1)CdCl_2$}$_2$]

Complex with L2 was obtained in 75% yield by slow evaporation of a methanol-acetonitrile solution containing L2 and cadmium bromide. Single, rectangular, block-shaped crystals of complex L2 were separated from the clump and subjected to single crystal X-ray crystallography. The structure obtained by X-ray crystallography reveals the formation of a dinuclear complex, [$(CdBr_2)_2(L2)(CH_3OH)_2$]. In contrasts to the complex above, this complex crystallizes in the monoclinic space group, $P2_1/c$ with half a molecule of L2, one cadmium atom, two coordinated bromide anions and one coordinated methanol in the asymmetric unit (Figure 7). In this structure, the ligand acts as a tetradentate bridge to link two cadmium atoms and form a discrete dinuclear complex with a 2:1 metal to ligand ratio. The cadmium atom has distorted trigonal bipyramid geometry with one of the chelating pyridyl and one coordinated methanol donor occupying the axial positions. The monodentate pyridine donors twist back towards the core of the ligands in the similar manner to that observed in the dinuclear complexes described earlier. The Cd-N

distances are between 2.3119(19) – 2.365(9)Å, typical for such entities. By contrast to complexes of L1, the chelating rings in this complex is twisted by ca. 63.3° from the plane of the central phenyl core, which is approximately three times greater than the torsion angles observed in previous complexes reported by us [17]. Due to the para substitution of the central arene core, complex of L2 have a considerably longer Cd-Cd distance (12.261 Å) than those observed in complex of L1. In the crystal structure, it was seen that the discrete complexes were connected to each other by intermolecular hydrogen bonding interactions between the oxygen of the carbonyl group and the coordinated methanol solvent ($d$ = 1.903Å) to form 1-dimensional hydrogen bond chains (Figure 8). The crystallographic data for the three crystals compounds described in this study is listed in Table 2 for reference.

## Conclusion

The synthesis and coordination chemistry of doubly bidentate bridging ligands with dpma units have been successfully explored. It was confirmed from this study that ligands L1 and L2 used all four nitrogen donor atoms from dpma chelating units to bind with the cadmium ions, and forming stable multinuclear complexes. Like other ligands incorporating two di-2-pyridylmethyl chelating motifs, ligands L1 and L2 readily bridge two metals with bidentate chelation at each metal centre. The work described in this paper could be further expanded by finding conditions to limit hydrolysis of the ligands upon reaction with other metal salts, as from this study, only cadmium complexes can be isolated.

# PREPARATION OF DATE SEED ACTIVATION FOR SURFACTANT RECOVERY

## (Penyediaan Biji Kurma Teraktif Untuk Pemulihan Surfaktan)

**Abstract**

Surfactants also known as surface-active agents are one of the water pollutants that can lead to the deterioration of the environment. In this study, activated carbon was prepared from date seeds (DAC) by using phosphoric acid as an activating agent. The activation process was carried out at 500 °C for two hours. DAC was characterized by Fourier-Transformed Infrared Spectrometer (FTIR), Field Emission Scanning Electron Microscopy (FESEM), Energy-Dispersive X-Ray Spectroscopy (EDX) and Nitrogen Adsorption at 77 K. The BET surface area of DAC was 1187 $m^2/g$. The adsorption capacities of surfactants (CTAB and TX-100) were determined. This study showed that the adsorption capacity of CTAB (23.0724 mg/g) onto DAC was greater than TX-100 (11.3868 mg/g). The adsorption process between both surfactants onto DAC was done by physisorption through electrostatic forces. Thus, this study showed that the date seeds have a greater tendency to be microporous activated carbon and an adsorbent for surfactants recovery.

**Keywords**: activated carbon, phosphoric acid, date seed

**Abstrak**

Bahan aktif permukaan juga dikenali sebagai surfaktan adalah salah satu bahan pencemar air yang boleh membawa kepada kemerosotan alam sekitar. Dalam kajian ini, karbon teraktif telah disediakan daripada biji kurma (DAC) dengan menggunakan asid fosforik sebagai ejen pengaktifan. Proses pengaktifan telah dilakukan pada suhu 500 °C selama dua jam. Karbon teraktif (DAC) telah dicirikan oleh Spektroskopi Inframerah Transformasi Fourier (FTIR), Mikroskopi Medan Pancaran Imbasan Elektron (FESEM), Sebaran Tenaga Sinar-X (EDX) dan penjerapan gas nitrogen pada suhu 77 K. Luas permukaan BET kawasan DAC adalah 1187 $m^2/g$. Kapasiti penjerapan surfaktan (CTAB dan TX-100) telah dikaji. Kajian ini menunjukkan bahawa kapasiti penjerapan CTAB (23.0724 mg/g) pada DAC adalah lebih tinggi daripada TX-100 (11.3868 mg/g). Proses penjerapan antara bagi kedua-dua surfaktan DAC adalah secara penjerapan fizikal melalui daya elektrostatik. Oleh itu, kajian ini menunjukkan bahawa biji kurma mempunyai kecenderungan yang lebih besar sebagai karbon teraktif berliang mikro dan bahan penjerap yang baik untuk pemulihan surfaktan.

**Kata kunci:** karbon teraktif, asid fosforik, biji kurma

## Introduction

The deterioration of environment in the process of economic growth has started to give impact on mankind. Lack of knowledge to deal with pollution and incapability of the natural environment to decompose unnatural generated element have made the occurrence of pollution inevitable. One of the environmental pollutions that needs to be

made aware of is water pollution which happens because of human activities such as raw sewage discharge [1]. Raw sewage is wastewater that comes from residential areas, industries, and agricultural processes. It contains a wide variety of contaminants and can be hazardous to human and animal if untreated.

Surface-active agent or also known as surfactant is one of the common water pollutants that comes from the production of detergents, fabric softeners, emulsifiers, paints, and adhesive. It is discharged to the sewer system upon application [2]. About 50 % of surfactants consumption comes from detergents and cleaners. Another source of surfactants contamination comes from surfactants dispersants for fuel oil spillages. These surfactants are resistant to bio-degradation by bacteria and have a toxic effect upon breakdown [3]. Synthetic surfactants also do not biodegrade sufficiently in the treatment plant, even when they are left for a long time [4]. Hence, the amount of surfactants must be reduced to an acceptable level before being discharged into the body of water.

Currently, there are a few techniques to remove surfactant from wastewater, which include biosorption [5], biodegradation [3], oxidation [6], adsorption [7], ultra-filtration, and ion-exchange [8]. Among these techniques, the adsorption method is easy to implement and low in cost while some of the adsorbents can be reused. Activated carbon is one of the efficient adsorbents that can be used in the adsorption method because it has a large specific surface area and pH-independent capacity with strong carbon–surfactant interaction. The combination of a large specific surface area and pH-independent means that activated carbon has a large adsorption capacity in order to remove the surfactants, which make it as effective adsorbents in removing surfactants from wastewater [9].

Activated carbons are carbonaceous materials characterized by their extraordinary large specific surface areas and well-developed porosity [10]. However, the commercial activated carbons are quite costly to purchase as they use high cost precursors such as petroleum residue, wood, coal, peat, and lignite that are non-renewable [11]. Hence, other sources of activated carbon such as from agricultural by-product were studied. By using agricultural by-product, the reliance on raw materials and cost can be reduced [12]. In recent years, there is a growing research interest in the agriculture by-product that is chosen based on price, purity, potential extent of its activation and also stability of its supply such as corncob [13], rice husk [14], olive seed [15], sugarcane bagasse [16] and date seeds [17].

Date seeds are one of the lignocellulosic materials from agriculture by-products that come from the date fruit which is mostly grown in the Middle East Asia, North African, and North American desert regions [18]. Dates are composed of fleshy pericarp and seed are mostly used in the food industries to manufacture various products such as date powders, syrup, and juice, chocolate coated dates and date confectionery [19]. Upon consumption or usage for the manufacturing process, the seeds are removed from the date fruit. Hence, there is an availability to use the date stones as raw materials to produce activated carbon [20] as Malaysia has increased the number of imported dates from 7.339 to 17.756 metric tonnes from 2005 to 2015 [21].

Thus, in this study, date seeds were choose as the raw material to prepare activated carbon based on the stated criteria for surfactants recovery.

## Materials and Methods

### Materials

Date seeds were used as the raw material. The chemicals used in this study are 85% ortho-phosphoric acid ($H_3PO_4$), cetyltrimethylammonium bromide (CTAB), TritonX-100 (TX100), deionised water, sodium hydroxide (NaOH) and distilled water.

### Preparation of activated carbon

The date seeds were collected by purchasing one box of dates from the market. The date pericarps were removed to obtain the seeds used as the raw material. An amount of about 100.00 g of date seeds were then washed thoroughly with tap water and dried under the sunlight. Next, the date seeds were soaked with 250 mL of 30% aqueous solution phosphoric acid for 24 hours to give acidic conditions to the seeds (pre-treated process). Then, the date seeds were washed with distilled water and dried under room temperature [22].

After that, the pre-treated date seeds were impregnated with 85% of concentrated phosphoric acid with the ratio of 2:1 (200 mL of phosphoric acid : 100 g of date seed). Next, the mixtures were heated by using a hot plate in a temperature range between 70 °C to 90 °C for 4 hours or until they appeared to be apparently semi-dried in the fume cupboard. The drying procedure was continued in the oven for 24 hours with the temperature at 110 °C [22].

Then, the activation process was modified based on a previous study where the samples were carried out in the muffle furnace at 500 °C for two hours [17]. Lastly, the activated carbon samples were washed with distilled water and tested with the pH meter until it was neutral. Finally, the prepared activated carbon were kept in the desiccator and used for characterization and adsorption studies [22]. The prepared activated carbons were named as date activated carbon (DAC).

**Characterization of activated carbon**

DAC was characterized by FTIR (Perkin Elmer model FTIR spectrum 100) to determine the fundamental vibrations bands at mid infrared region (4000 – 400 $cm^{-1}$). The Field Emission Scanning Electron Microscope with Energy Dispersive X-ray (FESEM-EDX) Spectroscopy (Hitachi SU8020) was used to examine the surface morphology and confirm the elements present in DAC. Meanwhile, multiple point nitrogen adsorptions analysis (BET) was used to determine the surface area of DAC.

**Adsorption capacity of activated carbon**

Cationic and non-ionic surfactants which are cetyltrimethylammonium bromide (CTAB) and TritonX-100 (TX100) were used to study the adsorption capacity onto DAC. Deionized water was used for making up the solution. About 0.5 g of DAC was weighed in 50 mL conical flasks, and then each surfactants solution was pipetted into the conical flasks, which were wrapped with parafilm and placed into an electronic bath shaker. The shaker was set at a constant speed of 100 rpm for 2 hours. After that, the mixture was filtered and 10 mL of the filtrates were diluted into a 50 mL volumetric flask and filled up with deionized water [22]. The solutions were analysed with T80+ UV/Visible Spectrometer instrument. The concentration of CTAB was determined by measuring the UV absorbance at $\lambda_{max}$ 193 nm while the concentration of TX100 at $\lambda_{max}$ 223 nm.

## Results and Discussion

**Percent yield of DAC**

The product yield of the DAC from 100 g of raw date seeds were calculated using Equation 1 as follows:

$$Yield\ \% = \frac{W_2}{W_1} \times 100 \quad (1)$$

where $W_1$ is the initial weight of date seeds (100 g) and $W_2$ is the final weight of date seeds after activation and carbonization. The percent yield of the DAC in this study was 47.12%. The result of percentage yield may be affected by the impregnation ratio and activation temperature used in the preparation steps [23]. In keeping with Prahas et al., the impregnation ratio is a crucial parameter that affects the quality of the carbon. The presence of excess phosphoric acid in the impregnation process promoted gasification of char and increased the total weight loss of carbon [24]. The presence of phosphoric acid was supported by the FTIR and EDX analyses.

**Characterization of DAC: Fourier transfrom infrared spectroscopy**

The adsorption frequency of the raw date seeds and DAC was studied using FTIR spectrometer instrument. The spectra obtained in this study are shown in Figure 1. The functional groups present in the raw date seeds and DAC spectrum listed in Table 1.

From the raw date seed spectrum, it shows that there was a broad hydroxyl group (O-H) peak at 3375.25 $cm^{-1}$ which may result from the water molecules, because date seeds contains hemicellulose and cellulose in their fiber. However, the hydroxyl peak disappeared at DAC spectrum due to loss of water moisture when the date seeds were carbonised. There was also the presence of alkanes group (C-H) peak stretch at 2924.91 $cm^{-1}$ and 2851.92 $cm^{-1}$. This indicated the presence of carbon and hydrogen in the date seeds. The adsorption band present at 1746.77 $cm^{-1}$ was the carbonyl group (C=O), which stretch showed the presence of oxygen. Lastly, the presence of adsoption present

peak at 1647.97 $cm^{-1}$ corresponded to the C=C double bond stretching that showed alkenes or aromatic group compound also present in the date seeds.

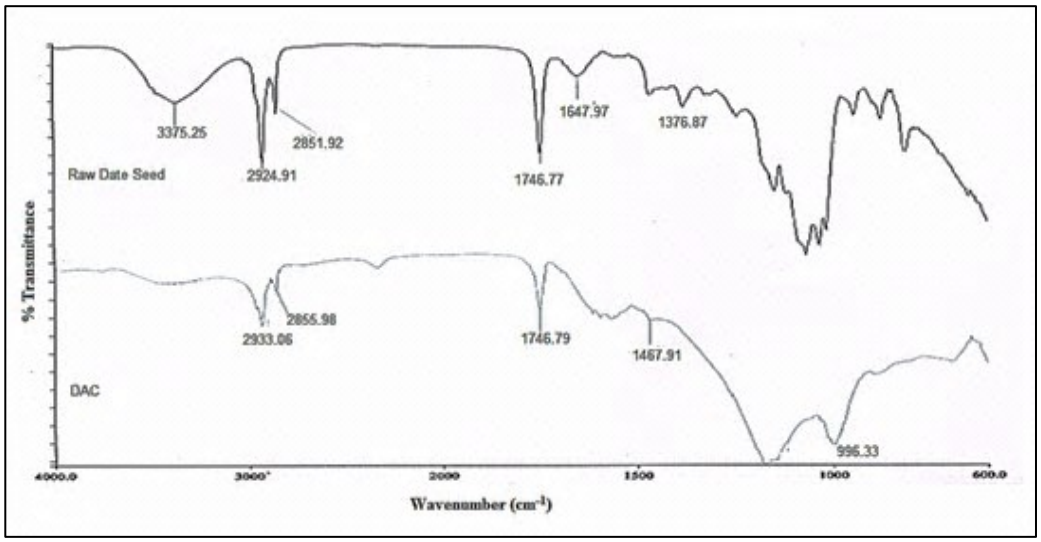

Figure 1. FTIR spectrum of raw date seed and DAC

Table 1. Functional group present in raw date seeds and DAC spectrum

| Sample | Functional Group | Wavenumber ($cm^{-1}$) |
|---|---|---|
| Raw Date Seed | O-H streching | 3375.25 |
| | C-H streching | 2924.91, 2851.92 |
| | C=O streching | 1746.77 |
| | C=C streching | 1647.97 |
| DAC | C-H streching | 2933.06, 2855.98 |
| | C=O streching | 1746.79 |
| | P-O-C streching | 1467.91, 996.33 |

The functional group of DAC showed the presence of alkanes group (C-H) stretching absorption bands at 2933.06 $cm^{-1}$ and 2855.98 $cm^{-1}$, respectively. The presence of carbonyl group (C=O) peak can be also seen in DAC at absorption band 1749.13 $cm^{-1}$. Besides, bands at 1467.91 $cm^{-1}$ and 996.33 $cm^{-1}$ indicated the stretching of carbon bonded to P-O groups of phosphates [24]. The P-O functional group was present due to the use of phosphoric acid in the preparation process of activated carbon.

From the FTIR results, it is shown that the appearance and disappearance of functional groups in the raw date seeds and DAC happened due to the carbonization and impregnation process that took place at the high temperature of 500 °C [24].

**Field emission scanning electron microscope**

In this study, the surface morphology of the DAC was obtained from Field emission scanning electron microscope (FESEM). The micrographs of DAC sample with magnifications 1.00Kx and 1.50Kx are shown in Figures 2(a) and 2(b), respectively. From both micrographs, the pores of DAC were shown homogenously distributed and well

developed on the external surface. The pores are seen to be uniformly developed in the mixture of oval and circle patterns. This was due to the activation process which involved the used of phosphoric acid as an activating agent, which helped to create more pores in the activated carbon and thus increased the surface area and pores volume. These were proven by the nitrogen gas adsorption results where the surface area of DAC was 1187 $m^2/g$, which was higher compared to 682 $m^2/g$ activated carbon from date stem activated with pure steam at 450 °C [17]. Other than that, the micrographs also observe the presence of white particles inside some of the pores and scattered over the surface which are the ash [22].

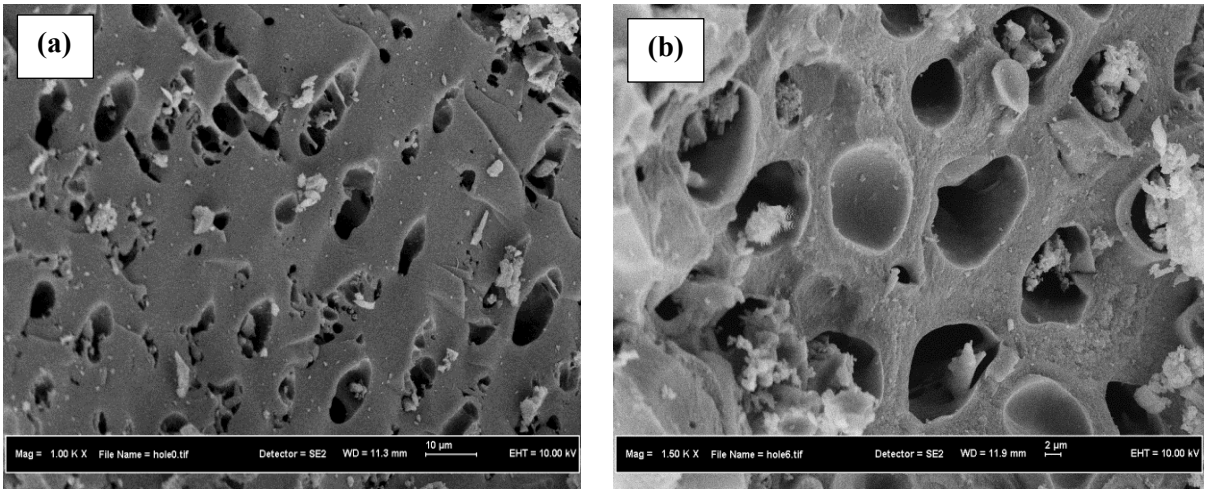

Figure 2. (a) DAC with magnification 1.00Kx and (b) DAC with magnification 1.50Kx

**Energy dispersive X-ray spectroscopy**

In this study, Energy dispersive X-ray (EDX) was used to determine the surface composition of the DAC. The spectrum obtained from EDX is shown in Figure 3 and element percentage is summarised in Table 2. From Table 2, the presence of 79.78% carbon (C), 13.10% oxygen (O), and 7.12% phosphorus (P) on the surface of the DAC can be seen. The high percentage of carbon indicated that the volatile organic compounds in the date seeds were reduced and resulted in char containing a higher content of fixed carbon [11]. Phosphorus element was present on the DAC due to the activating agent used in this study which was phosphoric acid. This indicated that phosphorus compounds were strongly bound to the oxygen and carbon and therefore not easily removed by washing, either with the cold or hot distilled water [17].

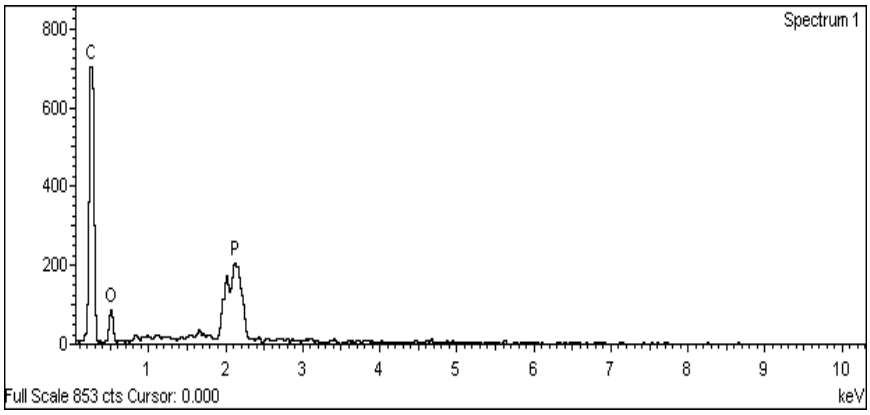

Figure 3. EDX spectrum for DAC

Table 2. Composition of elements presence on the DAC surface

| Element | Weight Percentage (%) | |
|---|---|---|
| | Weight | Atomic |
| Carbon | 79.78 | 86.37 |
| Oxygen | 13.10 | 10.64 |

**Nitrogen gas adsorption analysis**

The solid-gas adsorption study was determined using BET surface area model and adsorption isotherm. The BET surface area ($S_{BET}$) was carried out by using nitgogen gas analysis at 77 K. The results are shown in Table 3.

Table 3. The specific surface area, average pores diameter and total pores volume of DAC

| Sample | Specific surface area, $S_{BET}$ ($m^2/g$) | Total pores volume, $V$ ($cm^3/g$) | Average pores diameter, $d$ (Å) |
|---|---|---|---|
| DAC | 1187 | 0.482 | 16.21 |

From the results, the $S_{BET}$ of the DAC activated by $H_3PO_4$ was high which was 1187.6844 $m^2/g$ compared to the date seeds that used other activation agents such as ferric chloride (780 $m^2/g$) [25] and calcium acetate (702 $m^2/g$) [26]. This indicated that $H_3PO_4$ was a good activating and dehydrating agent as the process of dehydrating the raw material helped in the development of the higher surface area by penetrating deep into the raw material. The total pores volume of the DAC was 0.482 $cm^3/g$ with the average pores diameter of 16.21 Å, indicating that micropores were present ($d$ < 20 Å) [27].

The adsorption isotherm result for DAC is shown in Figure 4. From the results, it is shown that the physisorption isotherm was Type I isotherm, also known as Langmuir isotherm according to IUPAC classification [27]. The isotherm showed that the adsorption was reversible and the amount of gas adsorbed was approaching the limiting value as $P/P_o \rightarrow 1$. This indicated that the DAC consisted of micropores with a micropores filling mechanism.

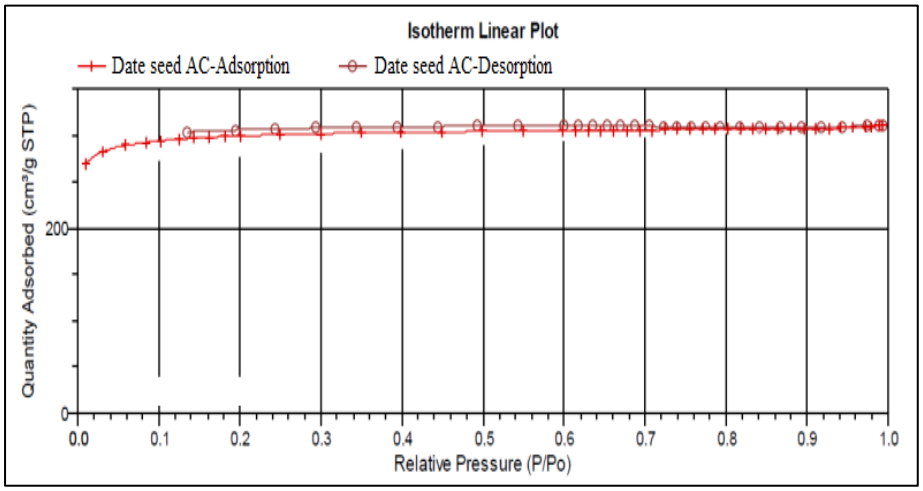

Figure 4. Adsorption isotherm of DAC

Based on the pores size distribution graph (Figure 5), DAC sample also had macropores represented by a small shoulder peak in between pore width of 50 Å to 60 Å [27]. This result can be explained by the activation process where the phosphoric acid used can enhance and produce relatively large pores [28]. It was revealed that DAC exhibited a well-developed porous network structure which contained macropores. This porosity is an advantage for DAC where large sized pores will act as feeder during the adsorption process [17].

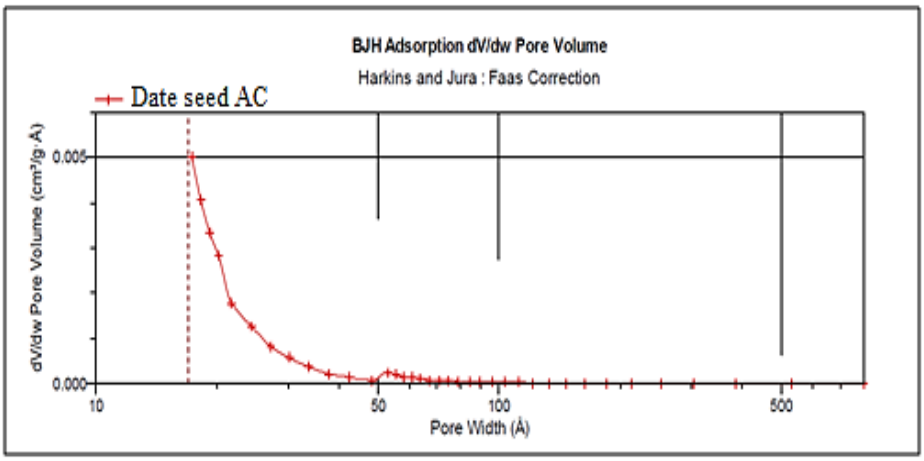

Figure 5. Pores size distribution plot of DAC

**Adsorption capacity of activated carbon**

In this adsorption study, two types of surfactants were used, namely CTAB and TX-100. Both adsorptions were performed at room temperature (28°C). The adsorption capacities of DAC for both surfactants are shown in Table 4.

Table 4. Adsorption capacity of CTAB and TX-100 onto DAC

| Type of surfactants | Adsorption capacity, $q_e$ (*x/m*) | Adsorption's percentage (%) |
|---|---|---|
| CTAB | 23.0724 mg $g^{-1}$ | 92.33 |
| TX-100 | 11.3868 mg $g^{-1}$ | 95.63 |

From the results, it is shown that CTAB adsorption capacity was higher (23.0724 mg $g^{-1}$) compared to TX-100 (11.3868 mg $g^{-1}$). The difference in the adsorption capacity could be due to the charge of the surfactants. CTAB carried positively charged hydrophilic part which could be easily attracted and adsorbed to the surface of negatively DAC. The DAC was supported by the EDX result which consisted of phosphorus element that carried the $P^{3-}$ charge from phosphoric acid, $H_3PO_4$. This phenomenon explained that CTAB molecules formed a monolayer coverage on DAC surface at equilibrium through the van der Waal's forces (electrostatic forces) [29]. Nevertheless, the low adsorption capacity of TX-100 was because it is a non-ionic surfactant that not carry any charged on the hydrophilic part. Thus, TX-100 is difficult to adsorb on a charged surface. However, in order to increase the adsorption of TX-100 onto the surface, it needs enough energy adsorption force such as increasing the temperature to overcome the strong interaction of water molecules with DAC surface [30].

## Conclusion

According to all the data obtained, date seeds could be a good precursor in order to prepare an activated carbon. The preparation of DAC by using the high concentration of phosphoric acid (85%) with the ratio 2:1 as the chemical activating agent at low activation and carbonization temperature (500 °C) contributed a well-developed porosity.

Apart from that, DAC showed a high surface area from this method of preparation. Thus, these characteristics directly enhanced the adsorption process of surfactants onto DAC, especially for CTAB due to the electrostatic force. Therefore, activated carbon prepared from date seeds (DAC) has shown its availability to be a good adsorbent in surfactant recovery.

**Abstract**

The presence of microplastics (<1 mm) in wild and cage-cultured Asian sea bass (*Lates calcarifer*) was successfully studied. Fish samples were collected from Setiu Wetlands in October 2016. Microplastics were isolated from fish samples using the alkaline solution method (10 M of NaOH solution). Microplastics were sorted visually according to their shapes and colours after being observed under dissecting microscope. A total of 4,498 pieces of microplastics were identified and threadlike shape was the most abundant microplastic particles found during this study. The identification of functional groups in the composition of microplastics was achieved using Fourier transform infrared (FTIR) spectroscopy. Microplastics, with the presence of strong peaks at $\upsilon$=3342 $cm^{-1}$ (N-H str), 1510 $cm^{-1}$ (N-H bend) and $\upsilon$=1706 $cm^{-1}$ (C=O str) are associated with the materials consist of polyamide. Additionally, peaks related to the polyvinyl alcohol groups are recorded at $\upsilon$= 3321 – 4323 $cm^{-1}$ (O-H str), 1706 $cm^{-1}$ (C=O str), 1219 $cm^{-1}$ (O-H wag) and $\upsilon$=1028 – 1128 $cm^{-1}$ (C-O str). The abundance levels of microplastics ingested by wild and cage-cultured fishes are statistically significantly different, $p < 0.05$.

**Keywords:** Asian sea bass, fish ingestion, microplastics, polymer, wetland environment

**Abstrak**

Kemunculan plastik-mikro (<1 mm) di dalam ikan siakap liar dan sangkar ternakan (*Lates calcarifer*) telah berjaya dikaji. Sampel ikan diambil dari tanah bencah Setiu semasa bulan Oktober 2016. Plastik-mikro telah diasingkan daripada sampel ikan mengunakan kaedah larutan beralkali (10 M larutan NaOH). Plastik-mikro telah diasingkan secara visual dibawah mikroskop mengikut perbezaan warna dan bentuk. Sejumlah 4,498 pecahan plastik-mikro telah dikenalpasti dan bentuk benang merupakan partikel yang paling kerap dijumpai semasa kajian ini dijalankan. Pengenalpastian kumpulan berfungsi bagi komposisi plastik-mikro telah dicapai menggunakan spektroskopi FTIR. Analisis plastik-mikro menunjukkan kehadiran puncak yang jelas pada $\upsilon$=3342 $cm^{-1}$ (N-H str), 1510 $cm^{-1}$ (N-H bend) dan $\upsilon$=1706 $cm^{-1}$ (C=O str) bagi komposisi polimer kumpulan poliamida. Tambahan, puncak yang menunjukan kehadiran kumpulan polivinil alkohol dicatatkan pada $\upsilon$= 3321 – 4323 $cm^{-1}$ (O-H str), 1706 $cm^{-1}$ (C=O str), 1219 $cm^{-1}$ (O-H wag) dan $\upsilon$=1028 – 1128 $cm^{-1}$ (C-O str). Aras kehadiran plastik-mikro yang dihadam oleh ikan liar dan sangkar ternakan adalah berbeza secara signifikan, $p < 0.05$.

**Kata kunci:** ikan siakap, penghadaman oleh ikan, plastik-mikro, polimer, persekitaran tanah bencah

## Introduction

Microplastics are generally defined as plastics with size less than 1 mm in diameter [1], which makes much easier for them to be displaced into biota. Despite no possibility of danger regarding microplastics and marine organisms recorded at this stage, there is a great concern about the potential risks that microplastics may pose to organisms via

ingestion, which is then transferred to food chain and ultimately poses risks to human health. Studies over the past decades have shown that microplastics are widespread in the marine environment including sea surface, shoreline or sea bed, and their abundance has increased annually.

Microplastics could have both physical and chemical effects on the organisms that ingest the pollutant. If ingested, microplastics may pass through the gut or retained in the digestive tract [2]. Fibres may knot or clump and it could be hazardous if the passage of food is blocked. The accumulation of debris in the digestive tract leads to the difficulty in breathing as some plastic particles could choke the organism. According to Ivar do Sul et al. [3], microplastics accumulation occurred through the food web, from the smallest organisms like plankton to the largest fish.

In fact, small-sized microplastics have a great potential to be ingested by a wide range of marine organisms including fish. A great variety of fish species across the world have been proven to ingest synthetic polymers. For instance, a total of 35% of five mesopelagic and one epipelagic fish species from the North Pacific were found to have ingested plastics with an average of 2.1 pieces of plastic per fish [4]. Meanwhile, three different species of bottom-feeding catfish were investigated in a Brazilian estuary and as a result, 17 – 33% of the sampled fishes had ingested plastics [5]. Lusher et al. [6] in their work found that ten fish species from the English Channel had ingested microplastics (both pelagic and demersal species), with a total of 37% of the sample studied was affected.

Foekema et al. [7] found that only 2.6% of the fish from the North Sea contained microplastics, but this was after excluding textile fibres from their data analysis. Of the seven-species investigated, five of the subjects studied contained plastics. Atlantic cod (*Gadus morhua*) was one of the species studied and the abundance levels varied depending on the location, in which 0 – 15% of the individuals contained microplastics. A recent study carried out by Rummel et al. [8] also found relatively low plastic content in fish (both pelagic and demersal species) from the North Sea and the Baltic Sea, where 5.5% of all fishes were affected by this pollutant. To date, no study has cited the comparison of microplastic particles between two fishes derived from different habitat locations.

In Malaysia, the research exploration related to the issue of microplastics is still limited. To the best of our knowledge, there are several studies documenting the occurrence of microplastic in mangrove sediment [9], sandy beaches [10], and bivalves [11]. Indeed, there have been no studies documenting the ingestion of microplastics among estuarine fishes of Malaysia.

*Lates calcarifer* or commonly known as the Asian sea bass in Malaysia is a commercial fish found in great abundance along the estuary of Setiu Wetlands, Terengganu. They are found in both open environment and cage-cultured by the local fishermen. This area has nine distinctive ecosystems namely beach, sea, mudflat, river, lagoon, estuary, island, coastal forest, and mangroves. Thus, Setiu Wetlands is the only wetland in Malaysia that can be found with a great diversity of ecosystems [12]. The presence of microplastic particles in the lower trophic level organisms such as bivalves has been proven in our previous work [11] and the abundance levels are remarkably high in this area. Thusly, this extended work conveys the ubiquity of microplastics in the upper trophic level in order to understand the translocation, which could further be found in human body.

Therefore, the main goal of this study is to evaluate the abundance levels of microplastics ingested by estuarine fish with different life habits (wild and cage-cultured). Physical and chemical characterisations were carried out to identify the main shape and colour of microplastics, polymer composition, and their relationship towards spatial variation.

## Materials and Methods

### Sample collection

Cage-cultured and wild *L. calcarifer* (n = 4) were caught from Setiu Wetlands in October 2016. Each location was coordinated and illustrated as shown in Table 1 and Figure 1, respectively. Wild *L. calcarifer* was collected using a drift net (100 m length × 2 m width) located at Stations 3 and 4, where the net was left overnight. Meanwhile, cage-cultured *L. calcarifer* was purchased from a local fisherman at the aquaculture site. The weight of each sample was

set in the range of 300 – 400 g regardless of their habitual area. The samples were kept in a cool box filled with ice cubes before the samples were transferred to the laboratory for further analysis.

Table 1. The coordinate of sampling location in Setiu Wetlands

| Station | Latitude (N) | Longitude (E) |
|---|---|---|
| 1 (Cage Cultured) | 05° 37'10.34 | 102° 47'31.51 |
| 2 (Cage Cultured) | 05° 39'03.80 | 102° 44'55.32 |
| 3 (Wild) | 05° 41'30.77 | 102° 41'54.98 |
| 4 (Wild) | 05° 43'21.08 | 102° 47'31.51 |

**Sample preparation**

In the laboratory, the fish samples were thawed at room temperature and general biological parameters such as length (cm) and weight (g) were measured. The gastrointestinal tract for each sample was removed by dissection as described in previous works reported by Lusher et al. [6] and Rocha-Santos and Duarte [13]. In general, each sample was cut from the top of the oesophagus through the end of the gastrointestinal tract, which was then digested and stored individually in a 250-mL glass jar containing 80% ethanol solution until further identification. Plastic materials were not used throughout this study as it would cause cross contamination and generate bias in the final result.

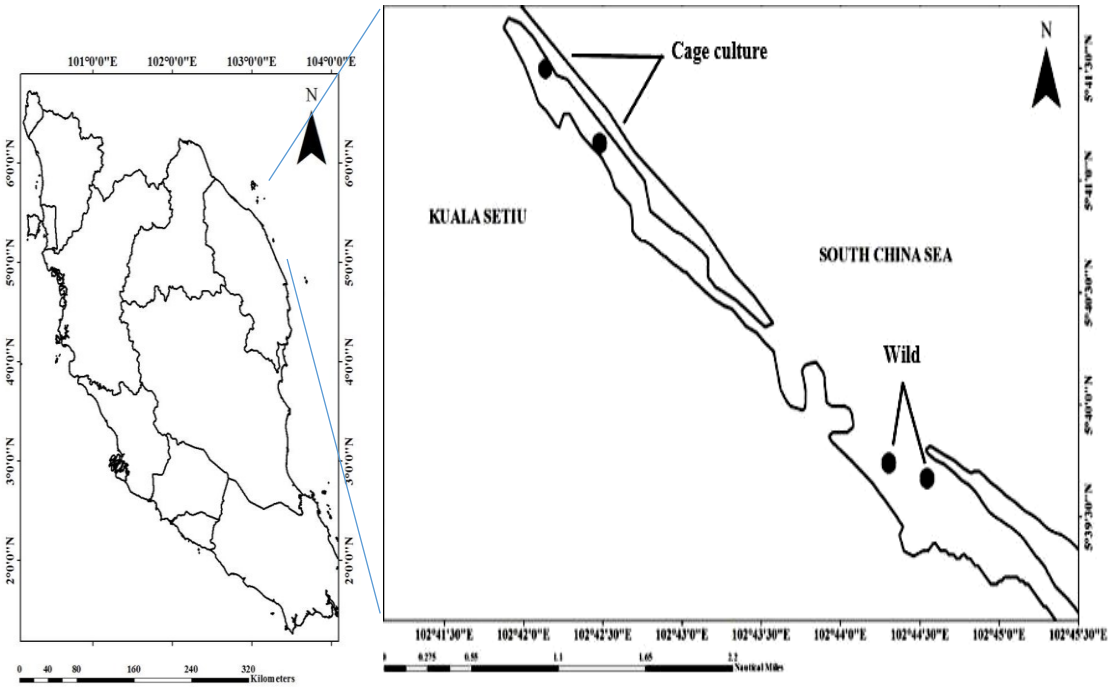

Figure 1. Location of sampling activity in Setiu Wetlands (on left side is map of Peninsular Malaysia)

**Digestion procedure**

The samples were digested using the alkaline method as described by Cole et al. [14] in their work. An amount of 10 M of sodium hydroxide (NaOH) was chosen as the digestion solution and introduced into the beaker containing the gastrointestinal tract. Later, the 50 – 60 g digested samples were placed in a water bath with the temperature set at 60 °C and shaken constantly (130 rpm) during the incubation period in order to speed up the digestion process. The digestion steps were carried out in triplicate. After 21 days, the digestion solution was filtered and analysed using a stereoscopic microscope (Leica ZOOM 2000, Cole-Palmer, IL, USA) to observe the presence of microplastic materials.

**Microplastic sorting and identification**

The sorted microplastics were photographed and the maximum length, colour, and shape (threadlike, fragment or spherical) were noted using a dissecting microscope (Olympus SZX7, Olympus Corp. Tokyo, Japan). Particles which presented the characteristic features of synthetic polymers were identified as microplastics (mouldable items with consistent thickness and colour which do not break when pressed with stainless forceps). In case of doubt, a hot metal tip was applied on the object. The collected microplastics were kept in individual glass urine bottles pertaining to its original shape. Centrifugation process was carried out to enhance the separation of the microplastic particles from the supernatant before further analysis.

Fourier transform infrared spectroscopy (FTIR) (IR Tracer-100, Perkin Elmer, MA, USA) was used to identify the functional groups associated with polymer chemical properties. Microplastic particles were analysed using attenuated total reflection (ATR) in the mid-IR range of 4000 – 650 $cm^{-1}$ and 18 scans per analysis. One-way ANOVA was performed to evaluate the significant level of microplastic abundance among location and shape types. Differences at $p < 0.05$ were considered statistically significant. Statistical analyses (one-way ANOVA) and Pearson correlation were conducted using SPSS statistical package Version 23.0.

## Results and Discussion

**Microplastic abundance**

The microplastic size collected in this study was recorded between 4.3 and 15.7 µm with an average length of 50.1 µm. The total number of microplastics found in all samples was 4,498. The highest abundance of microplastics was found in the gastrointestinal tract of wild *L. calcarifer* containing 1,260 and 1,277 of digested and microplastic particles, respectively. Meanwhile, the lowest level of ingestion was recorded in cage-cultured fish samples, with a total of 1,961 microplastic fragments in both samples. The microplastic abundance observed between wild and cage-cultured *L. calcarifer* was statistically significant at $p < 0.05$. Most of the microplastics found had threadlike shape with distinctive colours (i.e. black, blue, red, green, purple, orange or colourless).

Figure 2 and Figure 3 show the shape and colour distribution of the microplastic particles isolated from the gastrointestinal tracts of *L. calcarifer* during this study, respectively. Black threadlike shape was the most abundant microplastic particle found in both cage-cultured and wild *L. calcarifer* at different sampling locations, followed by transparent and blue threadlike shapes. The image of microplastic captured under dissecting microscope is presented in Figure 4. Statistical analysis also elucidated that the microplastic abundance based on the colour observed was significantly different between sample type and station at $p < 0.05$.

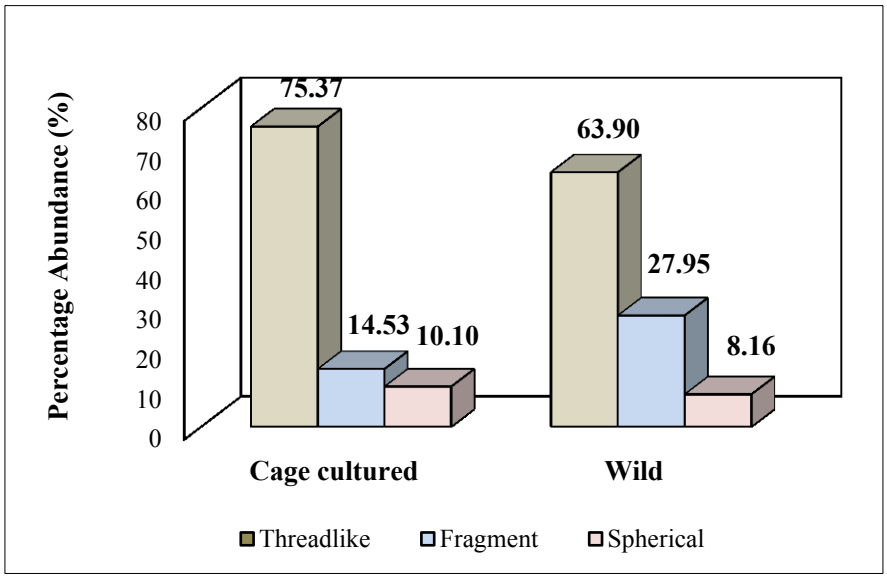

Figure 2. Percentage abundance (%) of microplastic based on shapes between cage cultured and wild *L. calcarifer* from Setiu Wetlands

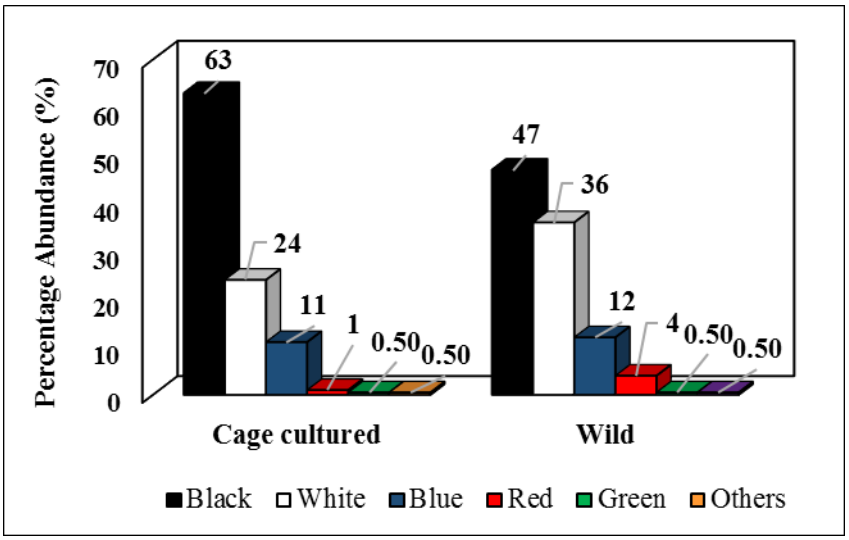

Figure 3. Percentage abundance (%) of microplastic based on colours between cage cultured and wild *L. calcarifer* from Setiu Wetlands

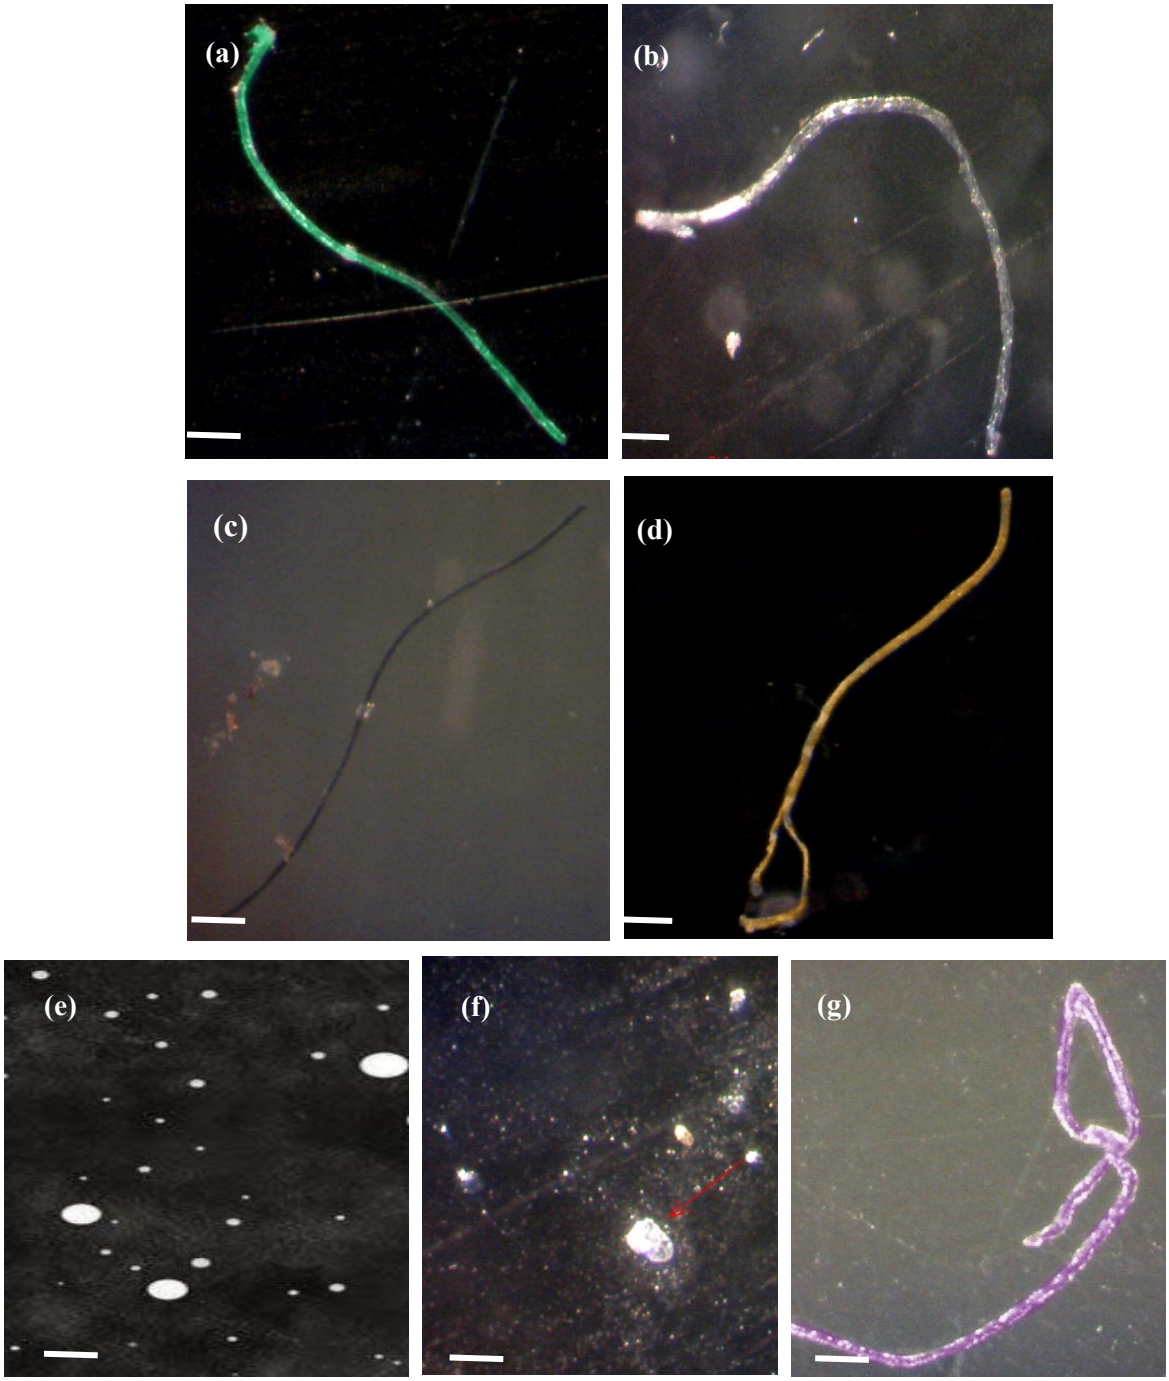

Figure 4. The shapes and colours of microplastic found in cage cultured and wild *L. calcarifer* a) green threadlike b) transparent threadlike, c) black threadlike, d) orange threadlike, e) white spherical, f) white fragment, and g) purple threadlike. Scale bars: 0.1 mm

**Characterisation of microplastics**

The FTIR spectra associated to microplastics are shown in Figure 5 and Figure 6. The collected microplastic particles identified by FTIR spectroscopy analysis proposed that the microplastics found in both wild and cage-cultured *L. calcarifer* were mostly polyamide (PA) (Figure 5) and polyvinyl alcohol (PVA) (Figure 6). In Figure 5, the functional group associated towards microplastic composition shows a strong peak at 3342 $cm^{-1}$ for N-H stretching vibrations from the terminal amine group. Additionally, the N-H bending shows the vibration at ν=1510 $cm^{-1}$. The absorption band at ν=2852 $cm^{-1}$ may be attributed to C-H aliphatic stretching modes, with the band at ν=1428 $cm^{-1}$ matches with the bending of C-$H_2$ vibrations, showing the existence of alkyl chains in the collected microplastics. These findings are in agreement with the previous works reported by Charles et al. [15] and Pavia et al. [16] to elucidate the composition of nylon (polyamide). The band at ν=1706 $cm^{-1}$ corresponds to the C=O carbonyl stretching group vibration, which implies a small part of swaying vibration in the microplastic sample obtained.

The FTIR spectra of PVA carrying all major peaks related to hydroxyl and acetate groups were observed during this study (Figure 6), and similar to the pure PVA spectra recorded by Mansur et al. [17] and Nicodom [18] in their research. The bands observed at ν=3321 – 3423 $cm^{-1}$ are linked to the stretching of O–H from the intermolecular and intramolecular hydrogen bonds, which is suggested due to the high hydrophilic forces among PVA polymeric chains [19]. The vibrational band observed at ν=2840 – 3000 $cm^{-1}$ refers to the stretching of C–H from alkyl groups. Moreover, the arrangement of carbonyl, C=O, which can be distributed randomly along the alkyl chain demonstrated by the bands showed around ν=1706 $cm^{-1}$, is due to the stretching of C=O from the acetate group remaining from PVA [20]. This overlaps with the O-H bending peak [17]. The peaks between ν=1174 and 1219 $cm^{-1}$ show the C-$H_2$ wagging and C-O carboxyl stretching at ν=1028–1128 $cm^{-1}$ vibration absorptions. Thus, it indicates the amorphous and crystalline nature of PVA [17, 20]. PVA is usually amorphous, albeit can be found as a semicrystalline structure for some products. Therefore, this band has been used previously as an indicator for PVA structure as semicrystalline synthetic polymer [17, 21].

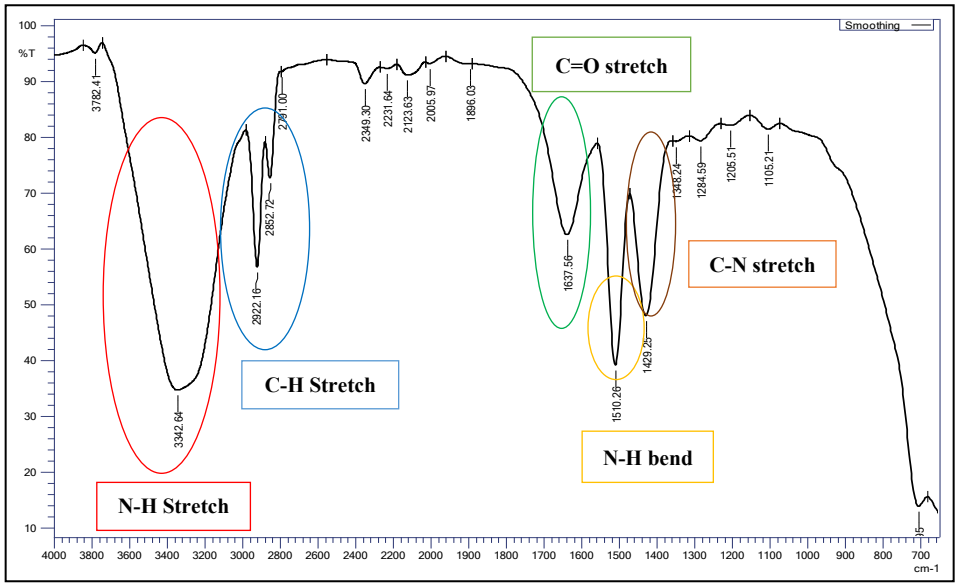

Figure 5. FT-IR spectrum showing the functional group associated to polyamide composition

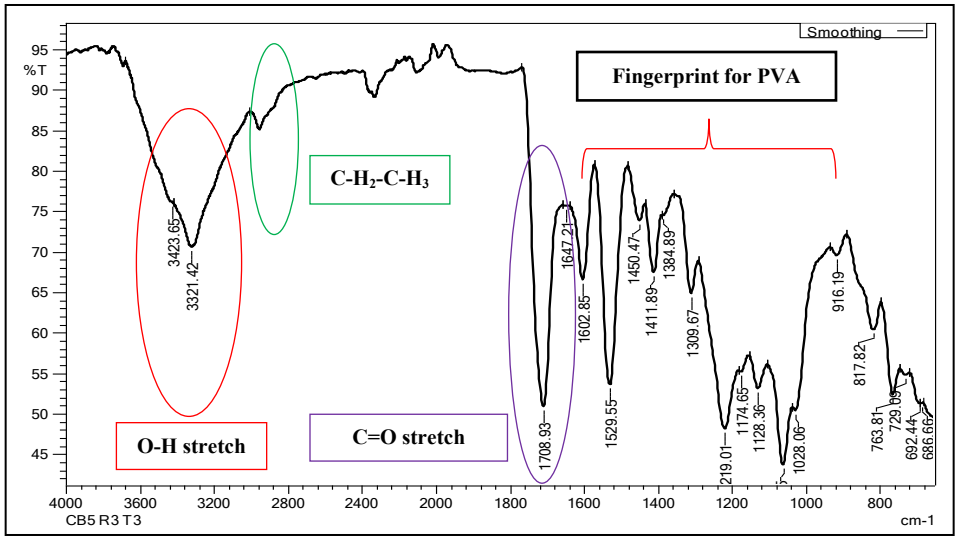

Figure 6. FT-IR spectrum showing the functional group associated to polyvinyl alcohol composition

**Spatial variation**

In this study, wild fish showed significantly higher abundance of microplastics than cage-cultured fish ($p < 0.05$). Microplastic ingestion is closely related to different feeding strategies [22, 23, 24]. Brandao et al. [25] suggested that fouling and high density plastics are examples of items that can be ingested by fish through feeding habitat. In this case, this ingestion is probably linked to the normal feeding activity of the fish. Wild fishes of *L. calcarifer* are known to feed on various preys emerging from different locations and environment as they drift all over the estuary. In contrast, cultured fishes are known to have feeding activities limited to their aquaculture area.

Feeding habitat also plays an important role in the ingestion of debris and lead to the increase of the abundance or bioavailability of microplastics. Higher abundance may be related to different habitats of fishes, and the presence of plastic debris near the seabed is normally high [26]. Referring to Figure 1, the sampling locations of wild and cage-cultured *L. calcarifer* are far from each other. Cage-cultured fishes were collected northwards from Setiu Wetlands, adjacent to the settlement area. Meanwhile, wild fishes were caught nearer to the passage of South China Sea, where several fishermen boats and ships commute in and out of the wetland. The area sampled for wild species has a possibility of higher microplastic particle content in water column as it could be transported from the sea via ocean current and wind. Distinctive habitat also contributes to the difference in microplastic ingestion of the fishes.

The highest microplastic recorded in the gastrointestinal tract of both wild and cage-cultured species is threadlike form; however, the colour coated or additives do not really determine the types of microplastics [27]. Besides the likely contribution from fisheries to the billions of synthetic fibres in the water column, fibres are common in the aquatic environments to which they are delivered in large concentration via wastewater outflow. Browne et al. [28] suggested that the possible sources of fibres in the marine environment are related to the discharge from the sewage sludge or fishing industry, which makes it as the main factor contributing to the emerging microplastics. In fact, cage-cultured fishes ingested more threadlike particles compared to wild species of *L. calcarifer*, probably resulting from the disintegration of nets used in the aquaculture ponds. In contrast, the fragment type was reported remarkably higher in quantity for wild fishes, as it could be denser than water, expected to sink and therefore being accidentally ingested by wild *L. calcarifer*. Pearson correlation also exhibits strong relationship between threadlike and fragment ($r = 0.90$) but weak towards spherical shape ($r = 0.18$).

The main polymers found are PA and PVA, where both polymers are slightly denser than water. The standard type of cage used for fish aquaculture, which is made up of synthetic materials, explains the higher number of PA existed in the gastrointestinal tract of cage-cultured species. PA is one of the major materials used to manufacture the nets. In addition, the chances of natural food supply in cages are much less; hence a regular stock of food is necessary.

The foods are usually composed of raw materials of animals such as small fish heads and inner organs. Thus, there is a higher possibility for the presence of microplastics in cage-cultured species, which is caused by the foods fed. Higher PVA inhabits wild species due to its property that is denser than water and disintegrated fragments from the settlement of abandoned fishing gears and nets on the bottom floor. Furthermore, the existence of human settlements is believed to have contributed to the large volume of microplastic waste, particularly from domestic activities.

**Comparison with literature studies**

Since this study is considered as the first report for estuary fishes, the occurrence of polymer type was compared with previously documented literature. A study carried out in the Norwegian coast explicates that the polyester materials become the major fraction of microplastics observed in fish gut samples [29]. Microplastic abundance high in this area is closely linked to high density of population and anthropogenic activities (Bergen City Harbour). Polyester materials were believed to be derived from polypropylene rope, synthetic clothing, and other polyester products. Moreover, it accounted for 88% of the microplastics found in full stomach samples, which leads to the understanding that the materials are retained longer in the fish body similar to their foods. The comparison of the main polymers found in fish samples is tabulated in Table 2.

In Durban Harbour, 72.8% of the microplastics were observed in mullet samples. Polystyrene is one of the polymer subjects found in this study, but it only contributed 7.3% of the total plastics [30]. The most abundant is in fibre form with white colour. It is worth to note that the correlation between plastic ingestion and fish length or size is not significantly different. The source of pollution especially the emergence of fibres is believed to have originated from domestic or industrial discharge nearby. Meanwhile, recent studies reported by Pazos et al. [31] and Güven et al. [32] indicated that the emergence of a new contaminant affects the multispecies of fishes collected in estuary and coastal areas, respectively. Fibres become the prevalent type of microplastics found in both areas.

Table 2. Comparison of polymer type found in microplastics debris in this study and literature

| Species | Study area | Polymer Identifed | Reference |
|---|---|---|---|
| *Gadus morhua* | Norwegian coast, Norway | Polyester | [29] |
| *Mugil cephalus* | Durban Harbour, South Africa | Polystyrene | [30] |
| Multi species[a] | Rio de la Plata estuary, Brazil | - | [31] |
| Multi species[b] | Mediterranean coast, Turkey | Polypropylene, Polyethylene, Polyester | [32] |
| *Lates calcarifer* | Setiu Wetland, Malaysia | Polyamide and Polyvinyl alcohol | This study |

[a] 11 species fish, [b] 28 species fish

## Conclusion

In this present study, microplastic ingestion has been reported to be pervasive in the gastrointestinal tract of both wild and cage-cultured species of *L. calcarifer* from Setiu Wetlands, Terengganu. The abundance of microplastics is higher in wild species compared to cage-cultured species, which is linked to the dynamics of habitat and feeding activity. PA and PVA are the main polymer compositions found in the gastrointestinal tract of the fishes examined. To the best of our knowledge, the result reported in this study is the first evidence of estuarine fish contaminated by microplastics. Therefore, we highly recommend that in future work, the whole gastrointestinal tract and digestion process should be used in the investigation of microplastic pollution in fish and also not limited to Asian sea bass species only.

**Abstract**

Cellulose from oil palm fronds (OPF) was extracted using a cost-effective method combining physical treatment (high pressure steaming) and repeated chemical treatments (alkali and bleaching). Alkali and bleaching treatments were performed using low concentrations of sodium hydroxide and sodium chlorite, respectively. High levels of cellulose were successfully extracted, with 4 grams of cellulose for every 10 grams of raw oil palm fronds. The morphology of the cellulose was investigated using variable pressure scanning electron microscope (VPSEM). Fourier transform infrared spectroscopy (FTIR), X-ray diffraction (XRD) and thermogravimetric analyser (TGA) were used for structural analysis. The extracted cellulose was found to have smaller diameter (8 – 10 µm) and smoother surface compared to the untreated fibres. The results from FTIR, XRD and TGA indicate that the hemicelluloses and lignin were extensively removed from the isolated cellulose. Alkali treatment helped in removal of hemicelluloses, while bleaching assisted in delignification. The extracted cellulose showed high crystalline index of 68.75% and degradation temperature of 350 $^{o}$C resulted from removal of lignin and hemicelluloses via alkali and bleaching treatments.

**Abstrak**

Selulosa telah diekstrak daripada pelepah kelapa sawit dengan menggunakan kaedah yang menjimatkan kos iaitu gabungan kaedah fizikal (pemanasan pada tekanan tinggi) dan rawatan kimia (alkali dan pelunturan). Rawatan alkali dilakukan dengan menggunakan sodium hidroksida manakala rawatan pelunturan pula dilakukan dengan menggunakan sodium klorit. Kedua-dua bahan kimia tersebut digunakan pada kepekatan yang rendah. Sebanyak 4 gram selulosa berjaya diekstrak daripada setiap 10 gram pelepah kelapa sawit. Morfologi selulosa yang diekstrak telah dikaji dengan menggunakan mikroskopi elektron pengimbas tekanan berubah-ubah (VPSEM). Manakala spektroskopi inframerah transformasi Fourier (FTIR), analisis belauan sinar-X (XRD) dan analisis termogravimetri (TGA) telah digunakan bagi tujuan menganalisis struktur selulosa. Selulosa yang diekstrak mempunyai diameter yang lebih kecil (8 – 10 µm) dan permukaan yang lebih licin berbanding gentian yang tidak dirawat. Hasil daripada FTIR, XRD dan TGA menunjukkan bahawa hemiselulosa dan lignin telah dibuang dalam jumlah yang tinggi selepas rawatan-rawatan tersebut dijalankan. Rawatan alkali membantu membuang hemiselulosa manakala rawatan pelunturan pula membantu membuang lignin daripada sampel. Selulosa yang diekstrak mempunyai tahap kristal yang tinggi iaitu 68.75% dan suhu degradasi yang tinggi iaitu 350 $^{o}$C berikutan daripada pembuangan hemiselulosa dan lignin selepas rawatan alkali dan pelunturan dilakukan.

## Introduction

*Elaeis guineensis*, commonly known as oil palm, is one of the main crops in Malaysia and is widely planted all over the country, especially in Sabah, Sarawak and Johor. With oil palm covering about 4.49 million hectares. Malaysia is the world's second largest palm oil exporter, accounting for 39% of the world palm oil production [1]. The oil palm plantation industry contributes to huge amount of agricultural wastes (lignocellulosic biomass) every year such as the OPFs from thinning, replanting and pruning processes. The huge amounts of waste generated from the oil palm industry have led to concerns over the managements of the wastes. The most common disposal methods for such agricultural waste include use in mulching or leaving it to decompose naturally in the plantation area. These practices are harmful to the environment. The decomposing OPFs interfere with plantation processes and serve as pest breeding sites [2], especially for insects like rhinoceros beetles.

Natural plant fibres are made up of cellulose, amorphous polymers (hemicelluloses and lignin) and small number of extractives. Cellulose is a naturally occurring hydrophilic polymer and is the main substance that makes up plant cell walls and contributes to the physical stability of the cells [3]. Thus, cellulose is probably the most abundantly available organic compound on Earth. Cellulose does not dissolve in water, and has high crystallinity and high molecular weight [4].

The OPFs are composed of 58% cellulose, 24% hemicelluloses, 5% lignin, 8% extractives and 5% ashes [5]. The amount of cellulose in the OPF is higher than other waste parts (leaves and empty fruit bunches) of oil palm trees [6].

The accumulating amount of the agricultural waste or OPFs could serve as an inexpensive cellulose source compared to wood, that could be exploited for many uses and purposes. The common uses of cellulose are in paper, film, textiles, building material and food additives production. Recent studies have shown strong interest in this organic polymer due to its superior characteristics, such as high water absorption capacity [7] and large surface areas, compared to other biomaterials. Besides the traditional uses of cellulose, some of the latest cellulose-based innovations are focusing on solving environmental problems, such as cellulose-based absorbents for oil spills and heavy metal pollution on water or land [8]. Additionally, there have been studies on the uses of cellulose in bio-based filters for industrial [9] and municipal wastewater treatment [10].

The extraction of cellulose from oil palm fronds using an inexpensive method could serve as an alternative environmental friendly way of managing the largely produced agricultural wastes. The purpose of this study was to extract the cellulose from oil palm fronds using a cost-effective method, namely a combination of physical and chemical methods. The physical method used was the high pressure steaming, while the chemical methods were alkali and bleaching treatments. Then, the extracted cellulose was characterized using a variable pressure scanning electron microscope (VPSEM), Fourier transmission infrared (FTIR), thermogravimetric analyser (TGA), and X-ray diffraction (XRD).

## Materials and Methods

### Materials

Fresh Oil Palm Fronds (OPFs) were collected from the MPOB (Malaysian Palm Oil Board), Bangi, Selangor. The chemical reagents used were sodium hydroxide (NaOH) and sodium chlorite ($NaClO_2$). To assist in physical treatment, an autoclave (Hirayama, HVE50) was used.

### Pre-treatment

The collected OPF were cut into smaller pieces (15 – 20 cm) before dried at room temperature for 3 days. The dried OPFs were then ground into smaller size of 5 – 6 cm and soaked in water for 3 days. The water was changed daily. The samples were then rinsed with distilled water several times to remove dirt and sand particles. Then, the samples were autoclaved at 121$^{o}$C, 21 psi for 15 minutes. The dark brown supernatant was removed and the samples were washed with distilled water a few times until clear water was observed. The OPFs were dried at room temperature and ground into 1 – 2 cm pieces.

**Extraction of OPF-cellulose**
Cellulose extraction from OPF was done using the method from Chan et al. [11] with some modifications. The autoclaved and dried samples were treated with 4% sodium hydroxide (NaOH) at 80 $^{o}$C for 2 hours with continuous stirring. Then, a bleaching treatment was applied using 1.7% sodium chlorite ($NaClO_2$) at pH 4.5 and 80 $^{o}$C for 4 hours with continuous stirring. The alkali and bleaching treatments were repeated three and four times, respectively. The ratio of sample to solvent was 5:100 (g/mL). After each treatment, the samples were rinsed few times using distilled water. The extracted cellulose was dried in an oven at 60 $^{o}$C and the dried weight of the cellulose was determined.

**Characterization: Variable pressure scanning electron microscope**
The morphological studies of extracted cellulose from OPF were carried out with a variable pressure scanning electron microscope (Leo 1450VP/ Zeiss)

**Fourier transmission infrared spectroscopy**
The chemical investigation of functional groups in extracted cellulose from OPF was done using Fourier Transmission Infra-Red Spectroscopy (Perkin Elmer Spectrum 400 FT-IR/FT-NIR and Spotlight 400 Imaging System).

**X-ray diffraction**
The crystallinity of the extracted cellulose was studied using an X-ray diffractometer (Bruker/D8 Advance). The crystalline index was determined based on the method by Segal [12] using the following equation:

$$X_c = \frac{I_{002} - I_{am}}{I_{002}} \text{ x } 100 \quad (1)$$

where $X_c$ is the crystalline index, $I_{002}$ is the peak intensity of crystalline materials and $I_{am}$ is the peak intensity of amorphous materials.

**Thermogravimetric analysis**
Thermogravimetric analysis was carried out using Mettler Toledo thermogravimetric analyser (TGA/SDTA 85-F) to measure the thermal stability of all samples. Measurements were made with a nitrogen gas flow of 10 mL min$^{-1}$ and heated from room temperature to 600 $^{o}$C with heating rate of 10 $^{o}$C min$^{-1}$.

## Results and Discussion

**Extraction of OPF-cellulose**
The combination of physical and chemical methods succeeded in extracting high total cellulose yield, 40% (w/w) on a dry weight basis. The pre-treatment of samples by high pressure steaming played a role in removing loose substances from the surface of the fibres and assisted in penetration of the alkali and bleaching reagents by reducing the polymerization degree of the fibres.

**Morphological analysis**
The colour of the raw oil palm frond fibres changed from brown to white after treatment (Figure 1). The extracted cellulose fibres had smaller diameters (8 – 10 µm) and smoother surfaces compared to the untreated fibres, which had diameters ranging from 150 to 300 µm and rough surfaces (Figure 2).

Both colour and morphological changes were due to removal of lignin and other extractives during high pressure steaming and bleaching treatments, resulting in lighter colour and smoother surface of the fibres, respectively. The colour of wood is determined by the phenolic substances (lignin and extractives). The removal of extractives caused a slight colour change, while removal of lignin caused a more significant colour change [13]. The removal of the binding substance also induced the dispersal of the fibre bundles into individual fibres by cleavage of the bonds between the hemicelluloses and lignin, producing fibres with smaller diameters. A smoother surface of the extracted cellulose resulted from all the treatments (high pressure steaming, alkali and bleaching treatments) which removed impurities from the surface of the fibres.

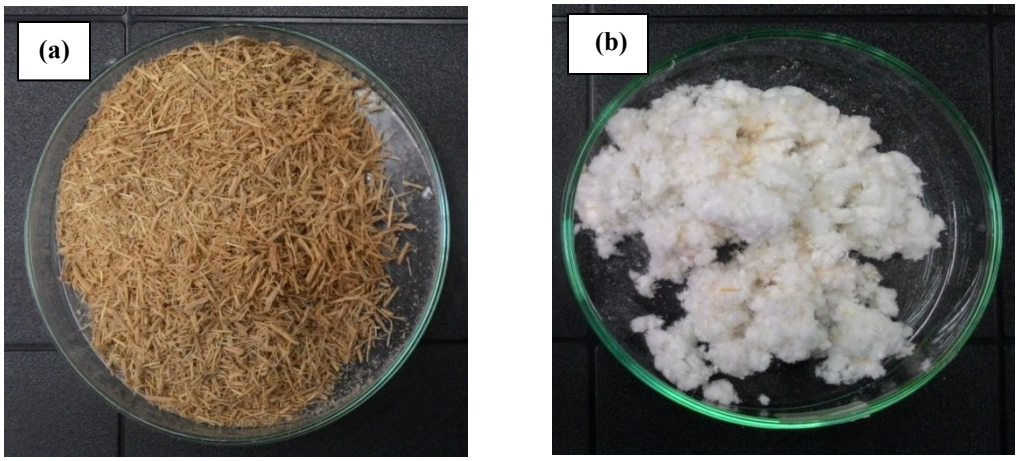

Figure 1. Ground oil palm fronds. (a) Before treatments and (b) after treatments

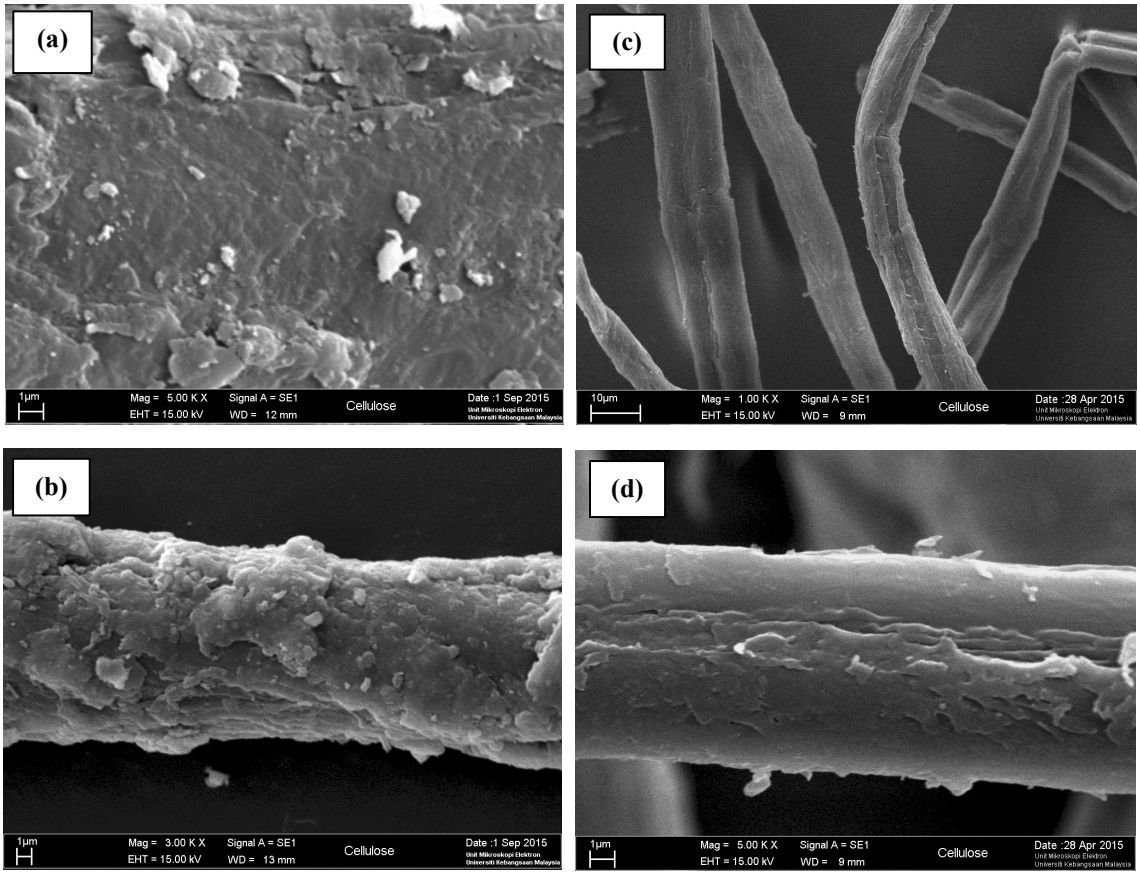

Figure 2. Variable pressure scanning electron microscope micrographs of oil palm frond samples. (a) and (b) before treatments, while (c) and (d) after treatments

**FTIR spectroscopy analysis**

The FTIR results (Figure 3) suggest the complete removal of the functional groups of both lignin and hemicelluloses from the extracted cellulose. The peak 1246.70 $cm^{-1}$ (C-O-C, aryl-alkyl-ether) which is the ether bond between the hydroxyl groups of lignin and the carbohydrates in the raw OPF was completely removed after alkali treatment. This indicates the complete removal of the hemicelluloses. Meanwhile, the intensity of the peak 1594.81 $cm^{-1}$ (C=C of lignin aromatic ring) was reduced after alkali treatment and completely removed after bleaching. As reported by Johar et al. [14], the alkali treatment removed hemicelluloses and other impurities from the raw samples, while partially removed the cementing material of lignin.

The peaks at 897.86 $cm^{-1}$ and 3318.87 $cm^{-1}$ were attributed to the ß-glycosidic linkage of cellulose and adsorbed water in the samples, respectively. The peaks at 2922.03 $cm^{-1}$ and 1031.86 $cm^{-1}$ indicate the C-H and C-O groups of the cellulose. The high pressure steaming treatment softened the lignin and released it from the cell wall to the fibre surface. This physical treatment played a role in increasing the accessible surface area and size of cell wall pores for penetration of the alkali and bleaching reagents.

The alkali treatment removed hemicelluloses from the sample through hydrolysis of glycosidic bonds in hemicelluloses and led to the cleavage of the ester bonds between the hydroxyl groups of lignin and the carboxyl groups of the hemicelluloses. Hemicelluloses are susceptible to the two degradation reactions by alkali reactions due to the high number of end-groups resulted from low polymerization level. The hemicelluloses were released from the fibres and complete removal was achieved by the repeated washing of the samples with distilled water.

Delignification of the fibres was achieved by complete removal of the lignin on the fibre surface. The lignin was degraded by the bleaching treatments using an oxidising agent, sodium chlorite which oxidized the ether bonds between the hydroxyl groups of lignin and the carbohydrates. The most common chemicals used in bleaching process are hydrogen peroxide, oxygen, and sodium chlorite. Sodium chlorite is the most effective for bleaching without reducing total carbohydrate [15]. Acidified sodium chlorite has been reported to cleave the phenolic ether bonds in plant cell walls at high temperatures [16]. The bleaching treatment also removed remaining hemicelluloses by oxidation reactions that cleaved the glycosidic linkages of the residues [15].

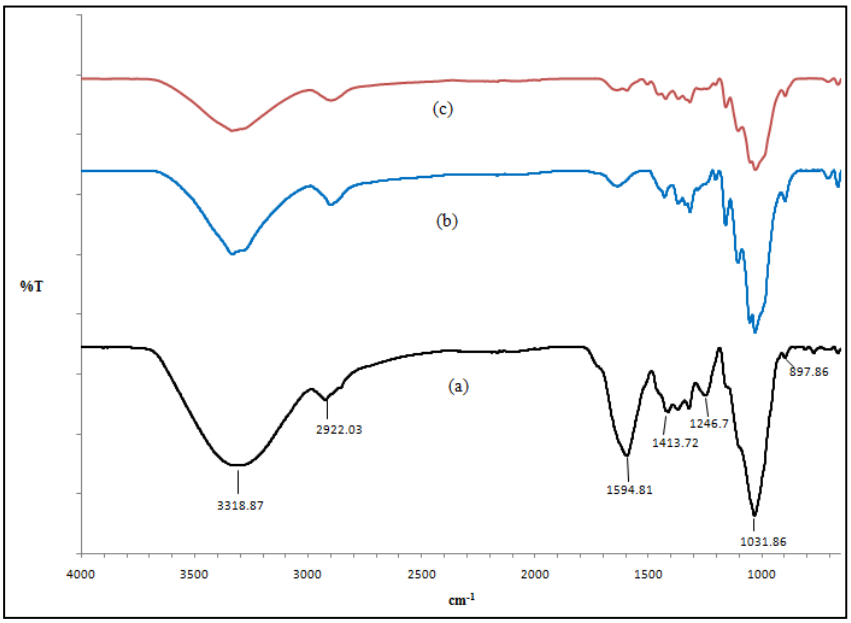

Figure 3. Fourier transmission infrared spectroscopy spectra of the extracted cellulose from oil palm fronds: (a) raw oil palm frond, (b) after alkali treatment and (c) after bleaching treatment

**X-ray diffraction measurements**

Cellulose is made of diverse crystalline arrangements which result from the hydrogen bonding of the hydroxyl groups. The major peaks (22.6º) in the X-ray diffractogram are attributed to the crystalline structure of the cellulose, while the low intensity at 18º reflects the amorphous background of the samples.

X-ray diffraction results (Figure 4) show a crystalline index of 24.31% for the raw oil palm fronds, which progressively increased after alkali treatment (52.46%) and bleaching treatment (68.75%). The crystalline index values of all samples are listed in Table 1. The increasing crystalline index of the samples after alkali and bleaching treatments were due to progressive removal of the hemicelluloses and lignin. According to Sheltami et al. [17], the crystallinity level of cellulose is influenced by removal of amorphous polymers.

The crystalline index of the extracted cellulose is higher compared to the 57.19% reported by Syamani et al. [18] for the extracted cellulose from oil palm fronds by pulping and bleaching using hydrogen peroxide. The amount of cellulose is higher due to higher removal of the amorphous polymers via alkali and sodium chlorite bleaching treatments. In addition, the major peaks progressively became sharper after each treatment, reflecting the greater distinguished crystalline structure of the samples.

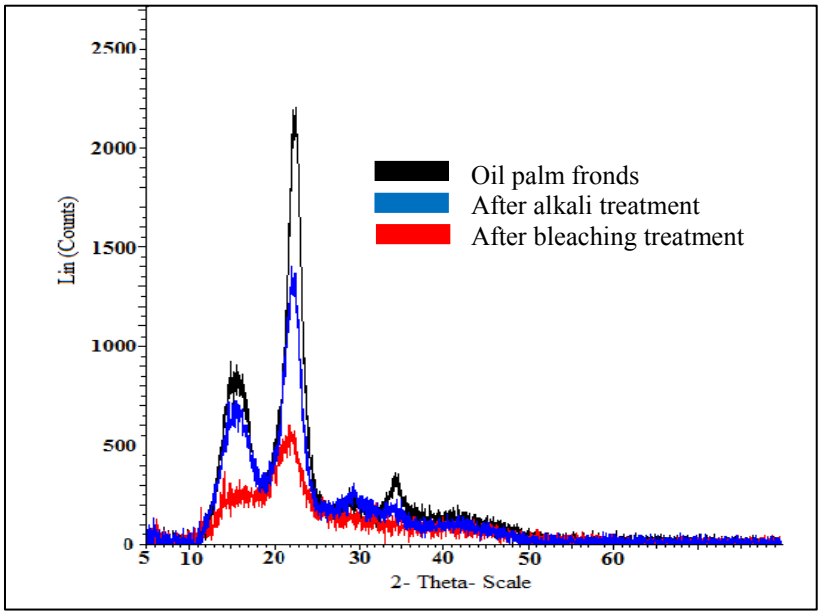

Figure 4. X-ray diffraction patterns for raw oil palm frond, after alkali treatment and after bleaching treatment

Table 1. Crystalline index of the oil palm fronds at different stages of treatment

| **Samples** | ***2θ*(am)(º)** | ***2θ*(002)(º)** | **Xc(%)** |
|---|---|---|---|
| Oil palm fronds | 18.5 | 22 | 24.31 |
| After alkali treatment | 18.8 | 22.5 | 52.46 |
| After bleaching treatment | 18.5 | 22.2 | 68.75 |

**Thermogravimetric analysis**

Both TG (Figure 5) and DTG curves (Figure 6) showed the thermal stability of the raw, alkali-treated and bleached samples. All three samples showed initial weight loss at temperature lower than 100 $^{o}$C which attributed to the water evaporation from the samples which was the moisture adsorbed to the fibre. After bleaching, weight reduction increased due to the hydrophilic nature of the cellulose, which had a higher level of moisture compared to the raw and alkali-treated samples.

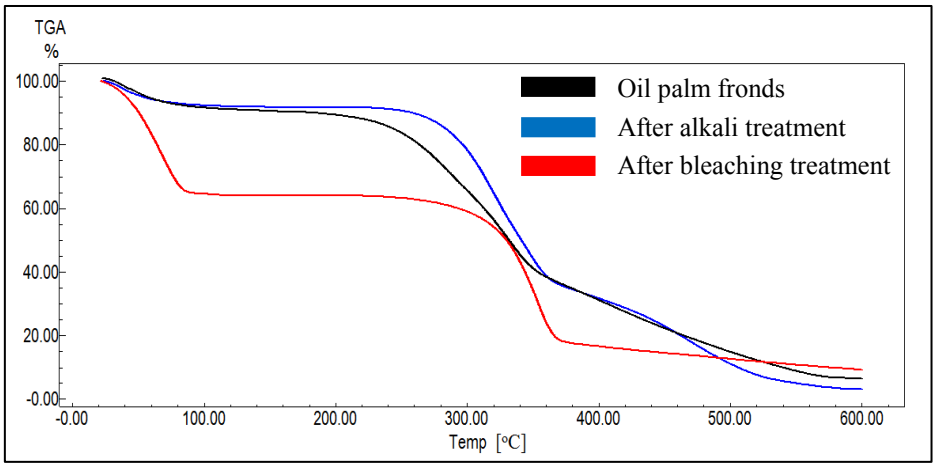

Figure 5. Residual mass (TG) curves of raw oil palm frond, after alkali treatment and after bleaching treatment

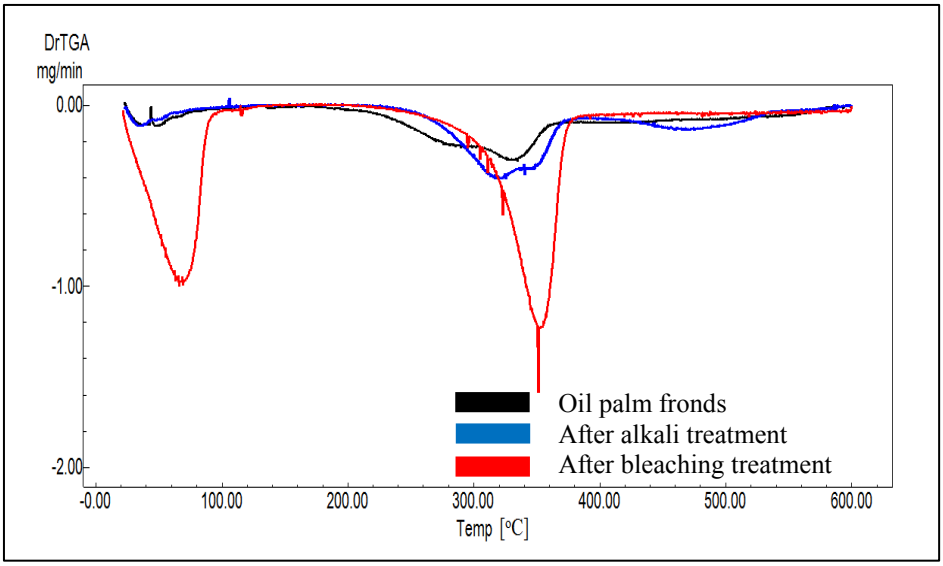

Figure 6. Differential residual mass (DTG) curves of raw oil palm frond, after alkali treatment and after bleaching treatment

For the raw and alkali-treated samples, there were small broad peaks at 280 $^{o}$C and 320 $^{o}$C before the major peak, reflecting the low molecular weight compounds, hemicelluloses and lignin [19]. These peaks were completely removed after bleaching treatment.

The major peaks of the DTG curves demonstrate the degradation temperatures of the samples. The bleached sample showed highest degradation temperature at 350 $^{o}$C compared to the raw and alkali-treated samples, which degraded at 330 $^{o}$C and 345 $^{o}$C respectively. The progressively increased degradation temperature of the samples after each treatment was due to the progressive removal of lignin and hemicelluloses. Hemicelluloses and lignin had lower decomposition temperatures compared to cellulose [20]. This was due to the higher crystallinity of the cellulose, which increased the thermal stability of the sample [21].

However, the bleached sample showed highest weight loss at the decomposition temperature. Meanwhile, the raw and alkali-treated samples retained higher residual mass. This was due to the presence of the lignin and ashes within the raw and alkali-treated samples [22]. Ashes were regenerated after the samples were burnt, causing only slight weight reduction of the samples [14]. These thermal analysis results are quite consistent with the results obtained from the FTIR and crystallinity measurements.

## Conclusion

Cellulose was successfully extracted from oil palm fronds using a cost-effective method, with a combination of physical treatment and low concentration chemical methods. High amounts of cellulose (40% w/w) were successfully extracted with a high crystalline index (68.75%) and thermal stability (350 $^{o}$C), demonstrating extensive removal of amorphous polymers from the samples. The extraction of cellulose from the oil palm fronds could be exploited on a larger scale and serve as a proper practice for agricultural waste management. Further research should be carried out to study the mechanical properties of cellulose, including tensile strength and moisture regain, for better understanding on the potential uses of the OPFs cellulose.

**Abstract**

Photolytic degradation of imazapyr and imazapic in aqueous solutions (pH 3, 7 and 9) and soil under direct sunlight were studied. A total of 0.1 mL of aqueous solutions containing herbicides were collected at 0, 1, 2 and 3 days and were directly analyzed using high performance liquid chromatography equipped with ultraviolet detector (HPLC-UV) without further clean-up process. Soils that were treated with herbicides were sampled at seven different days (0, 1, 5, 10, 16, 23 and 30). The photolytic results showed that imazapyr and imazapic degraded faster in solutions compared to soils (> 90%). Photolysis of imidazolinone herbicides became more effective as the pH value increased. The half-lives for imazapyr and imazapic degradation on soil surface under sunlight were calculated at 126 days and 85.56 days, respectively. Low degradation of imazapyr and imazapic in soil becomes a concern since it may contribute to the persistency of imidazolinone herbicides in this media. The use of these herbicides should be planned well to reduce the risk of herbicides leaching into groundwater and posing risk to non-target crops and organism.

**Keywords**: photolysis, imazapyr, imazapic, aqueous solutions, soil

**Abstrak**

Kajian degradasi fotolitik bagi imazapyr dan imazapic dalam larutan akueus (pH 3, 7 dan 9) dan tanah di bawah cahaya matahari telah dijalankan. Sebanyak 0.1 mL cecair larutan yang mengandungi racun rumpai telah diambil pada hari 0, 1, 2 dan 3 dan terus dianalisis menggunakan kromatografi cecair berprestasi tinggi dengan pengesan ultra-ungu (HPLC-UV) tanpa melalui sebarang proses pembersihan. Tanah yang telah dicampurkan dengan racun rumpai telah disampelkan pada tujuh hari yang berbeza (0, 1, 5, 10, 16, 23 dan 30). Keputusan fotolitik menunjukkan imazapyr dan imazapic lebih cepat terurai di dalam cecair berbanding dengan tanah (>90%). Fotolisis racun rumpai imidazolinon adalah lebih berkesan apabila pH meningkat. Jangka masa separuh hayat untuk imazapyr dan imazapic terurai di permukaan tanah di bawah cahaya matahari masing-masing adalah 126 dan 85.56 hari. Degradasi rendah bagi imazapyr dan imazapic dalam tanah telah menjadi suatu kebimbangan kerana ia boleh menyumbang kepada pengekalan racun rumpai imidazolinon di dalam media ini. Penggunaan racun rumpai ini perlu dirancang dengan sebaiknya bagi mengurangkan risiko untuk racun larut terlesap ke dalam air bawah tanah dan menimbulkan risiko kepada tanaman dan organisma yang bukan sasarannya.

**Kata kunci:** fotolisis, imazapyr, imazapic, larutan akueus, tanah

## Introduction

As one of the main contributors to Malaysian economy, the agriculture sector takes up a major part of the land used in this country [1]. Additionally, Malaysian government has invested millions of ringgit to ensure this sector is well developed and this includes introducing modern agricultural input such as herbicides [2]. This contributes to the increase of herbicide application in Malaysian agricultural areas [1]. Herbicide is the most common method used to prevent or control the unwanted weeds in agricultural areas. Not only that, it is also used to maintain the quality of crops and reduce the percentage of yield losses [2]. Some common examples of herbicides are 2,4-D dimethylamine, paraquat, glyphosate and propanil [1]. However, the use of herbicide is harmful in certain quantities as some herbicides may leach into the root zone once they are introduced into the environment. Consequently, this can either result in better weed control or cause damage to surrounding environment as not all of the applied chemicals are able to reach the target site [3]. Therefore, it is very important to understand the fate of the chemicals in the environment.

Currently, commercial herbicides containing two active ingredients (imazapyr and imazapic) are widely used in rice field area to control the growth of weedy rice [4, 5]. The growth of weedy rice in rice field affects the annual rice yield in Malaysia [2, 6] and this contributes to economic loss among farmers [3]. Thus, the combination of imidazolinone-tolerant rice (IMI-TR) seeds developed by MARDI and BASF (Malaysia) with a single application of imazapyr/ imazapic in rice field area [4, 5] are found to be able to reduce weed management cost and yield higher quality of rice [6]. Imazapyr and imazapic belong to imidazolinone group that can eliminate subjected weeds by inhibiting the action of plant enzyme acetohydroxyacid synthase (AHAS) and interfering with their growth [7, 8].

The applications of imidazolinone herbicides are assumed to be environmentally safe because of their low toxicity effects on mammals as well as being highly effective with a very low application rate [4, 9, 10]. This in turn reduces the amount of herbicides released into the environment and ecosystem [6]. However, the application of herbicides in rice field for a long period of time may give rise to several environmental issues. One of the environmental concerns is the persistency of imidazolinone herbicide in soil [11 – 14] and groundwater [15]. Since these herbicides are able to remain for a long period of time in the environment, it may pose risks to non-target organisms such as fish [16, 17].

There are many factors affecting the persistency of herbicides molecule in the environment and these may include sorption, volatilisation, leaching and degradation (abiotic and biotic) [3, 14]. Photodegradation may play an important role for the breakdown of herbicides in environment because all pesticides are susceptible to this process to a certain degree [3]. Since imazapyr and imazapic are applied to foliage or soil surface, they are more prone to break down by sunlight [3]. Therefore, the aims of this study were to determine the capability of imazapyr and imazapic herbicides to break down under direct sunlight as well as to calculate their half-life in aqueous solutions and soil surface.

## Materials and Methods

### Chemicals

Imazapyr and imazapic with 99.5% and 99.9% purity respectively were purchased from Active Advance Technology Company. Acetonitrile (ACN) grade for liquid chromatography (LC), acetic acid, monopotassium phosphate and sodium hydroxide (NaOH) were obtained from Merck (Malaysia). Potassium biphthalate, borax and hydrochloric acid (HCl) were purchased from Juara Saintifik (Malaysia). Imazapyr and imazapic solutions were prepared by dissolving the weighed herbicide in ACN.

### Preparation of buffer solutions

Three different buffer solutions (pH 3, 7 and 9) were prepared based on United States Environmental Protection Agency's (USEPA) Fate, Transport and Transformation Test Guidelines [18]. The buffer solutions were prepared by mixing 0.1N HCl with 0.1M potassium biphthalate (pH 3); 0.1N NaOH with monopotassium phosphate (pH 7); and 0.025 M borax with 0.1N HCl for pH 9. All buffers solutions and glassware used in this experiment were sterilised by using autoclave [9].

**Photolysis of imazapyr and imazapic in aqueous solutions**

Outdoor photodegradation experiments for imazapyr and imazapic in aqueous solutions and soil were conducted in greenhouse at Universiti Teknologi MARA Puncak Alam Campus. The photolysis activity was tested for individual and mixture of the herbicides using USEPA protocol [19]. All three prepared buffer solutions were then treated with herbicide solution in order to obtain 10 µg $mL^{-1}$ of imazapyr and imazapic concentration respectively as well as a mixture of imazapyr and imazapic in the ratio of 1:3. 10 mL buffered solutions of herbicide (pH 3, 7 and 9) were placed in three different sterilized glass test tubes before being exposed under sunlight. All these solutions were prepared in triplicate along with two control samples. The average temperatures during experimental days were varied between 26 ºC to 36 ºC. The sunlight intensity was also measured during the exposure. An amount of 0.1 mL of aliquots was pipetted aseptically from each test tube on day 0, 1, 2 and 3 into 2 mL amber vials for further analysis with High Performance Liquid Chromatography (HPLC) [20].

**Photodegradation of imazapyr and imazapic on soil**

For this research, the study of photodegradation on soil surface was carried out in reference to USEPA Guideline [21]. A soil sample was collected from the surface layer (0 to 10 cm) from the field. The sample was air-dried at room temperature, passed through 2 mm sieve and was later autoclaved at 121ºC twice [9]. An amount 5 grams of sterilized soil was weighed into sterile petri dish and herbicide solution was applied on the top of spread soil to obtain the initial concentration of 5 µg $g^{-1}$. For control samples, the petri dishes containing soil-herbicide were wrapped with aluminum foil to keep out light and maintain darkness. The samples were exposed to the sunlight and then were collected at 0, 1, 5, 10, 16, 23 and 30 days. Three exposed and control samples were sampled for each sampling day and transferred into sterile centrifuge tube for herbicides extraction. Herbicides were extracted from the soil samples by shaking 20 mL of 0.5 M NaOH and centrifuging at 2000 rpm for 10 minutes. These steps were repeated twice. The decanted supernatants were filtered through 0.45 µm filter and were analyzed directly using HPLC [20].

**HPLC analysis**

An Agilent 1200 High Performance Liquid Chromatography equipped with UV detector was used for quantification of imazapyr and imazapic residues [20]. The wavelength for the detector was set up at 251 nm. ACN: acidified water (pH 2.88) (35:65, v/v) was used as mobile phase with flow rate of 1.0 mL $min^{-1}$ while for chromatography, An Agilent Zorbax SB-C18 column (4.6 mm i.d. x 250 mm, 5 µm) was used.

**Data analysis**

The percentages of imazapyr and imazapic degradation were calculated using equation 1 [22]:

$$\text{Photodegradation (\%)} = (C_0 - C_t)/C_0 \times 100\% \quad (1)$$

Calculations for imidazolinone herbicides half-life were performed using kinetic equation 2 and 3, respectively [9, 19, 23]:

$$\ln (C_0/C_t) = kt \quad (2)$$

$$t_{1/2} = 0.693/k \quad (3)$$

where, $C_0$ refers to the initial concentration of herbicide, $C_t$ represents the herbicide concentration at time *t*, k is photolytic rate constant, and $t_{1/2}$ exemplifies the half-life.

## Results and Discussion

**Photolysis of imidazolinone herbicides in aqueous solutions**

The results for degradation of imidazolinone herbicides in aqueous solutions were shown in Table 1. These findings suggested that both imazapyr and imazapic herbicides were able to completely degrade (> 90%) within 72 hours under direct sunlight (light intensity ranged 162 to 1059 watt/$m^2$). The half-life values of imazapyr under direct sunlight were 16.54 hours (pH 3), 12.42 hours (pH 7) and 12.18 hours (pH 9). Imazapic was found to have half-lives of 32.35 hours, 10.06 hours and 10.76 hours in pH 3, 7 and 9, respectively. Trials on combination of both

herbicides under acidic pH level showed that imazapyr was completely degraded within 24 hours while imazapic residue was calculated at 20.94 percent within 72 hours.

Table 1. Photolysis of imidazolinone herbicides under direct sunlight in buffer solutions

| **Sampling Days** | **Percentage of Residues (%)** | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| **Herbicide** | **Imazapyr** | | | **Imazapic** | | | **Imazapyr: Imazapic (1:3)** | | |
| **pH solution** | **3** | **7** | **9** | **3** | **7** | **9** | **3** | **7** | **9** |
| 0 | 100 | 100 | 100 | 100 | 100 | 100 | 100:100 | 100:100 | 100:100 |
| 1 | 65.87 | 23.73 | 23.69 | 55.89 | 17.42 | 17.09 | 0:51.76 | 25.29:16.80 | 26.03:17.39 |
| 2 | 15.98 | 5.01 | 4.09 | 28.83 | 5.91 | 2.10 | 0:30.29 | 4.04:2.16 | 4.74:2.74 |
| 3 | 4.89 | 1.80 | 1.67 | 21.38 | 0.72 | 0.97 | 0:20.94 | 1.39:0.88 | 1.68:1.08 |

Results presented in Table 1 suggested that pH values of buffer solutions affected the photolysis rate for imazapyr and imazapic. Degradation rate of imidazolinone herbicides tested increased as pH increased, which was in agreement with previous studies [23, 24, 25]. This might be due to the effect of higher molar absorption coefficients at higher pH value [24]. Imazapyr and imazapic herbicides were more rapidly degraded in solution compared to on soil surface (Table 1 and Table 2). However, the photolysis rate of imidazolinone herbicides in actual water samples might be slower due to the presence of light screening compounds such as humic acid and natural organic matter (NOM) [3, 26].

**Photodegradation of imidazolinone herbicides on soil**

The percentages of photodegradation of two imidazolinone herbicides were tabulated in Table 2. Imazapic had a higher degradation rate ($t_{1/2}$= 85.56 days) compared to imazapyr ($t_{1/2}$= 126 days). The ability of these herbicides to remain longer might be due to the properties of the soil itself which absorbed the photons, therefore reducing the availability of photons to degrade the herbicides compounds [9, 27]. Previous study showed that imazapyr and imazapic had an enhanced adsorption and a lower desorption in rice field soil due to the presence of high clay content and organic matter [28], especially at low pH value. The soil sample used consisted of 57.50% clay, 37.50% silt, 0.90% sand, 4.26% total organic carbon and a pH of 5.29. Since the soil sample used in this study had the properties of high clay content and organic matter which were similar to a previous study [28], it suggested that these two imidazolinone herbicides were tightly bound to soil particles. This indicated that very little of these compounds were available for degradation via photolytic activity. Moreover, air-drying step of soil sample preparation in this study might cause an increase in soil-herbicide binding as the soil water content decreased [27]. Once the herbicides penetrated underneath the soil surface, the photodegradation activity became low [27] and this might contribute to their persistency in the environment. Since imazapyr and imazapic were able to remain longer in the soil, these herbicides also had a higher probability to leach into groundwater as reported previously [14, 29].

Table 2. Photodegradation of imidazolinone herbicides on soil exposed with direct sunlight

| **Sampling Days** | **Percentage of Residues (%)** | | |
|---|---|---|---|
| **Herbicide** | **Imazapyr** | **Imazapic** | **Imazapyr: Imazapic (1:3)** |
| 0 | 100 | 100 | 100: 100 |
| 1 | 98.24 | 92.77 | 98.69: 97.07 |
| 5 | 96.99 | 90.88 | 95.25: 94.20 |
| 10 | 94.52 | 87.66 | 93.58: 93.25 |
| 16 | 93.18 | 83.03 | 91.30: 92.01 |

| 30 | 84.75 | 78.40 | 78.12: 81.16 |

## Conclusion

Photodegradation of imidazolinone herbicides could be an important factor for their breakdown in the environment as demonstrated in the tabulated results. Degradation of imazapyr and imazapic in aqueous solutions were faster compared to on soil surface under direct sunlight. Low photolytic degradation in soil became a concern since it might pose risk to non-target crops and organisms. Further study on biotic degradation might expand new angle in this field since microbe could be used as a degrading organism to break down imidazolinone herbicides, especially under anaerobic condition. The approach in this paper could be taken as a general applied method to analyses other degraded pollutants, especially those that had similar functional group.

# CALCIUM CONTENT OF LIME MORTARS FROM 19th CENTURY CHURCH RUINS IN THE PHILIPPINES USING VOLUMETRIC ANALYSIS

## (Kandungan Kalsium Mortar Batu Kapur dari Runtuhan Gereja Abad Ke 19 di Filipina Menggunakan Analisis Volumetrik)

**Abstract**

A calcium determination method for lime mortars in old church ruins is described. Two volumetric analysis methods were employed: titration using EDTA solution, and with $KMnO_4$ solution. The binder fraction with sieve size (<0.075mm) was used for titration which is abundant in $CaCO_3$ as established by Fourier-Transform Infrared Spectroscopy (FTIR) technique. The mortar sample from Misamis Oriental yields a mean calcium concentration of 59.60% ± 4.64 and 60.48% ± 6.68 for EDTA and $KMnO_4$, respectively, while the Metro Manila mortar sample is 73.54% ± 2.68 for EDTA and 73.33% ± 6.88 for $KMnO_4$. Two tailed *t*-test and *F*-test analysis confirm that there is no statistical difference between EDTA and $KMnO_4$ methods in determining the calcium content. Atomic Absorption Spectroscopy (AAS) technique validated the mean concentration values obtained from each method with less than 6.4% difference. The proposed titration methods are simple, rapid and sufficiently precise, without the use of expensive analytical instruments. This study is a good alternative method to easily determine the amount of calcium in historic lime mortars which is valuable in heritage conservation work and restoration of old structures in the Philippines.

**Keywords:** lime mortar, titration, Fourier transform infrared spectroscopy, atomic absorption spectroscopy, cultural heritage conservation

**Abstrak**

Satu kaedah penentuan kalsium untuk mortar batu kapur dalam runtuhan gereja lama telah dibincangkan. Dua kaedah analisis volumetrik telah dibangunkan; pentitratan menggunakan larutan EDTA dan $KMnO_4$. Pecahan mengikut saiz ayak (<0.075mm) telah digunakan untuk pentitratan yang kaya dengan $CaCO_3$ yang telah ditentukan oleh teknik inframerah transformasi Fourier (FTIR). Sampel mortar batu kapur dari Misamis Oriental menghasilkan purata kepekatan kalsium 59.60% ± 4.64 dan 60.48% ± 6.68 untuk masing-masing EDTA dan $KMnO_4$, manakala sampel mortar batu kapur Metro Manila adalah 73.54% ± 2.68 untuk EDTA dan 73.33% ± 6.88 untuk $KMnO_4$. Analisis ujian-t dan ujian-F mengesahkan bahawa tidak ada perbezaan signifikan antara kaedah EDTA dan $KMnO_4$ dalam penentuan kandungan kalsium. Teknik spektroskopi serapan atom (AAS) telah menentusahkan nilai kepekatan yang diambil dari setiap kaedah memberikan perbezaan kurang daripada 6.4%. Kaedah pentitratan yang dicadangkan adalah mudah, cepat dan cukup tepat, tanpa menggunakan instrumen analisis mahal. Kajian ini merupakan alternatif yang baik dengan mudah menentukan kandungan kalsium dalam mortar batu kapur bersejarah yang berharga dalam kerja-kerja pemuliharaan warisan dan pemulihan struktur lama di Filipina.

**Kata kunci:** mortar kapur, pentitratan, spektroskopi inframerah transformasi Fourier, spektroskopi serapan atom, pemuliharaan warisan budaya

## Introduction

The overall amount of calcium is an important parameter for replicating historic lime-based mortars for restoration work. Calcium is the principal chemical element found in binders which is the component of mortars responsible for holding together the different stone and sand aggregates. Binders are essentially composed of lime or $CaCO_3$ produced by burning limestone. In the Philippines, lime can also be obtained from crushed seashells and corals [1]. The temperature and manufacturing process of lime is crucial in determining the mortar's physical properties and mechanical behaviour. Specifically, the crystal arrangement, porosity and the lime's reactivity when water is added (slaking) will be affected [2, 3]. The absence of standard methodologies in lime preparation in the past, as well as the lack of detailed documentation on its manufacture in the Philippines, have produced old lime-based mortars which are non-uniform and varied in chemical compositions relative to its location. Hence, proper scientific investigation to understand conventional lime-making techniques in the past based on calcium content is crucial for proper conservation work of historic structures in the Philippines.

This study describes the amount of calcium in a lime-based historic mortar from church ruins built during the Spanish Colonial Period in the Philippines. The country was under Spanish rule for almost 400 years from 1521 to 1898 and was heavily influenced by Roman Catholic traditions. The church ruin in Misamis Oriental in the southern island of Mindanao was built during the mid-1800's [4] while the one collected from Metro Manila, which is the capital city of the Philippines, was constructed in the early 1800's [5]. These sites were chosen for this study because of their different geographical locations, hence, different raw materials used in its construction. It also represents the unique building-making methods characteristic of the Jesuits (Misamis Oriental) and the Franciscans (Metro Manila) which are major Catholic religious orders during the Spanish Era in the Philippines.

Complexometric titration using ethylenediaminetetraacetic acid (EDTA) and oxidation-reduction (redox) titration with potassium permanganate ($KMnO_4$) were the techniques utilized to quantify the amount of calcium in the historic mortar samples from Misamis Oriental and Metro Manila. The accuracy of these methods was confirmed using atomic absorption spectroscopy (AAS). Statistical analysis (*t*-test and *F*-test) was also employed to determine if both titration methods yield comparable results. EDTA can be completely deprotonated to the anion, $EDTA^{4-}$ in basic solution, to form a 1:1 complex with the calcium ions present in the lime mortar sample as shown in equation (1). Since EDTA is a stronger complexing agent than the indicator, Eriochrome black T (EBT), it will displace the calcium-EBT complex forcing the indicator to return to its original form (blue color) marking the endpoint of the titration.

$$CaCO_3 + EDTA^{4-}_{(aq)} \rightarrow Ca(EDTA)^{2-}_{(aq)} + CO_3^{2-}_{(aq)} \quad (1)$$

The redox reaction between oxalic acid and $KMnO_4$ is another method to detect the amount of calcium in old mortar samples. Calcium was precipitated with oxalate ion and dissolved in dilute acid as represented by equation (2). The liberated oxalic acid was titrated with $KMnO_4$ as shown in equation (3), which is a strong oxidizing agent. Due to the intense color of the permanganate ion, it is already sufficient in detecting the endpoint of the titration. The permanganate ion which forms a $Mn^{+7}$ oxidation state was reduced to manganese ion with an oxidation state of $Mn^{+2}$ while carbon was oxidized from $C^{+3}$ to a $C^{+4}$ oxidation states.

$$CaC_2O_{4(aq)} + 2H^+_{(aq)} \rightarrow Ca^{2+}_{(aq)} + H_2C_2O_{4(aq)} \quad (2)$$

$$5H_2C_2O_{4(aq)} + 2MnO_4^-{}_{(aq)} + 6H^+_{(aq)} \rightarrow 10CO_{2(g)} + 8H_2O_{(l)} + 2Mn^{2+}_{(aq)} \quad (3)$$

Different complexometric and redox titration methods were applied for limestone [6, 7] using a variety of titrants and colored indicators, such as disodium EGTA, calcon and EBT indicators [8, 9], and azochromotropic acid derivative indicators [10]. Potentiometric titration using calcium sensitive electrodes [11] was also reported in literature, as well as flow-injection analysis [12] and atomic absorption spectroscopy methods [13]. Calcium oxide was determined in lime mortars by titrating with EDTA and methylene blue indicator [14]; however, the sample preparation and analysis are different from this study. In general, none of these reported methods were applied directly on historic lime-based mortars whose chemical properties were influenced by the local manufacturing process.

## Materials and Methods

### Mortar samples

The lime-based mortar samples were collected from two different sites in the Philippines. One sample was acquired from the southern Mindanao Island at Misamis Oriental in April 2015 and the other was obtained from the northern Luzon Island at Metro Manila, where the capital city of the Philippines is located (Figure 1), in April 2014. Each respective sample was found within the ruins of old Catholic churches built in the 19$^{th}$ century. The sample from Misamis Oriental (8.2g) was gently scraped-off from a coral-stone wall ruin, which is believed to be part of the church's window arch, while the Metro Manila sample (14.7g) was taken from a loose brick fragment wall believed to be a segment of the old church foundation. The mortars used in the analysis were removed from its surrounding materials at an approximate depth of about 0.5 to 1.5 cm from its surface to prevent contamination. Both mortars are made entirely of lime binder which was evident from its powdery texture.

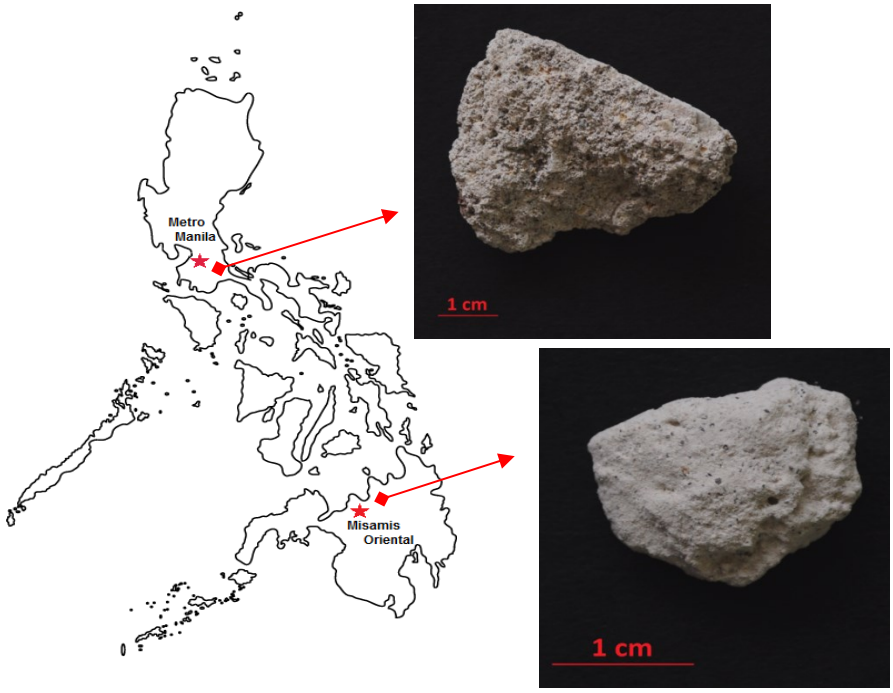

Figure 1. Location map showing the collection site at Misamis Oriental and Metro Manila. Inset photos show the historical lime mortars used for this study

Each mortar samples (between 4.0 to 8.0g) were gently pulverized into small pieces and disaggregated, ensuring that the original texture of the aggregate is not lost in this process. The crushed materials were sieved through sizes of 4.750, 2.360, 1.180, 0.600, 0.425, 0.250, 0.150 and 0.075 mm using a USA Standard Testing Sieve ASTME11 Specification. Fractions smaller than 0.075 mm and retained in the "pan" were also included. Efficient separation of the different fractions was achieved by having the sieves shaken in a mechanical shaker (US Tyler brand) for 5 minutes. The resulting fractions were individually weighed and labelled according to their respective retained sieve size.

### Analysis by Fourier transform infrared spectroscopy

For both mortar samples, a small portion of sieved fraction retained in the "pan" (<0.075mm) was mixed, grounded, and pressed together with KBr powder to form a thin and transparent pellet. The ratio of sample relative to the amount of KBr is about 1 to 2%. Pure analytical grade $SiO_2$ (Sigma-Aldrich) and $CaCO_3$ (Unichem, 98%) were also pelletized with KBr. The IR spectrum was recorded using a Thermo Scientific Nicolet 6700 FT-IR

Spectrophotometer in the finger print region 2400 – 400$cm^{-1}$ with a resolution of 4 $cm^{-1}$ and 32 scans per spectrum [15]. The spectrum was reported as absorbance relative to the wave number.

**Titration with EDTA solution: Standardization of EDTA**
The EDTA solution was prepared by mixing 2.0g EDTA powder (Himedia, 99.5%), 1.0g of NaOH (Unichem, 96%) and 0.15g of $MgCl_2 \cdot 2H_2O$ (Qualikems, 99%). It was diluted with distilled water in a 1L volumetric flask. All chemical reagents are analytical grade.

**Preparation of standard analyte**
The analyte was prepared by measuring 0.20g of oven dried (110$^0$C for 24 hours.) analytical grade $CaCO_3$ (Unichem, 98%) in three separate 100 mL beakers. Concentrated analytical grade HCl (Macron) was added drop wise until 6.0 mL. This was followed by the addition of 50.0mL distilled water and boiled in water bath for 5 minutes. The solution was transferred into a 250 mL volumetric flask after cooling and diluted with distilled water.

A 25.0 mL aliquot was pipetted in three individual 250 mL Erlenmeyer flasks and combined with 10.0 mL of ammonium buffer and 5 drops of EBT indicator (Merck). A titration set-up was assembled and the $CaCO_3$ solution in the flask was titrated with EDTA solution in the burette until the first appearance of a persistent clear blue color, marking the endpoint of the titration. The concentration of EDTA was calculated in molarity.

**Preparation of unknown analyte**
About 0.10 to 0.15g of mortar samples from the sieve size left in the pan (<0.075mm) were dried in an oven for 24 hours at 110 $^0$C. Drop-wise addition of concentrated HCl was done directly on the sample until dissolution was complete. It was then boiled in 50 mL distilled water, cooled and diluted to the mark with distilled water in a 250 mL volumetric flask. A 25.0 mL aliquot portion was titrated with the standardized EDTA solution until the appearance of a persistent clear blue color with EBT indicator. Three replicate trials were done. The concentration of calcium in the unknown sample was reported in terms of its percentage composition.

**Titration with $KMnO_4$ solution: Standardization of $KMnO_4$**
The $KMnO_4$ solution was prepared by dissolving 1.58g analytical grade $KMnO_4$ powder (Univar, 99%) in 50.0 mL distilled water and diluted in a 1L volumetric flask.

**Preparation of standard analyte**
A dried (110 $^0$C for 2 hours) $Na_2C_2O_4$ (Unichem, 99.8%) measuring about 0.22g was placed in a 500.0 mL beaker and dissolved in 250.0 mL 0.75M $H_2SO_4$ (Macron). It was heated and maintained at a temperature between 80 – 90 $^0$C, while being titrated with the prepared $KMnO_4$ solution. The appearance of a persistent pink color marks the end point of the titration. Three trials were done. A blank sample was also prepared by using 0.75M $H_2SO_4$ and titrated directly with $KMnO_4$. The volume obtained (0.2 mL) was subtracted from the volume of titrant acquired with the sample. The concentration of $KMnO_4$ was calculated and expressed in molarity.

**Preparation of unknown analyte**
The sieved fractions retained in the "pan" were dried for 3 hours at 120 $^0$C in an oven and cooled. About 0.25 – 0.30g were obtained for each dried mortar sample and placed in separate 250 mL beakers. To dissolve the solid samples, 20.0 mL drop-wise addition of concentrated analytical grade HCl (Macron) was carefully done. This was followed by mixing 40.0 mL distilled water and stirred for 10 minutes at room temperature (30 $^0$C) until all carbon dioxide was removed from the solution.

A 20.0 mL aliquot of the digested mortar samples was added with 3 drops of saturated bromine water and gently boiled for 3 minutes. Each sample portion was diluted with 20.0 mL distilled water, boiled and added with 15.0 mL of hot 6% (w/v) $(NH_4)_2C_2O_4$ (Mallinckrodt, 99%) solution. To precipitate the $CaC_2O_4$, 6M $NH_3$ (Merck, 25%) solution was added slowly until color changes from an intermediate yellow-orange or pH range from 4.5 – 5.5. The solution was allowed to stand for 20 minutes and filtered. The precipitate was washed several times with 5.0 mL of cold water to induce the formation of more precipitates.

The $CaC_2O_4$ precipitate from each trial was dissolved in 15.0 mL distilled water and 7.0 mL 3M $H_2SO_4$ in a beaker. It was heated and maintained at a temperature between 80 – 90 $^0$C while being titrated with the standardized $KMnO_4$. A blank volume was titrated (0.20 mL) and subtracted from the volume of $KMnO_4$ consumed. The percentage of calcium in the mortar samples was computed.

**Calcium determination by atomic absorption spectroscopy**

Calibration curves were prepared by diluting a commercially available 1000 ppm analytical standard grade calcium solution (Fluka) to concentrations of 0.10, 0.30, 0.50, 0.80 and 1.0 ppm, respectively, in separate 50 mL volumetric flasks. The concentration range assures that the calibration curve is linear as required by Beer's Law. A chemical suppressant (2.5 mL, 5.0% w/v strontium nitrate, $Sr(NO_3)_2$) were also added to each standard solution before diluting to the mark with distilled water. Absorbance readings were recorded in a Shimadzu AA-6300 Atomic Absorption Spectrophotometer in an air-acetylene gas mixture at a detection wavelength of 423 nm. Three replicate measurements were performed. Distilled water was used as solvent blank during the experiment [16].

For the mortar samples, 0.20 mL aliquot portion from the original 250 mL EDTA digested binder fraction (< 0.075 mm) was added with 0.50 mL of 5.0% $Sr(NO_3)_2$ in separate 100 mL volumetric flasks. The same AAS parameters mentioned in the preparation of the calcium standard curve were followed afterwards.

## Results and Discussion

**Particle size distribution in mortars**

The mechanical separation of different grain sizes in the mortar samples was achieved through sieve analysis. The relative sizes of the particles and their distribution in the mortar are related to their engineering behaviour [17]. Figure 2 shows the relationship between the mesh size and the percentage of particles retained in a specific sieve for both lime mortar samples. Based on the American Society for Testing and Materials (ASTM, 1980) classification system, the sample from Misamis Oriental is generally composed of fine sand aggregates since most of its weight retained in the 0.250 mm and 0.150 mm sieve sizes, respectively. The Metro Manila sample, however, is mainly made up of medium to fine sand aggregates due to more particles distributed within the sieve size range of 0.600 mm to 0.250 mm, respectively. The absence of particles retained in the 4.750 mm sieve size for the Misamis Oriental sample was compensated by a higher percentage amount of binder fraction from the "pan" (<0.075 mm) [18] which is comparable in weight with the 0.150 mm sieve size. This is in contrast with the Metro Manila sample which has a well-represented particle size distribution, hence, a relatively lower percentage of the binder fraction was observed. There was no evidence which may suggest that the aggregates in both mortar samples are calcitic ($CaCO_3$) in nature.

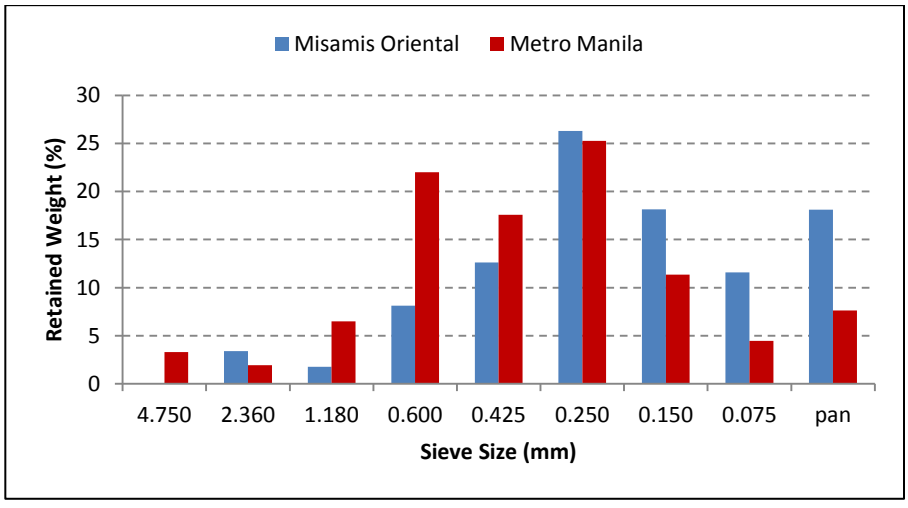

Figure 2. Grain size weight distributions of the mortar samples

To know if the old mortar samples were manufactured with good representations of each particle sizes, a gradation curve was plotted as shown in Figure 3. From this logarithmic plot, the important basic parameters of effective size ($D_{10}$), uniformity coefficient ($C_u$) and coefficient of curvature ($C_c$) were computed. $D_{10}$ is defined as the value for the grain size diameter (D) that passed through the sieve at 10% and was extrapolated on the graph. To compute for $C_c$ and $C_u$, the values for $D_{30}$ and $D_{60}$, or 30% and 60% of particles that passed through the sieve, respectively, were also obtained. The results were tabulated in Table 1 for each mortar samples. Since the values for $C_c$ are within the ranges of 1 to 3 and have $C_u$ values that are greater than 4, both Misamis Oriental and Metro Manila samples are considered as well-graded [19].

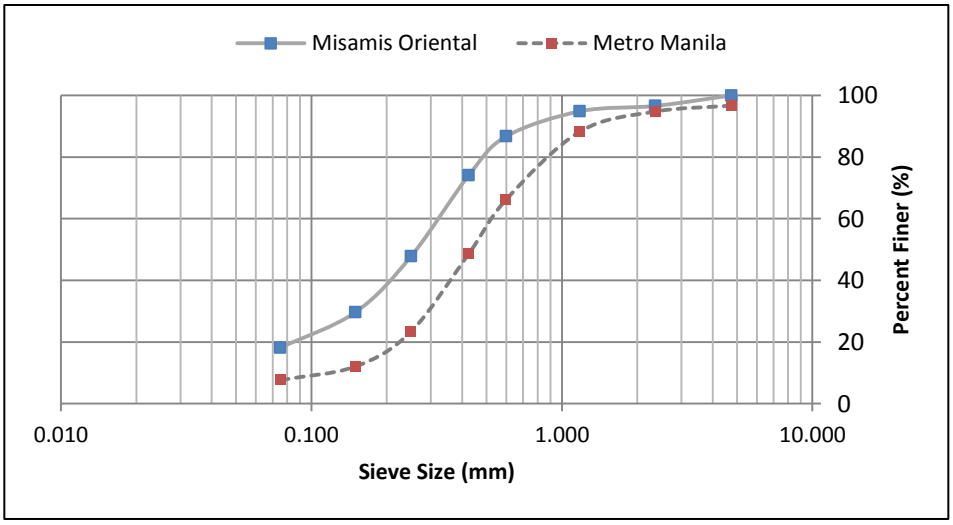

Figure 3. Particle size gradation curve of the mortar samples

Table 1. Soil parameters used for classification of mortar samples

| Parameters | Mortar Samples | |
|---|---|---|
| | Misamis Oriental | Metro Manila |
| $D_{10}$ | [a]0.040 | 0.125 |
| $D_{30}$ | 0.150 | 0.300 |
| $D_{60}$ | 0.325 | 0.525 |
| [b]$C_u$ | 8.13 | 4.20 |
| [c]$C_c$ | 1.73 | 1.37 |

[a]determined by extrapolation, [b]greater than 4, [c]between 1-3

**Binder characterization by Fourier transformation infrared spectroscopy**

There are evidences from X-ray diffraction (XRD) studies that peak intensities corresponding to calcite increases relative to the other minerals present in lime mortars as the sieve size decreases [18]. Hence, the finest fraction which was retained in the "pan" (<0.075 mm) is considered to be the binder fraction and concentrated with $CaCO_3$. Figure 4 shows the infrared spectrum of the mortar sample's binder fractions (<0.075) compared with pure calcium carbonate and pure silicon dioxide. These will serve as IR absorption standards for comparing the old lime mortar sample with sand (composed of $SiO_2$) and lime (mainly contains $CaCO_3$), respectively, which are raw materials in its manufacture. For calcium carbonate, the characteristic IR absorption peaks are the C-O in-plane bending ($\upsilon 4$) at 712 $cm^{-1}$ and C-O out-of-plane bending ($\upsilon 2$) at 876 $cm^{-1}$. These sharp peaks are suitable in determining the presence of $CaCO_3$ because few compounds absorb strongly at this wavenumber. Furthermore, the broad peak at 1419 $cm^{-1}$ is

attributed to the C-O asymmetric stretching (υ3) of $CaCO_3$. The most intense absorption bands of silicon dioxide are centered at 1082 $cm^{-1}$ assigned to the asymmetric stretching mode of Si-O-Si, 795 $cm^{-1}$ which is the symmetric stretching mode of Si-O-Si and the bending vibrations of Si-O-Si centered at 463 $cm^{-1}$, respectively [20,21]. Based on the IR spectrum in Figure 4, the binder fractions from both mortar samples have absorption peaks that are very similar with the bands of calcium carbonate. The absence of peaks attributed to silicon dioxide confirms that the binder fraction in the mortar sample is purely $CaCO_3$. Hence, this fraction was targeted for digestion with acid and titrated with EDTA and $KMnO_4$ to determine the calcium content.

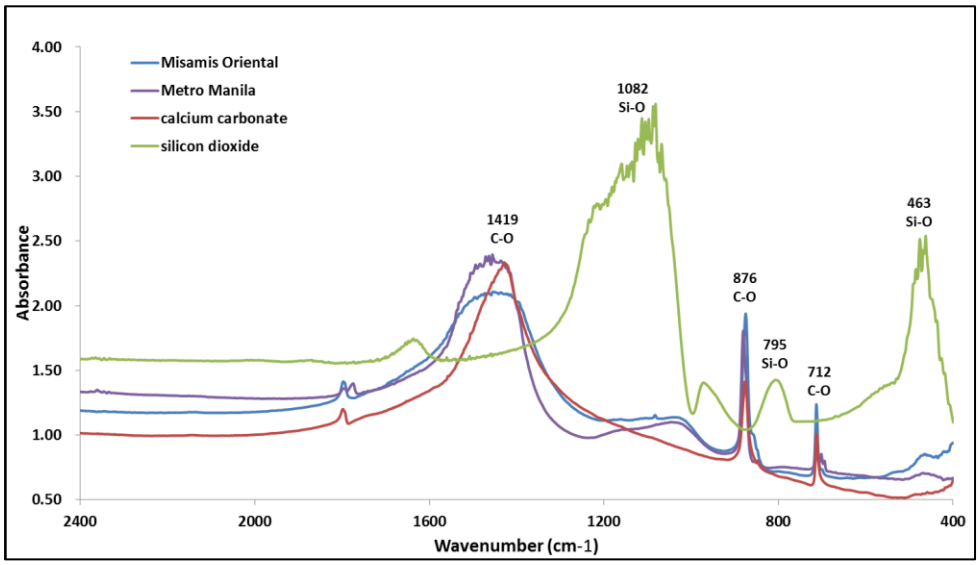

Figure 4. Spectrum of mortar fractions retained in pan (<0.075 mm) taken at finger print region (2400 – 400 $cm^{-1}$)

**Analysis of EDTA titration**

The mean value obtained from the standardization of EDTA solution using pure analytical grade $CaCO_3$ was 4743 ± 132.9 µM at 95% confidence level. The standard deviation of 1.49 x $10^{-5}$ indicates that the concentration of each trial run is precise. From this standardized EDTA concentration, mortar samples from Misamis Oriental and Metro Manila were titrated. Results show that calcium content of the binder fraction for Metro Manila sample (73.54%) is higher compared to the Misamis Oriental sample (59.60%), representing a difference of 13.94%. This implies that the lime material used for making mortars were sourced from different locations which is highly possible because the church ruins are geographically apart. Absence of direct trade of raw materials between Metro Manila and Misamis Oriental was also inferred. Moreover, difference in mortar preparation techniques may contribute to this variation. Since the Misamis Oriental church ruin is located on a promontory, probably sea shells or corals may have been used as sources of lime which accounts to the observed difference.

Table 2 shows the important parameters used to determine the percentage of calcium in the Misamis Oriental sample. Binder fractions in mortars are expected to be homogenously mixed [1, 5]. Therefore, a 95% confidence level for the mean calcium content of 59.60% ± 4.64 gives a range of 54.96% to 64.24%. This percentage represents the true amount of calcium in the entire mortar sample obtained from the site. The percentage calcium from each trial is also within the 95% confidence limits. Since the coefficient of variation is 3.14%, which is less than the acceptable percentage of 5%, the values from this titration are considered precise [22].

Table 2. Calcium content of Misamis Oriental sample using EDTA

| Mass of Mortar Sample (g) | Trial | Volume of EDTA Consumed (mL) | Concentration of Ca (ppm) | Mass of Ca (g) | % Ca (w/w) in Sample | Mean (w/w) and Standard Deviation |
|---|---|---|---|---|---|---|
| 0.1079 | 1 | 32.70 | 248.62 | 0.06216 | 57.60 | 59.60% ± 4.64* |
| | 2 | 34.80 | 264.59 | 0.06615 | 61.30 | (1.87) |
| | 3 | 34.00 | 258.50 | 0.06463 | 59.89 | |

* at 95% confidence level

Results from Table 3 shows that the Metro Manila sample has a 95% confidence level for the mean calcium content of 73.54% ± 2.68 or a calcium percentage range of 70.86% to 76.22%. Hence, the actual calcium content for the entire Metro Manila mortar sample obtained from the site should be within this interval range. The individually measured calcium concentration per trial also falls in these confidence limits. The titration of the Metro Manila sample was considered to be more precise than the Misamis Oriental sample based on the smaller confidence interval value which is attributed to random errors brought about by the visual determination of the end point color. The computed coefficient of variation (1.47%) supports this higher precision compared to the Misamis Oriental titration. Samples from both sites yielded mean calcium contents that are statistically consistent with each other suggesting that EDTA titration can be used for old lime mortar samples.

Table 3. Calcium content of Metro Manila sample using EDTA

| Mass of Mortar Sample (g) | Trial | Volume of EDTA Consumed (mL) | Concentration of Ca (ppm) | Mass of Ca (g) | % Ca (w/w) in Sample | Mean (w/w) and Standard Deviation |
|---|---|---|---|---|---|---|
| 0.1027 | 1 | 39.30 | 298.80 | 0.07470 | 72.74 | 73.54% ± 2.68* |
| | 2 | 39.50 | 300.32 | 0.07508 | 73.11 | (1.08) |
| | 3 | 40.40 | 307.16 | 0.07679 | 74.77 | |

* at 95% confidence level

**Analysis of $KMnO_4$ titration**

The $KMnO_4$ solution was first standardized using sodium oxalate and the mean concentration is 10660 ± 640.5 μM at a 95% confidence level. Precision for the standardization method was considered high due to the small value ($2.58 \times 10^{-4}$) of the standard deviation. The results of $KMnO_4$ titration on the Misamis Oriental sample shown in Table 4 is consistent with the mean calcium concentration values obtained from EDTA titration and differs only by 1.47 units. However, the confidence limits (± 6.68) and standard deviation equal to 2.69 is higher compared to that of the EDTA titration. This is due to the tedious process of crystallization and in maintaining the temperature during the titration which may introduce random errors in the system. Nevertheless, the measured calcium concentration values per replicate are within the allowable confidence limits and the coefficient of variation (4.45%) is still less than 5%, making the titration process precise.

Table 4. Calcium content of Misamis Oriental sample using $KMnO_4$

| Mass of Mortar Sample (g) | Trial | Volume of $KMnO_4$ Consumed (mL) | Mass of Ca (g) | % Ca (w/w) in Sample | Mean (w/w) and Standard Deviation |

The same pattern of consistency was also observed for $KMnO_4$ titration of Metro Manila sample shown in Table 5 compared to the results of EDTA titration and differs by 0.286 units. A high confidence limit value (± 6.88) and standard deviation (2.77) were also obtained from the Metro Manila sample supporting the idea that $KMnO_4$ titration method is more prone to random errors. A coefficient of variation of 3.78% and calcium concentration values per replicate, which are within the given confidence limits, make the data obtained precise and reliable.

Table 5. Calcium content of Metro Manila sample using $KMnO_4$

| Mass of Mortar Sample (g) | Trial | Volume of $KMnO_4$ Consumed (mL) | Mass of Ca (g) | % Ca (w/w) in Sample | Mean (w/w) and Standard Deviation |

**Comparison of EDTA and $KMnO_4$ titration methods**

Results of the two tailed *t*-test for two independent means performed on the Misamis Oriental mortar samples indicate that at 95% confidence level, the calculated *t* ($t_{calc}$) is 0.4653 which is less than the critical *t* ($t_{table}$) value of 2.776 for 4 degrees of freedom. Hence, the null hypothesis ($H_0$) is accepted and the two titration methods, EDTA and $KMnO_4$, are not significantly different at $p < 0.05$. For the Metro Manila mortar samples, the same *t*-test yielded a $t_{calc}$ value of 0.1242 which is also less than the $t_{table}$ (2.776) for a 95% confidence and 4 degrees of freedom. The null hypothesis is therefore accepted and there is no significant difference between the calcium concentrations resulting from the EDTA and $KMnO_4$ titration [23, 24].

The precision of the two different titration methods was evaluated using the *F*-test. For the Misamis Oriental mortar samples, the computed *F*-value ($F_{calc}$) is 2.07 and for the Metro Manila sample $F_{calc}$ is equal to 6.58. Since both $F_{calc}$ values did not exceed the tabulated critical value of *F* for a 95% confidence level at two degrees of freedom (19.0), there is statistically no significant difference between the standard deviations of the EDTA and $KMnO_4$ titration methods for both mortar samples [23].

The *t*-test and *F*-test analysis proves that the EDTA and $KMnO_4$ titration methods done in this study will provide the same analytical results and the observed difference are attributed entirely to random errors and not to systematic errors. This shows that both methods are comparable and either method is effective in determining the concentration of calcium on old lime mortar samples.

**Atomic absorption spectroscopy analysis of calcium**

AAS was used to further validate the results of the titration methods in determining the amount of calcium on the old mortar sample's binder fraction. Table 6 shows that the calcium concentration obtained in the AAS of the Misamis Oriental sample differs by about 1.2 to 2.3 units from the titration methods or a percentage difference of

about less than 3.9%. The Metro Manila sample however differs from the titration method by about 4.3 to 4.8 units which translates to a percentage difference of roughly less than 6.4% from the titration methods. These percentage differences are statistically acceptable considering the comparison is between a classical method and an instrumental method [25].

Table 6. Summary of AAS data for calcium content

| Sample Site | Trial | Mass of Sample (g) | Absorbance | % Ca | Mean and Standard Deviation |
|---|---|---|---|---|---|
| Misamis Oriental | 1 | 0.1079 | 0.0538 | 61.09 | 58.21% ± 6.31* (2.54) |
| | 2 | 0.1079 | 0.0506 | 57.19 | |
| | 3 | 0.1079 | 0.0499 | 56.34 | |
| Metro Manila | 1 | 0.1027 | 0.0640 | 77.26 | 78.11% ± 4.82* (1.94) |

## Conclusion

The calcium content of the binder fractions in the historic lime mortar samples were determined quantitatively using EDTA and $KMnO_4$ titration. This serves as a very useful baseline information for future renovation work of historic structures in the Philippines. Lime mortars are not manufactured the same since the two church ruins in this study have no direct relation with each other and are geographically apart. Both EDTA and $KMnO_4$ titration methods yielded comparable results and have high precision based on the statistical tests performed and supported by AAS data in this study. Hence, both titration techniques can be applied for calcium analysis of historic mortars. Furthermore, the approach of analyzing the sieved fractions separately is not common in literature, especially since the analysis of calcium content in this study was focused on the finest fraction (<0.075mm) which makes it unique. This study could be utilized readily for routine analysis of calcium in lime mortars that is simple, reproducible and cost-effective.

## Acknowledgement

The authors would like to convey their sincere gratitude to the Chemistry Department of the De La Salle University, Manila for the generous support in equipment use and for subsidizing the chemical reagents in this study. The helpful insights and assistance of the following persons are highly appreciated: Dr. Glenn Alea, Mr. Michael Ajero and Dr. Maria Carmen Tan. The authors would also like to acknowledge Ms. Mutya N. Reynancia, English Program Coordinator and Advanced English Proficiency Training Coordinator of the General Education Department of the Far Eastern University Diliman, Quezon City for her expertise in editing this article.

**Abstract**

In industrial hygiene, biomarkers maintain their promise to reveal the true extent of occupational exposure. The environmental limit values proposed by industrial hygienist associations are more than biological, health-based values indicating professional hazards to humans. High-throughput screening of samples is therefore the strategy of choice to detect occupational exposure biomarkers, yet it requires user-friendly apparatus that give relatively prompt results while ensuring high degrees of selectivity, precision, accuracy and automation, particularly in preparation processes. In light of the above, this contribution describes a novel gas chromatography/triple quadrupole mass spectrometry/positive chemical ionisation approach for determining urinary α-fluoro-β-alanine, a metabolite of 5-fluorouracil, the most widely employed antineoplastic drug. In this new procedure chromatography's sensitivity is combined with the user-friendliness of alkyl chloroformate/trialkyloxonium on-sample derivatizations followed by solid-phase microextraction sampling, to which is added the quantitative accuracy afforded using a specific isotope-labelled internal standard. The quantification limit for α-fluoro-β-alanine was 25.4 µg/L. Intra- (3.8%) and inter-session (4.5%) repeatability was also evaluated. This method serves to identify suitable risk-control strategies for occupational hygiene conservation programs.

## Introduction

5-fluorouracil has been one of the most frequently used antineoplastic drugs in the world for more than 20 years, and it is still considered to be among the most active cytostatic agents in advanced colorectal cancer as well as for malignancies of the head and neck [1]. In Italy, more than 400 kg are being administered each year [2]. In addition to the therapeutic effects, however, many side effects are known, such as leukopenia, stomatitis, diarrhea, nausea, thrombocytopenia and a decrease in erythrocyte precursors in the marrow [3, 4]. Several groups of workers, such as oncology nurses involved in the preparation and administration of this antineoplastic drug, as well as personnel employed in pharmaceutical plants, are occupationally exposed to this substance. In the processes of health risk-assessment at work, biological monitoring of occupational exposure often plays a central role in identifying the suitable risk-control strategies and hygiene conservation programs. The availability of a highly-sensitive, compound-selective and validated analytical method for measuring a suitable marker of occupational exposure would allow personnel to know the true extent of exposure.

Although the bio-transformation of 5-fluorouracil in humans was described 30 years ago, when a patient study found that 80% of the dose is quickly excreted in urine as α-fluoro-β-alanine (FBAL), no governmental industrial hygienist association has ever mentioned FBAL health-based values as indicators of human professional exposure to this anti-cancer drug. In the field of occupational medicine, few analytical methods have been published to measure urinary FBAL, and their very low number of positive biological samples demonstrates the need to adopt more sensitive analytical methods. The existing assays have limitations, namely: their complexity, their use of solvents, and/or the need for clean-up steps to extract and eliminate interfering compounds from the urine, all of which involved lengthy manual operations, bigger costs, uncertainty in the determination analysis, and the possible loss of analyte. For these reasons, simultaneous and more sensitive assay methods than those available were needed; furthermore, many researchers have called for standardization of analytical factors affecting FBAL determination [2, 5 – 12].

Sample preparation remains one of the more time-consuming and error-prone aspects of analytical chemistry. Over the last 10 years, miniaturization has attracted much attention and has driven solvent and sample savings, sample enrichment, rapid sample preparation, and easier automation. Solid-phase microextraction (SPME) analysis is considered one of the major advances that shaped 20$^{th}$ century analytical chemistry [13]. It integrates sampling, extraction, concentration and sample introduction into a single step, without any polluting, organic solvent for extraction [14-17].

Accordingly, we sought to simplify sample treatment by using the SPME technique. The efficiency of alkyl chloroformate/trialkyloxonium on-sample derivatizations has been demonstrated, as has the success of quantitative determination by gas chromatography (GC) coupled with triple quadrupole-mass spectrometry (QpQ-MS)/positive chemical ionisation (PCI). By combining these procedures, we propose a new user-friendly apparatus which provides relatively prompt results with high degrees of selectivity, precision and accuracy.

## Materials and Methods

### On-sample propyl chloroformate-trimethyloxonium tetrafluoroborate (TMO) derivatizations

To convert the FBAL (CAS n. 867-84-5, Cat. n. F0185, TCI Europe) into related N-propyl carbamate, 100 µL of propyl chloroformate (CAS n. 109-61-5, Cat. n. 249467, Aldrich) derivatizating agent was added to a 20.0 mL vial containing 0.5 mL of urine and 10 µL of 2,3,3-D3 (R, S)-3-amino-2-fluoropropanoic acid (FBAL-D3) internal standard (IS) water solution (5 µg/mL) and continuously agitated for 30 minutes with a magnetic stirring bar. To convert the FBAL carboxyl group, derivatization with TMO (CAS n. 420-37-1, Cat. n. 281077, Aldrich) was performed in two steps at room temperature with agitation, after previous dilution with 1.5 mL of water. About 20 mg of sodium carbonate ($Na_2CO_3$) were added and within 4 minutes approximately 30 mg of solid TMO were added in two aliquots. After 1 minute, the solution was neutralized with about 15 mg of sodium bicarbonate ($NaHCO_3$).

This procedure was repeated. Finally, sodium chloride (0.5 g) was added for salting out and the vials were processed for on-line or off-line extraction.

**On-line headspace (HS-SPME) and xyz robotic apparatus**
Automation of the GC procedure was achieved using a new Flex autosampler (EST Analytical, Fairfield, USA). For HS-SPME absorption, samples were incubated at 60 °C with a pulsed agitation (on for 2 s at 500 rpm and off for 4 s), before the polyacrylate (PA) 85 μm SPME fiber (Cat. n. 57305, Supelco) was inserted into the vial, under the same temperature/agitation conditions. After absorption, the SPME fiber was introduced into the GC injector port by *xyz* autosampler.

**Off-line HS-SPME sampling and *xyz* robotic apparatus**
The SPME Multi Off-Line Sampler (Chromline, Prato, Italy) is a holder designed to be used with FFA SPME fibers; in our case PA 85 μm SPME FFA (Cat. n. FFA 57294-U, Supelco) were used. The holder acts as a support when exposing the SPME fiber in the vial, after which it is placed on the plate of the 15-position magnetic stirrer (Chromline) at 60 °C. After exposure, the FFA is removed from the Multi Off-Line Sampler and placed into the 45-position Multi Fiber eXchange (MFX, Chromline, Prato, Italy), which performs automated exchanges of the fibers. For desorption the fiber is put into a Flex *xyz* autosampler (EST Analytical) with GC instrumentation equipped with Merlin Microseals (Cat. n. 24817-U, Sigma-Aldrich). A connection with the Laboratory Information Management System (Bika Lab System) provides a user-programmable suite of options.

**GC/QpQ-MS**
Analyses were performed with a Varian 3900 GC equipped with electronic flow control and a Varian 320-QpQ-MS (Varian Inc.) detector. A MEGA-5-MS fused silica capillary column (internal diameter 0.25 mm, length 30 m and film thickness 0.25 μm, Cat. No. MS-5-025-025-30, MEGA, Legnano, Italy) was used. For desorbing the analytes, the SPME fiber was introduced into the 1177 Varian GC injector port.

**Synthesis of FBAL-D3**
FBAL-D3 was synthesized following the protocol reported by Gani et al. [18] with slight modifications. First, DL-Serine D3 (850 mg, 8 mmol) was suspended in dry methanol (16 mL) in a nitrogen ($N_2$) atmosphere. After cooling down the suspension with an ice bath, thionyl chloride (1.635 mL, 12.5 mmol) was added slowly. The mixture was stirred for 10 minutes then warmed to room temperature (r.t.) and stirred for 1 hour. Evaporation of the solvent afforded an oily residue. Secondly, DL-Serine D3 methyl ester (980 mg, 8 mmol), benzyl bromide (2 mL, 16.8 mmol), $NaHCO_3$ (3.336 g, 40 mmol), dry tetrahydrofuran (THF) (10 mL) and dry dimethyl sulfoxide (3.2 mL) were placed in a flask in an $N_2$ atmosphere and heated to 80 °C. After 5 hours, the reaction was completed. The mixture was diluted with ethyl acetate (EtOAc) and washed with water three times, dried over sodium sulfate and concentrated. The residue was purified by flash column chromatography on silica gel (hexane/EtOAc 5:1, then 4:1), resulting in 1.44 g of pure product. Third, a solution of DL-serine D3 *N,N*-dibenzylamino methyl ester (1.20 g, 4.0 mmol) in dry THF (20 mL) was added slowly to a solution of diethylaminosulfur trifluoride (0.6 mL, 4.8 mmol) in dry THF (20 mL) at r.t in an $N_2$ atmosphere and stirred for 30 minutes.

Ice and EtOAc were added to the solution followed by solid $NaHCO_3$ until effervescence ceased. The aqueous phase was extracted with EtOAc. The organic phases were combined, washed with water three times and dried on $Na_2SO_4$. The solvent was removed under reduced pressure (r.p.). Fourth, DL-α-Fluoro-β-*N,N*-dibenzyl alanine D3 methyl ester (970 mg, 3.2 mmol) was dissolved in absolute ethanol (50 mL) and 1M HCl (1 eq); to this solution 10% Pd/C (100 mg) was added. The mixture was stirred in a hydrogen atmosphere for two days, then filtered on Celite and washed with ethanol. The alcohols were concentrated under r.p. and treated with 6M HCl for 90 min. The solvent was removed under r.p. and the residue dissolved in water and applied to a column of Amberlite IR45 (OH) using water as eluent. After 100 mL of eluent, the solution was concentrated under r.p. and precipitated from water/acetone, obtaining pure FBAL-D3 as a white solid (236 mg, 50% yield).

**Method validation**
Calibration samples were prepared and analyzed to obtain a calibration curve. Six calibration samples were obtained (30, 60, 120, 240, 480, 960 μg/L) and six analyses for each of the calibration samples were performed. Least-square

linear regression (LSLR) analysis was used to estimate slopes (m) and intercepts (b) of calibration lines y = mx + b, where y is the ratio between the chromatographic area of the analyte and the relative IS, and x the concentration of FBAL (μg/L of urine). The limit of detection (LOD) of the assay was calculated according to the following equation 1:

$$LOD = (3SE_b + b)/m \quad (1)$$

where $SE_b$ is the internal standard error of the intercept [19]. The precision of the assay (as a coefficient of variation, CV%) was based on both within-session and inter-session repeatability. Accuracy was evaluated by the recoveries (calculated from the percentage ratio between the measured and the nominal concentration solutions) at all concentrations used for the calibration plot. Values of accuracy were then compared with the requirements of the US Food and Drug Administration for analytical method validation.

## Results and Discussion

In previous studies, the oft-reported use of solvents and/or clean-up steps were necessary to extract and eliminate most of the interfering compounds from the urine. These procedures resulted in many manual operations, uncertainty of the determination, higher overall costs of the method, and possible analyte loss. Accordingly, we developed a method where the HS-SPME technique was applied after on-sample derivatization, and then coupled with quantitative determination via GC/QpQ-MS. Four fundamental aspects motivated this choice.

### HS-SPME

The first objective was to develop derivatization conditions on HS-SPME technologies to obtain compounds which are not only stable under a variety of conditions, but also easily amenable to sampling, to GC separation, and to MS identification. Since FBAL determination in urine by this technique for previous alkylchloroformate/ trialkyloxonium derivatizations had not been previously reported, the equilibrium and kinetics of the reaction product, with regards to SPME, had to be both theoretically explored and experimentally proven. In a previous work [20], the HS-SPME technique had been used in a three-phase process in which a liquid polymeric coating, a headspace and an aqueous solution were involved. The mass (n) of analytes absorbed by the coating after the equilibrium has been reached is related to the overall equilibrium of analytes in the three-phase system as follows in equation 2:

$$N = (C_0V_1V_2K_1K_2)/(K_1K_2V_1 + K_2V_3 + V_2) \quad (2)$$

where $K_1$ is the SPME coating/HS partition coefficient, $K_2$ is the HS/aqueous matrix partition coefficient, $C_0$ is the initial concentration of the analyte in the aqueous solution, and $V_1$, $V_2$ and $V_3$ are the volumes of the coating, the aqueous solution, and the HS, respectively. Since the K values of the analytes (where $K = K_1 \times K_2$) are often very close to the octanol–water partition coefficient ($K_{ow}$), and $K_2 = K_H/RT$, where $K_H$ is Henry's constant ($C_0$, concentration gas phase/$C_0$, concentration liquid phase). It follows that the equilibrium is controlled by $K_{ow}$ and $K_H$ values. The values $K_{ow}$ and $K_H$ can be found in the literature or calculated, and in this way, it is possible to know in advance whether the HS-SPME method offers some advantages or vice versa. Moreover, the constant of distribution estimated from physicochemical tables or by using the structural unit contribution method can anticipate trends in SPME analysis.

For example, Performs Automated Reasoning in Chemistry (ARChem, Danielsville, Georgia, USA) is a physicochemical calculator that uses computational algorithms based on the fundamental chemical structures to foresee a wide variety of reactivity parameters strictly based on molecular structure. The $K_H$ of the N-propyl carbamate/methyl ester FBAL-derivate was 0.13 atm $cm^3$/mol (Table 1), which agreed with that reported by Pacenti et al. [21]; this confirmed that HS-SPME is efficient under such conditions.

Table 1. Physical properties and partition coefficients of N-propyl carbamate/methyl ester FBAL-derivates evaluated using SPARC software

| SMILES strings | $T_{eb}$ (°C) | $D_{water}$ ($cm^2/s$) | $D_{air}$ ($cm^2/s$) | $K_H$ (atm $m^3$/mol) | $K_{ow}$ (Log) | $P_{vap}$ (log(atm)) |
|---|---|---|---|---|---|---|
| O=C(NCC(F)C(=O)OC)OCCC | 271.8 | $6.52*10^{-6}$ | 0.0483 | $1.25*10^{-7}$ | 1.31 | -5.3 |

**Alkyl chloroformate derivatization conditions**

Chloroformates have been widely used to convert amines into carbamates in aqueous media. One-step treatment of amino acids with chloroformates and alcohols of the same alkyl with catalysis by pyridine met the basic criteria required for an ideal procedure: very simple sample handling in aqueous solutions and derivatization completed within a few seconds with microliter amounts of reagent of negligible cost [22 – 25]. Modification in the reaction conditions towards using reagents with different alkyls appeared to be useful [26, 27] in enabling researchers to prepare a wide variety of esters tailored to the analytical needs of specific tasks. In our method, we decided to carry out such derivatization in water, without using any alcoholic solvent, in order to avoid the formation of undesired side products as those described by Wang et al. [28].

A novel approach to the derivatization of carboxylic groups by the use of TMO, a methyl group of oxonium ions reacts with the anion of the carboxylic group to form methyl ester. This method employs a sample derivatization technique to convert polar substances into hydrophobic compounds, whose volatility is sufficiently high for HS-SPME/GC determination. Trialkyloxonium ions (Meerwein salts), $R_3O^+$, with various counterions such as $SbF_6^-$, $BF_4^-$, $SbCl_6^-$ and $PF_6^-$, are excellent alkylating agents for nucleophiles containing such heteroatoms as N, O, or S [17, 21, 29 – 31]. The application of TMO as a methylating agent together with propyl chloroformates as agent without catalysis by pyridine was implemented in this work. The reaction, occurring under mild conditions at room temperature, is completed in a few minutes (Figure 1).

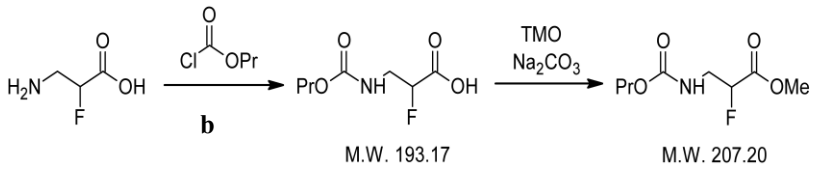

Figure 1. (a) FBAL and (b) propyl chloroformate reaction to related (c) alkyl chloroformate and subsequent trialkyloxonium derivatization which forms (d) FBAL-N-propyl carbamate-methylester

**$^1$H-NMR analysis of propyl chloroformate/TMO derivatization**

The reaction of FBAL and propyl chloroformate was investigated by NMR spectroscopy in D2O, in order to ensure the conversion of the amino group into the corresponding propyl carbamate. The sample was placed in a clear tube and analyzed by a Varian Gemini NMR instrument at 200 MHz. Following the addition of sub stoichiometric quantities of propyl chloroformate, a new set of signals appeared immediately, as the intensity of the reagent's signals decreased, until completely disappearing when a stoichiometric amount of the chloroformate was added. This confirms that FBAL spontaneously reacts with propyl chloroformate in aqueous phase in a quantitative yield. After alkalization of the same solution with $Na_2CO_3$, TMO was added stepwise till a stoichiometric amount was reached. NMR spectra showed an increasing signal of methyl ester until the reagent was completely converted.

**Choice of GC/QpQ-MS/Positive Chemical Ionization (PCI)**

In this work, PCI was used for the analysis of FBAL-derivates to increase the signal intensity of the molecular ions, and then coupled with QpQ-MS during Selected Reaction Monitoring (SRM) to increase their selectivity compared to the background matrix. For PCI we selected methane as the reactive gas, which produced a few fragments of FBAL, as the parent ion was m/z 208 $(M+H)^+$ as peak to be used as precursor ion in QpQ-MS (Figure 2).

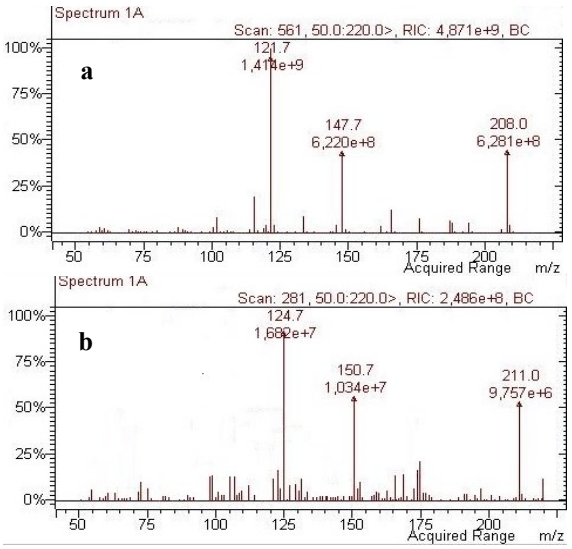

Figure 2. GC/SCAN-MS/PCI spectrum of FBAL (a) and FBAL-D3 (b)

The GC and QpQ-MS/PCI parameters are displayed in Table 2. As indicated in Table 3, the resulting calibration curves for FBAL were linear in the investigated range, showing a correlation coefficient >0.99.

Table 2. GC and QpQ-MS/PCI parameters

| **GC conditions** | |
|---|---|
| Injection | 300°C, 2:1 split mode. Liner 0.75 mm i.d. |
| Oven | 50°C (1 min) increased at 10 °C/min to 180 °C and 30 °C/min to 300°C (2 min). (Run time 20.00 min) |
| Column flow | Helium (99.999%) at a flow rate of 1.2 mL/min |
| Retention times | FBAL (12.141 min) FBAL-D3 (12.131 min) |
| GC interface | 280 °C |
| **MS parameters** | |
| Mode | Positive CI |
| Filament | Electron energy, 70 eV. Filament current, 50 µA |
| Source | Temperature, 200 °C. Pressure, 8 Torr |

| Within-session repeatability (%) | 3.8 |
| Inter-session repeatability (%) | 4.5 |

Accuracy was within 15% of the theoretical concentration, in line with the requirement of the US Food and Drug Administration. The new SPME Multi Off-Line Sampler proposed in this study integrates the MFX (Figure 3).

Figure 3. SPME Multi Off-Line Sampler holder

Several preparation steps immediately before sample injection have been automated, allowing just-in-time sample preparation. Below is an example of the advantages of using an SPME FFA Multi Off-Line Sampler: calculate an extraction time of 40 minutes for FBAL-derivate equilibrium in a three-phase SPME system plus an analysis time of 20 minutes (Figure 4).

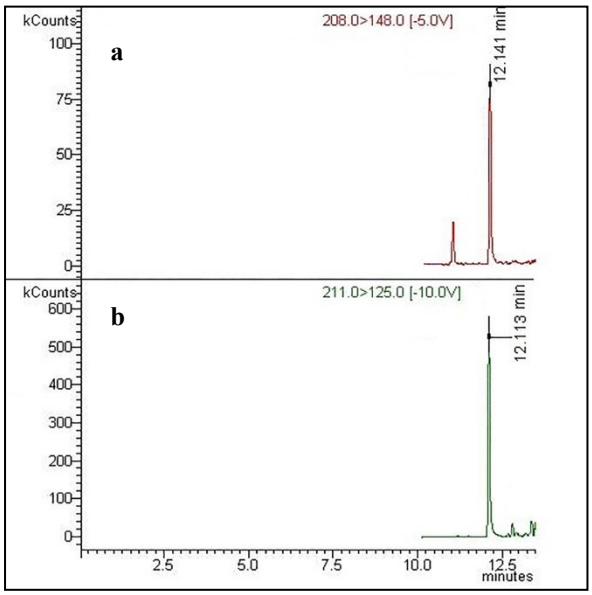

Figure 4. GC chromatograms of FBAL- (a) and FBAL-D3- (b) derivate

The results are excellent, with a reduction in total analysis time of 725 minutes (30 samples processed), compared to conventional SPME on-line analysis (Figure 5).

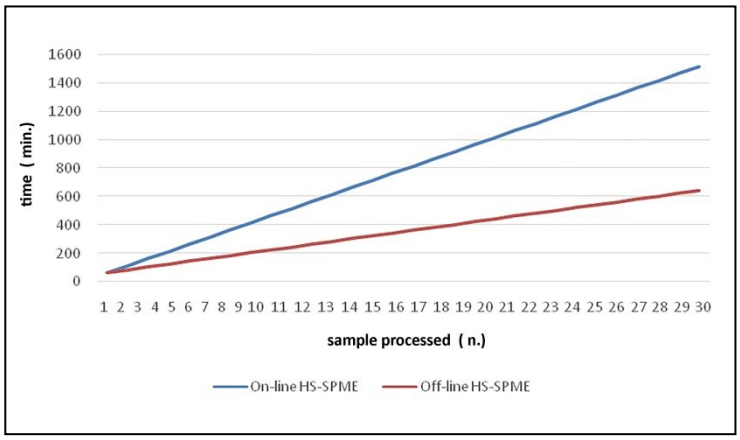

Figure 5. Off-Line vs. On-Line SPME extraction

## Conclusion

Our data suggests that automated SPME extraction coupled with GC/QpQ-MS/PCI is a viable alternative for FBAL analyses. Customized, automatized MS apparatus for high-throughput screening are not only user-friendly, but they reduce the costs of monitoring occupational health hazards. New sample preparation techniques are currently being increasingly explored because of the considerable need for information management, the automation of sample preparation, and the integration of data management into the analytical process. Lastly, we expanded the application of this methodology by carrying out analyses of other amino acids.

**Acknowledgements**

We thank the Azienda Ospedaliero-Universitaria Careggi (Florence, Italy), one of the largest polyclinics in Italy, for allowing us access to the wards and their employees, and particularly Fabrizio Niccolini, Daniela Tognoni and Anna Maria Tognoni, for enduring our presence and participating in the study. Furthermore, the authors gratefully acknowledge Marco Colpo for statistical analysis support.

# RESPONSE SURFACE METHODOLOGY OPTIMIZATION OF OIL REMOVAL USING BANANA PEEL AS BIOSORBENT

## (Pengoptimuman Kaedah Gerak Balas Permukaan Untuk Penyingkiran Minyak Menggunakan Kulit Pisang sebagai Penjerap-Bio)

**Abstract**

Improper waste management of oil causes environmental pollution particularly water pollution. Conventional method in treating oil contaminants are expensive and have low removal efficiency, hence the use of natural adsorbent is suggested because of its reliability and affordability. This study aimed to use banana peel as a biosorbent for oil removal and the application of response surface methodology to identify the optimum conditions of oil removal. The adsorptive capacity of household wastes derived from banana peel towards oil were studied by using different parameters such as oil concentration, adsorbent dosage and contact time. Maximum oil adsorption of 98.86% was achieved using banana peel. The optimum conditions for oil removal were found at a dosage of 4.94 g, for 10.29 hours contact time and the initial oil concentration as high as 8.74%. The rate of oil adsorption was mathematically described as a function of experimental parameters and was modelled through response surface methodology via Box-Behnken design. The results showed that the responses of oil adsorption were significantly affected by the quadratic term of oil concentration, adsorbent dosage and contact time. The statistical analysis was performed by ANOVA which indicated good correlation of experimental parameters.

**Keywords**: banana peel, oil removal, response surface methodology

**Abstrak**

Pengurusan sisa minyak yang tidak teratur menyebabkan pencemaran alam sekitar terutamanya pencemaran air. Kaedah konvensional untuk merawat pencemaran minyak adalah mahal dan tahap penyingkiran minyaknya adalah rendah, maka penggunaan penjerap semulajadi adalah dicadangkan kerana kebolehannya menyerap minyak dan lebih menjimatkan. Matlamat kajian ini adalah untuk menggunakan kulit pisang sebagai biopenjerap untuk penyingkiran minyak dan aplikasi kaedah gerak balas permukaan untuk mengenal pasti keadaan optimum kapasiti penyingkiran minyak. Kapasiti penjerapan daripada sisa rumah yang diambil daripada kulit pisang terhadap minyak telah dikaji dengan menggunakan parameter yang berbeza seperti kepekatan minyak, kuantiti penjerap dan tempoh masa. Penjerapan minyak secara maksimum, pada kadar 98.86% telah dicapai oleh kulit pisang. Keadaan optimum untuk menyingkirkan minyak adalah pada kadar 4.94 g, 10.29 jam dan kepekatan minyak sebanyak 8.74%. Kadar penjerapan minyak telah diterangkan secara matematik dalam fungsi parameter eksperimen dan telah dimodelkan melalui reka bentuk Box-Behnken (kaedah gerak balas permukaan). Hasil kajian menunjukkan bahawa tindak balas penjerapan minyak sangat dipengaruhi oleh kepekatan minyak, kuantiti penjerap dan tempoh masa. Analisis statistik ANOVA menunjukkan korelasi yang baik bagi setiap parameter eksperimen.

**Kata kunci:** kulit pisang, penyingkiran minyak, kaedah gerak balas permukaan

## Introduction

Water pollution affects not only individual living species, but also populations and entire functioning ecosystems that exist in the water. Oil and grease is toxic to some aquatic organisms. The oil film also prevents oxygen transfer from the atmosphere and causes low dissolved oxygen levels in the water [1]. Cities spend billions of dollars every year unplugging or replacing grease-blocked pipes, repairing pump stations, and cleaning up costly and illegal wastewater spills [2].

Conventional methods to remove oil and grease are the use of skimming tanks, oil and grease traps and interceptors in treatment plants. The main disadvantage of these methods is low efficiency of removal [1]. Biosorption process involves a solid phase (sorbent) and a liquid phase (solvent, normally water) containing a dissolved species to be sorbed (sorbate, e.g. oil). Due to the higher 'affinity' of the sorbent for the sorbate species the latter is attracted into the solid and bound there by different mechanisms [3]. The production of biosorbent will save cost, be environmentally friendly, effective in treating oil pollution, minimization of sludge upon usage and ability of regeneration of biosorbent [4]. Other study for oil removal has been conducted by Vlaev et al. [5], using rice husk ash, where at a given temperature, black rice husk ash sorbed more crude oil than diesel fuel. Hussein et al. [6], studied about carbonized peat bagasse where the result showed that the fibres extracted from bagasse and carbonized at 300 °C for 2 hours were found to have a high performance for sorption, recovery and recycling of heavy oils, even the viscous ones. Peat-based sorbents has been tested by Cojocaru et al. [7], where the removal efficiency of 99.21% was achieved. Sawdust has also been tested, where oleic acid grafted sawdust (OGSD) had the best sorption capacity for crude oil as well as weathered oil [8]. In addition, a study on sugarcane bagasse conducted by Brandao et al. [9] showed great potential when it was able to adsorb up to 99% of oil. Said et al. [10] tested grafted raw bagasse in pure oil, and sorption capacity of 3g/g was achieved after about 15 minutes. A study on vegetable fibres also showed a very high degree of hydrophobicity and oil sorption capacity of approximately 85 g oil/g sorbent in 24 hours [11].

Response surface methodology (RSM) is an effective statistical technique for optimizing complex processes. It can reduce the number of experimental trials needed to evaluate multiple parameters and their interactions. Moreover, Box-Behnken design (BBD), as a type of response surface design, is also widely used in many research work [12]. RSM is a very effective technique for this study because it presents statistical models which can be used to know the relationship between the parameters that have been optimized [13].

Hence, the goal of this study is to utilize banana peel as a biosorbent for oil removal and the application of RSM to identify the optimum conditions of oil removal. By considering the initial concentration of oil, biosorbent dosage and contact time, a regression model for surface area (response) was developed.

## Materials and Methods

### Materials

Cooking oil was used as a synthetic oil wastewater. The solvent used was n-Hexane (95% pure, Bendosen). The water used was distilled water that was produced in the Environmental Science Laboratory, Universiti Malaysia Kelantan. Banana peels were collected from a local store in Jeli, Kelantan.

### Untreated banana peel (UBP)

Banana peels were separated from the fruit gently, washed thoroughly with distilled water to remove other inorganic impurities. Then, it was dried under sun light for 5 days and heated using an oven (Model FD115, Binder, Korea) at 70 °C for 1 hour. The dried banana peels were then cut into small pieces, ground using a blender and sieved with 200 – 400 μm.

### Treated banana peel (TBP)

The method was the same with untreated banana peel but the dried banana peel was then treated with 0.5M hydrochloric acid for 24 hours at speed rate of 4 rpm. The modified banana peel was washed several times with deionized water to remove any excess acid. It was dried for 24 hours at 60 °C in an oven before starting the experiments.

**Biosorption studies**
Different biosorption studies were carried out for contact time, biosorbent dosage and oil concentration, and how the parameters influenced the biosorption process, all of this was performed at room temperature.

The experiments were conducted in a 250-ml conical flask containing 100 ml of synthetic oil wastewater (oil-in-water mixture). The sample was prepared by mixing cooking oil and distilled water using a blender following the desired concentrations. The synthetic oil wastewater with different percentages was treated differently with various quantities of biosorbent for a desired time, in an incubated shaker at a speed of 150 rpm.

At the end of the treatment, the biosorbent was removed from the oil and water mixture by passing it through cloth coffee filters. The concentration of oil before and after treatment was calculated using gravimetric method. The control experiment was the flask without biosorbent.

**Gravimetric-based methods**
100 ml of synthetic oil wastewater was added in a clean separatory funnel. The acidity of the sample was adjusted at pH 2 or less by adding 4 ml hydrochloric acid solution, 6.0 N (1:1). It was then serially extracted three times with n-hexane in a separatory funnel.

After separating the solvent (now containing oil) from the water sample, it was placed into a round bottom flask, which has been weighed beforehand. It then underwent a distillation process to remove n-hexane. After that, the flask was placed in an oven for 12 hours at 106 °C to evaporate excess water. After the solvent was evaporated, the flask now containing the residual oil is dried and weighed. Knowing the weight of the empty flask, the amount of residual oil can be calculated [14].

**Screening of biosorbent**
The experiments were conducted in a 250-ml conical flask containing 100 ml of 1:1 ratio oil and water mixture, prepared by mixing cooking oil with distilled water using a blender and its pH was measured.

The synthetic oil wastewater with 50% w/v concentration was treated with 0.5g of UBP and TBP for 3 hours, in an orbital shaker (Model SI-300/300R/600/600R, JEIO TECH, Korea) at a speed of 150 rpm. At the end of the treatment, biosorbents were filtered by passing them through cloth coffee filters. The concentration of oil before and after treatment was calculated using the gravimetric method.

The percentage of oil removal and the uptake capacity of the biosorbent for each different oil concentration were calculated. The results were then used to decide which high and low concentration of oil will be used in RSM for optimization.

The percentage (%) removal oil and amount of oil adsorbed by banana peel (qe) was calculated by equation (1) and (2), respectively:

$$\text{Oil removal concentration (\%)} = \frac{100\,(C_0 - C_e)}{C_0} \quad (1)$$

$$q_e = \frac{(C_0 - C_e)}{m}\,V \quad (2)$$

where $C_0$ is the initial oil concentration (mg/L) and $C_e$ is the concentration of oil left (mg/L), $V$ the solution volume (L) and $m$ is the mass of biosorbent (g). All adsorption experiments were duplicated and the mean values were used in data analysis.

**Experimental design and optimization using response surface methodology**
Three different parameters namely oil concentration (0.5 – 10 %), biosorbent dosage (0.5 – 5g) and contact time (1 – 24 hours) were selected as the critical variables. The experiments were randomly conducted and the measurements of percentage of oil removal for each experiment were calculated. A software package by Design Expert Version 6.0.8 was used to fit the second-order model.

The effects of oil concentration, biosorbent dosage and contact time at three variable levels (-1, 0, 1) in the reaction were evaluated in Table 1:

Table 1. Ranges of the factors investigated using Box–Behnken Design

| Variables | Symbols | Levels | | |
|---|---|---|---|---|
| | | -1 | 0 | 1 |
| Oil Concentration (%) | A | 0.5 | 5.25 | 10 |
| Biosorbent dosage (g) | B | 0.5 | 2.75 | 5 |
| Contact time (h) | C | 1 | 12.5 | 24 |

To determine the relationship between the preparation variables and the responses under consideration, the data collected must be analysed by a statistical approach of using regression equations. For regression equation, the preparation variables were coded according to equation (3):

$$y = \beta_0 + \sum_n^k \beta_i \, x_i + \sum_n^k \beta_{ii} \, x_i^2 + \sum_n^k \beta_{ij} x_i \, x_j + \varepsilon \quad (3)$$

where $y$ is the response (dependent variables), $\beta_0$ is constant coefficient, $\beta_1$, $\beta_{ii}$ and $\beta_{ij}$ are the regression coefficients for linear, quadratic and interaction terms, respectively, whereas $x_i$ and $x_j$ are the independent variables, while $\varepsilon$ is the error [15].

## Results and Discussion

### Screening of biosorbent for oil removal

From the bar chart (Figure 1), UBP adsorbed oil more efficiently with the higher percentage oil removal of 31.63%, whereas TBP with 5.675% of oil concentration. The surface activity of banana peels is mainly due to the presence of carboxyl, hydroxyl and amide groups on its surface and the high surface area of banana peels adds to the property and makes it an excellent and economic adsorbent, for water purification processes [16]. As shown by the result, UBP adsorbed better than TBP, so UBP was then used in RSM for the optimization process.

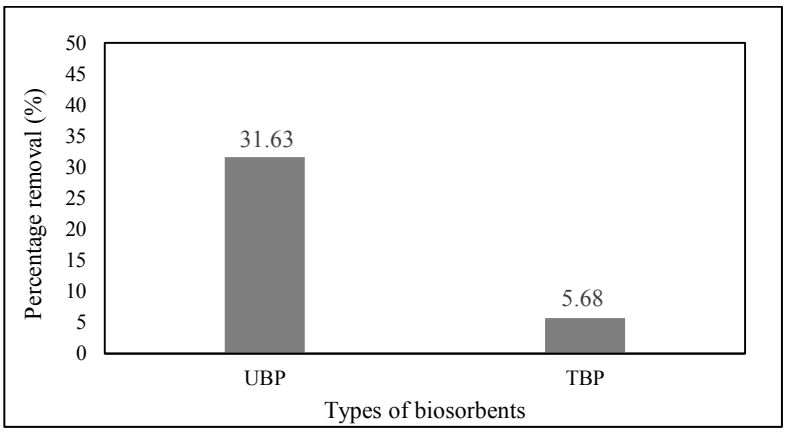

Figure 1. Percentage oil removal and uptake capacity of biosorbents

### RSM experiments and model fitting

The results for the actual values acquired from the response from the experimental runs and the predicted values obtained from the generated quadratic model that corresponded to the percentage removal of oil are tabulated in Table 2.

Table 2. Design of RSM and its actual and predicted values

| Std | Factor 1 A: Oil Concentration (%) | Factor 2 B: Dosage (g) | Factor 3 C: Time (hour) | Percentage Oil Removal (%) | |
|---|---|---|---|---|---|
| | | | | Actual Value | Predicted Value |
| 1 | 0.5 | 0.5 | 12.5 | 65.72 | 66.91 |
| 2 | 10 | 0.5 | 12.5 | 67.72 | 69.54 |

The maximum removal efficiency of oil was found to be 98.25%. The best fitting model was established by a regression analysis. The following equation is a regression model with the experimental results in terms of coded factors:

$$Y = 91.4756 + 8.1154A + 4.2906B + 10.3175C - 22.324A^2 + 3.3721B^2 - 3.7837C^2 + 6.7993AB - 23.333AC - 2.201BC \quad (4)$$

where $Y$ is the percentage oil removal (%), A is oil concentration (%), B is the biosorbent dosage (g) and C is the contact time of biosorbent to oil (hour).

**Regression model and Analysis of Variance (ANOVA)**
Statistical testing of the model was performed with the Fisher's statistical test for analysis of variance (ANOVA), as shown in Table 3.

The significance of each model is assessed from the coefficient ($R^2$) which is found to be 0.97. The high coefficient of determination between the predicted and experimental adsorption activities confirmed that the quadratic polynomial model was adequate to explain the actual relationship between the response and the significant variables.

The F statistic value of 29.63 implies that the model is significant and there is only a 0.01% chance that the model could occur due to noise. The significance of each term in this model is also evaluated by P value (Prob > F) that was less than 0.05. This was supported by a P-value which confirmed that the quadratic model was statistically significant and sufficient to explain the actual relationship between the response and the significant variables.

Table 3. Analysis of variance for the response of the uptake capacity for cooking oil

| Source | Sum Squares | Degrees Freedom | Mean Square | F Value | Prob > F (P-value) |
|---|---|---|---|---|---|
| Model | 6127.18 | 9 | 680.80 | 29.63 | < 0.0001 |
| A | 526.87 | 1 | 526.87 | 22.93 | 0.0020 |
| B | 147.28 | 1 | 147.28 | 6.41 | 0.04 |
| C | 851.61 | 1 | 851.61 | 37.06 | 0.0005 |
| $A^2$ | 2099.95 | 1 | 2099.95 | 91.39 | < 0.0001 |
| $B^2$ | 47.88 | 1 | 47.88 | 2.08 | 0.20 |
| $C^2$ | 60.28 | 1 | 60.28 | 2.62 | 0.15 |
| AB | 184.92 | 1 | 184.92 | 8.05 | 0.03 |
| AC | 2177.72 | 1 | 2177.72 | 94.78 | < 0.0001 |
| BC | 19.38 | 1 | 19.38 | 0.84 | 0.39 |
| Residual | 160.84 | 7 | 22.98 | | |
| Lack of Fit | 128.91 | 3 | 42.97 | 5.38 | 0.07 |
| Pure Error | 31.93 | 4 | 7.98 | | |
| Corrected Total | 6288.02 | 16 | | | |

$R^2$ = 0.98, Coefficient of variation = 5.94, Adj $R^2$= 0.94, Pred $R^2$= 0.66, Adeq precision = 21.73

The ANOVA test indicates that the F-value for the lack of fit (5.38) was lower than the tabulated value, suggesting that the lack of fit was insignificant relative to the pure error, thereby indicating the data in the experimental domain was well represented by the model. There is a 6.68% chance that a "Lack of Fit F-value" this large could occur due to noise.

**Effect of process variables on the percentage removal of cooking oil**

Figure 2 below illustrates the effect of the process variables, namely oil concentration, biosorbent dosage and contact time on the percentage removal of cooking oil.

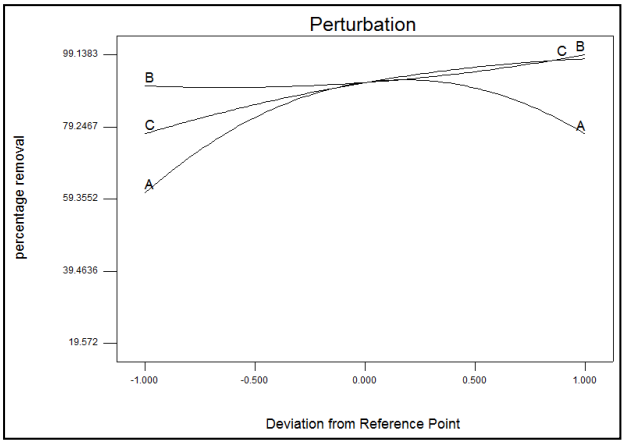

Figure 2. Deviation of reference point for the oil concentration, biosorbent dosage and contact time on the percentage removal of cooking oil

The percentage removal of cooking oil increased at first but then decreased with the increase of (A) oil concentration, whereas the percentage removal of cooking oil showed an upward trend with the increase of (B) biosorbent dosage into the oil. From the figure, it can also be seen that the increase in (C) contact time of biosorbent with oil also increased the percentage removal of oil.

**Effect of oil concentration and biosorbent dosage**

Figure 3 illustrates the response surface curve and contour plot for the oil concentration (A) and biosorbent dosage (B), and their mutual interaction on the percentage removal of cooking oil by UBP.

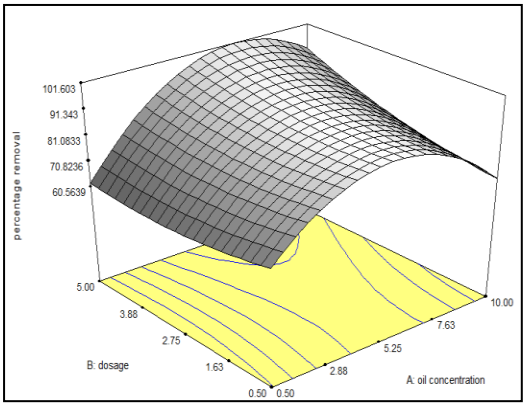

Figure 3. Effect of oil concentration (A) and biosorbent dosage (B) response surface plot on percentage removal of oil

It has been found that the efficiency of biosorbents to adsorb oil initially increases with increasing oil concentration. At lower oil concentrations in the solution, the oils would interact with the sorbent and thus facilitated adsorption whereas at higher concentrations, more oils are left un-absorbed in the solution due to the saturation of the binding sites [17].

The increasing initial oil concentration would decrease oil removal efficiency. This must be caused by the decrease in surface area of the biosorbent due to the increasing of the amount of oil adsorbed per unit weight of biosorbent [18].

At high initial concentration, the gradient between the solution sample and the center of particle enhances oil diffusion through the film surrounding the particle and in the porous network of the biosorbent. Eventually, as time goes by, the adsorbed oil will start to clog the pores near the outer surface so oil residue can no longer diffuse to the active sites deep within the interior surface [19].

**Effect of oil concentration and time**

Figure 4 illustrates the response surface curve and contour plot for the oil concentration (A) and time (C), and their mutual interaction on the percentage removal of cooking oil by UBP.

It was observed that the interactions of the two reaction parameters, oil concentration (A) and time (C) were significant because of the small p-value (< 0.0001) that is less than 0.05. Increasing the contact time between the biosorbent and oil significantly elevated the percentage removal of oil. It can be concluded that the reaction time had a positive effect on percentage removal of oil. Hence, the prolonged contact time increased the probability of effective collisions between oil and biosorbent. In addition, at longer mixing time, breakage of the oil droplets are enhanced, thus reducing the diameter of the oil droplets (emulsification) which leads to more interfacial area for the adsorption to occur and encourages the adsorption of residue oil by biosorbent [19]. Therefore, interaction time between the oil molecule and biosorbent particles is very important in oil removal.

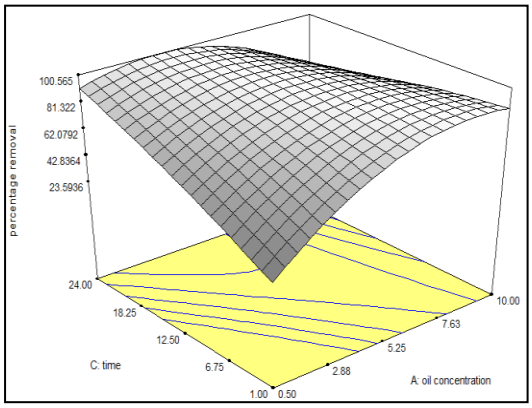

Figure 4. Effect of oil concentration (A) and time (C) response surface plot on percentage removal of oil

The increased rate of percentage removal of oil is due to the larger surface area of the biosorbents being available at the beginning of adsorption of oil. The increasing contact time increased the oil adsorption and it remains constant after equilibrium is reached [20]. However, contact time plays an important role only at the beginning of oil adsorption, and is less important near equilibrium. At near equilibrium, only a small increase in oil removal is observed due to limited availability of biosorbent surfaces for oil entrapment [13].

**Effect of biosorbent dosage and time**

Figure 5 illustrates the response surface curve and contour plot for the biosorbent dosage (B) and time (C), and their mutual interaction on the percentage removal of oil by UBP.

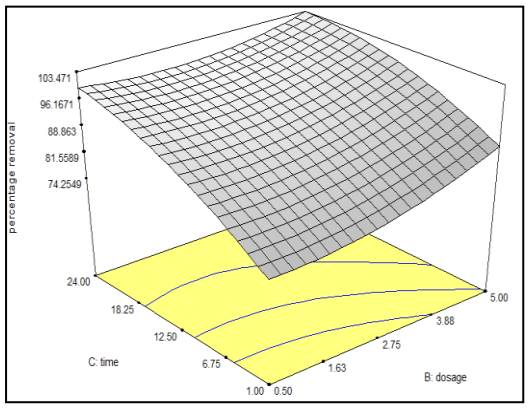

Figure 5. Effect of dosage (B) and time (C) response surface plot on percentage removal of oil

It could be noted that for both an increase in contact time and the biosorbent dosage, the percentage removal increases. An increase in biosorbent dosage results in more binding sites available for the oil molecules to be adsorbed, whereas, an increased contact time provides enough time for the molecules to bind on the adsorbent sites. Adsorption is a surface related phenomenon, at equilibrium most of the oil molecules were adsorbed on the surface and in the intermolecular pores of the adsorbent [21]. Hence, at higher dosage, the oil adsorbed are higher due to the availability of more empty binding sites as compared to lower dosages which has less binding sites to adsorb the same amount of oil in the adsorbate solution [17].

The increase in active sites will lead to a higher percentage removal but with lowered oil uptake per unit of adsorbent. This is due to the abundancy of active sites available on biosorbent for oil to be adsorbed at a higher dosage, thus leading to a higher interaction between oil particles and adsorbent [22]. However, saturated oil binding sites occurred with the increasing biosorbent dosage. In addition, saturation effect also reduces the efficiency of oil removal when maximum sorption capacity is reached [23].

**Optimum conditions and model verification**

The optimum condition for percentage of oil removal is shown in Table 4. The model capable of predicting the maximum adsorption capacity showed that the optimum condition for the oil removal were concentration of oil at 8.74%, with a dosage of 4.94 g and a duration of 10.29 hours. Under these conditions, the predicted adsorption capacity was 99.18% which was in good agreement with the experimental value of 98.86%.

The obtained results were found to be relatively close to the predicted percentage removal and this confirmed the eligibility of the quadratic model suggested by the software. Thus, RSM with appropriate experimental design could be effectively applied to optimize the process parameters in this investigation.

Table 4. Optimum conditions for percentage of oil removal

| Number | Oil Concentration (%) | Dosage (g) | Time (h) | Actual Percentage Removal (%) | Predicted Percentage Removal (%) |
|---|---|---|---|---|---|
| 1 | 8.74 | 4.94 | 10.29 | 98.86 | 99.18 |

## Conclusion

The optimum conditions of UBP as oil adsorbent were obtained as follows; oil concentration 8.74%, dosage 4.94 g, time 10.29 hours. Under these optimum conditions, the predicted value from the model is 99.18% and the obtained result was 98.86% and this indicates the successful development model because of a small deviation error. Statistical optimization on UBP production was successfully performed using RSM via DOE software by conducting a BBD by varying the activation temperature and contact time.

UBP can benefit the oil pollution issue with a more affordable solution and this can also reduce the abundance of household waste problems. The use of UBP in oil removal needs to be further investigated to promote large-scale use of non-conventional adsorbents. The uses of UBP for wastewater treatment applications today are strongly recommended due to their local availability, technical feasibility, engineering applicability, and cost effectiveness. Undoubtedly, UBP can benefit commercial purposes in the future.

**Abstrak**

Hidrogel terbiodegradasi berasaskan selulosa bakteria (BC) daripada *nata de coco* dihasilkan melalui proses radiasi ultra lembayung terawat. Selulosa bakteria (BC) telah digabungkan bersama akrilamida (AM) pada nisbah yang berbeza. N,N-metilena bisakrilamida (BIS) dan kalium persulfat (KPS) kemudiannya ditambah untuk mensintesis hidrogel dengan nisbah 5% w/v (hidrogel A) dan 10% w/v (hidrogel B). Hidrogel berasaskan AM juga turut disintesis dengan label hidrogel pemalar. Dalam kajian ini, akrilamida (AM) bertindak sebagai monomer dan terikat pada struktur tulang belakang selulosa. Kalium persulfat (KPS) bertindak sebagai bahan pemula cahaya di mana ianya membantu dalam menghasilkan radikal bebas dan N,N-metilena bisakrilamida (BIS) pula berfungsi sebagai agen pentaut silang. Berdasarkan penggunaan teknik radiasi dan bahan pemula cahaya, tindak balas yang terlibat adalah pempolimeran radikal bebas. Lima analisis telah dilakukan bagi mencirikan hidrogel A dan B iaitu ujian pengembangan menggunakan lima larutan penimbal pH, analisis struktur kimia, analisis gravimetri termal (TGA), analisis kalorimetri pengimbasan pembezaan (DSC) dan analisis pembelauan sinar-X. Morfologi permukaan bagi kedua – dua hidrogel A dan B juga telah ditentukan menggunakan analisis mikroskopi pengimbasan elektron (SEM). Hasil analisis telah menunjukkan kewujudan liang – liang terbuka dalam hidrogel A adalah lebih banyak berbanding dengan hidrogel B.

**Kata kunci:** hidrogel, selulosa bakteria, ultra lembayung terawat

**Abstract**

A rapid biodegradable hydrogel made up of bacterial cellulose (BC) from *nata de coco* was prepared by curing it under the ultra violet (UV) radiation. Bacterial cellulose (BC) is grafted with acrylamide (AM) at different proportions. Potassium persulphate (KPS) and N,N-methylene bisacrylamide (BIS) are added to synthesize hydrogels at the ratio of 5% w/v (hydrogel A) and 10% w/v (hydrogel B). Acrylamide hydrogel is also synthesized as a control hydrogel. In this research, acrylamide acts as a monomer that binds itself to the cellulose backbone while potassium persulfate (KPS) as an intiator where it produces free radicals. The N,N-methylene bisacrylamide (BIS) is used as a cross linker. Here, free radical polymerization is involved. Several analyses have been done to characterise hydrogel A and B which are swelling test in five different buffer solutions, chemical structure analysis, thermal gravimetry analysis (TGA), diffrential scanning calorimetry (DSC) and X-ray diffraction (XRD). The surface morphology for both hydrogel A and B are also determined by using scanning electron microscopy (SEM) analysis. The images found that the pores in hydrogel A were more than in hydrogel B.

**Keywords:** hydrogel, bacterial cellulose, curable ultra violet

## Pengenalan

Hidrogel merupakan bahan polimer yang boleh menyerap sejumlah besar air tanpa ia melarut dalamnya [1]. Hidrogel merupakan gel kimia yang distabilkan oleh jaringan paut silang secara kovalen [2]. Polimer hidrogel boleh dikategorikan kepada dua kelas iaitu sintetik dan berasaskan bahan semulajadi [3]. Sejak bermulanya kajian berkaitan hidrogel, ia telah menjadi salah satu bahan polimer yang paling banyak dikaji terutamanya dalam bidang biologi. Malah, disebabkan oleh kesedaran terhadap teknologi hijau dan bio-serasi pada masa kini, kebanyakan hidrogel diperbuat daripada sumber semulajadi dan salah satunya adalah selulosa. Penggunaan selulosa sedikit sebanyak dapat mendorong penghasilan hidrogel yang mempunyai sifat ketulenan, keseragaman dan juga kekuatan mekanikal yang tinggi [4].

Selulosa merupakan salah satu sumber semulajadi yang banyak dan mudah untuk didapati di muka bumi. Selulosa terbahagi kepada dua jenis iaitu daripada sumber bakteria dan tumbuhan [5]. Secara kimianya, selulosa bakteria (BC) adalah sama seperti selulosa tumbuhan (PC) walaupun mempunyai struktur makromolekular dan sifat fizikal yang berbeza. Selulosa dari kedua-dua sumber ini terikat pada ikatan 1,4-β-glukosidik yang menjadikan kadar penghabluran selulosa adalah tinggi dan tidak mudah larut dalam air. Walau bagaimanapun, biosintesis BC menghasilkan fiber bersaiz nano dengan magnitud dua kali ganda lebih kecil berbanding dengan fiber PC. Oleh itu, selulosa bakteria menunjukkan jaringan fiber ultra halus yang berkebolehan untuk menyerap air dengan banyak dan mempunyai daya ketegangan yang lebih tinggi daripada PC [6]. Salah satu selulosa yang biasa digunakan dalam industri makanan adalah selulosa bakteria (BC). Selulosa bakteria boleh dihasilkan daripada pelbagai sumber dan salah satu contoh BC adalah *nata de coco*. *Nata de coco* merupakan sejenis pencuci mulut berbentuk kiub gelatin dan berwarna putih. Secara asasnya, kiub gelatin tersebut diperbuat daripada air kelapa melalui proses fermentasi oleh organisma *Acetobacter xylinium* [6].

Oleh kerana hidrogel menawarkan pelbagai aplikasi [7], maka kajian ke atas hidrogel telah mendapat perhatian umum dan dijalankan secara meluas. Sebagi contoh, hidrogel telah digunakan sebagai medium penghantaran ubat dalam sistem tubuh manusia [8], bahan penjerap, salutan [7] dan nanoreaktor. Bagi menghasilkan suatu hidrogel yang terbaik, kaedah yang dipilih mestilah efektif bagi mengurangkan kos serta menjimatkan masa. Antara kaedah yang pernah digunakan untuk mensintesis hidrogel adalah kaedah sinaran gamma, sinaran alur elektron, gelombang mikro dan kaedah kimia [9].

Seperti yang telah diketahui, kebanyakan hidrogel yang telah dihasilkan adalah berasaskan polimer sintetik. Walaupun ia telah digunakan secara meluas, namun, polimer sintetik merupakan bahan yang tidak boleh diperbaharui dan proses penghasilannya yang rumit turut menyebabkan kos untuk menghasilkannya adalah tinggi. Malah, polimer sintetik juga merupakan bahan yang tidak mesra alam dan tidak boleh terbiodegradasi [9]. Sesetengah daripada bahan kimia yang digunakan dalam penghasilan hidrogel adalah toksik, dan jika tidak dirawat dengan sempurna ia akan menyumbang kepada pencemaran alam sekitar. Oleh yang demikian, kini kajian yang dijalankan adalah lebih bertumpu kepada penghasilan produk mudah terbiodegradasi dan mesra alam.

Memandangkan tiada kajian berkaitan penghasilan hidrogel terbiodegradasi berasaskan nata de coco dengan menggunakan teknik radiasi ultra lembayung terawat pernah dilakukan, ini merupakan satu peluang yang baik untuk meneroka dan mengkaji teknik tersebut. Ini kerana kaedah ini menawarkan satu teknik yang mudah, boleh alih dan kos efektif berbanding kaedah radiasi gamma, alur elektron serta gelombang mikro yang memerlukan tempat khas dan mahal. Oleh itu, kajian ini dilakukan bertujuan untuk mensintesis hidrogel berasaskan selulosa bakteria dengan menggunakan teknik radiasi ultra lembayung terawat. Hidrogel yang dibangunkan menggunakan teknik ini kemudiannya akan dianalisa serta dicirikan terhadap hidrogel dengan menggunakan ujian pengembangan, analisis spektroskopi inframerah transformasi Fourier (ATR-FTIR), kalorimetri pengimbasan pembezaan (DSC), analisis gravimetri termal (TGA), pembelauan sinar-X (XRD) dan mikroskopi pengimbasan elektron (SEM). Hasil kajian diharapkan akan menjadi kaedah alternatif bagi membangunkan hidrogel dan digunakan dengan lebih meluas.

## Bahan dan Kaedah

### Bahan

Selulosa bakteria yang disediakan daripada *nata de coco* (diperoleh dari industri makanan Kuala Selangor, Malaysia) yang telah ditulenkan dan dikisar. Bahan kimia seperti akrilamida (AM), kalium persulfat (KPS), penaut

silang N,N-metilena bisakrilamida 99% (BIS), natrium hidroksida (NaOH) dan urea diperoleh daripada pembekal Sigma-Aldrich, larutan penimbal dan air suling.

**Penyediaan serbuk selulosa bakteria daripada *nata de coco***
Penyediaan serbuk selulosa bakteria telah dilakukan mengikut kaedah yang dilaporkan oleh Halib et al. [6]. *Nata de coco* terlebih dahulu dibasuh dengan menggunakan air suling sebelum direndam dalam air suling yang telah dididihkan. Kemudian, natrium hidroksida akan dimasukkan dan dibiarkan semalaman dengan tujuan membolehkan sisa protein dalam *nata de coco* akan terlarut dalam air suling. Seterusnya, ianya dibasuh dengan menggunakan air untuk membuang sisa protein yang terlarut dalam air rendaman *nata de coco*. Proses diteruskan dengan merendamnya dalam air suling didih selama 2 jam sebelum dibasuh. Langkah ini diulangi sehingga nilai pH yang diperoleh adalah neutral. *Nata de coco* yang telah ditulenkan akan dikisar dengan menggunakan pengisar bahan basah sebelum dikeringkan dalam oven. Kepingan *nata de coco* yang telah kering dikisar dengan menggunakan pengisar kering untuk mendapatkan serbuk selulosa yang halus.

**Penyediaan hidrogel selulosa bakteria**
Penghasilan hidrogel terbiodegradasi di mana selulosa bakteria (BC) bertindak sebagai ko-monomer telah dilakukan dengan menggunakan kaedah yang digunakan oleh Pandey dan Amin [10]. Larutan selulosa bakteria (BC) disediakan dengan menyerakkan serbuk BC ke dalam 8% larutan NaOH dan 4% larutan urea. Sampel kemudiannya disimpan di dalam peti sejuk beku pada suhu 4 °C selama 24 jam. Larutan beku ini kemudiannya dikacau untuk menghasilkan larutan BC yang homogany.

Sebanyak 10 mL larutan selulosa bakteria dimasukkan ke dalam bikar bersama dengan pengacau bermagnet untuk proses pengacauan. Proses pengacauan ini dibiarkan selama 3 minit tanpa adanya proses pemanasan untuk memastikan larutan selulosa bakteria adalah homogen. Akrilamida (AM) kemudiannya ditimbang sebelum dicampurkan ke dalam larutan selulosa bakteria (BC). Berdasarkan kajian penyelidikan terdahulu [6,10] nisbah akrilamida yang dipilih dan digunakan dalam kajian ini adalah sebanyak 5% (w/v) (hidrogel A) dan 10% (w/v) (hidrogel B). Proses pengacauan diteruskan lagi setelah akrilamida dimasukkan. Setelah akrilamida larut sepenuhnya, kalium persulfat (KPS) dimasukkan ke dalam larutan BC di mana KPS bertindak sebagai bahan pemula cahaya. Nisbah berat KPS yang dimasukkan telah ditetapkan kepada 5% daripada nisbah berat akrilamida yang digunakan. N,N-metilena bisakrilamida (BIS) kemudiannya dicampurkan setelah kalium persulfat telah larut sepenuhnya. Dalam kajian ini, BIS berfungsi sebagai agen pentaut silang. Nisbah berat BIS yang dicampurkan ke dalam larutan pula telah ditetapkan kepada 10% daripada nisbah berat akrilamida yang digunakan.

Apabila kesemua bahan telah larut sepenuhnya, proses pengacauan dihentikan. Campuran tadi kemudiannya dimasukkan ke dalam piring petri kaca dan diradiasikan dengan menggunakan teknik radiasi ultra lembayung (instrumen UV kristal terawat model MKD-UV-800 Photo, USA) selama 360 saat. Hidrogel yang telah diradiasi kemudiannya dimasukkan ke dalam ketuhar pada suhu 40 – 45 °C selama semalaman untuk proses pengeringan.

**Ujian pengembangan**
Ujian pengembangan hidrogel dilakukan dengan menggunakan larutan penimbal pada pH yang berbeza bertujuan untuk mengetahui kesan pH yang berlainan terhadap hidrogel. Oleh itu, lima larutan penimbal dengan nilai pH 3, 5, 7, 9 dan 12 telah disediakan. Hidrogel kemudiannya direndam di dalam larutan penimbal ini dan beratnya akan ditimbang pada setiap selang lima minit selama 1 jam. Ujian ini dijalankan pada suhu bilik dan sebarang perubahan diperhatikan. Nisbah pengembangan hidrogel dikira dengan menggunakan persamaan seperti berikut:

$$\% S = Mt - MoMo\ x\ 100\% \quad (6)$$

di mana $Mo$ (g) adalah jisim asal hidrogel dan $Mt$ (g) adalah jisim hidrogel yang telah mengembang pada masa t (minit).

**Spektroskopi inframerah transformasi fourier**
Kajian ini telah menggunakan Jumlah Pantulan Teratenuat-Spektroskopi Inframerah Transformasi Fourier (Perkin Elmer, USA) sebagai salah satu analisis yang dijalankan terhadap hidrogel bakteria selulosa. Instrumen ini

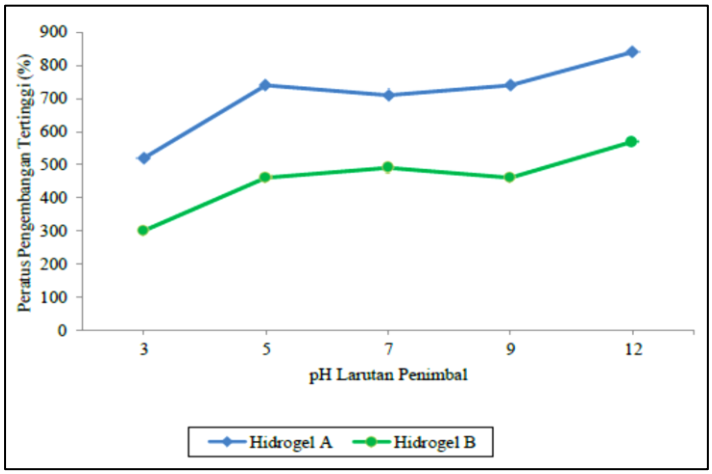
digunakan untuk mengenal pasti kumpulan berfungsi dalam hidrogel bakteria selulosa.

**Analisis gravimetri termal-kalorimetri pengimbasan pembezaan**
Analisis gravimetri termal adalah berdasarkan kepada ukuran perubahan jisim dalam keadaan sampel dipanaskan, disejukkan ataupun pada suhu malar. Selain daripada jisim sampel, TGA-DSC (Mettler Toledo, USA) juga boleh digunakan untuk mengukur aliran haba sampel. Hal ini membolehkan instrumen ini mengesan perubahan termal yang tidak melibatkan perubahan jisim seperti peleburan, peralihan kaca dan peralihan pepejal-pepejal. Malah, isyarat DSC juga boleh dinilai secara kuantitatif sekaligus membolehkan peralihan dan entalpi tindak balas ditentukan.

**Pembelauan sinar-X**
Analisis pembelauan sinar-X (D8 Advance, Bruker, USA), secara teorinya elektron dalam medan elektromagnet ulang-alik akan berayun pada frekuensi yang sama. Apabila alur sinar-X mengenai atom, elektron di sekitar atom akan mula berayun pada frekuensi yang sama dengan alur yang masuk.

**Mikroskopi pengimbasan elektron**
Mikroskopi pengimbasan elektron (JSM 5610, JEOL, USA) merupakan instrumen saintifik yang menggunakan alur elektron bertenaga tinggi untuk menentukan morfologi objek pada skala yang sangat kecil terutamanya dalam bidang biologi, perubatan dan sains bahan [11].

## Keputusan dan Perbincangan



**Kesan pH ke atas peratus pengembangan hidrogel**
Peratus pengembangan tertinggi bagi kedua-dua hidrogel A dan hidrogel B pada setiap pH telah dicatatkan seperti dalam Jadual 1 di atas. Berdasarkan peratus pengembangan ini, graf perbandingan bagi kedua – dua hidrogel A dan B kemudiannya telah diplot seperti dalam Rajah 1.

Jadual 1. Perbandingan peratus pengembangan tertinggi bagi kedua-dua hidrogel untuk setiap nilai pH

| pH | Peratus Pengembangan Tertinggi Hidrogel (%) | | |
|---|---|---|---|
| | Hidrogel A | Hidrogel B | Perbezaan |
| 3 | 520 | 300 | 220 |
| 5 | 740 | 460 | 280 |
| 7 | 710 | 490 | 220 |
| 9 | 740 | 460 | 280 |
| 12 | 840 | 570 | 270 |

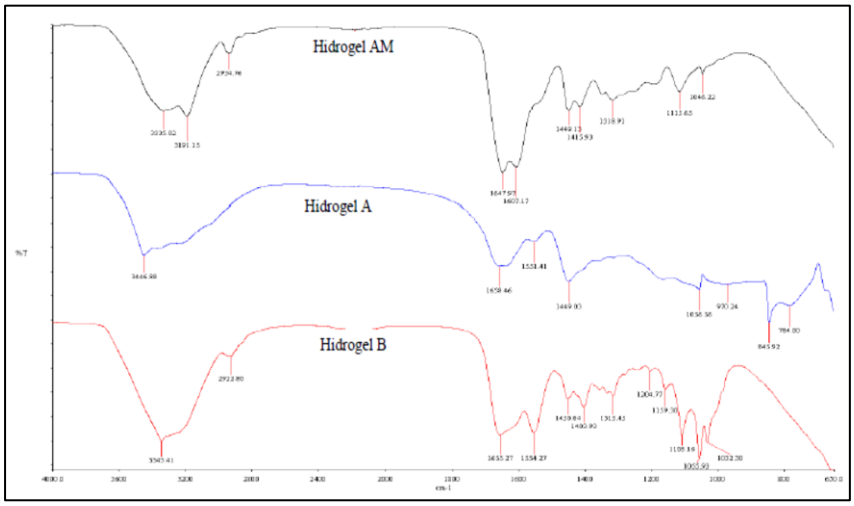
Merujuk kepada graf dalam Rajah 1, dapat dilihat berlakunya penurunan peratus pengembangan bagi kedua –dua hidrogel pada pH yang berbeza. Bagi hidrogel A, peratus pengembangan hidrogel pada pH 3 adalah 520% dan meningkat sehingga 740% pada pH 5. Namun, peratus pengembangan hidrogel ini telah menurun kepada 710% dalam larutan penimbal pH 7. Kemudian, peratus pengembangan hidrogel A kembali meningkat sehingga 740% pada pH 9 dan seterusnya 840% pada pH 12. Keputusan yang diperoleh adalah signifikan dengan keputusan yang pernah dilaporkan sebelum ini [12].

Bagi hidrogel B pula, peratus pengembangan tertinggi hidrogel pada pH 3 adalah 300%. Peratus pengembangan ini semakin meningkat pada pH 5 dengan nilai peratus sebanyak 460% dan seterusnya 490% pada pH 9. Walau bagaimanapun, peratus pengembangan hidrogel ini telah menurun sehingga 460% pada pH 9 sebelum kembali meningkat pada pH 12 dengan 570%. Menerusi Jadual 1 dan Rajah 1, dapat dilihat hidrogel A iaitu hidrogel dengan nisbah AM kepada selulosa bakteria 5% w/v mempunyai daya serapan yang lebih tinggi daripada hidrogel B dalam semua nilai pH. Hal ini menunjukkan kadar pengembangan hidrogel A adalah lebih cepat berbanding dengan hidrogel B.

Rajah 1. Graf peratus pengembangan tertinggi (%) terhadap pH bagi hidrogel A dan hidrogel B

Peratus pengembangan kedua-dua hidrogel A dan B yang tertinggi adalah pada larutan penimbal pH 12. Hal ini kerana, larutan dengan nilai pH yang tinggi akan menyebabkan kumpulan $-CONH_2$ dihidrolisiskan. Apabila kumpulan $-CONH_2$ dihidrolisis, penolakan antara kumpulan karboksilat yang bercas akan berlaku sekaligus memanjangkan ikatan polimer. Hal ini akan mewujudkan ruang yang besar dalam hidrogel untuk menyerap air dan meningkatkan pengembangan hidrogel. Walau bagaimanapun, apabila hidrogel telah mencapai tahap serapan air yang maksima, ianya akan menyebabkan hidrogel tersebut menjadi rapuh dan mudah pecah.

Secara keseluruhannya, kedua-dua hidrogel menunjukkan kebolehan menyerap air yang baik. Nilai peratus pengembangan hidrogel yang paling minimum adalah 520% bagi hidrogel A manakala sebanyak 300% bagi hidrogel B. Berdasarkan Rajah 1, nilai peratus pengembangan paling minimum bagi kedua-dua hidrogel ini adalah pada pH 3.

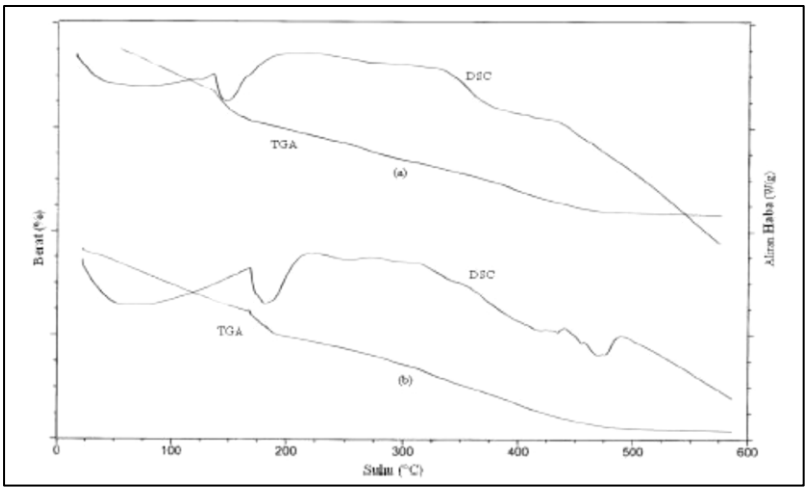


**Spektroskopi inframerah transformasi fourier**

Kajian berdasarkan Rajah 2 di atas, spektrum menunjukkan ketiga – tiga hidrogel mempunyai puncak utama yang hampir sama tetapi ketara berbeza dari segi keamatannya. Hal ini kerana interaksi yang berlaku antara jaringan selulosa bakteria dan akrilamida sewaktu pembentukan hidrogel bagi ketiga-tiga jenis hidrogel adalah sama.

Spektrum inframerah untuk kedua-dua hidrogel A dan B menunjukkan puncak keamatan masing-masing pada sekitar 3362 $cm^{-1}$ dan 3343 $cm^{-1}$ yang mewakili kumpulan –OH bagi selulosa yang mempunyai ikatan hidrogen. Selain itu, spektrum hidrogel B mempunyai puncak pada 2922 $cm^{-1}$ yang menunjukkan kesan regangan $-CH_2$ dari kumpulan $-CH_2OH$ yang terdapat dalam selulosa bakteria [6]. Manakala, puncak 1658 $cm^{-1}$ bagi hidrogel A dan 1655 $cm^{-1}$ bagi hidrogel B terhasil daripada getaran C=O kumpulan $–CONH_2$ yang terdapat dalam akrilamida.

Malah, pembentukan puncak 1658 $cm^{-1}$ bagi hidrogel A dan 1655 $cm^{-1}$ bagi hidrogel B telah menunjukkan bahawa berlakunya hidrolisis poliakrilamida yang membawa kepada penukaran kumpulan $-CONH_2$ kepada $–COO^-$ [8]. Kedua-dua spektrum bagi hidrogel A dan B juga telah menunjukkan puncak keamatan pada julat 3500 – 3100 $cm^{-1}$ yang mewakili kumpulan N-H dalam akrilamida. Getaran regangan C-O-C dalam ikatan eter selulosa bakteria pula ditunjukkan pada puncak 1165 $cm^{-1}$ bagi hidrogel A dan 1159 $cm^{-1}$ bagi hidrogel B.



Jika dibandingkan dengan hidrogel A dan B, spektrum bagi hidrogel akrilamida mempunyai puncak yang lebih tajam pada 1647 $cm^{-1}$. Puncak yang terhasil ini adalah disebabkan oleh kehadiran kumpulan C=O dalam ikatan bersama amida. Selain itu, puncak 2934 $cm^{-1}$ pula menunjukkan kesan regangan $-CH_2$ daripada kumpulan $-CH_2OH$. Malah turut dapat diperhatikan juga kehadiran kumpulan N-H dalam spektrum hidrogel akrilamida pada julat 3500 – 3100 $cm^{-1}$ [13].

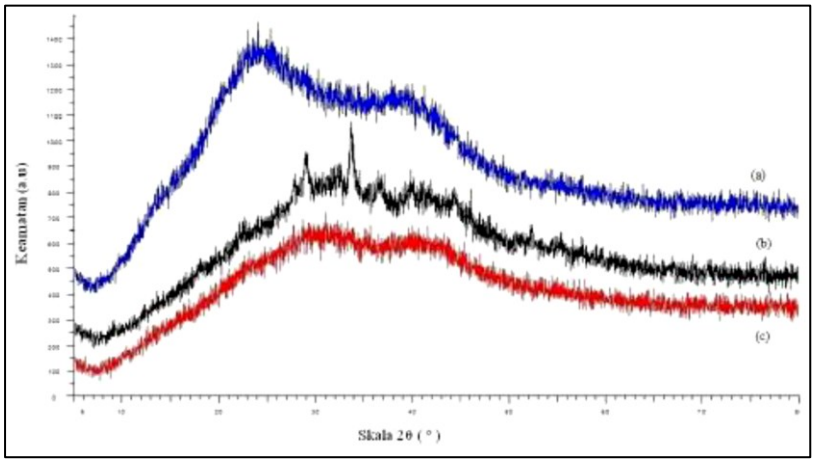
Rajah 2. Perbandingan spektrum inframerah bagi ketiga-tiga hidrogel di mana a) hidrogel AM b) hidrogel A dan c) hidrogel B

**Analisis gravimetri termal-kalorimetri pengimbasan pembezaan**

Analisis perbandingan keluk kalorimetri pengimbasan pembezaan dan analisis gravimetri termal (DSC/TGA) bagi hidrogel A dan B dapat dilihat seperti yang ditunjukkan dalam Rajah 3 di bawah. Berdasarkan keluk TGA, dapat dilihat bahawa kadar kehilangan berat maksimum bagi hidrogel A berlaku dalam julat suhu 150 – 200 °C manakala bagi hidrogel B pula berlaku dalam julat suhu 175 – 200 °C. Pada julat suhu 475 – 600 °C pula, keluk kedua-dua hidrogel A dan B menunjukkan tiada kehilangan berat berlaku seiring dengan penurunan nilai peralihan menghampiri peleburan.

Rajah 3. Perbandingan keluk TGA-DSC bagi a) hidrogel B dan b) hidrogel A

Manakala, puncak yang terhasil pada keluk DSC bagi kedua-dua hidrogel berkemungkinan disebabkan oleh peralihan fasa yang berkaitan dengan pembentukan dan pemutusan jaringan selulosa bakteria [14]. Menurut Halib et al. [6], selulosa bakteria mempunyai banyak kumpulan hidroksil di mana kumpulan ini akan bertindak balas dengan air untuk membentuk ikatan hidrogen sekaligus membolehkan hidrogel selulosa bakteria mengembang. Berdasarkan



keluk DSC, nilai peralihan kaca bagi hidrogel A berlaku dalam julat suhu 175 – 225 °C manakala nilai peralihan kaca bagi hidrogel B berlaku dalam julat suhu 150 – 200 °C. Hal ini menunjukkan bahawa hidrogel A mempunyai kestabilan terma yang lebih tinggi berbanding hidrogel B kerana peningkatan jumlah molekul air yang terikat pada selulosa bakteria akan meningkatkan nilai peralihan kaca. Perbandingan nilai peralihan kaca dan pengurangan berat maksimum bagi kedua-dua hidrogel dapat dilihat dengan lebih jelas seperti dalam Jadual 2 di bawah.

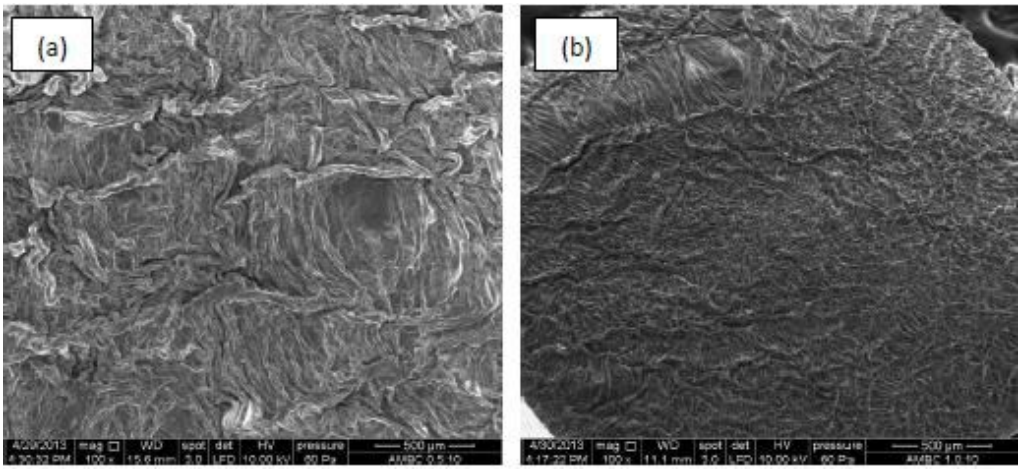
Jadual 2. Perbandingan termogram bagi kedua-dua hidrogel A dan B

| **Nisbah hydrogel** | **Nilai pengurangan berat maksimum/ Nilai peralihan kaca ($^{o}$C)** | |
|---|---|---|
| | **TGA** | **DSC** |
| Hidrogel A | 150 – 200 | 175 – 225 |
| Hidrogel B | 175 – 200 | 150 – 200 |

**Pembelauan sinar-X**

Dalam kajian ini, analisis pembelauan sinar-X telah digunakan untuk mencirikan peratusan penghabluran hidrogel berasaskan selulosa bakteria [15]. Rajah 4 telah menunjukkan perbandingan peratus penghabluran antara hidrogel akrilamida, hidrogel A dan juga hidrogel B.

Rajah 4. Perbandingan peratus penghabluran di antara hidrogel a) hidrogel akrilamida, b) hidrogel A dan c) hidrogel B



Berdasarkan Rajah 4 di atas, spektrum menunjukkan puncak keamatan bagi hidrogel A adalah hampir sama seperti hidrogel B. Tetapi, hidrogel A mempunyai beberapa puncak puncak yang lebih tinggi dan tajam jika dibandingkan dengan puncak bagi hidrogel B yang kelihatan lebih luas. Puncak keamatan hidrogel B yang lebar dan luas menunjukkan bahawa hidrogel ini mengandungi lebih banyak komponen amorfus. Manakala, puncak keamatan hidrogel A yang lebih tajam pula menunjukkan peratus penghabluran bagi hidrogel A adalah lebih tinggi berbanding dengan hidrogel B.

Rajah 4 juga menunjukkan hidrogel akrilamida mempunyai puncak yang lebih tinggi dan kurang lebar berbanding dengan hidrogel A dan juga hidrogel B. Hal ini menunjukkan peratus penghabluran bagi hidrogel akrilamida adalah lebih tinggi. Walau bagaimanapun, peratus penghabluran yang terlalu tinggi boleh mendorong kepada peningkatan kadar kerapuhan hidrogel [16].

**Mikroskopi pengimbasan elektron**

Dalam kajian ini, analisis mikroskopi pengimbasan elektron (SEM) telah digunakan untuk membandingkan

morfologi permukaan antara hidrogel A dan juga hidrogel B. Berdasarkan Rajah 5, morfologi permukaan kedua – dua hidrogel menunjukkan wujudnya liang – liang terbuka dalam hidrogel. Kewujudan liang – liang ini membolehkan proses penyerapan air berlaku dari semua arah sekaligus dapat menentukan tahap keporosan hidrogel [12].

Rajah 5. Mikrograf SEM bagi hidrogel berasaskan selulosa di mana a) hidrogel A dan b) hidrogel B

Berdasarkan ujian pengembangan, didapati hidrogel A mempunyai nilai peratus pengembangan yang lebih tinggi berbanding hidrogel B. Hal ini kerana hidrogel A mempunyai tahap keporosan yang lebih tinggi memandangkan liang – liang yang terdapat dalam hidrogel A adalah lebih banyak dan besar daripada hidrogel B.

## Kesimpulan

Hidrogel berasaskan selulosa boleh diketengahkan sebagai bahan bio untuk diaplikasikan dalam pelbagai bidang seperti kejuruteraan tisu, penghantaran ubat dan komponen elektronik. Berdasarkan kajian yang telah dan sedang dijalankan, hidrogel berasaskan selulosa bakteria telah berjaya dihasilkan dengan menggunakan teknik ultra lembayung terawat. Teknik telah menghasilkan sampel hidrogel berasaskan selulosa bakteria bagi dengan ciri-ciri yang setara dengan sampel yang dihasilkan menggunakan sinar gamma dan sinar alur elektron (EB). Malah teknik ini menawarkan satu kaedah yang murah dan mudah sebagai alternatif kaedah konvensional dan teknik radiasi yang lain.

# INCORPORATION OF GRAPHENE INTO COUNTER ELECTRODE TO ENHANCE THE PERFORMANCE OF DYE-SENSITIZED SOLAR CELLS

## (Pengabungan Grafin dalam Elektrod Lawan untuk Meningkatkan Prestasi Sel Suria Terpeka Pewarna)

**Abstract**

Platinum (Pt) is a conventional material for counter electrodes of dye-sensitized solar cells (DSSCs) due to its excellent electrocatalytic activity in the redox process. However, the high cost of Pt motivates researchers to search for composite materials of Pt to reduce its consumption. This study is aimed to reduce Pt usage by incorporating reduced graphene oxide (rGO) with Pt of different ratios in counter electrode thin films and to determine the optimum ratio with the highest efficiency. A DSSC-based platinum/rGO (Pt/rGO) counter electrode composite was fabricated using doctor-blade method. X-ray diffraction analysis was performed to examine the crystallite structure of the Pt/rGO thin film. The optimum ratio was found to be 70:30 of Pt:rGO, with current–voltage characterization showing an efficiency of 5.5%, open-circuit voltage of 0.739 V, current density of 12.5 mA/cm$^2$, and fill factor of 59.24%.

**Keywords**: counter electrode, dye-sensitized solar cell, graphene, platinum, thin film

**Abstrak**

Platinum (Pt) adalah bahan konvensional untuk elektrod lawan sel suria terpeka pewarna (DSSC) memandangkan ia mempunyai aktiviti pemangkinan-elektro dalam proses redoks yang sangat baik. Namun begitu, harga Pt sangat mahal mendorong para pengkaji untuk mencari bahan komposit Pt yang boleh mengurangkan penggunaannya. Kajian ini menumpukan pengurangan penggunaan Pt dengan menggabungkannya dengan grafin oksida terturun (rGO) dengan Pt dalam filem nipis elektrod lawan pada nisbah berbeza dan untuk menentukan nisbah paling optimum yang meningkatkan kecekapan. DSSC berasaskan komposit elektrod lawan platinum/grafin oksida (Pt/rGO) telah difabrikasikan menggunakan kaedah *doctor blade*. Analisis Pembelauan sinar-X (XRD) telah dijalankan untuk memeriksa struktur kristal pada filem nipis Pt/rGO. Nisbah optimum yang dicapai adalah 70:30 kepada Pt:rGO dimana pencirian arus-voltan (*I-V*) menunjukkan nilai kecekapan ialah 5.5%, dengan nilai litar voltan terbuka $V_{oc}$, ketumpatan arus $J_{sc,}$ dan faktor mengisi *FF*, masing-masing dengan nilai 0.739 V, 12.5 mA/cm$^2$ dan 59.24 %.

**Kata kunci:** elektrod lawan, sel suria terpeka pewarna, grafin, platinum, filem nipis

## Introduction

Over the past decade, green and renewable energy sources have been explored and used [1] to reduce $CO_2$ emissions [1-3]. Several types of renewable energy include hydro, wind, and solar or photovoltaic (PV). Among these sources, PV is the third most valued energy source that leads to the intense development of PV cell technology in recent years [1]. The sun is the best source of energy among the renewable or non-renewable energy because it provides 174,000 TW per year to the earth [4]. In other words, the energy from the sun should be utilized optimally. Ongoing

intense research is currently still being conducted for PV energy sources. Currently, PV energy sources have three generations of solar cell. The first generation is the silicon solar cell, in which the power conversion efficiency achieved 25% [5]. Presently, the silicon solar cell has dominated the market, but the high production cost has limited the spread of cell application. The second generation is the compound solar cell, in which gallium arsenide reached 28% [6] efficiency and cadmium telluride attained 20% [6, 7]. However, similarly the second generation also bears a high cost of production, which leads to the third generation. The third generation consists of dye-sensitized solar cells (DSSCs), organic solar cell, and quantum dots solar cells [8]. Third generation cells have lower cost production than conventional solar cell and have green technology that minimizes the environmental effect.

DSSC is one of the third generations of PV devices that gained the attention from most researchers. DSSC has several important parts that make up the cells; these parts include the titanium dioxide ($TiO_2$) photoanode, which helps excite the electron to the covalent bond; platinum (Pt) counter electrode, which acts as a catalyst in redox process; ruthenium dye (N719), which acts as a sensitizer that absorbs photon from light; and iodide electrolyte, which helps transfer the electron between two electrodes and also works in the redox process [9, 10]. Pt is a catalyst material that helps in reducing the triiodide ions into an iodide ion at counter electrode and electrolyte interface [11]. A faster rate of reducing the triiodide ions results in fast electron charge transfer. However, Pt is corrosive toward iodide electrolyte and is commercially expensive [12]. Therefore, replacing Pt with other materials or reducing Pt consumption using Pt composite materials is crucial. In addition, it is necessary to find the material that has a high electrocatalytic activity compared with Pt.

Recently, graphene has attracted much attention as a counter electrode material because of its electrical properties, corrosive resistance, low cost, and abundance [13]. The rGO structure is a three-dimensional network and has an oxygen-containing functional group that contributes to the electrocatalytic activity of rGO counter electrode [14]. Graphene is considered as a promising composite material with Pt. Hence, several ratios of composite Pt/rGO thin films were prepared in the starting ratio of the weight of the Pt to rGO 99:1 as the first ratio. The ratio of the rGO and the Pt will continuously increase and decrease, respectively. This paper focuses on determining the optimum ratio of rGO that can be incorporated into the Pt-based DSSC while reducing the use of Pt to achieve higher efficiency than Pt-based DSSC.

## Materials and Methods

### Materials

$TiO_2$ (WER2-0, Solaronix) was used as photoanode thin film, platinum paste PT-1 was purchased from Dyesol-Australia, and rGO-B026 purchased from graphenea were used as the counter electrode thin films. The N719 ruthenium dye sensitizer purchased from Dyesol were diluted with ethanol to form 0.3 mM solution mixture. Iodide electrolyte (Iodolyte, AN-50) performed as an electrolyte. An 8 $\Omega$ $cm^{-2}$ FTO glass substrate (FTO Tec 8, Dyesol) and 15 $\Omega$ $cm^{-2}$ FTO thin film (FTO Tec 15, Dyesol) will function as a counter electrode and photoanode glass substrate, respectively. Surlyn (Meltonix) is an adhesive material that helps photoanode and counter electrode glass substrate to attach together.

### Preparation of the counter electrode thin films

Pt/rGO CE thin films were prepared with commercially available Pt paste and rGO powder. The Pt/rGO thin films were prepared as the ratio of the weight of Pt to rGO are 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. The Pt paste and rGO powder were ultrasonicated by the ultrasonic bath for approximately 15 minutes to create homogeneous composite mixture. Then, the mixture was stirred for another 15 minutes using the magnetic stirring bar and pasted onto the glass substrate of the 1.5 cm × 2 cm, 8 $\Omega$ $cm^{-2}$ fluorine-doped tin oxide (FTO) using doctor-blade method. Pt/rGO CE thin films were annealed for 30 minutes at 450 °C.

### Fabrication of the DSSC

$TiO_2$ photoanode thin films were also prepared using the doctor-blade method, and the thin films were then immersed in the N719 ruthenium dye for 16 h with an active area of 0.25 $cm^2$. The photoanode and counter electrode were attached together by using a warm press machine to melt the Surlyn placed between the two electrodes. The active area part was injected with iodide electrolyte through the aperture between the electrodes. Then, the aperture was sealed to complete the fabrication of DSSC.

## Results and Discussion

### X-ray diffraction analysis

The X-ray diffraction (XRD) pattern of Pt, composite Pt/rGO of different ratio, and rGO are illustrated in Figure 1. Pt has been observed to have a prominent peak at (111) plane attributed to 39.8° with JCPDS of 03-065-2868. The Pt peak decrease until ratio 90:10 and rise slightly at ratio 85:15 before decreasing again at ratio 80:20 as the weight ratio of rGO increases. rGO has a weak intensity, shown in J of Figure 1, where the *hkl* plane of (006) attribute to 26.6° with JCPDS of 00-026-1076. $SnO_2$ diffraction angle is 26.5°, which is close to the rGO at (110) plane. The presence of Pt has concealed the rGO peak when Pt is mixed with the rGO. This process resulted in no visible rGO peak for the XRD pattern of Pt/rGO CE thin film. Thus, Pt is more crystallized than rGO. The crystallite size for each CE thin film can be calculated using Debye–Scherrer equation as in (1) [15],

$$D = \frac{0.9\lambda}{\beta \cos\theta} \tag{1}$$

where $D$ is the crystallite size, $\lambda$ is the wavelength, $\beta$ is the full width at the half maximum in radians, and $\theta$ is the diffraction angle. The crystallite sizes of the CE have been calculated, and the plotted graph is depicted in Figure 2. From the graph, the crystallite size increase until ratio of Pt:rGO is 95:5 and the crystallite size began to fluctuate at the range 29 – 36 nm approximately until ratio of Pt:rGO is 75:25. The crystallite size continues to decrease again at the ratio of Pt:rGO 70:30 although the amount of rGO keeps increasing. The larger the size of crystallite leads to high surface roughness of the thin films. The higher surface roughness of the thin film contributes to large surface area that instigates the high conductivity of the counter electrode thin film. Thus, from Figure 2 we can determine that counter thin film of Pt/rGO with ratio 80:20 has better conductivity among other due to large size of crystallite.

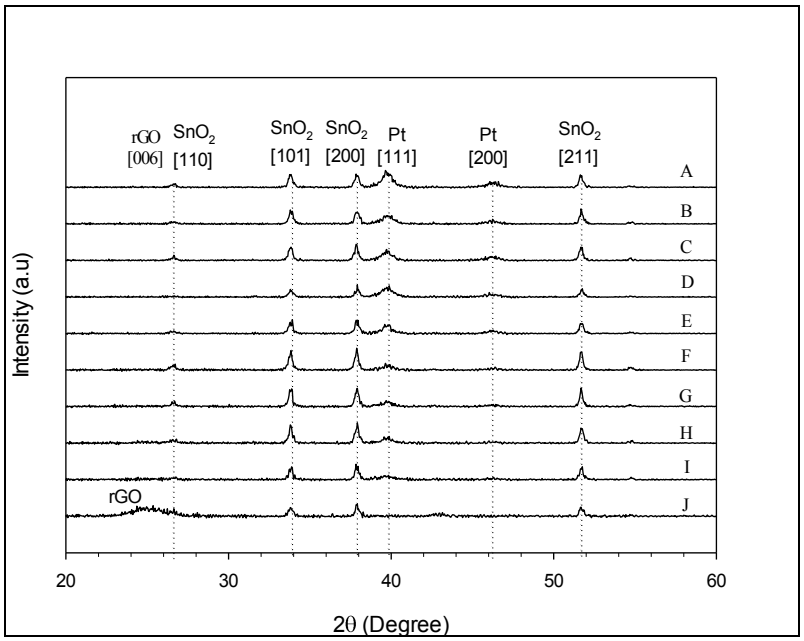

Figure 1. XRD of CE thin film. A is Pt. B–I is Pt:rGO with ratio 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. J is rGO

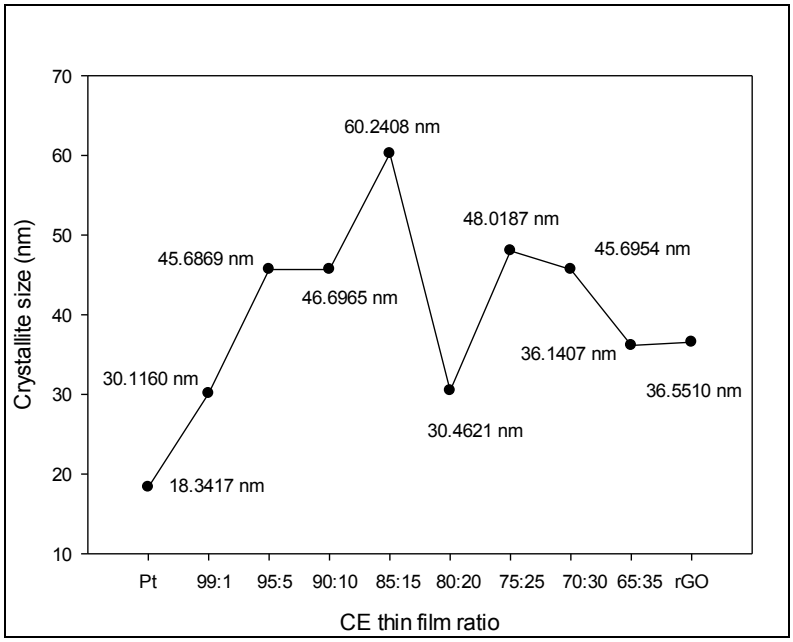

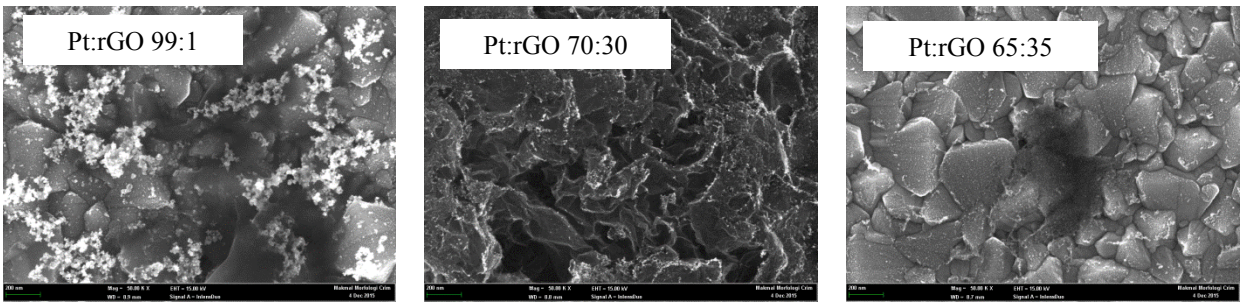

Figure 2. Crystallite size for Pt, rGO, and Pt:rGO at various ratios CE thin film

**Field emission scanning electron microscopy analysis**

The field emission scanning electron microscopy (FESEM) images of the thin films are used to study the morphology of the composite Pt:rGO counter electrode thin films (Figure 3). Pt is observed to have nano-like particle that spread homogeneously on the FTO glass substrate, and rGO is a nanosheet that has randomly aggregated. The three ratios of composite Pt/rGO thin films of the counter electrode are displayed in Figure 3. The Pt:rGO of ratio 99:1 is the first ratio, where we can observe that Pt nanoparticles are more than the rGO nanosheets. The Pt nanoparticles decrease with the increase of the rGO, and the Pt:rGO of ratio 70:30 is the optimum ratio with higher efficiency. In ratio 70:30, the Pt nanoparticles were well blended in the rGO nanosheets. When the rGO increases, the Pt nanoparticle can no longer blend with the rGO nanosheets as presented in Figure 3. In ratio 65:35, we hardly observe the Pt nanoparticle and a small amount of rGO nanosheets attached to FTO glass substrate.

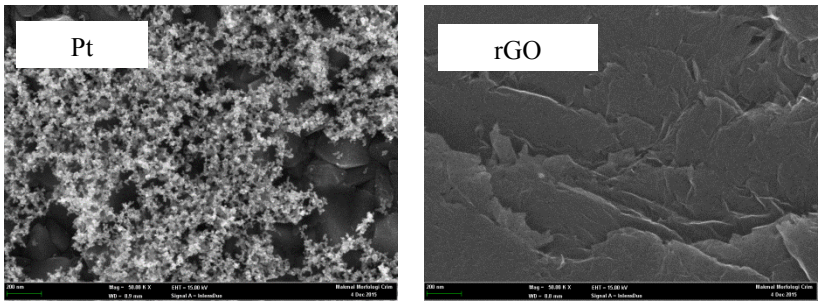

Figure 3. FESEM image of Pt, rGO, Pt:rGO of 99:1, 70:30, and 65:35

**Current-voltage analysis**

Figure 4 shows the current–voltage characterization for the DSSC with a different type of CE. The efficiency of the DSSC can be calculated by Martinson et al. [16] using equation 2:

$$\eta = \frac{VocJscFF}{Pin} \tag{2}$$

where $\eta$ is the efficiency of the device equals to the product of $V_{oc}$, $J_{sc}$, and FF divided by an $V_{oc}$ of 100 mW/cm$^2$ under AM 1.5 ($P_{in}$). The *I–V* curve for rGO is the lowest with $J_{sc}$ of 8.40 mA/cm$^2$ and an $V_{oc}$ of 0.62 V, resulting in poor efficiency of 1.97% as presented in Table 1. It can be seen that the conductivity of the thin film increase as the value of $J_{sc}$ increase following the increase of the amount of rGO. This is due to the rGO is more conductivity than Pt, the adding of the rGO improves the conductivity of the thin films. The *I–V* curve of Pt/rGO-based DSSC of ratio 70:30 shows high $J_{sc}$ (12.50 mA/cm$^2$) with $V_{oc}$ of 0.74 V, resulting in high efficiency of 5.5 %, which is better than Pt-based DSSC. Table 1 summarizes all the *I–V* curve parameter of DSSC. Therefore, the addition of the rGO in CE thin film increases the efficiency of the DSSC until the ratio of Pt:rGO of 70:30. The efficiency decreases when more rGO is added. Thus, 70:30 is the optimum ratio of rGO that can be incorporated with Pt as a CE material.

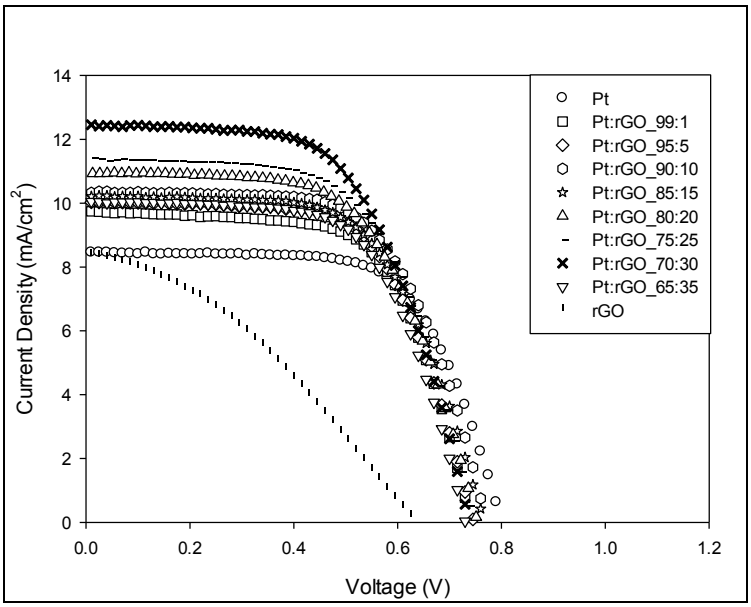

Figure 4. *I–V* Characterization of DSSC

Table 1. *I–V* characterization parameter of DSSC with Pt CE, various ratio of Pt:rGO, and rGO

| Counter electrode | $V_{oc}$ (V) | $J_{sc}$ (mA/cm$^2$) | *FF* (%) | $\eta$ (%) |
|---|---|---|---|---|
| rGO | 0.62 | 8.40 | 37.30 | 1.97 |
| Pt | 0.80 | 8.43 | 66.23 | 4.46 |
| Pt:rGO 99:1 | 0.74 | 9.73 | 64.59 | 4.67 |
| Pt:rGO 95:5 | 0.75 | 10.00 | 64.07 | 4.8 |
| Pt:rGO 90:10 | 0.77 | 10.30 | 63.55 | 5.10 |
| Pt:rGO 85:15 | 0.77 | 10.20 | 61.59 | 4.80 |
| Pt:rGO 80:20 | 0.75 | 10.90 | 60.66 | 5.00 |
| Pt:rGO 75:25 | 0.74 | 11.40 | 61.80 | 5.20 |

## Conclusion

The composite of Pt/rGO counter electrode thin films with different ratios were successfully prepared using doctor-blade method annealed at 450 °C for 30 min. The ratio of Pt/rGO that has been prepared were 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. The pattern of the increase and decrease of the efficiency of the DSSCs is observable after reaching the optimum ratio. Pt and rGO CE thin film are also prepared using the same technique as references. The Pt/rGO of ratio 70:30 shows the highest efficiency of 5.5% with the $J_{sc}$ value of 12.50 mA/cm$^2$, $V_{oc}$ value of 0.74 V, and FF is 59.24. The Pt counter electrode-based DSSC incorporated with rGO has higher efficiency at an optimum ratio of 70:30 in comparison with the Pt efficiency, which is 4.46%. The objective to reduce the use of Pt in the counter electrode of DSSC is achieved.

**Abstract**

Crystalline silicon (c-Si) wafers are the dominating substrate materials for solar cells in current photovoltaic (PV) industry. Silicon (Si) wafer with positive-type (*p*-type) based solar cells dominates almost 95% of the global PV market. Recent goal in Si solar cell industry is focusing on cost reduction through inexpensive manufacturing processes. Standard manufacturing process of Si solar cell fabrication consist of damage removal, cleaning, texturing, phosphorus oxytrichloride ($POCl_3$) diffusion, anti-reflective coating (ARC) deposition, metallization by screen printing technique, firing and light current-voltage (LIV) testing. These fabrications line are time–consuming and high temperature process which lead to high manufacturing cost. This study presents the simplification of Si solar cell fabrication on *p*-type Si wafer. Simplified fabrication process eliminates the ARC deposition by plasma enhanced chemical vapour deposition (PECVD). Simplified Si solar cell was fabricated without silicon nitride (SiN) as ARC layer. In commercial solar cell, both pyramid texture on Si wafer and SiN have been used to reduce reflectance and enhanced the light absorption. From the reflectance measurement, it can be seen that SiN and pyramid texture shows an average reflectance curve. The efficiency obtained by commercial, fabricated and simulated solar cells were 17.09%, 9.44% and 9.67%, respectively. From the simulation study, it is proven that the low efficiency of simplified solar cell was attributed by low minority carrier lifetime of *p*-type Si wafer.

**Keywords**: crystalline silicon solar cell, *p*-type Si wafer, anti-reflective coating, minority carrier life time, PC1D simulation

**Abstrak**

Kepingan silikon kristal (c-Si) adalah bahan substrat yang mendominasi sel suria untuk industri fotovolta (PV) masa kini. Sel suria berasaskan kepingan silikon (Si) berjenis-*p* menguasai hampir 95% daripada pasaran PV global. Matlamat terkini dalam industri sel suria Si memfokuskan kepada pengurangan kos melalui proses pembuatan yang murah. Piawai pembuatan fabrikasi sel suria Si terdiri daripada penyingkiran kotoran, pembersihan, pentekstur an, penyerapan fosforus oksitriklorida ($POCl_3$), pemendapan lapisan anti-pantulan (ARC), penyaduran dengan teknik percetakan skrin, pembakaran dan ujian cahaya arus-voltan (LIV). Proses fabrikasi piawai ini memakan masa dan menggunakan suhu tinggi yang menyebabkan kos pengeluaran yang tinggi. Kajian ini membentangkan peringkasan proses fabrikasi sel suria Si di atas Si wafer jenis-*p*. Proses fabrikasi teringkas ini membuang proses pemendapan ARC oleh pengendapan kimia dipertingkat plasma (PECVD). Sel suria Si teringkas telah difabrikasi tanpa lapisan silikon nitrida (SiN) sebagai ARC. Dalam sel suria komersial, tekstur piramid pada Si wafer dan SiN telah digunakan untuk mengurangkan pantulan dan meningkatkan penyerapan cahaya. Dari pengukuran pantulan, SiN dan tekstur piramid menunjukkan pantulan yang agak sama. Kecekapan yang diperolehi oleh sel suria komersial, diringkas dan simulasi adalah masing-masing pada 17.09%, 9.44% dan 9.67%. Daripada kajian simulasi, ia membuktikan bahawa kecekapan yang rendah bagi sel suria teringkas adalah disebabkan oleh jangka hayat pembawa minoriti yang rendah pada Si wafer jenis-*p*.

**Kata kunci:** kristal silikon sel suria, kepingan silikon jenis-*p*, lapisan anti-pantulan, jangka hayat pembawa minoriti, simulasi PCID

## Introduction

Solar cell is a semiconductor device which converts sunlight into electricity. Silicon (Si) is the most developed and widely used element in manufacturing solar cells. It is an indirect bandgap semiconductor and can be doped by impurities such as boron or phosphorus to form highly conductive positive or negative regions. It also absorbs light over a broad spectral range from ultra-violet (UV) to near infra-red (NIR) range. Si is a non-toxic material and the second most abundant element (after oxygen) on earth with a concentration of 28% [1]. The Si solar cell essentially has three functional elements: (a) absorption of sunlight to form electron-hole ($\bar{e}$-*h*) generation pairs, (b) an internal electric field (*p*-*n* junction) to separate $\bar{e}$-*h* pairs, and (c) external electrical contacts to extract current [2]. The Si wafer itself acts as the light absorber to generate $\bar{e}$-*h* pairs. The junction inside the semiconductor prevents $\bar{e}$-*h* pairs from recombination and guides oppositely charged carriers to respective electrical contacts. Finally, the contacts act as wires to carry photo-generated current into a load. Market review reveals that *p*-type wafer based solar cell dominates almost 95 % of the worldwide PV market [3].

Figure 1(a) shows the standard manufacturing process in solar cell fabrication that consist of damage removal, texturing, junction formation by phosphorus oxytrichloride ($POCl_3$) diffusion, Silicon nitride (SiN) deposition as ARC, metallization by screen printing technique, firing and IV testing. SiN is widely used as ARC layer in commercial c-Si solar cell deposited by PECVD. ARC deposition and diffusion processes consumed 50% to 70% energy from total energy consumption in solar cells fabrication process [4]. In addition, SiN uses silane toxic gas while $POCl_3$ diffusion requires temperature of 1000 °C for junction formation. High temperature process leads to high fabrication cost, meanwhile SiN deposition is a toxic-based process. Therefore, this study presents simplified fabrication process for c-Si solar cell on *p*-type wafers. This process eliminates the use of SiN as ARC layer (Figure 1(b)). Previous study has presented the *in-situ* oxidation process of silicon dioxide ($SiO_2$) as ARC layer [5]. However, in this paper, we presented performance evaluation of Si solar cell without ARC layer by experiment and PC1D simulation. Solar cell simulation model PC1D is used to understand dependence of solar cell performance on wafer and process parameters.

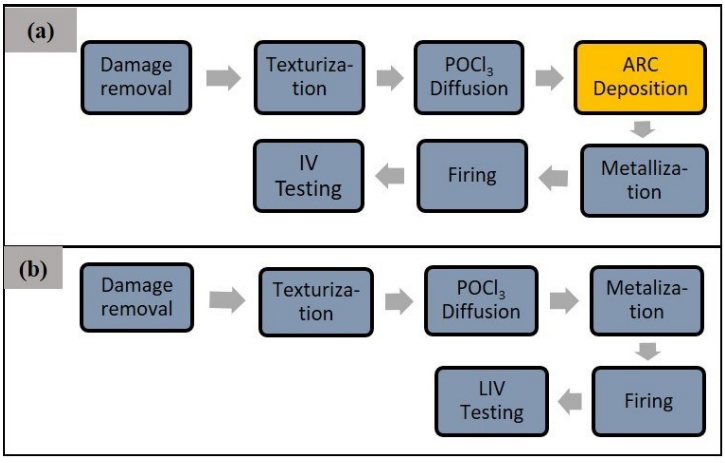

Figure 1. Comparison of (a) standard manufacturing process for Si solar cell fabrication, and (b) fabrication process for simplified Si solar cell on *p*-type Si wafer. There is an elimination of ARC deposition process in simplified Si solar cell

## Materials and Methods

### Fabrication of simplified *p*-type Si solar cell

Figure 2(a) schematically describes the commercial solar cell configuration, meanwhile Figure 2(b) describes simplified solar cell configuration without ARC layer. The saw damage in as-cut boron wafers was removed by etching in 10% sodium hydroxide (NaOH) solution. A mixture of 6000 ml deionized (DI) water and 600 g of NaOH

was prepared in Pyrex beaker and the solution was heated to 70 $^{o}$C. Si wafers were fully immersed into heated solution for 10 minutes. This process removes surface saw damage and other contaminants from the wafering process. The etched wafers are rinsed in DI water and immersed in dilute hydrofluoric (HF) solution to remove native oxide. Appropriately processed wafers will exhibit shiny surface and are completely hydrophobic. An alkaline solution is highly effective in creating a uniform texture for the texturing process on <100> crystalline orientation. A mixture of isopropyl alcohol:potassium hydroxide:deionized water (IPA:KOH:$H_2O$) was prepared based on volume ratio 5:1:123. The solution was heated up at 70 $^{o}$C. The saw-damage removed wafers are immersed in this solution for 30 minutes. Finally, the wafer is rinsed in DI water and immersion in 10% HF solution. With appropriate texture process, surface appearance is grey and shiny at large oblique angles due to high reflection of <111> crystalline facets. Such rough surfaces enhance light trapping and reduce reflection.

A *p-n* junction is formed based phosphorous diffusion with liquid source $POCl_3$ solution. A vapour solution containing $POCl_3$ is transported to a high temperature quartz furnace to form Phosphorous Oxide film on the Si wafer surface. Next, the metallic pastes were screen printed on both the front and rear surfaces of the Si wafer. At the front, Ag paste is screen printed and dried in low temperature oven at 200 ºC for 10 minutes. Following front surface screen printing, rear surface is screen printed by with an Al paste and dried in low temperature oven at 200 ºC for 10 minutes. The drying process removes excess organic solvent from the pastes and provides stable adhesion between paste and wafer surfaces. The aim of this process is to form low resistance ohmic contacts between metallic films and Si. In this process, wafers were placed on the top of the conveyer belt and passes through six temperature zones. Each of temperature zones is heated up by infrared quartz lamps. The finished solar cells were characterized by light current-voltage (LIV) measurement system and quantum efficiency (QE) measurement systems using Keithley 237.

**PC1D simulations of simplified *p*-type Si solar cell**

PC1D simulation software was used to simulate performance of *p*-doped wafer solar cell in terms of critical solar cell parameters such as bulk conductivity, front surface field and minority carrier lifetime [6]. Figure 2 described the differences schematic configuration between (a) ARC and (b) non-ARC solar cell configuration. Non-ARC simulation was carried out for 100 $cm^2$ area p type silicon solar cell with fixed series resistance, shunt conductance, and 200-$\mu$m wafer thickness. Pyramidal texture was assumed with fixed 10 % front surface reflectance. Base contact and internal conductor were respectively set at 0.0015 Ω and 0.3 S [7]. Bulk conductivity concentrations were varied in $1.513\times10^{11}/cm^3$ to $1.513\times10^{16}/cm^3$ range. The front surface emitter doping concentration was varied from $1.27\times10^{17}/cm^3$ to $1.27\times10^{22}/cm^3$. The minority carrier lifetime was varied from 0.001 $\mu$s to 1000 $\mu$s. Finally, the front surface recombination velocity was varied in $1\times10^{6}$ cm/s to 100 cm/s. Table 1 shows the details of simulation parameters.

| Collector circuit | Zero |

## Results and Discussion

The investigation on reflectance measurement has been performed to investigate the photon reflection of pyramid texture Si wafer and SiN as ARC layer. Scanning electron microscopy (SEM) images of pyramid textured and ~70 nm thin SiN layer on Si wafer shown in Figure 3(a) and Figure 3(b). In commercial solar cell, both pyramid texture and SiN layer have been used to reduce light reflectance and enhanced photon absorption. Figure 4 shows the reflectance measurement of planar (un-textured) wafer, textured wafer and SiN layer on Si wafer. The high reflectance shown by planar wafer indicates that the light is highly reflected on un-textured and non-ARC wafer. Therefore, the planar wafer is not appropriate in Si solar cell fabrication as it has high photon and reflection losses. Meanwhile, textured wafer and SiN layer shows an average performance on reflectance measurement. This average performance of the reflectance measurement proves that non-ARC Si solar cell can potentially produce a good performance output of solar cell compared to commercial solar cell.

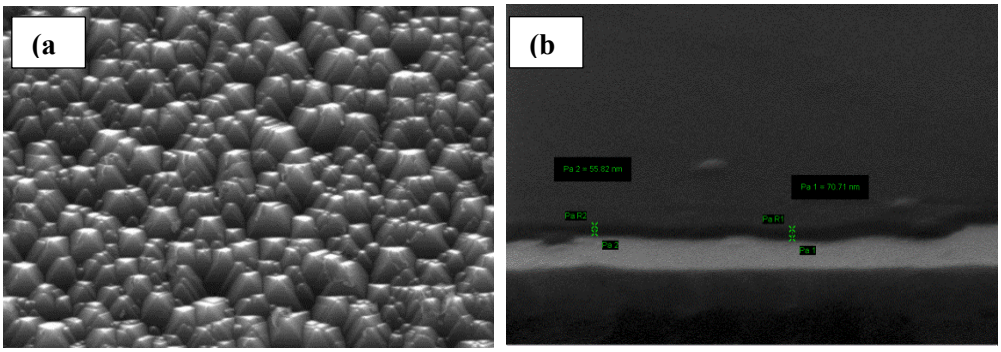

Figure 3. SEM images of (a) pyramid texture on Si wafer, and (b) SiN layer as ARC on commercial Si solar cell

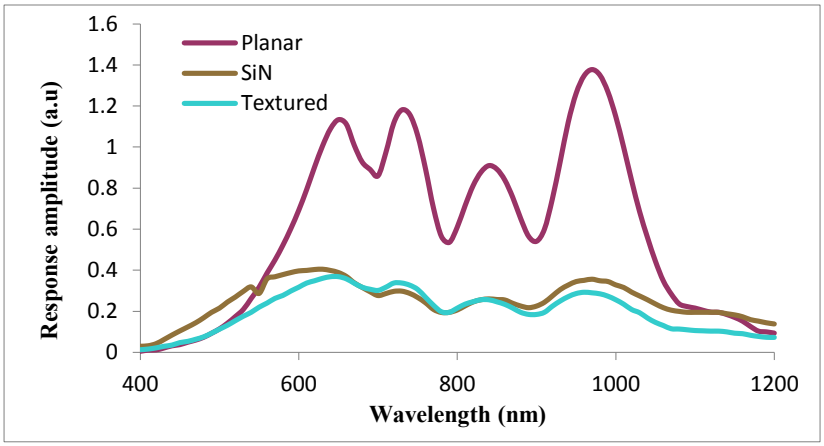

Figure 4. Reflectance measurement on planar wafer, textured wafer and SiN layer on Si wafer

Figure 5 plots current-voltage (I-V) measurements at air mass (AM) 1.5 illumination for commercial solar cell, fabricated and simulated simplified Si solar cell on *p*-type Si wafer. Table 2 summarizes the solar cells performances. In Figure 5, the commercial solar cell as reference cell exhibits significantly superior performance in comparison with simplified solar cell. The efficiency obtained by commercial, fabricated and simulated solar cells were 17.09%, 9.44% and 9.67%, respectively. The commercial solar cell has textured Si wafer and SiN layer as ARC, while fabricated simplified solar cell is non-ARC solar cell and textured. It can be seen that there is a sub-standard performance between commercial and non-ARC solar cell with ~8% of difference in solar cell efficiency. This proves that non-ARC solar cell can still produce a function solar cell without SiN layer. These findings raise up an approach to have the non-toxic solar cell at low fabrication cost.

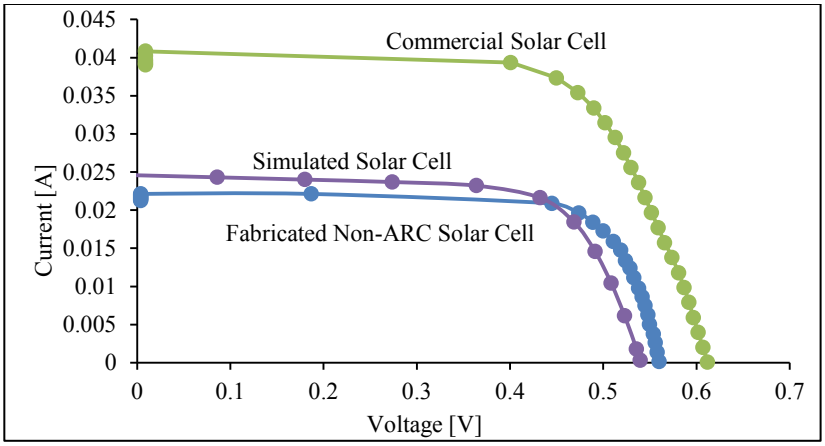

Figure 5. I-V curve of commercial, simulated and fabricated solar cell under AM 1.5 illumination

Table 2. Solar cell performances of commercial, fabricated and simulation solar cell

| **Device Performances** | **Commercial Solar Cell** | **Fabricated Solar Cells** | **Simulated Solar Cell** |
|---|---|---|---|
| Voc (V) | 0.612 | 0.56 | 0.50 |
| Isc [A] | 0.041 | 0.02 | 0.025 |
| FF | 0.671 | 0.7467 | 0.724 |
| Efficiency (%) | 17.09 | 9.44 | 9.67 |

The minority carrier lifetime of *p*-type Si wafer has been varied in PC1D simulation at 0.15 $\mu$s, 0.6 $\mu$s and 1.1 $\mu$s to investigate the significance of the lifetime to the simplified solar cells performance. The lack performance of fabricated simplified solar cell can be attributed to the relatively poor minority carrier lifetimes of *p*-type Si wafers. Figure 6 shows minority carrier lifetime at 0.15 $\mu$s, 0.6µs and 1.1 $\mu$s resulting solar cell efficiency of 10.34%, 12.30% and 13.03% respectively. This result indicated that the front surface emitter field is able to collect large majority light-generated $\bar{e}$-*h* pairs prior to recombination. However, poor lifetime means that a majority of $\bar{e}$-*h* pairs are lost to recombination prior to collection by the junction. *I-V* curve in Figure 5 and 6 shows a good agreement.

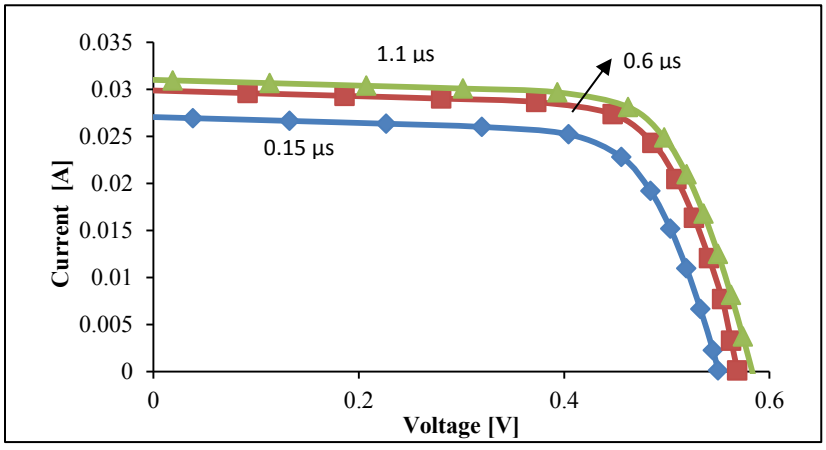

Figure 6. *I-V* response of simulated simplified solar cell with a variation of minority carrier lifetime at 0.15 $\mu$s, 0.6 $\mu$s and 1.1 $\mu$s by PC1D simulation

In addition, this behaviour can be explained in terms of electron-hole pair diffusion across the 200 $\mu$m thickness of the solar cell. Diffusion length is related to lifetime by the equation (1).

$$L_{DIFF} = (\tau * D)^{1/2} \quad (1)$$

where $\tau$ is minority carrier lifetime in second and $D$ is Si diffusivity in $m^2$/sec; for Si, $D=8.8\times10^{-5}$ $m^2$/sec. Therefore, for $\tau$=0.001 $\mu$s, $L_{DIFF}$=0.3 $\mu$m which is 667 times smaller than wafer thickness; therefore, almost all $\bar{e}$-$h$ pairs are likely to be lost to recombination. In contrast, for $\tau$=500 $\mu$s, $L_{DIFF}$=210 $\mu$m, which is larger than wafer thickness; therefore, almost all $\bar{e}$-$h$ pairs will likely reach junction prior to recombination [7]. Ergo, higher efficiency of simplified solar cell can be achieved by using higher minority carrier lifetime of Si wafer. Higher lifetime wafers can produce an average performance of simplified solar cell similar as commercial solar cell that has SiN layer.

## Conclusion

Simplified Si solar cells or non-ARC solar cell have been fabricated and modelled in PC1D. The efficiency obtained by fabricated and simulated solar cells were 9.44% and 9.67%, respectively. The commercial solar cell with ARC layer shows an efficiency of 17.09%. Good agreement is observed between the experimental and simulation results. The low efficiency of the fabricated solar cell has been attributed to the no ARC layer and poor minority carrier lifetime of Si wafer. However, the efficiency of simplified solar cell and the reflectance measurements shows that non-ARC Si solar cell potentially produce an average performance output of solar cell compared to commercial solar cell. Therefore, high minority carrier lifetime is required in order to produce high efficiency of simplified solar cell. This work also contributes to the simple approach of solar cell fabrication at low cost.

**Abstract**

Increasing reliance on carbon-based fossil fuel is likely to cause irreversible damage to global environment. Crystalline silicon (Si) based on pollution free photovoltaic (PV) electricity generation technology is expected to play a dominant role in this electricity generation transition from carbon to silicon. Since Si wafer represents almost 50% of the PV conversion cost, thinner wafers are highly effective at reducing the production cost. Therefore, there is an urgent need to develop alternative device configurations and processing methods for thinner Si wafer. Si wafer has to go through cleaning process, thinning process, textured process and partially transparent technique. In this work optical transmission through Si is investigated as a function of wafer thickness. For this improved performance, surface morphology, optical properties and the optical transmission near band gap is measured with custom-designed rear infra-red (IR) transmission measurement system. Si wafer with the textured surface have more light absorption than the as-cut and planar Si wafer.

**Keywords**: optical transmission, thin silicon wafers, infrared light, light absorption

**Abstrak**

Peningkatan kebergantungan terhadap penggunaan bahan bakar berasaskan sumber karbon mengakibatkan pencemaran alam sekitar. Fotovolta (PV) sifar pencemaran berasaskan silikon kristal merupakan teknologi tenaga elektrik generasi terkini dijangkakan menjadi sumber yang mendominasi perubahan sumber bahan api berasaskan karbon kepada silikon. Tambahan pula, kepingan silikon meliputi 50% kos keseluruhan pembuatan PV, pengurangan kos yang efektif didapati melalui penipisan kepingan.. Oleh itu, kaedah alternatif kepada pembaharuan bagi konfigurasi sistem penipisan silikon harus di cadangan. Kepingan silikon harus melalui proses pembersihan, proses penipisan, proses tekstur dan teknik separa telus. Dalam kajian hubungan di antara ketebalan kepingan silicon dan maklumat optik diteliti. Bagi meningkatkan prestasi, morfologi permukaan, sifat optik, dan penghantaran optik menghampiri jurang jalur diukur dengan menggunakan sistem pengukuran penghantaran gelombang IR.

## Introduction

Silicon wafer-based photovoltaic module production has been growing over 30% since the last decade [1]. Generally, the cost of Si accounts for almost 50% of a photovoltaic panel [2]. Historically, a pathway to reduce cost has been realized by economic use of Si in the form of thinner substrates; current Si wafer is in 150 – 200 $\mu$m thickness [3]. Si PV technology is almost exclusive based on mono-facial solar cells in which light is incident from the front surface with the back surface completely metallized. The bifacial solar cell is an emerging solar cell configuration in which electrical grid patterns are identical on both front and back surfaces. This device

configuration has the potential to generate more power by capturing scattered light from the rear surface than the mono-facial solae cell. The challenging problems in bifacial solar cell is to ensure that the photo-generated electron-hole ($\bar{e}$-$h$) pairs absorbed near the back surface are collected by the front surface emitter prior to recombination. This experiment can be done by using appropriate surface texturing methods, light trapping can be enhanced and absorption in the rear-infrared (NIR) [4-6]. The optical properties of a broad range of different bifacial configurations with varying surface morphologies and rear side reflectors have been extensively investigated in the literature. Although wafer thickness reduction translates into smaller recombination losses and large open circuit voltages; absorption is reduced as well [7].

These considerations have led to extensive research on performance limiting factors in amorphous [8], multi-crystalline [9], and single crystalline solar cells [10, 11]. Due to its indirect band gap, crystalline silicon has weak optical absorption particularly in the range (~900 – 1100) nm. Therefore, in solar cell studies aimed at increasing the efficiency, the primary goal is to enhance light absorption while minimizing recombination losses. Surface texturing aimed at enhanced absorption in silicon has been extensively investigated by geometrical optic [12]. Geometrical textures reduce reflection light into the semiconductor. Despite their effectiveness and industrial applications, geometrical texturing schemes suffer from several disadvantages that limits their effectiveness. Some of those are listed below [13]:

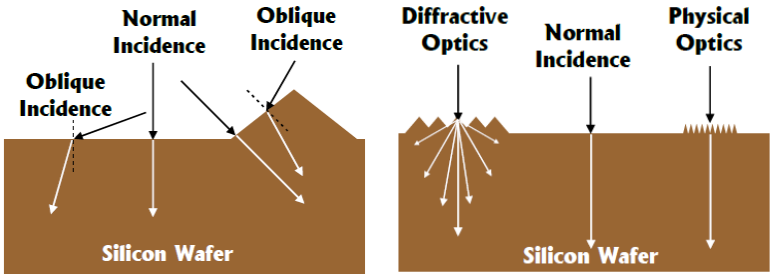
i) Wet-chemical alkaline anisotropic etching used to form random pyramids in (100) oriented crystal is not effective in texturing of flow cost multi-crystalline (mc-Si) wafers, ii) Anti-reflection films have a resonant structure which limits their effectiveness to a narrow range of angles and wavelength, iii) Sufficient IR absorption in thin film ( < 10 $\mu$m) silicon solar cells is not possible with geometrical optics based texturing.

Light trapping schemes based on geometrical optics considerations have been developed for enhancing oblique coupling beyond narrow angle range of (~16°) defined as $sin^{-1}(1/n)$, where $n$ is the refractive index of silicon [14]. In general, the required feature dimensions for geometrical optical path length enhancement are optical wavelength, therefore their applicability to thinner wafers is impractical. Periodically textured surfaces based on diffractive [15] and waveguide optics [16] have been shown to significantly enhance optical absorption. For a weakly absorptive medium, statistical analysis by Yablonovitch [17] and optical analysis of scattering from a lambertian surface predicted absorption enhancement in textured surfaces by (~$4n^2$) over a planar surface, where $n$ is the refractive index of the material. Absorption in such structure is opposed to conventional horizontal, thin-film waveguide structures as proposed by Sheng [18].

In literature application of diffractive and physical optics structures aimed enhancement of optical absorption in thin Si films and solar cells have been reported with good results [19 – 28]. Lambertian schemes and related geometrical optics-based ray tracing approached were applied to both amorphous silicon [29] and crystalline silicon solar cells [30] with successfully results. A lambertian surface capable of filling all the available $k$-space with light beams of equal intensity is difficult to achieve in practice. A close approximation is a randomly textured surface supporting sub-wavelength features. Therefore, the random surface can be described by Fourier summation-over a large number of periods. Although the resulting diffractive scattering ensures almost complete filling of the $k$-space. Light incident on such surfaces normally is diffractively scattered over a broad angular range determined by using equation 1 below

$$\theta_{\mathrm{m,i}}=\sin^{-1}(m_{\mathrm{i}}\lambda/nd_{\mathrm{i}}) \tag{1}$$

where $n$, $d_{\mathrm{i}}$ represents the $m^{\mathrm{th}}$ diffraction order corresponding to the spatial period $d_{\mathrm{i}}$ and $n$ is Si refractive index. Optical path length in geometrical optics is simply the sum of number of passes through a thin film of thickness, $t$. For a single grating the total optical path length enhancement is given by summing over the lengths of all transmitted diffraction order (equation 2):



$$d_{\mathrm{opt}}^{\mathrm{grating}} = \sum i\ \gamma_{\mathrm{i}} d_{\mathrm{i}} \tag{2}$$

where $\gamma_i$ is fraction of incident energy coupled into diffractive, $d_i$. For a normally propagating zero order, $d_0$ is identical to *t*; for the diffraction orders the optical path is *t*/cos $\theta_{ij}$ where $\theta_i$ the angle of propagation of the $i^{th}$ diffraction order. For a random sub-wavelength diffractive surface the total optical path length is summed over all grating (*i*); each of which generates diffraction orders (*j*) as defined as (equation 3):

$$d_{opt}^{random} = \sum_{i,j} \gamma_{i,j} d_{i,j} \quad (3)$$

Comparison of the three cases (planar, single period and random surface) illustrate that an appropriately designed random surface is highly effective in filling the *k*-space and therefore in reaching the $4n^2$ enhancement limit.

For a good solar cell it is crically important that all of the incident energy to be scattered into obliquely propagating transmitted orders in order to enhance optical path length hence increase absorption rate. This can be achieved for feature dimensions either substaintially larger (Figure. 1(a)) or comparable or substaintially smaller than optical wavelength (Figure. 1 (b)). The first configuration refers to geometrical optics, the second to diffractive optics, and the third to physical optics. In the physical optics approach deeply etched subwavelength structures are created in three dimensions, on the surface and through the substrate. Rigorous coupled wave analysis [14] has been used to calculate optical absorption in these 3D grating structures. Physical optics also described in terms of subwavelength surfaces (sws) essentially acting as multi-layer anti-reflection films [31]. Structures play no role in optical path length enhancement. In this paper, near IR transmission in (~800 – 1700) nm spectral range for planar and randomly textured Si wafers have been investigated for Si wafers with thickness of (~200 $\mu$m).

## Materials and Methods

Single crystalline silicon (c-Si) wafer with thickness about (~200 $\mu$m) is used. *P*-type Si wafers with resistivity ranging between (0.5-3.0) Ω.cm with doping density between $10^{10}$ to $10^{16}$ were used. The silicon (Si) wafer was initially cleaned by dipping into solution of hydrofluoric acid (HF) and nitric acid ($HNO_3$) in a ratio of 1:100 for 10 minutes. After rinsing with deionized water, it was then dipped into HF and water in a ratio of 1:50 for 1 minute. The wafer was immersed in 10% potassium hydroxide (KOH) at a temperature of 70 – 80 ℃ for 5 minutes. Subsequently, the wafer was repeatedly cleaned in HF:$H_2O$ for 1 minute. Then the wafers were rinsed with deionized water for about 2 minutes and dried with nitrogen gas. Etching process led to the decrease in thickness of Si wafers. Figure 2(a) shows an etching process by using KOH solution. Si wafer with damage removal needs to go through the texturing process with ratio of 1:5:125. The texturing process is a combination of 4 g of KOH pallets, 20 ml of isopropanol and 90 ml of deionized ( DI ) water. The Si wafer will be laminated by using the laminator. Then, the laminated wafer will be transferred into a beaker which contained 10% KOH solution.

The estimated time would be 1 hour and 45 minutes at the temperature of 70 – 80 ℃. Next, the IR transmission data will be measured. Figure 2(b) shows the etching process by using HF:$HNO_3$ with a ratio of 1:10. Then, Si wafer-textured were dipped in a solution of HF:$HNO_3$ with ratio of 1:10 for 1 hour and 45 minutes. Then, the wafers were

rinsed and dried with nitrogen gas. The IR transmission data is recorded from (600 – 1200) nm wavelength with sub-wavelength 25 nm. Figure 2(c) shows a process flow for paste Black Etching Surface (BES) paste process on silicon wafer with 200 $\mu$m thickness. Next, the oxidation process was applied to the Si wafers. The time estimated to produce the oxide layer approach 350 Å is 1 hour and 30 minutes at the temperature 1100 ℃. The Si wafers size were then cut into 4 cm x 4 cm.The BES paste contains level of carbon black and *n*-methyl-2-pyrrolidone by EMD Chemicals Company is placed onto the mask and at the same time the Si wafer is placed under the mask. After that, the etched Si wafer is heated in the furnace at the temperature of 350 ℃ for 90 seconds. Next, Si wafer is soaked in 1% KOH for 1 minute at 40 ℃. After the BES paste is peeled out from the Si wafer, the Si wafer is placed into 10% KOH solution for 1 hour and 15 minutes at 70 ℃. Then, the Si wafer is rinsed using deionized (DI) water and dried with nitrogen gas.

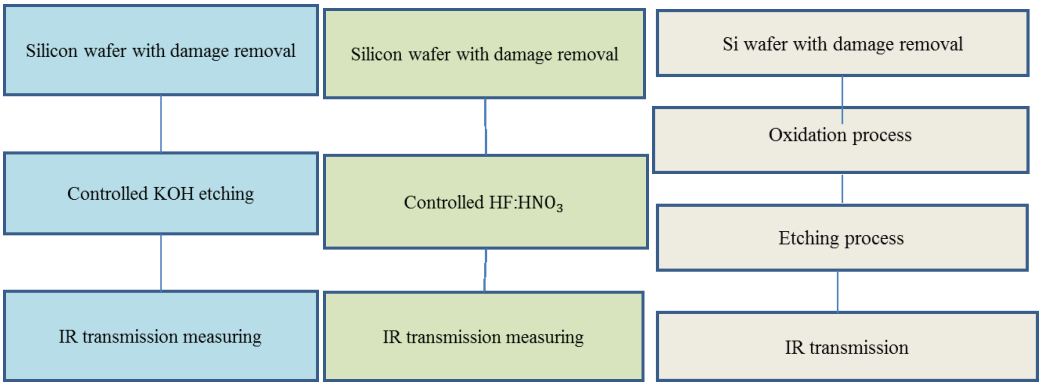

Figure 2. (a) Process flow for KOH etching process on silicon wafer with 200−µm thickness (b) Process flow for HF:$HNO_3$ etching process on silicon wafer with 200−$\mu$m thickness (c) Process flow for BES paste process on silicon wafer with 200−$\mu$m thickness.

A simple experimental setup based on optical configuration described in Figure 3 has been developed for characterization of near IR transmission as a function of wavelength. This system is designed to measure optical transmission system in near and far infrared (IR) range specifically for the wavelength. A computer controlled IR monochromator is used to vary wavelength in the desired range. Spectrally variable light from te monochromator is incident normally on the sample under measurement (SUM). The transmitted light from the sum is collected focusing lens onto an InGaAs photodetector. The output from photodetector is connected to a lock-in amplifier, which is connected to a computer. Intensity variation as a function of wavelength is measured with a LABVIEW based computer programme.

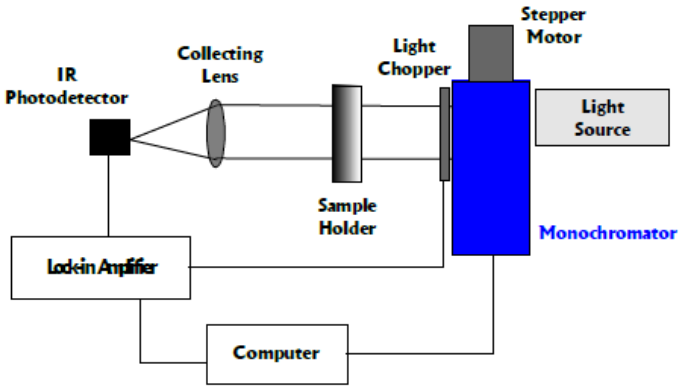

Figure 3. Schematic diagram for IR transmission measurement system

**Results and Discussion**

In order to reduce the reflectivity of the surface and to trap the light in solar cell, texturing process by using KOH solution have developed good achievement in capturing the light.In this work, thining process include KOH etching pocess whereas the Si wafers were immersed in 10 % KOH solution with different time eching such as 30, 60, 90 and 180 minutes. In figure. 4 shows the surface morphology from scanning electron microscope (SEM) analysis for KOH-etched surface. Table 1 conclude that the SEM data at 30 minutes the Si wafer reduced to 58. 4 $\mu$m and the etching rate is 1.94 $\mu$m/ min. Table 2 summarize from surface profiler at 30 minutes the Si wafer reduced to 31.24 $\mu$m and the etching rate is 1.04 $\mu$m/min. These etch results show that etch rate is significantly slowed as etch time increase, this may be attributted to loss of water in the solution to the evaporation resulting in a higher KOH concentration which in turn, slow the etch rate.

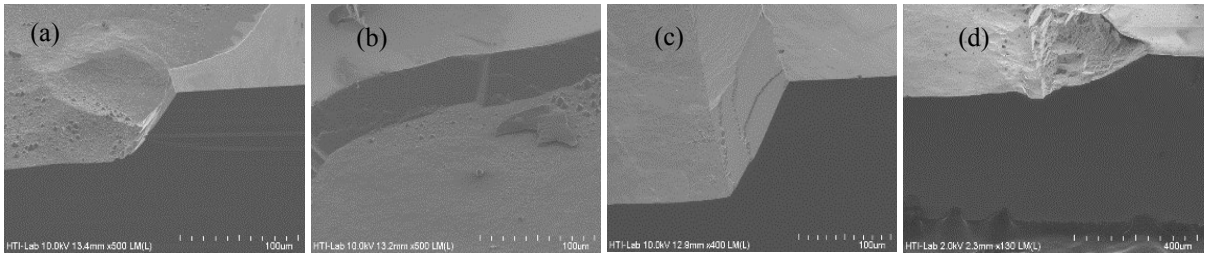

Figure 4. Topographical images for KOH-etched Si surfaces for etching times of 30 minutes (a), 60 minutes (b), 90 minutes (c) and 180 minutes (d)

Table 1. Result of the thickness for KOH etching vs time from SEM data

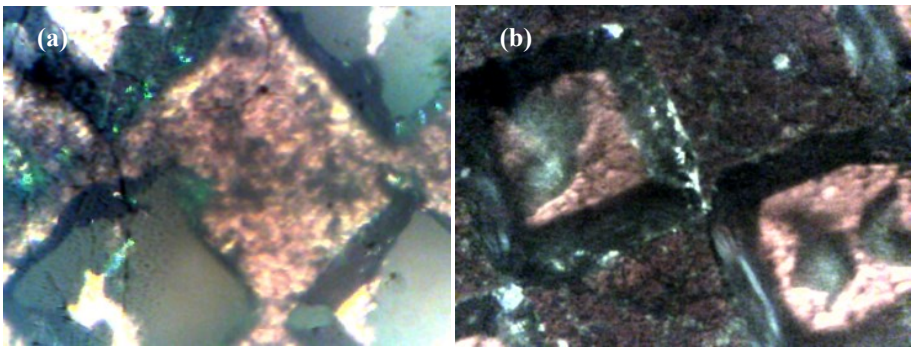
| Samples (minutes) | Thickness ($\mu$m) | Etching Rate ($\mu$m/min) |
|---|---|---|
| 30 | 58.4 | 1.94 |
| 60 | 41.3 | 0.63 |
| 90 | 97.3 | 1.08 |
| 180 | 135.2 | 0.75 |

Table 2. Result of the thickness for KOH etching vs time from surface profiler

| Samples (minutes) | Thickness ($\mu$m) | Etching Rate ($\mu$m/min) |
|---|---|---|
| 30 | 31.238 | 1.04 |
| 60 | 58.056 | 0.96 |
| 90 | 91.862 | 1.02 |
| 180 | 213.18 | 1.18 |

Figure 5 shows Si wafer surface after through the KOH etching process. Etching of Si in orientation-dependent alkaline solutions is very well characterized. The etch anisotropy of the alkaline solutions basically results from the fewer surface Si-OH bonds per unit cell on <111> compared to <100> and <110> surfaces. Due to this, it leads to higher energy to break bonds of the <111> surface Si atoms. This anisotropy effect is employed to generate V-grooves in <100> Si wafers using openings in an appropriate mask such as an oxide layer. The wafer release two

configurations: a) through holes and b) no holes. According to these results, it show that an oxide layer on Si wafer is not uniformly grown. Figure 5(a) shows the morphology of Si wafer at area with holes by using AMSCOPE 3.0 MD400E digital microscope and Figure 5(b) shows the morphology of Si wafer with partially holes.



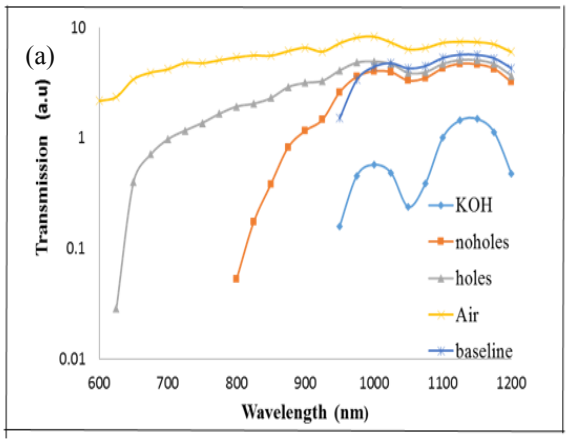


Figure 5. MD400E digital microscope pictures after through KOH etching process (a) the morphology of Si wafer at area with through holes and (b) morphology of Si wafer with partially holes.

Figure 6 shows plots as recorded transmission data as a function of wavelength: comparison transmission response in air and the Si wafer with damage removal known as a baseline have also been plotted. The transmission responses have been plotted on a log scale due to several orders of magnitude variation in transmitted signal. Transmission through air in (yellow line) is has the highest value. The transmission through Si wafer with holes (gray line) is second highest due to lack of absorption of wafer. However, light can be transmitted through Si wafer without reflections. Therefore, the transmission of the Si wafer is highest than planar wafers. Transmission through Si wafer with partially holes (orange line) can trap light and transmit less. Moreover, the Si wafer surface becomes more textured compared with holes. This is due to the increase of light absorption in a textured surface. Transmission through relatively planar polished sample (dark blue line) is lower absorption in a planar and non-textured surface. The sample thickness reaches approximately at (~180 $\mu$m) after going through the damage removal process. Therefore, more light will be reflected. The transmission through Si wafer with KOH-textured etching process is the lowest in 1000 – 1200 nm range (bright blue). The wafer with KOH etching is completely textured with estimated thickness of (~ 80 $\mu$m). The absorption of incident light is enhanced due to texture-based trapping. The Si wafer with 10% KOH have high quality of absorption light in IR wavelength. The surface texture also significantly enhances the light trapping in the long wavelength region, 800 – 1000 nm.

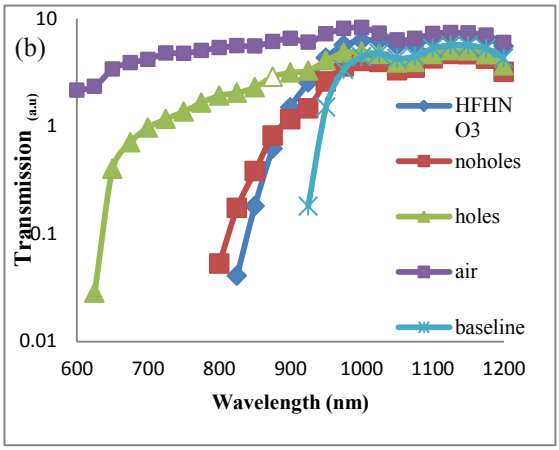

Figure 6. Comparison of optical transmission measurements a) with KOH and BES paste etching method and b) with HF:$HNO_3$ and BES paste etching method.

Figure 6(b) plots as recorded transmission data as a function of wavelength; comparison transmission response in air without Si wafer and the Si wafer with damage removal known as a baseline have also been plotted. The transmission responses have been plotted on a log scale orders of magnitude variation in transmitted signal. Transmission through air (yellow line) is highest. Transmission through Si wafer with holes (grey line) is lower than through air due to lack of absorption in wafer. However, light can transmit through wafer directly without reflection. Therefore, the transmission of the Si wafer is higher than planar wafers. Transmission through Si wafer with no holes (orange line) is reduced due to Si wafer surfaces. Moreover, the Si wafer surfaces had become more textured as the absorption of light increases. Transmission through Si wafer with HF:$HNO_3$ solution at 1:10 ratio (bright blue line) is lower due to its surface. As etching time increase, the Si wafer thickness is reduced to make it thinner. However, as etching time increased wafer starts to develop substantial texture and no longer planar. Therefore, the absorption of light is higher due to surface texturing.

## Conclusion

A simple IR spectral transmission system based on InGaAs photodetector and monochromator was successfully developed for spectral optical measurement. Based on feature dimensions, incident light interaction can be described in terms of geometrical, diffractive and physical optics. The thinner, textured-Si wafer gives the lowest transmission due to a combination of low reflection and diffractive scattering. A more detailed analysis in terms of measured thickness and surface textured will be reported elsewhere.

**Abstract**

Nowadays, the studies on organotin(IV) complexes with hydrazone ligand become more interesting due to their potential in various applications including medicinal area. In our recent studies, four new organotin(IV) complexes $MeSnCl_2(C_{12}H_{12}N_4)$ (**2**), $BuSnCl_2(C_{12}H_{12}N_4)$ (**3**), $PhSnCl_2(C_{12}H_{12}N_4)$ (**4**) and $Ph_2SnCl(C_{12}H_{12}N_4)$ (**5**) were synthesized by the direct reaction of methyl-2-pyridylketone-2-hydrazinopyridine ligand (**1**) and organotin(IV) chloride(s) in absolute methanol. These complexes have been characterized by UV-Visible, FT-IR, $^1H$ and $^{13}C$ NMR spectroscopies. All of the synthesized compounds were screened for antibacterial activity against *Escherichia coli* and *Staphylococcus aureus*. However, the complexes showed weak activity against the bacteria compared to the free ligand.

**Keywords**: hydrazone ligand, spectral studies, coordination, biological potential

**Abstrak**

Pada masa ini, kajian tentang kompleks organostanum(IV) dengan ligan hidrazon semakin menarik kerana sangat potensinya dalam banyak aplikasi termasuk bidang perubatan. Dalam kajian ini, empat organostanum(IV) kompleks iaitu $MeSnCl_2(C_{12}H_{12}N_4)$ (**2**), $BuSnCl_2(C_{12}H_{12}N_4)$ (**3**), $PhSnCl_2(C_{12}H_{12}N_4)$ (**4**) dan $Ph_2SnCl(C_{12}H_{12}N_4)$ (**5**) telah disintesis melalui tindak balas terus metil-2-piridilketon-2-hidrazinopiridin ligan dan organostanum(IV) klorida di dalam metanol. Kesemua kompleks telah dicirikan oleh kajian spektrum UV-nampak, FTIR, $^1H$ dan $^{13}C$ RMN. Semua sebatian yang disintesis telah diuji untuk aktiviti antibakteria terhadap *Escherichia coli* dan *Staphylococcus aureus*. Walaubagaimanapun, kompleks menunjukkan aktiviti yang agak lemah menentang bakteria berbanding ligan bebas.

**Kata kunci**: ligan hidrazon, kajian spektra, koordinasi, potensi biologi

## Introduction

Schiff base metal complexes containing hydrazone group have been studied extensively due to the interesting ligand systems containing different donor sites in heterocyclic rings. Hydrazones are the organic molecule that usually bonded to the metal atom through nitrogen and oxygen but also there was through sulphur atom. These hydrazone chelate derivatives also act as good potential oral drugs to cure the genetic disorders for example thalassemia [1]. Besides, hydrazones have many pharmacological properties including anti-tubercular activities and iron scavenging [2, 3]. The biochemical activity of organotin compounds commonly depend on the structure of the molecule and the coordination number of the tin atoms [4]. Organotin(IV) complexes are known to stimulate therapeutic effects on

various tumor cells [5]. Besides, Sharma and Kaushik [6] found that they are suitable as wood preservatives and active either towards Gram-positive or Gram-negative bacteria.

Thus, there are many of previous researchers reported on the potential of hydrazone metal complexes in biological activities. Bendre et al. [7] have been produced copper(II) complexes of 1,3-bis(2'-pyridyl)-1,2-diaza-2-butene and all of the synthesized compounds showed inhibition activities against mushroom tyrosinase. A few years later, organotin(IV) complexes with vitamin-$K_3$-2-hydrazinopyridine have been successfully synthesized and evaluated for toxicity and anti-termitic potential by Affan et al. [8]. The result indicated that ligand and organotin(IV) moderately active against *Artenia salina* and *Coptotermes* sp. Again, organotin(IV) complexes with *ortho*-vanillin-2-hydrazinopyridine exhibited better toxicity against *A. salina* and moderate to high activity against four types of bacteria which were *Bacillus cereus, Staphylococcus aureus, Escherichia coli* and *Enterobacter aerogenes* [9]. Evidently, the transition metal and organotin(IV) complexes with 2-hydrazinopyridine derivatives showed many potentials especially in biological activities studies.

Therefore, it is our interest to synthesize, characterize and evaluate the antibacterial activities of organotin(IV) complexes with methyl-2-pyridylketone-2-hydrazinopyridine. This is because this ligand contains N,N-donor atoms which are also still limited, plus the Sn-N coordination bond formed with complexes was believed to contribute to the antibacterial activities of the complexes.

## Materials and Methods

### Preparation of methyl-2-pyridylketone-2-hydrazinopyridine ligand (1)

A solution of methyl-2-pyridylketone (0.242 g, 0.002 mol) in ethanol (10 mL) was added dropwise to a refluxing ethanolic solution of 2-hydrazinopyridine (0.218 g, 0.002 mol). Three drops of concentrated sulphuric acid were added to the reaction mixture, which was later refluxed for 3 hours. Next, the reaction mixture was allowed to cool to room temperature for one hour. The pink precipitate formed were filtered off and the filtrate was evaporated until milky yellow colour precipitate form. The milky yellow precipitate obtained was recrystallized by slow evaporation of hot absolute ethanol solution at room temperature.

### Synthesis of [$MeSnCl_2(C_{12}H_{12}N_4)$] (2)

The ligand ($C_{12}H_{12}N_4$) (**1**) (0.212 g, 0.001 mol) was dissolved in hot absolute methanol (10 mL) in a Schlenk round bottom flask. A methanolic solution of methyltin(IV) chloride (0.240 g, 0.001 mol) was added dropwise into the resulting mixture causing the solution to change from orange to red in colour. The solution was refluxed further for another 5 hours and allowed to cool to room temperature. The precipitate formed was filtered and finally dried in vacuum over silica gel overnight. The methyltin(IV) complex was obtained as shiny red precipitate by recrystallization from methanol.

### Synthesis of [$BuSnCl_2(C_{12}H_{12}N_4)$] (3)

Complex **3** was synthesized using the same procedure as **2** with organotin(IV) chloride (0.282 g, 0.001 mol).

### Synthesis of [$PhSnCl_2(C_{12}H_{12}N_4)$] (4)

Complex **4** was synthesized using the same procedure as **2** with organotin(IV) chloride (0.302 g, 0.001 mol).

### Synthesis of [$Ph_2SnCl(C_{12}H_{12}N_4)$] (5)

Complex **5** was synthesized using the same procedure as **2** with organotin(IV) chloride (0.343 g, 0.001 mol).

### Antibacterial activity

The antibacterial activity of ligand (**1**) and its complexes (**2-5**) were studied against *Escherichia coli* O157:H7 and *Staphylococcus aureus* using turbidimetric kinetic method [10]. The inoculums could grow on media containing nutrient broth at 37 °C with permanent shaking at 250 rpm for 18 hours. 7 mL of culture medium with increasing concentration of the compounds dissolved in DMSO were inoculated with 0.14 mL of inoculums and the mixture was shaken again at 250 rpm at 37 °C. The solvent was used as negative control and the clinical antibiotic, amoxicillin was used as positive control. Aliquots of each replicate were taken at every 1 hour interval for 6 hours and the transmittance (T) was registered in a Metertech Plus SP-830 UV-Visible spectrophotometer. The

antibacterial activity was determined by graph as ln Nt which related to the number cfu/mL (colony forming units/mL) for the bacteria versus time.

## Results and Discussion

**Characterization study: Methyl-2-pyridylketone-2-hydrazinopyridine ligand (1)**

Yield: 0.321g, 70%. M.p: 82-83 °C. UV-Visible (DMSO) $\lambda_{max}$(nm): 331. IR ($\nu_{max}$ $cm^{-1}$) (KBr): 3343 (NH), 1605 (C=N), 994 (N-N), 776 (pyridine in plane). $^1$H NMR (DMSO-$d_6$, 500 MHz) δ: 9.98 (s, 1H, NH), 8.55 (d, 1H, py-$H_6$), 7.68-8.16 (m, 3H, py-$H_3$-$H_5$), 6.84-7.32 (m, 3H, pyridine ring), 2.39 (s, 3H, $CH_3$) ppm. $^{13}$C NMR (DMSO-$d_6$, 500 MHz) δ: 157.21 (1C, ***C***=N), 107.34-155.80 (10C, pyridine ring), 11.33 (1C, $H_3$***C***–C=N) ppm.

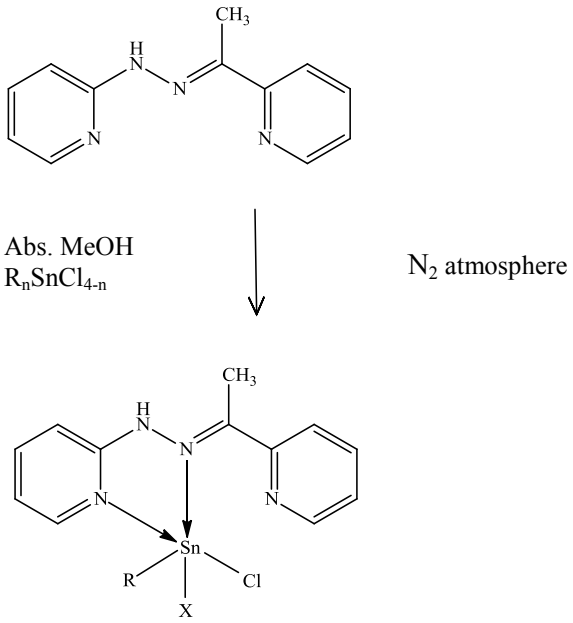
**[$MeSnCl_2(C_{12}H_{12}N_4)$] (2)**

Yield: 0.391 g, 87%. M.p: 285-287°C. UV-Visible (DMSO) $\lambda_{max}$(nm): 331, 499. IR ($\nu_{max}$ $cm^{-1}$) (KBr): 3069 (NH), 1599 (C=N–N=C), 1001 (N-N), 781 (pyridine in plane), 566 (Sn–C), 414 (Sn–N). $^1$H NMR (DMSO-$d_6$, 500 MHz) δ: 10.18 (s, 1H, NH), 8.55 (d, 1H, py-$H_6$), 8.06-8.36 (m, 3H, py-$H_3$-$H_5$), 2.58 (s, 3H, $CH_3$), 1.57 (s, 3H, Sn-$CH_3$) ppm. $^{13}$C NMR (DMSO-$d_6$, 500 MHz) δ: 157.11 (1C, ***C***=N), 113.58-144.59 (10C, pyridine ring), 12.14 (1C, $H_3$***C***–C=N) 12.70 (1C, Sn-***C***$H_3$) ppm.

**[$BuSnCl_2(C_{12}H_{12}N_4)$] (3)**

Yield: 0.320 g, 65%. M.p: 253-254°C. UV-Visible (DMSO) $\lambda_{max}$(nm): 331, 500. IR ($\nu_{max}$ $cm^{-1}$) (KBr): 3049 (NH), 1597 (C=N–N=C), 997 (N-N), 771 (pyridine in plane), 565 (Sn–C), 417 (Sn–N). $^1$H NMR (DMSO-$d_6$, 500 MHz) δ: 9.96 (s, 1H, NH), 8.77 (d, 1H, py-$H_6$), 7.96-8.33 (m, 3H, py-$H_3$-$H_5$), 6.74-7.75 (m, 4H, pyridine ring) 2.58 (s, 3H, $CH_3$), 0.95-2.25 (m, 9H, Sn-$CH_2CH_2CH_2CH_3$) ppm. $^{13}$C NMR (DMSO-$d_6$, 500 MHz) δ: 157.24 (1C, ***C***=N), 113.51-144.82 (10C, pyridine ring), 12.17 (1C, $H_3$***C***–C=N) ppm 30.09, 28.56, 25.20, 13.74 (4C, Sn-***C***$H_2$***C***$H_2$***C***$H_2$***C***$H_3$).

**[$PhSnCl_2(C_{12}H_{12}N_4)$] (4)**



Yield: 0.352 g, 85%. M.p: 268-269°C. UV-Visible (DMSO) $\lambda_{max}$(nm): 332, 406. IR ($\nu_{max}$ $cm^{-1}$) (KBr): 3070 (NH), 1598 (C=N–N=C), 1000 (N-N), 778 (pyridine in plane), 566 (Sn–C), 445 (Sn–N). $^1$H NMR (DMSO-$d_6$, 500 MHz) δ: 9.96 (s, 1H, NH), 8.55 (d, 1H, py-$H_6$), 7.65-7.69 (m, 5H, Sn-$C_6H_5$), 6.66-8.35 (m, overlapping of pyridine-H and phenyl ring protons of phenyl ring attached to the center tin(IV) atom), 2.65 (s, 3H, $CH_3$) ppm. $^{13}$C NMR (DMSO-$d_6$, 500 MHz) δ: 157.08 (1C, ***C***=N), 113.74-144.37 (pyridine ring/Sn-***C***$_6H_5$, 15C), 12.12 (1C, $H_3$***C***–C=N) ppm.

**[$Ph_2SnCl(C_{12}H_{12}N_4)$] (5)**

Yield: 0.256 g, 46%. M.p: 269-270 °C. UV-Visible (DMSO) $\lambda_{max}$(nm): 331, 496. IR ($\nu_{max}$ $cm^{-1}$) (KBr): 3068 (NH), 1598 (C=N–N=C), 999 (N-N), 778 (pyridine in plane), 566 (Sn–C), 446 (Sn–N). $^1$H NMR (DMSO-$d_6$, 500 MHz) δ: 9.95 (s, 1H, NH), 8.55 (d, 1H, py-$H_6$), 7.28-7.93 (m, 10H, Sn-$(C_6H_5)_2$), 6.66-8.35 (m, overlapping of pyridine-H and phenyl ring protons of phenyl ring attached to the center tin(IV) atom), 2.65 (s, 3H, $CH_3$) ppm. $^{13}$C NMR (DMSO-$d_6$, 500 MHz) δ: 157.33 (1C, ***C***=N), 113.76-148.40 (22C, pyridine ring/Sn-$(***C***_6H_5)_2$, 12.13 (1C, $H_3$***C***–C=N) ppm.

**Synthesis**

The methyl-2-pyridylketone-2-hydrazinopyridine (**1**) was initially synthesized by the acid-catalyzed condensation reaction of methyl-2-pyridylketone with 2-hydrazinopyridine in ethanolic solution in 1:1 mole ratio. Afterwards, four new organotin(IV) complexes (**2-5**) were synthesized by direct reaction of organotin(IV) chloride(s) with ligand (**1**) under nitrogen atmosphere. The organotin(IV) complexes were prepared as shown in Scheme 1. All the newly synthesized organotin(IV) complexes were coloured solids and soluble in DMSO, pyridine and DMF.

R=Me X=Cl (**2**)
R=Bu X=Cl (**3**)
R=Ph X=Cl (**4**)
R=Ph X=Ph (**5**)

Scheme 1. Synthesis route of organotin(IV) complexes (**2-5**)

**UV-visible spectra**

The absorption spectrum of ligand (**1**) was recorded in methanol with concentration of $1x10^{-4}$ M at room temperature. There is only one absorption band appeared at $\lambda_{max}$ of 331 which are suggested to be causes by n-$\pi$* transition of imine group. The electronic absorption spectra of complex (**2-5**) were also recorded in DMSO at room temperature. The first peak at 331-332 nm region is attributed to n-$\pi$* transition which has bathochromic shift suggested the free imine (>C=N) group of ligand (**1**) is coordinated to the tin(IV) atoms. Another new peak in the range 496-502 nm indicated the complexation occurred via ligand-to-metal transfer (LMCT) transition [11].

**Infrared spectra**

To clarify the mode of the ligand coordination to the tin centre, IR spectra in the range of 4000 – 400 $cm^{-1}$ were recorded. The IR spectrum of ligand (**1**) in showed the peak appeared at 3343 $cm^{-1}$ was assigned to NH strectching bond. Another important stretching bands are at 1605 and 994 $cm^{-1}$ which are assigned to υ(C=N), υ(N–N) and υ(pyridine in plane), respectively.

Upon complexation, the stretching vibration azomethine (C=N) is shifted to the lower frequency in all complexes (**2-5**) indicating that azomethine nitrogen is involved in coordination with tin(IV) ion [1]. The υ(N–N) stretching vibration value also shifted to the higher frequency which is 997-1001 $cm^{-1}$ compared to the free ligand further supporting that the coordination of azomethine nitrogen to the Sn(IV) atom. A very strong band of υ(pyridine in plane) also showed increases in its value after complexation compared to the free ligand which is 776 $cm^{-1}$. The band of υ(pyridine in plane) went to the higher frequencies at 778 – 781 $cm^{-1}$ in all complexes (**2-5**), indicating that the pyridyl ring nitrogen involved in coordination to the Sn(IV) atom. This is probably because of the occurrence of electron reduction upon complexation [8].

Besides, a new band has been identified at 414 – 446 $cm^{-1}$ in all the organotin complexes (**2-5**) confirming that there were Sn–N bond have been formed and showed that the coordination occurred at azomethine nitrogen and pyridine-N atom. Furthermore, the new band of υ(Sn–C) also indicating that alkyl or aryl group coordinated to the Sn(IV) atom [8].

**$^{1}$H NMR spectra**

The ligand (**1**) showed resonance signals at 9.98, 8.55, 7.68 – 8.16, 6.84 – 7.32 and 2.39 ppm due to the NH, py-$H_6$, py-$H_3$-$H_5$, pyridine ring and $H_3C$–C=N respectively. The $^{1}$H NMR spectra of complexes (**2-5**) were also successfully obtained. Upon complexation, the NH resonance signals for the complex (**2**) shifted to the downfield region (10.18 ppm) while complexes (**3-5**) shifted to the upfield region (9.95 – 9.96 ppm). This showed the occurrence of complexation NH–C=N nitrogen atom to the tin(IV) atom. The py-$H_6$ signal shifted to downfield region at 8.55 – 8.87 ppm compared to the free ligand (**1**) in all complexes (**3-5**), suggesting the involvement of pyridyl ring nitrogen atom in the coordination to tin(IV). Other signals for pyridine ring protons were also shifted to the downfield region but the signals could not be identified properly because of the overlapping of pyridyl ring protons. The $H_3C$–C=N resonance signal for complexes (**3-5**) shifted to the downfield region (2.58 – 2.65 ppm) compared to the free ligand (**1**) also supported the complexation of $H_3C$–C=N nitrogen atom to the tin(IV) atom. In complex (**2**), a sharp resonance signal appeared as singlet at 1.57 ppm attributed to methyl group attached to tin(IV) atom. The resonance signals were appeared at 0.95 – 2.25 ppm in spectra of complex (**3**) assigned to the butyl group attached to tin(IV) atom. Complexes (**4**) and (**5**) exhibited multiplet signals in the region of 7.28 – 7.93 ppm due to the Sn-Ph protons.

**$^{13}$C NMR Spectra**

The $^{13}$C NMR spectrum of free ligand (**1**) showed the resonance signals at 157.21, 107.34 – 155.80 and 11.33 are due to the $\delta$(***C***=N), $\delta$(pyridine ring) and ($H_3$***C***−C=N), respectively. After complexation, the carbon signals of the ***C***=N group shifted to the 157.08 – 157.33 ppm in the complexes (**2-5**) when comparing to the ligand (**1**), indicating participation of the ***C***=N group in coordination to the tin(IV) atom. Besides, the coordination of ligand (**1**) to the tin(IV) atom can be observed through the chemical shifts shown by $H_3$***C***−C=N in the free ligand (**1**) was observed at 11.33 ppm which were shifted to down field region at 12.12 – 12.17 ppm. These observations indicated that the azomethine-N is coordinated to the tin(IV) moiety [12]. The $\delta$ value of carbon atoms in pyridine ring slightly shifted to upfield in the complexes (**2-5**) as compared to the free ligand showed that the pyridine ring nitrogen coordinated to the Sn(IV) atom.

The methyl group attached to the tin(IV) core appeared at 12.70 ppm in complex (**2**). The butyl group attached to the organotin(IV) moiety in complex (**3**) gave four resonance signals at 30.09, 28.56, 25.20 and 13.74 ppm. Apart from that, the phenyl group in complexes (**4**) and (**5**) probably overlapped with pyridine ring from ligand (**1**) and result to the appearance of the resonance signals at 113.74 – 148.40 ppm.

**Antibacterial activity**

The antibacterial activities of ligand (**1**) and its complexes (**2-5**) were assayed at the concentration 50, 80, 100 ppm against bacteria *E. coli* O157:H7 and *S. aureus* at 37 °C. The antibacterial activities of ligand (**1**) and complexes (**2-5**) were compared with DMSO and amoxicillin as a control. All the synthesized compounds demonstrated a quite similar of bacteriostatic activities upon introduction at different concentrations. The equation of $\ln N_t = 27.1 - 8.56T$ was used to indicate the condition of the microbial specific growth and the amount of drug concentration used. The graph of control showed inactive for antibacterial activity, when tested against *E. coli*. The effect of ligand (**1**) and complexes (**2-5**) was also further shown by their minimum inhibitory concentrations (MIC). The MIC of these compounds were determined by extrapolating the concentration at the zero growth rate of *E. coli* (μ=0). Compound with the MIC value >200 ppm is not suitable to be used as antibacterial agent for clinical purpose [13]. The MIC of these compounds were determined by extrapolating the concentration at the zero-growth rate of bacteria (μ=0).

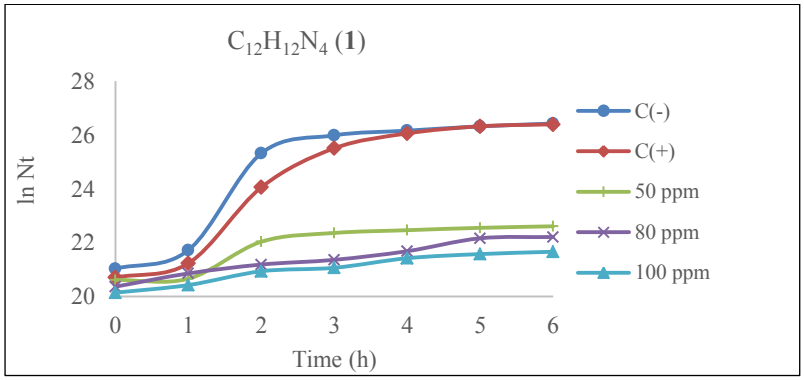


Table 1 shows the MIC values for all synthesized compounds. According to the table, MIC value for ligand (**1**) was lower than 200 ppm, while all complexes (**2-5**) were greater 200 ppm. Based on the results, almost all organotin complexes (**2-5**) showed weak activities against *E. coli* and *S. aureus*. Meanwhile, the antibacterial activity of the

ligand (**1**) showed relatively better antibacterial activity than all of the complexes. Among all of the complexes, complex (**5**) showed the moderate activity against the bacteria strain. Hence, the coordination of tin(IV) atom to the ligand did not raise much of the antibacterial activities. The presence of phenyl group in the complexes (**4**) and (**5**) bonded with the tin atom can improve the antibacterial activity, however in this scenario it is turned out into moderate activity. This is due to the presence of steric hindrance which is preventing the active sites to contact receptor site of the bacteria [9].

Table 1. MIC of ligand (**1**) and complexes (**2-5**)

| **Compound** | **MIC (ppm)** | |
|---|---|---|
| | ***E. coli*** | ***S. aureus*** |
| $C_{12}H_{12}N_4$ (**1**) | 128 | 160 |
| $[MeSnCl_2(C_{12}H_{12}N_4)]$ (**2**) | >200 | 339 |
| $[BuSnCl_2(C_{12}H_{12}N_4)]$ (**3**) | >200 | 372 |
| $[PhSnCl_2(C_{12}H_{12}N_4)]$ (**4**) | >200 | >200 |
| $[Ph_2SnCl(C_{12}H_{12}N_4)]$ (**5**) | 463 | 204 |
| Amoxicillin | >200 | 85 |

In addition, the chloride ion(s) in the structure of the complexes (**2-5**) should be improved the antibacterial activity due to the ability of chloride(s) ion to kill the microbes by inhibiting the multiplication of the bacteria through blockage of the bacteria active sites [9]. However, the presence of the chloride(s) ion in this complexes series did not contribute much to the activity of the complexes. Generally, all the synthesized compounds also more effective against Gram positive bacteria. When comparing the MIC values of the compounds with the clinical antibiotic, amoxicillin, all of the compounds have better activities against *E. coli* but weak activities against *S. aureus*. Figure 1 and 2 shows the inhibition activities of compounds (**1-2**) towards *E. coli* shown as ln $N_t$ for *E. coli* growth *vs.* time and inhibition activities of compounds (**1-2**) towards *S. aureus* shown as ln $N_t$ for *S. aureus* growth *vs.* time, respectively.

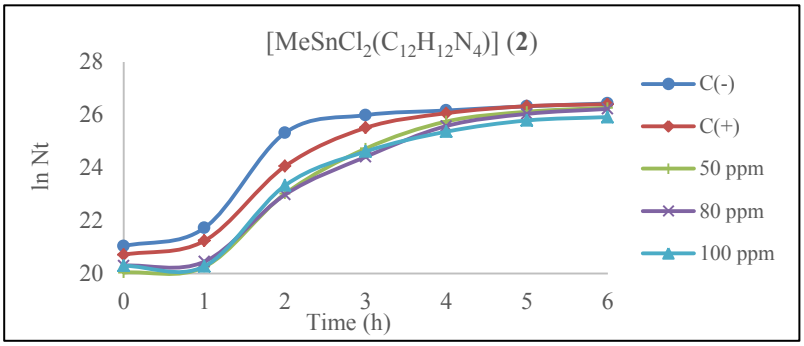

Figure 1. Inhibition activities of compounds (**1**-**2**) towards *E. coli* shown as ln $N_t$ for *E. coli* growth *vs.* time

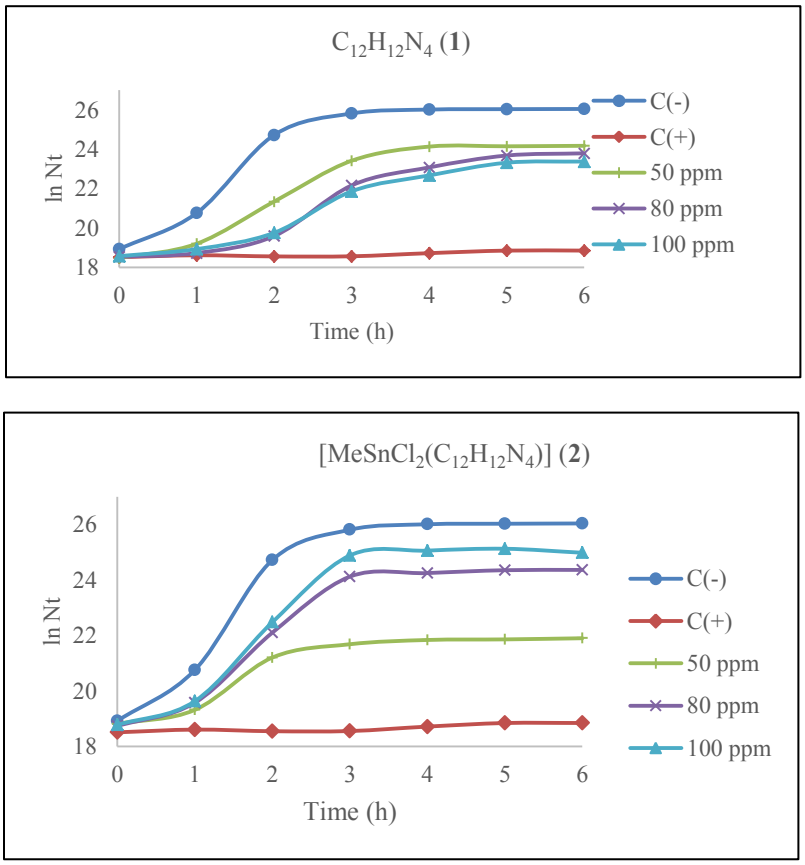

Figure 2. Inhibition activities of compounds (**1**-**2**) towards *S. aureus* shown as ln $N_t$ for *S. aureus* growth *vs.* time

## Conclusion

From the spectral analysis, it is suggested the bonding of ligand to the Sn(IV) atom was at the azomethine nitrogen (C=N) and pyridyl nitrogen atoms. The antibacterial activity evaluation showed that the complexation does not raise the antibacterial activities of the complexes in this study since ligand showed better activity than all of the

complexes. Therefore, it is recommended to investigate more on structure-activity relationship in order to improve the activity of the complexes and screened the antibacterial activities against more than one species of bacteria.

**Abstract**

Copper(II)-*β*-mangostin complex was prepared by 2:1 molar reaction of ligand, *β*-mangostin and copper(II) acetate in one-pot reaction. The resulting complex, $[CuL_2(H_2O)_2]$ has been characterized by using spectroscopic techniques. Ligand and its metal complex were tested against *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Klebsiella pneumonia* and *Salmonella pneumoniae* bacteria to assess on their antibacterial properties using Minimum Inhibitory Concentrations (MICs) and Minimum Bactericidal Concentrations (MBCs) method. The UV-Vis result showed that the complex has an octahedral geometry. The general formula $[ML_2(H_2O)_2]$, in which L = *β*-mangostin, is determined from UV-Vis, FTIR and CHNS data. Ligands were completely inactive against bacteria whereas the copper(II) *β*-mangostin complex has significant action on bacteria, indicating that it has a good potential as bactericide.

**Keywords**: *β*-mangostin, copper(II) complex, antimicrobial, xanthones

**Abstrak**

Kompleks kuprum(II)-*β*-mangostin disediakan dengan nisbah 2:1 mol antara ligand, *β*-mangostin dan kuprum asetat dalam tindak balas satu-bekas. Kompleks yang dihasilkan, $[CuL_2(H_2O)_2]$ dicirikan dengan menggunakan teknik spektroskopik. Ligan dan logam kompleks diuji ke atas bakteria *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Klebsiella pneumonia* and *Salmonella pneumoniae* untuk menilai tindak balas bakteria menggunakan kaedah Kepekatan Perencatan Minimum (KPM) dan kaedah Kepekatan Bakteria Minimum (KBM). Keputusan UV-Vis menunjukkan kompleks mempunyai geometri oktahedron. Formula umum $[ML_2(H_2O)_2]$, yang mana L = *β*-mangostin ditentukan dari data UV-Vis, FTIR dan CHNS. Ligand sepenuhnya tidak aktif ke atas bakteria, manakala komplex kuprum(II) *β*-mangostin memberikan tindak balas yang signifikan ke atas bakteria, menunjukkan ia mempunyai potensi yang baik sebagai bactericide.

**Kata kunci**: *β*-mangostin, kuprum(II) kompleks, antimikrob, xanthones

## Introduction

Transition metal ions such as copper(II), iron(II), iron(III) and zinc(II) have been known for many years to exert wide biological activity, for example against tumor cells [1]. Also chromones, flavonoid and coumarins have been known for similar properties. These two facts have attracted the attention of researchers to check whether metal complexes are more effective against anticancer and antibacterial than free ligands.

Copper is an essential trace mineral present in all body tissues. Copper works with iron to help the body to form red blood cells and increase the iron absorption. It also helps to keep the blood vessels, nerves, immune system and bones healthy. Copper has a major role in the production of the very reactive hydroxyl radical through the Fenton and Haber-Weiss reaction. Copper(II) can binds and manifests large hyperchromic and bathochromic shifts in the molecular absorption spectra [2].

Another class of less explored naturally occurring ligands are xanthones. These bioactive compounds are hetero-tricyclic compounds originally isolated as secondary metabolites from plants and microorganisms. Previous phytochemical studies on *Garcinia mangostana* have resulted in isolation of more than 50 xanthones. The major components in *Garcinia mangostana* are xanthones, such as $\alpha$-mangostin, $\beta$-mangostin, and $\gamma$-mangostin [3]. The xanthone derivatives has a remarkable effect on antiulcerogenic, antifungal activity, antibacterial activity, inhibitors of proteinkinase, anticancer activity, antioxidant and anti-inflammatory [4], which depend on their wide range of structures modified by substituents on the ring [5].

Simultaneously, synthetic and medicinal chemistry studies of xanthones derivative have been performed [6]. In contrast, there are only a few reports that deal with complexation of metal ions with xanthones derivatives. So far, complexation having xanthones as a ligand only involve synthetic xanthones. The synthetic xanthone was prepared via reaction dihydroxyxanthone with crown ether [7] or piperidinyl [8], respectively. The macrostructure of crown ether helps to stabilize the Cu(II) complexes formed whereas piperidinyl structure contributed basicity properties to encourage formation of Cu(II) and Zn(II) complexes with simple oxygenated xanthones.

In this work, the isolated $\beta$-mangostin from *Garcinia mangostana* will be used as a ligand to synthesize a new metal complex having copper(II) as the central metal. The newly synthesized compound will be tested for antimicrobial properties. Isolated $\beta$-mangostin was inactive against antimicrobial [9] and anticancer [10]. The inclusion of copper(II) could alter the overall structure of newly formed synthesized compound and thus can increase the biological properties of the compound.

## Materials and Methods

### Materials

All the chemicals used were Analar grade. Copper(II) acetate and ethanol were used as received.

### Extraction, Isolation and Purification of β-mangostin

Around 5-6 kg barks samples of *Garcinia mangostana* were obtained from Sarawak. 2.3 kg of powdered air-dried stem barks samples from *Garcinia mangostana* was macerated with chloroform for 48 hours at room temperature. The solvent was removed under reduced pressure using a rotavapor. The crude chloroform extract was isolated using Liquid Vacuum Chromatography and afforded 27 fractions. Same $R_f$ values on the TLC plates of $\beta$-mangostin were combined. The purity of $\beta$-mangostin was determined using Agilent HPLC Series 1260 Infinity.

### Synthesis of Cu(II) complexes

The procedure to obtain metal complex was adopted from established method by Bukhari et al. [11]. 0.589 mmol of copper(II) acetate was dissolved in ethanol. Then, 0.1178 mmol of $\beta$-mangostin was added and the colour of the solution was olive green. The mixture was refluxed for 3 hours. After refluxed, the mixture solution was filtered and washed with ethanol for few times. The filtrate was evaporated at room temperature. The resulting complex has been characterized using UV-VIS, Fourier Transformation Infrared (FTIR) and CHNS.

### Instrumentations

Ligand, $\beta$-mangostin and its metal complex were determined using Gas Chromatography – Mass Spectrometry (GCMS), Nuclear Magnetic Resonance (NMR), UV-Visible, Fourier Transformation Infrared (FTIR), High Performance Liquid Chromatography (HPLC) and CHNS analyser.

Elemental analyses (C, H and N) was performed on elemental analyser Model vario MICRO cube. Infrared spectra of $\beta$-mangostin and its metal complex were recorded on a Perkin-Elmer Frontier FTIR using KBr pellet in the

spectral range of 4000-400 $cm^{-1}$. Electronic spectra of the ligands and its metal complexes will be carried out by using Perkin-Elmer Model Lambda 25.

$^{1}H$ and $^{13}C$ NMR measurements were obtained on Bruker at 400 MHz, a 5 mm probe head in acetone-$d_6$ at room temperature. HPLC analysis for *β*-mangostin was carried out on Agilent G1316A (150 mm x 4.6 mm, 5 μm) column, the mobile phase was (80:20, v/v) acetonitrile/water mixture at room temperature with 1 mL $min^{-1}$ flow rate and a 5 *μl* injection loop. Detection was performed with a UV detector in HPLC at 320 nm. The xanthone scaffold having good absorption at this wavelength and only a few number of other compounds absorb making 320 nm wavelength for xanthone detection [12].

**Antimicrobial activities**

Antibacterial test for ligand and synthesized compound were carried out using Minimum Inhibitory Concentrations (MICs) and Minimum Bactericidal Concentrations (MBCs) method. The following bacteria were used as test organisms: *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Klebsiella pneumonia* and *Salmonella pneumoniae*.

## Results and Discussion

**Structural elucidation of β-mangostin**

Fraction 11 until 13 from previous vacuum column chromatography were fractionated using gravity column chromatography yielded *β*-mangostin. Recrystallization from chloroform yielded yellow needle crystals with melting point of 174 – 175 °C (Lit. 175 – 176 °C [13]). The $R_f$ value was 0.575 using a solvent system of chloroform. The molecular ion peak was found at m/z 424 indicating a molecular formula of $C_{25}H_{28}O_6$. Figure 1 showed the structure of *β*-mangostin. The UV-Visible spectrum exhibited characteristic absorption bands of xanthone at $\lambda_{max}$ (ethanol) 244, 259, 315 and 355 nm. The IR spectrum showed the presence of hydroxyl group at 3399 $cm^{-1}$ and a chelated carbonyl group at 1648 $cm^{-1}$. The absorption band situated at 1600, 1571, 1458 and 1278 $cm^{-1}$ are related to carbon vibration in benzene rings. The purity of isolated *β*-mangostin was 98% determined from HPLC analysis.

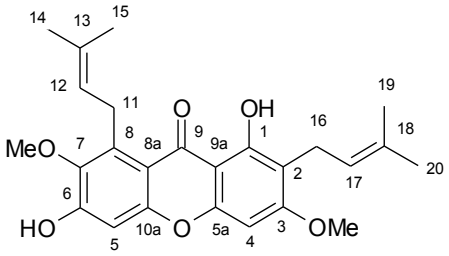

Figure 1. *β*-mangostin

$^{1}H$-NMR and $^{13}C$-NMR data were compared with reported data by Shen et al. [15]; Al-Massarani et al. [16] and Syam et al. [17]. The $^{1}H$ NMR spectrum showed the presence of one chelated hydroxyl group at δ 13.66. In addition, typical signals of four allylic methyl groups at $\delta_H$ 1.67 (3H, s, H-14), 1.84 (3H, s, H-15), 1.65 (3H, s, H-19) and 1.79 (3H, s, H-20); two pairs of methylene proton at $\delta_H$ 4.15 (2H, d, $J$ = 6.6 Hz, H-11) and 3.34(2H, d, $J$ = 7.2 Hz, H-16); and two olefinic protons at 5.22 (2H, t, $J$ = 7.3 Hz, H-12) and 5.29 (2H, t, $J$ = 6.7 Hz, H-17) were observed in the $^{1}H$ NMR spectrum.

The $^{13}C$ NMR spectrum gave a total of twenty five carbons which was validated for the molecular formula, $C_{25}H_{28}O_6$. A signal at $\delta_C$182.0 indicated a carbonyl group in the middle ring. Meanwhile, the methoxyl carbons signals were observed at $\delta_C$ 55.7 and $\delta_C$ 60.5. The locations of the two prenyl moieties were located at the C-2 ($\delta_C$110.9) and C-8 ($\delta_C$137.3). In the COSY spectrum the nature of the allylic and homoallylic coupling systems within the isoprene unit was clearly demonstrated. It showed correlation between the olefinic proton of C-12 and benzylic proton of C-11, and the germinal dimethyl group of C-14 and C-15. The same correlations above were also

observed for the other prenyl moiety.

**Physical properties of Cu(II) complexes**

Metal complexes involving *β*-mangostin and copper metal produced green complex which was stable at room temperature. The ligand, *β*-mangostin (L) on interaction with copper(II) acetate yields complex corresponding to the general formula $[ML_2(H_2O)_2]$. The analytical data showed that the metal to ligand ratio is 1:2. (Yield 72%) Analytical calculation for $CuL_2(H_2O)_2$ (MW = 946 $gmol^{-1}$): C=62.6%, H=5.4%. Found: C=63.4%, H=6.1%.

**Spectroscopic study of Cu(II) complexes**

IR spectra of *β*-mangostin has shifted in υ(C=O) peak from 1648 $cm^{-1}$ to 1615 $cm^{-1}$ and the Δυ(ligand – complex) is 33 [7, 8]. These absorption frequencies demonstrated that the group has lost its original characteristics and formed a coordinative bond with Cu(II) ion. Thus, this shows that the electron density in the carbonyl is slightly decreased probably due to back bonding process. Free OH stretching at 3399 $cm^{-1}$ was absent and replaced with a broad υ(OH) which was observed at 3438 $cm^{-1}$ indicating coordination of water with *β*-mangostin. These data suggested that the oxygen of the carbonyl and hydroxyl have formed a coordination bond with the $Cu^{2+}$ cation.

Another significant difference between the ligand and its metal complex was observed from UV spectrum. The UV spectrum of copper(II) complex shows a broad band at 22 000 $cm^{-1}$ ($\lambda_{max}$, 450 nm) which presumably corresponded to *d-d* transition with octahedral arrangement [18]. The chelation of Cu(II)-*β*-mangostin complex with bidentate ligand occurred with hydroxyl and carbonyl group at $C_9$ and $C_1$ respectively. The proposed structure of the complex was shown in Figure 2. The chelation formation in this study was similar to Farhan [19] and Wang et al. [7].

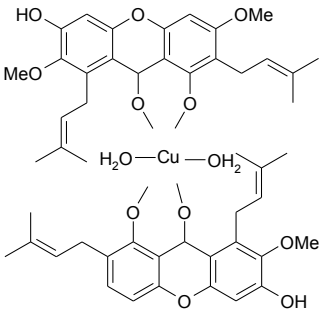

Figure 2. The proposed structure of Cu(II)-*β*-mangostin

**Antimicrobial properties**

*β*-mangostin was classify as inactive against the five bacteria tested. This antimicrobial result of *β*-mangostin was similar to Angia et al. [9]. Whereas the copper(II) complex showed weak inhibition with MIC value of 900 μg/ml to *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Klebsiella pneumonia* and *Salmonella pneumoniae* but moderate inhibition with MIC value of 450 μg/ml towards *Escherichia coli*. The MIC value for positive control, streptomycin sulphate is 7.03 μg/ml for all bacteria used.

## Conclusion

Copper(II)-*β*-mangostin complex, $[CuL_2(H_2O)_2]$ was successfully synthesized with an octahedral geometry. The copper(II) complex showed more potent antimicrobial activity compared to ligand itself. This finding could lead to the development of new metal based bioactive compounds with enhanced antimicrobial properties, suitable for medical application and cosmetic products.

## Acknowledgment

Authors are highly thankful to the Faculty of Applied Sciences, Universiti Teknologi MARA, Campus Samarahan 2, Sarawak and Ministry of Higher Education for given Fundamental Research Grant Scheme (FRGS) grant (FRGS/1/2014/ST01/UiTM/02/3) to support this study.

**Abstract**

*Artocarpus odoratissimus* is native to Borneo and Mindanao Island. In Sarawak, it is locally known as Terap. Previous studies showed *Artocarpus* species are rich in phenolic compounds, including flavonoids, stilbenoids and arylbenzofurons. The chemical profile of the indigenous plants from Sarawak, such as *A. odoratissimus* has not been studied intensively and the analyses of medicinal properties have not been explored. Thus, a phytochemical study is carried out on the root extracts of *A. odoratissimus* using various chromatographic methods and it has led to the isolation of two known flavonoids, namely pinocembrin (**1**) and pinostrobin (**2**). The structures are identified by comparison of their $^{1}$H and $^{13}$C NMR data with those reported in the literature. Flavonoid molecule incorporated as multifunctional in the pharmaceutical industry. It has a vast range of pharmacological activities, such as antimicrobial, anti-inflammatory, antioxidant, and anticancer activities. Pinocembrin and pinostrobin which are successfully synthesized with 2-hydroxy,4,6-methoxyacetphenone and benzaldehyde as starting materials were discussed.

**Keywords**: *Artocarpus odoratissimus*, terap, pinocembrin, pinostrobin

**Abstrak**

*Artocarpus odoratissimus* berasal dari Borneo dan Pulau Mindanao. Di Sarawak ia dikenali sebagai Terap. Kajian terdahulu menunjukkan yang spesis *Artocarpus* kaya dengan sebatian fenolik, termasuk flavonoid, stilbenoid dan arilbenzofuron. Profil kimia tentang tumbuhan yang berasal dari Sarawak, seperti *A. odoratissimus* masih belum dikaji secara intensif dan analisis tentang khasiat perubatan masih belum lagi diterokai. Oleh itu, kajian fitokimia yang telah dilakukan ke atas krud ekstrak akar *A. odoratissimus* dengan menggunakan pelbagai kaedah kromatografi telah berjaya memencilkan dua sebatian flavonoid, iaitu pinosembrin (**1**) dan pinostrobin (**2**). Bentuk struktur telah dikenal pasti melalui perbandingan data $^{1}$H dan $^{13}$C NMR dengan kajian literatur. Molekul flavonoid mempunyai pelbagai fungsi di dalam industri farmaseutikal. Ia mempunyai aktiviti farmakologi yang sangat meluas seperti antimikrob, anti-radang, antioksidan, dan antikanser. Pinosembrin dan pinostrobin yang telah berjaya disintesis dengan menggunakan 2-hidroksi,4,6-metoksiasetofenon dan benzaldehid sebagai bahan pemula telah dibincangkan.

**Kata kunci**: *Artocarpus odoratissimus*, terap, pinosembrin, pinostrobin

## Introduction

*Artocarpus odoratissimus* is native to Borneo. It is cultivated in the Philippines and is also found in the wild abundantly in Brunei Darussalam, Sabah and Sarawak [1]. *Artocarpus* species are used as traditional medicines such as treatment against inflammation, malarial fever, diarrhea, diabetes and tapeworm infection. According to Jagtap and Bapat [2] compounds from *Artocarpus* species exhibited diverse biological activities including antibacterial, antitubercular, antiviral, antifungal, antiplatelet, antiarthritic, tyrosinase inhibitory and cytotoxicity. Some *Artocarpus* species are used as traditional medicines. For example *Artocarpus odoratissimus* (terap) is used by local communities in Sarawak as an antidote against centipede and scorpion stings by applying the ash from the leaves on the wounds, while for treatment of scabies the ash is added with a little amount of coconut oil [3]. Ee et al. [4] reported that the isolation of a new prenylated pyranoflavone derivatives, artosimmin and traxateryl acetate. Artosimmin exhibited significant cytotoxicity against cancer cell lines (HL-60 and MCF-7) and showed antioxidant properties.

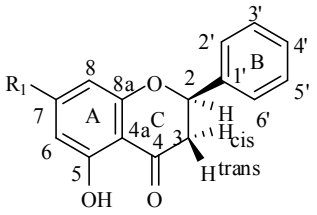
*Artocarpus* species also rich in phenolic compounds, including flavonoids, stilbenoids and arylbenzofurons. Most of the pharmacological effects can be explained by the presence of phenolic compounds [5]. However, there are very few studies on the *Artocarpus* species from Sarawak, therefore it would be interesting to develop a chemical profile of such Sarawakian species. Thus, a phytochemical study is carried out on the root extracts of *Artocarpus odoratissimus* using various chromatographic methods and it has led to the isolation of two known flavonoids, namely pinocembrin and pinostrobin.

Pinocembrin is a flavanone, a type of flavonoid. It is an antioxidant found in damiana, honey, and propolis. Pinocembrin is a major flavonoid molecule incorporated as multifunctional in the pharmaceutical industry. Its vast range of pharmacological activities has been well studied including antimicrobial, anti-inflammatory, antioxidant, and anticancer activities. Pinocembrin has potential as a drug to treat cerebral ischemia, neurodegenerative diseases, cardiovascular diseases and atherosclerosis as well as other clinical conditions [6]. Pinocembrin also exhibits various interesting biological activities such as antibacterial [7], antifungal [8] and anti-inflammatory [9], [10]. Furthermore, pinocembrin plays a pivotal role in prevention and cure of various neurodegenerative diseases, such as Alzheimer's disease (AD), Parkinson's disease and other neuronal dysfunctions [11].

Pinostrobin is a potent flavonoid inducer of mammalian phase 2 chemoprotective and antioxidant enzymes [12]. Pinostrobin isolated from *Polygonum lapathifolium* nodosum could quickly penetrate through cytoplasm to the cellular nucleus of the cultured cells and gives intensive apoptotic response in stimulating leukemic cells *in vitro*. As such, it may be considered as a good candidate for a leukemia chemopreventic agent [13]. Pinostrobin from Temu Kunci (*Kaempferia pandurata* Roxb) has anticancer activity againts benzo(a)pyrene-induced fibrosarcoma cancer on mice *in vivo* [14]. With increasing concentration, pinostrobin caused a gradual leakage, also contributing to breakage of the envelope and virus inactivation. Treatment effect of oral pinostrobin *in vivo* showed that pinostrobin possesses definite therapeutically effect in the development of lesion score [15].

The interest in the biological properties of pinocembrin and pinostrobin attracted the intense synthetic efforts towards the synthesis of various derivatives compounds. By synthesis we can also save the usage of natural resources of raw material.

## Materials and Methods



### Plant materials

The root of *Artocarpus oddoratissimus* was collected from Kampung Krokong Pisa, Bau Sarawak. Voucher specimen of the plant is kept in the School of Chemistry and Environmental Studies, Faculty of Applied Sciences at the Universiti Teknologi MARA (UiTM) Kota Samarahan 2 Campus, Sarawak, Malaysia.

### Extraction and isolation

The air-dried root (722.14 g) of *Artocarpus odoratissimus* was extracted by a cold extraction method for 24 hours and repeated thrice using n-hexane, ethyl acetate and methanol as solvents. The removal of solvents under reduced pressure gave hexane (AORH), ethyl acetate (AOREA), and methanol (AORM) crude extracts respectively. The crude extracts were fractionated using silica gel vacuum liquid chromatography (VLC) with a stepwise gradient

solvents system such as hexane, hexane-ethyl acetate, ethyl acetate-methanol and methanol, followed by column chromatography to give major fractions. Fractions with spots of the same $R_f$ values were combined and rechromatographed in appropriate solvent systems until pure isolates were obtained. The crude ethyl acetate root afforded two known flavonoids namely pinocembrin **(1)** and pinostrobin **(2)** (Figure 1)

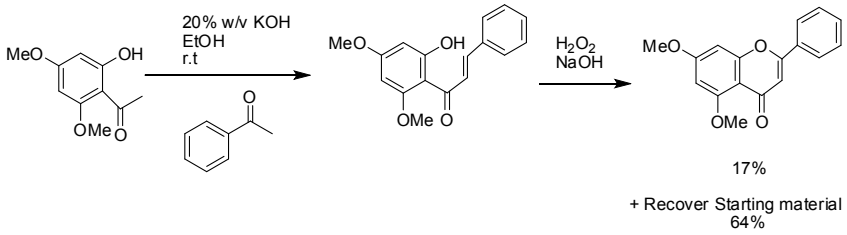

Figure 1. Structure of compounds (**1-2**) isolated from *A. odoratissimus*

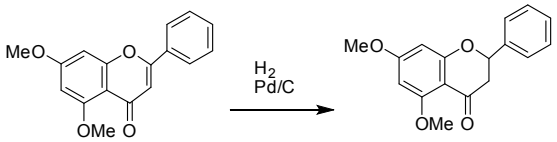
**Synthesis of pinocembrin and pinstrobin: Synthesis of 2-hydroxy-4,6-dimethoxychalcone via Claisen-Schmidt condensation**

20% of aqueous KOH (2 mmol) was added to a solution of benzaldehyde (4 mmol) and 2-hydroxy-4,6-dimethoxyacetophenone (4 mmol) in $C_2H_5OH$ (25 mL). The reaction mixture was stirred at room temperature untill completion of reaction (monitored by TLC). The reaction mass was then poured into ice water and neutralized with aqueous 10% HCl solution. The precipitate was filtered, washed with excess of water, dried and recrystallized from methanol to obtain pure 2-hydroxy-4,6-dimethoxy chalcones.

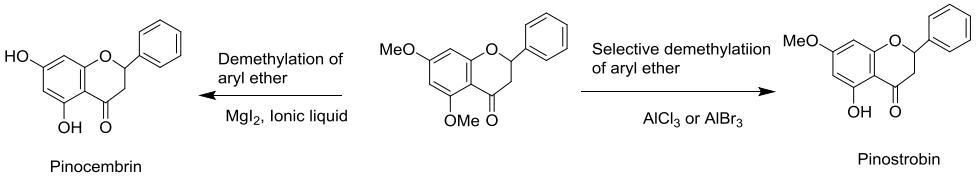
**Synthesis of flavonol**



A suspension of a mixture of powdered 2-hydroxy-4,6-dimethoxychalcone (0.10 g, 0.45 mmol) in EtOH, an aq. NaOH solution (8 M, 1.0 ml) and a 30% hydrogen peroxide solution (0.25 g) was stirred at room temperature for 2 hours. The crude product was filtered off, washed with water to give flavonol (Scheme 1). Recrystallization of the crude product from MeOH gave pure compound.

Scheme 1. Formation of flavonol

**Formation of flavanone via hydrogenation reaction**



The reaction involves hydrogenation of flavonol to form flavanone (Scheme 2).

Scheme 2. Formation of flavanone

**Demethylation of aryl methyl ethers**

To a solution of aryl methyl ether (1.0 mmol) in [BMIM]$BF_4$ (2 mL) was added magnesium iodide (0.42 g, 1.5 mmol). The reaction mixture was stirred at 50 $^oC$ for 4 – 7 hours. After addition of 5% aqueous sodium thiosulfate (10 mL), the product was extracted with ether (2 × 10 mL), washed with brine (5 mL), and extracted with ether (2 × 10 mL), washed with brine (5 mL), and dried over $MgSO_4$. The solvent was removed in vacuo and the crude mixture was purified by silica gel chromatography using ethyl ether: hexane (1:3) as eluent to give the desired phenolic product (Scheme 3).

Scheme 3. Formation of phenolic product

## Results and Discussion

The extraction and separation from the root extract of *Artocarpus odoratissimus*, afforded two flavonoids, which were identified and characterized as pinocembrin **(1)** and pinostrobin **(2)** based on data comparison literature.

**Characterization study: Pinocembrin (1)**

White yellowish crystalline; mp 201-202 °C; IR (KBr) $\nu_{max}$ $cm^{-1}$: 3435 (Ar-H stretching), 1744 (C=O ester), 1497, 1578 (C=C Aromatic), 1248 (C-O) and 976 (=C-H) $cm^{-1}$; EI-MS m/z (% rel. int.); 256 (100) [$M^+$ $C_{15}H_{12}O_4$], 238 (14), 179 (70), 152 (80), 124 (45), 104 (18), 77 (20), 69 (20) and 51(9); $^1$H NMR (400 MHz; $CDCl_3$): δ 2.86 (3-cis), 3.10 (3-trans), 5.43 (2H, t, J=6.7), 6.03 (H-6), 6.03 (H-8), 7.41-7.49 (H-2'-H6'), 12.07 (C-5-OH). $^{13}$C NMR (100 MHz; $CDCl_3$): δ 43.37 (C-3), 79.18 (C-2), 95.56 (C-8), 96.81 (C-6), 102.97 (C-4a), 126.16 (C-2', C-6'), 128.87 (C-3', C-4', C-5'), 138.42 (C-1'), 163.11 (C-8a), 164.34 (C-5), 195.65 (C-4).

**Pinostrobin (2)**

Colorless crystal; mp 100-102 °C; IR (KBr) $\nu_{max}$ $cm^{-1}$: 3467 (Ar-H stretching), 1741 (C=O ester), 1497, 1578 (C=C Aromatic), 1538, 1360 (C-O) and 968 (=C-H) $cm^{-1}$; EI-MS m/z (% rel. int.); 270 (90) [$M^+$ $C_{16}H_{14}O_4$], 269 (50), 252 (8), 193 (100), 166 (80), 138 (50), 110 (18), 95 (35), 78 (15) and 51 (20);. $^1$H NMR (400 MHz; $CDCl_3$): δ 2.81 (3-cis), 3.86 (C-7-OMe), 3.10 (3-trans), 5.43 (2H, t, J=6.7), 6.03 (H-8), 6.04 (H-6), 7.28-7.49 (H-2'-H6'), 12.07 (C-5-OH). $^{13}$C NMR (100 MHz; $CDCl_3$): δ 43.36 (C-3), 55.60 (C-7-OMe), 79.25 (C-2), 95.49 (C-6, C-8), 103.20 (C-4a), 126.17 (C-2', C-6'), 128.92 (C-3', C-4', C-5'), 138.30 (C-1'), 163.16 (C-5), 164.36 (C-7), 164.63 (C-8a), 195.79 (C-4).

Compound (**1**) was obtained as white yellowish crystalline with melting point 201 – 202 °C. The mass spectrum showed the molecular ion peak at m/z 256, indicated the formal formula $C_{15}H_{12}O_4$. In the $^1$H NMR, one proton singlet at δ 12.07 sited the free hydroxyl at position 5 with H-bridge to O at the carbonyl at position 4. Two doublets at δ 6.03 attributed to meta H-6 and H-8. A five-proton multiplet at δ 7.41 – 7.49 confirmed the non-substitution of the B-ring. Two doublet-doublet of one proton each at δ 2.86 and δ 3.10 attributable to H-3 (*cis*) and H-3(*trans*), respectively. The $^{13}$C NMR spectrum showed 15 carbons signals including one methylene, eight methine and six quaternary carbon atoms.

Compound (**2**) was obtained as colorless crystal with melting point 100 – 102 °C. The mass spectrum showed the molecular ion peak at m/z 270 indicating that the compound had the formula $C_{16}H_{14}O_4$. The IR spectrum showed the presence of aromatic stretch at 3467 $cm^{-1}$, carbonyl group, ester (C=O) at 1741 $cm^{-1}$ as well as an olefin functional group (C-O) at 1538 $cm^{-1}$ . In the $^1$H NMR, a methoxy group was seen as a singlet at δ 3.86. A one-proton singlet at δ 12.07 sited the free hydroxyl at position 5 with H-bridge to O at the carbonyl at position 4. The $^{13}$C NMR

spectrum showed 16 carbons signals including one methyl, one methylene, 8 methine and 6 quaternary carbon atoms. Among these signals the carbon signal of methoxy group is clearly assigned due to the presence of chemical shift 55.60.

The Claisen-Schmidt condensation of 2-hydroxy-4,6-dimethoxyacetophenone with benzaldehyde under basic condition (KOH 50%) in ethanol proceeded smoothly to furnish 2-hydroxy-4,6-dimethoxychalcone in excellent yield, (97.1%). The cyclisation of 2-hydroxy-4,6-dimethoxychalcone in ethanol and aqueous sodium hydroxide solution and a 30% hydrogen peroxide solution gave flavonol and the hydrogenation of flavonol produced flavanone. The reaction of aryl methyl ether and magnesium iodide gave pinocembrin and with aluminum trichloride gave pinostrobin as product.

## Conclusion

The isolation of *Artocarpus odoratissimus* root extract had successfully led to two known flavonoids, namely pinocembrin and pinostrobin. These compounds were then successfully synthesized with 2-hydroxy-4,6-dimethoxyacetphenone and benzaldehyde as starting materials. The identification of compounds was carried out using spectroscopic methods: Infrared (IR) spectroscopy, Nuclear Magnetic Resonance (NMR) spectroscopy and Gas Chromatography Mass Spectroscopy (GC-MS) and a comparison with the literature data of compound.

## Acknowledgment

The authors would like to acknowledge the financial assistance provided by the Ministry of Higher Education, under Research Grant of (600-RMI/TRGS 5/3/(1/2014)-2) and (600-RMI/RAGS 5/3 (95/2013). The authors also extended their thanks to Research Management Institute, Universiti Teknologi MARA (UiTM), Malaysia for their excellent support and assistance.

**Abstract**

Our continuing interest in anthraquinone had led the researchers to look at the synthesis of metal complex by reacting our major compound, nordamnacanthal with transition metal, Fe(II). Fe(II)-nordamnacanthal complex had been synthesized successfully via telescoping synthesis/ one-pot reaction. The ligand and its metal complex were established by 1D and 2D nuclear magnetic resonance spectroscopy, UV-Visible, CHNS analyzer, gas chromatography mass spectrometry and infrared analysis. They were evaluated for their antimicrobial activity using minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC). Fe(II)-nordamnacanthal complex showed stronger inhibition against *Pseudomonas aeruginosa* at the concentration of 450 μg/mL while *Proteus vulgaris*, *Klebsiella pneumoniae* and *Salmonella pneumoniae* at the concentration of 225 μg/mL compare to nordamnacanthal. In this work, the synthesized compound, Fe(II)-nordamnacanthal showed better antimicrobial activity compared to the ligand itself.

**Keywords**: nordamnacanthal, transition metal Fe(II), Fe(II)-nordamnacanthal complex, antimicrobial activity

**Abstrak**

Kesinambungan perhatian kami terhadap antrakuinon telah membawa kami untuk melihat kepada sintesis kompleks logam dengan menghasilkan tindak balas sebatian utama kami, nordamnacanthal dengan logam peralihan, Fe(II). Kompleks Fe(II)-nordamnacanthal telah berjaya disintesiskan melalui teleskop sintesis/tindak balas satu-periuk. Sebatian dan kompleks logam dikenalpasti melalui 1D dan 2D spektroskopi resonan magnetik nukleus, UV-Vis, CHNS, kromatografi gas spektometri jisim dan analisis inframerah. Sebatian dan kompleks logam tersebut telah dinilai untuk aktiviti antimikrob dengan menggunakan kepekatan perencatan minimum (MIC) dan minimum kepekatan bakteria (MBC). Kompleks Fe(II)-nordamnacanthal menunjukkan perencatan yang kuat terhadap *Pseudomonas aeruginosa* pada kepekatan 450 μg/mL manakala *Proteus vulgaris*, *Klebsiella pneumoniae* dan *Salmonella pneumoniae* pada kepekatan 225 μg/mL berbanding dengan nordamnacanthal. Dalam kajian ini, sebatian yang disintesis, kompleks Fe(II)-nordamnacanthal menunjukkan aktiviti antimikrob lebih baik berbanding dengan sebatian itu sendiri.

**Kata kunci**: nordamnacanthal, logam peralihan Fe(II), kompleks Fe(II)-nordamnacanthal, aktiviti antimikrob

## Introduction

Anthraquinones are biocompounds that are widely obtained from fungi and higher plant families [1, 2]. Anthraquinones have nearly one thousand known compounds, which contain different types of substituents at different positions, leading to a large variety of pharmacological activities [3, 4]. The bioactivities of these

compounds can be attributed to their structure. Presence of substituents namely OH group and carbonyl group on the ring structure of anthraquinones opens up a possibility of forming a coordinated bond with metal ions. The inclusion of transition metal ion is expected to increase the planarity of the compound thus will enhanced the bioactive properties of the new prepared complexes. Anthraquinones structures also plays an important role in the cancer activity as it allows for many sites for the phenolic group substituents on the bridged benzene rings on either side of the carbonyl bridge, while still maintaining its aromaticity. This allows for intercalation of the anthraquinones to DNA in cells, as well as hydrogen bonding between the carbonyl and ether bridges with amino acid residues in enzymes [5].

Similarly, the anthraquinones' structure also plays an important role in the cancer activity of *Morinda citrifolia* as it allows for many sites for the phenolic group substituents on the bridged benzene rings on either side of the carbonyl bridge, while still maintaining its aromaticity. This allows for intercalation of the anthraquinones to DNA in cells, as well as hydrogen bonding between the carbonyl and ether bridges with amino acid residues in enzymes [2].

The underlying bioactive role of such compounds relates to the intracellular interaction of the compounds with DNA molecule with one of the effects is leading to the damaged of the cell. Such disruptive consequence is an inhibitor to the continuous growth of cell and thus resulting in cell death [6]. The inclusion of transition metal complexes namely copper, zinc and iron could enhance such bioactive role of the compounds. This is particular as the presence of such metals could alter the overall structure of the newly formed complex and thus can increase the affinity of the compound to DNA [7, 8].

This could result in the improvement of biological activities of the compounds. This research was carried out on *Morinda citrifolia* and focused on isolation of anthraquinones from the *Morinda citrifolia* stem bark extract and synthesize of Fe(II) complex which is having anthraquinones as ligands.

## Materials and Methods

### Plant material

An amount 5 – 6 kg of stem barks sample of *Morinda citrifolia* were collected from Sarawak. Herbarium voucher specimens were prepared.

### Extraction, isolation and purification

The plant was allowed to air-dry in the laboratory and then the dried sample was grinded. Powdered air-dried samples (2 – 3 kg) were extracted by soaking the sample with organic solvents in sequential polarity which started with hexane and followed by ethyl acetate, chloroform and methanol. The samples were allowed to stand for 48 hours and the process was repeated twice at 48 hours-interval.

The extract from each solvent extraction was filtered and concentrated using a rotavapor under vacuum pressure. The extracts were purified using liquid vacuum column (KCV) chromatography, gravity column chromatography and chromatoron. Fractions which were obtained from the isolation were purified using the gravity column chromatography and chromatotron using hexane and chloroform with ratio (6:4) as a solvent system to obtain the major compound, nordamnacanthal.

### Preparation of the metal complex

Fe(II)-nordamnacanthal complex was synthesized by reacting the major compound, nordamnacanthal, 0.0500 g, 0.1864 mmol with an ethanolic solution 30 mL of 0.0186 g, 0.0932 mmol iron(II) acetate. The mixture was stirred and refluxed for 3 hours. Brown precipitate was yielded during the reflux. It was allowed to cool at the room temperature and was filtered. The solid was washed with ethanol and then air-dried.

### Instrumentation

The ligand, nordamnacanthal and its metal complex were established by gas chromatography mass spectrometry (GCMS), nuclear magnetic resonance (NMR), UV-Visible spectra, Fourier transformation infrared spectrophotometer and CHNS elemental analyzer.

**Bioassay (antimicrobial)**

Antimicrobial nordamnacanthal and Fe(II)-nordamnacanthal were evaluated using minimum inhibitory concentration (MIC) determines by broth micro dilution method using 96-well microplates against the 5 bacteria, *Escherichia coli, Salmonella pneumoniae, Pseudomonas aeruginosa, Proteus vulgaris and Klebsiella pneumonia*. The MIC will be tested according to Güllüce et al. [9]. Nutrient broth was prepared and autoclaved. 3.6 mg of ligand and its metal complex were weighed and dissolved in 2 mL DMSO (Stock solution, 1800 µg/mL).

The inoculated of the microbial strains were prepared from 24 hours broth cultures and suspensions were adjusted to 0.5 McFarland standard turbidity. The sterile nutrient broth was added (100 µg/mL) to wells in row B to H. The stock solution was added (100 µg/mL) to row A and B. The well mixture of nutrient broth and sample at row B were transferred to each well in order to obtain a twofold serial dilution of stock samples (1800, 900, 450, 225, 112.5, 56.25, 28.13 and 14.07 µg/mL). 100 µg/mL of the last row of the well need was removed out. The prepared bacteria were added (100 µg/mL) to all wells (A to H). T96-wells plate were covered with lid, sealed and incubated at 37 ˚C for 24 hours. The microbial growth was observed by turbidity and present of pallet at the bottom.

Minimum bactericidal concentration (MBC) method was used to extend evaluating the results of MIC by determine the number of surviving organism by observing the growth of bacteria. MBC is defining as the number concentration at which 99% of the bacteria were killed. The solution at the clearest stage/concentration in the 96-wells plate (during MIC analysis) were taken out and spread on the plate containing agar using sterilized metal loop. The plates were sealed and incubated at 37 ˚C for 24 hours. The plates were observed. The plate was clear during observation, means the bacteria are not growth and the MBC result is the same as MIC. Meanwhile, if the agar turns cloudy or not clear, MBC result showed concentration one step lower than MIC.

## Results and Discussion

**Structural elucidation of nordamnacanthal**

Nordamnacanthal was isolated via column chromatography (CC) and recrystallised from chloroform as an orange-yellow solid and with the melting point of 217 – 218 °C Temperature of this compound ranging 218 –220 °C was reported by Prista et al. [10]. The phenolic nature of this compound was indicated by the positive $FeCl_3$ test. The difference can be noticed from the molecular ion peak at m/z 268, which corresponds to the molecular formula $C_{15}H_8O_5$. Strong peak at m/z 240 was due to the α-cleavage of the bond to the carbonyl group also occurred in nordamancanthal. The difference of the two compounds can also be observed from the UV spectrum where the absorption wavelength of nordamnacanthal was centered at 246 nm while another was shifted longer wavelength at 290 nm. This is due to the pi-pi* transition in the aromatic rings. There was also an additional weak absorption at 420 nm that indicating the hydroxyl group. The IR spectrum showed strong absorption bands at $\nu$= 3071, 1667, 1573, 1456, 1309 and 1262 $cm^{-1}$ were due to the presence of the hydroxyl group, chelated carbonyl group and the C-O stretch, respectively.

The $^1H$ NMR spectrum showed a singlet signal of aromatic proton ($\delta_H$ 7.34, H-4) and two doublet of doublets protons ($\delta_H$ 8.32, H-5 and H-8) and two multiplets at $\delta_H$ 7.84 (H-6 and H-7). The five signals at aromatic range displayed signals for a 1,2,3-trisubstituted aromatic ring. The assignments were made according to the equivalent protons values of the two protons and their coupling constant values which were 7.3 and 1.8 Hz. These values also confirmed the occurrence of the orto coupling and meta coupling among these protons. The characteristic $^{13}C$ NMR spectra revealed a normal skeleton of anthraquinone attached by two hydroxyl, and a formyl group.

Additional information from the HMBC proved the assignment of the formyl group in the structure, the $^3J$ coupling between the aldehyde proton at $\delta_H$ 10.50 and C-3 ($\delta_C$ 169.2), and $\delta_C$ 168.1 (C-1) with the one proton singlet at $\delta_H$ 7.34 was assigned as H-4. Besides, the substituents in the ring A were identified to have the two hydroxyl groups at position 1 and 3, and the formyl group at position 2. The positions of these substituents were confirmed by the two one-proton singlets at $\delta_H$ 14.06 and 12.68, that represented the chelated hydroxyl protons.

**Characterization of Metal Complex**

The structure of Fe(II)-nordamnacanthal complex was established through the elemental analysis CHNS, IR and UV-Visible spectral data. The synthesis of metal complex was carried out by reacting our major compound,

nordamnacanthal with transition metal, Fe(II). Fe(II)-nordamnacanthal complex had been synthesized successfully via telescoping synthesis/ one-pot reaction. The ligand, nordamnacanthal (L) on interaction with iron(II) acetate. The analytical data show that the metal to ligand ratio is 1:2. (yield 42%). Elemental analysis was found to be C (39.97%); H (3.514%); N (0.2777%) and S (0.06%). Calculated for Fe(II)-nordamnacanthal complex: C (40.00%); H (3.111%); N (0.0%) and S (0.0%). The Fe(II)-nordamnacanthal complex showed molecular ion peak at m/z 450, supported the formation of the complex.

IR spectra of the free ligand, nordamnacanthal (Figure 1) was compared with the IR spectra of the metal complex. IR spectra of ligand showed a strong band at 3071 $cm^{-1}$ that is assigned to the OH group while the band is gone in the spectra of Fe(II) complex indicating the coordination of the hydroxyl group through the deprotonation. Broad absorption band at 3429 $cm^{-1}$ in the spectra of Fe (II) complex may show the presence of $H_2O$ stretching vibration. The band position of ν (C=O) group appeared at 1658 – 1667 $cm^{-1}$ range in the spectra of the free ligand was shifted by in the spectra of the complex, indicating the coordination of C=O of the ring to the Fe ion. While the additional peaks a very low frequency in IR spectra of Fe(II)-nordamnacanthal complex at 463.05 $cm^{-1}$ was attributed to *ν*(M-O), which was supported the formation of the complex [11].

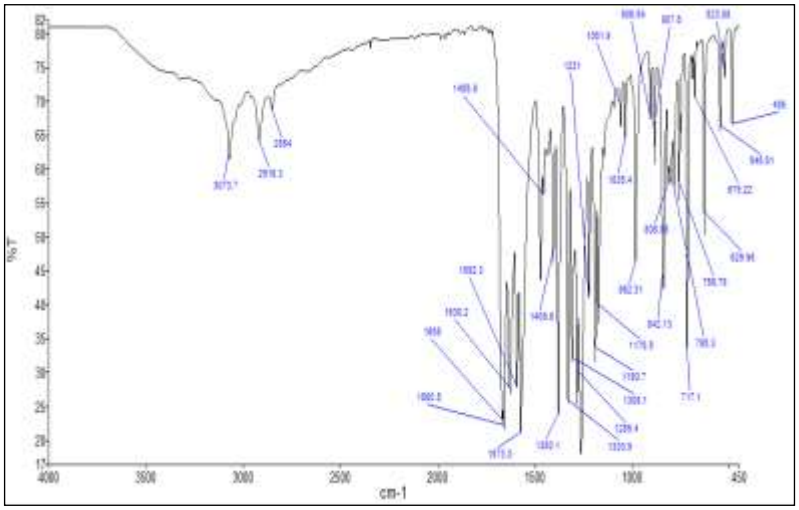

Figure 1. FTIR spectrum of nordamnacanthal

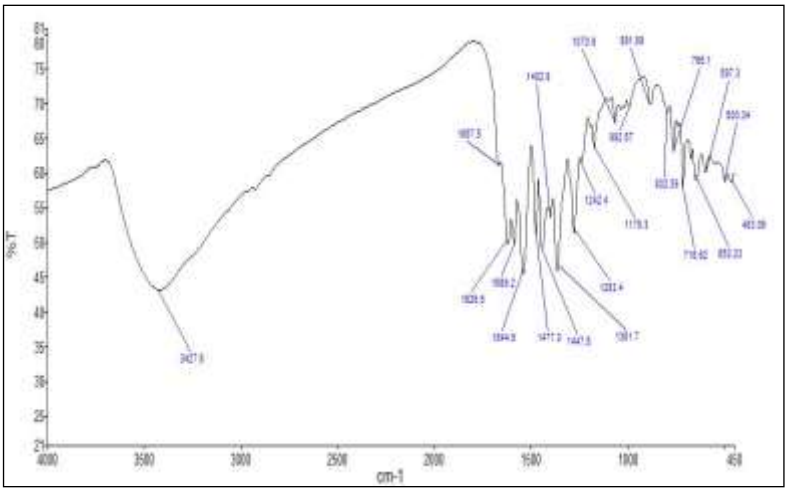

Figure 2. FTIR spectrum of Fe(II)-nordamnacanthal complex

The UV-Vis absorption spectra of nordamnacanthal (Figure 3) showed bands at 258.21 and 268.71 nm, which are due to $\pi \rightarrow \pi^*$ intra ligand transitions. The absorption band were shifted from 258.21 to 274.70 and 268.13 to 309.89 respectively in UV-vis spectra of Fe (II)-nordamnacanthal complex (Figure 4) and additional absorption at 421.78 was shifted to 548.05 nm in Fe (II)-nordamnacanthal complex may be due to a metal-to-ligand charge transfer [12]. Based on these results, ligand nordamnacanthal was confirmed coordinate with Fe(II) metal.

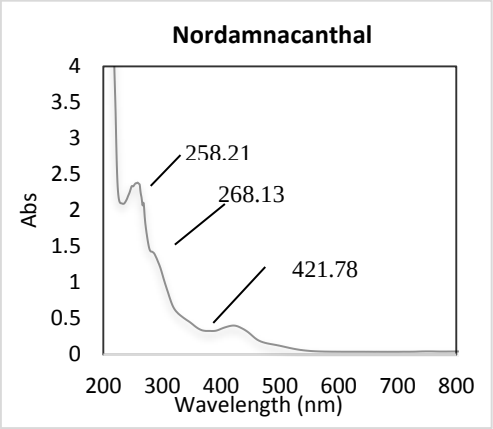

Figure 3. UV VIS spectra of nordamnacanthal

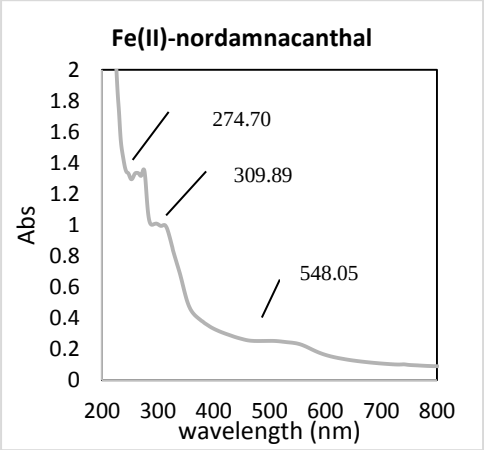

Figure 4. UV VIS Spectra of Fe(II)-nordamnacanthal complex

**Antimicrobial activity**

Antimicrobial activity of the ligand, nordamnacanthal and synthesized compound, Fe(II)-nordamnacanthal complex were compared. They were evaluated for the antimicrobial activity using minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC). Fe(II)-nordamnacanthal complex showed stronger inhibition against *Pseudomonas aeruginosa* at the concentration of 450 μg/mL whereas *Proteus vulgaris, Klebsiella pneumoniae* and *Salmonella pneumoniae* at the concentration of 225 μg/mL compared to nordamnacanthal. In this work, the synthesized compound, Fe(II)-nordamnacanthal complex showed better antimicrobial activity compared to the ligand itself.

## Conclusion

Fe(II)-nordamnacanthal complex had been synthesized successfully based on the telescoping synthesis/ one-pot reaction. The synthesized compound, Fe (II)-nordamnacanthal complex showed better antimicrobial activity compared to the ligand itself.

## Acknowledgment

The study was financially supported by FRGS grant (FRGS/1/2014/ST01/UiTM/02/3). The authors would like to extend our sincere appreciation to Faculty Applied Science, UiTM Kampus 2 Samarahan, Sarawak for providing materials and chemicals needed to conduct this study successfully.

**Abstract**

Biological activities (e.g. antibacterial) of hydrazone compound have received much attention from the synthetic chemists since last two decades. Herein, we would like to report the synthesis pathways as well as the spectroscopic characterization of three etherified hydrazone Schiff base compound, which were initiated from 2-hydroxyacetophenone. Hydrazone Schiff base compound was obtained through condensation reaction between 2-hydroxyacetophenone with benzhydrazide. Meanwhile the etherified derivatives of hydrazone Schiff base were prepared *via* Williamson ether synthesis under reflux condition. All the synthesized compounds were characterized using Fourier transformation infrared, UV-Vis and $^1$H nuclear magnetic resonance spectroscopy. In addition, the antibacterial activities of these compounds were also conducted using disc diffusion method against *Bacillus cereus* and *Escherichia coli*. The results are discussed in this present paper.

**Keywords:** hydrazone Schiff base, etherified derivatives, antibacterial

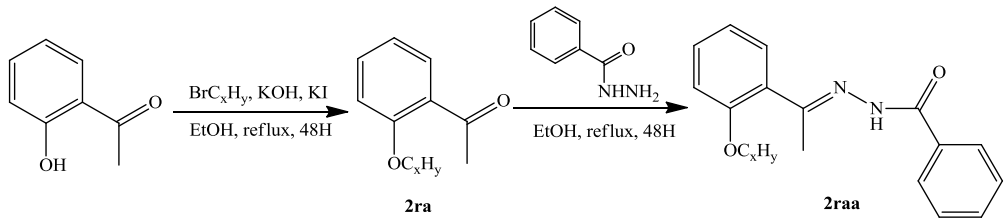
**Abstrak**

Aktiviti biologi (contoh: antibakteria) sebatian hidrazon telah menerima banyak perhatian daripada ahli kimia sintetik sejak dua dekad yang lalu. Di sini, kami ingin melaporkan kaedah sintesis serta pencirian spektroskopi tiga hidrazon yang telah di eterifasi, dimulakan dari 2-hidroksiasetofenon. Bes-Schiff hidrazon telah diperolehi melalui tindak balas pemeluwapan antara 2-hidroksiasetofenon dengan benzihidrazida. Sementara itu, terbitan yang telah di eterifasi daripada bes Schiff hidrazon telah disediakan melalui kaedah sintesis eter Williamson di bawah keadaan refluks. Semua sebatian yang disintesis dicirikan menggunakan inframerah transformasi Fourier, spektroskopi UV-Vis dan $^1$H magnetik nukleus resonan. Di samping itu, aktiviti antibakteria sebatian ini juga dijalankan dengan menggunakan kaedah cakera penyebaran terhadap *Bacillus cereus* dan *Escherichia coli*. Keputusan dibincangkan dalam kajian ini.

**Kata kunci**: bes Schiff hidrazon, terbitan yang telah dieterifasi, antibakteria

## Introduction

Hydrazones generally are prepared by reacting a stoichiometric amount of hydrazide (R-NH-$NH_2$) and a carbonyl (C=O) compound in suitable solvent under reflux condition [1]. Hydrazone Schiff base compounds and complexes have attracted considerable amount of attention since last two decades due to their pharmaceutical activities such as antiproliferative effect, antimicrobial, antibacterial, antifungal, anti-inflammatory [2], anticonvulsant, antitubercular, antiviral, antioxidative effects and inhibition of tumor growth [3]. These biological activities enable the hydrazone



compounds and their complexes are suitable to be used as herbicides, insecticides, nematicides, rodenticides and plant growth regulators [4].

On the other hand, compounds with long carbon chain i.e. $C_8$ and above, received much interest from the researchers as they were reported to bear the potential as organogels in nanostructure formation [5], surfactant and in antibacterial [6]. In addition, the existence of the long carbon chain in the structure was reported to support the ability of the molecule to self-assemble into various architectures, enhance lipophilicity and antibacterial properties of the compound [6].

In this project, we report the synthesis of three hydrazone Schiff base compounds bearing carbon chains of $C_8H_{17}$, $C_{10}H_{21}$ and $C_{12}H_{25}$. The compounds were prepared by reacting etherified ketones with benzhydrazide *via* condensation reaction as shown in Scheme 1. Antibacterial study using disc diffusion method was conducted to find the correlation between the presences of long carbon chain with the antibacterial properties of the compound.

## Materials and Methods

All $^1$H Nuclear Magnetic Resonance (NMR) spectra were recorded by 500 MHz of JEOL ECA-500 using $CDCl_3$ and DMSO-$d_6$ as solvent and TMS as internal standard for $^1$H NMR. UV-Vis spectra were recorded using Jasco V-630 spectrophotometer. The Fourier Transformation Infrared (FTIR) were recorded using Thermo Scientific Nicolet iS10.

Scheme 1. Synthesis of hydrazone Schiff base compound and its derivatives

**Synthesis of etherified ketone: Synthesis of 2ra8**

1-Bromooctane (0.01mol) was added dropwise to the yellow ethanolic solution of 2-hydroxyacetophenone (0.01mol). Pellet of potassium hydroxide (0.01 mol) and powder of potassium iodide (1 g) were added into the mixture prior before mixture was heated under reflux for 48 hours. The resulting solution which appeared in red liquid was cooled, filtered and extracted using water and diethyl ether obtaining a thick yellow liquid. Yield: 60%.

**Synthesis of 2ra10**

The experimental procedure is similar to that in synthesis of **2ra8** except 1-bromooctane was replaced with 1-bromodecane. Compound **2ra10** was obtained as thick yellow liquid. Yield: 52%.

**Synthesis of 2ra12**

The experimental procedure is similar to that in synthesis of **2ra8** except 1-bromooctane was replaced with 1-bromododecane. Compound **2ra12** was obtained as thick yellow liquid. Yield: 75%.

**Synthesis of derivatives of hydrazone Schiff base: Synthesis of 2raa8**
Benzhydrazide (0.001 mol) was dissolved in 20 ml hot ethanol in a round bottom flask. To the ethanolic solution of benzhydrazide, yellow liquid of **2ra8** (0.001 mol) was added dropwise with constant stirring and heating. The mixture was heated under reflux for 48 hours in ethanol. Resulting yellow liquid was cooled and after 3 days slow evaporation, white solid obtained. Yield: 56%, white solid.

**Synthesis of 2raa10**
The experimental procedure is similar to that in synthesis of **2raa8** except **2ra8** was replaced with **2ra10** (0.001 mol). Yield: 60%, pale yellow solid.

**Synthesis of 2raa12**
The experimental procedure is similar to that in synthesis of **2raa8** except **2ra8** was replaced with **2ra12** (0.001 mol). Yield: 45%, yellow solid.

**Synthesis of parent compound, 2-hydroxyacetophenonebenzhydrazone, 2raa**
The experimental procedure is similar to that in synthesis of **2raa8** except **2ra8** was replaced with 2-hydoxyacetophenone. Yield: 89%, white powder.

**Antibacterial evaluation of the compounds**
The assay was carried out on the parent compound (**2raa**) and the derivatives (**2raa8 – 2raa10**) using disc diffusion method [7]. One colony of *Bacillus cereus* ATCC 33019 from a streak plate was inoculated in 20 ml of Luria-Bertani broth. After 16 hours of incubation, the optical density of the inoculums was measured and further diluted to achieve McFarland standard of 0.5. Using sterile cotton swab, agar plate was uniformly swabbed with diluted inoculums of the bacteria before sterile filter paper (6 mm) which were impregnated with different concentrations of **2raa** and the derivatives **2raa8-2raa10** (0.16%-0.2%) using DMSO as solvent were placed on the agar. The measurements of the inhibitory zones (mm) were taken after 24 hours of incubation. The procedures were conducted in another set for *Escherichia coli* ATCC 35150 and were performed in triplicate.

## Results and Discussion

**FTIR spectroscopy**
The parent compound namely, 2-hydroxyacetophenonebenzhydrazone (**2raa**) was prepared by reacting 2-hydroxyacetophenone with benzhydrazide under reflux using ethanol as solvent, whereas for the preparation of derivatives of hydrazone Schiff base compound, the starting material, 2-hydroxyacetophenone, was reacted with bromoalkane of C8, C10 and C12 carbons chain in the presence KOH and KI to obtain etherified ketones **2ra8 – 2ra12** (Scheme 1). The presence of long carbon chain in the compounds were indicated by the presence of C-H alkane stretching band in range of 2925.26 and 2852.54 $cm^{-1}$ in IR spectrum [8]. The OH stretch that presence in the starting material ketone is no longer detected in the etherified ketone, **2ra8 – 2ra12** (Figure 1).

The etherified ketones, **2ra8 – 2ra12** were then reacted with benzhydrazide under reflux using ethanol as the solvent to obtain the derivatives of hydrazone Schiff base compounds, **2raa8 – 2raa12**. The formation of the hydrazone Schiff base compounds were supported by the presence of stretching band at 3204 $cm^{-1}$attributed to the presence of N-H moiety in the hydrazone Schiff base [3]. On top of N-H band, the appearance of C=N stretching at 1600 $cm^{-1}$ also supported the formation of hydrazone Schiff base [3]. The major difference between parent ligand and the derivatives is the presence of alkane stretch at 2922.23 to 2825.42 $cm^{-1}$[8].

**UV-Vis**

The UV-Visible electronic spectra of parent compound, **2raa** and derivatives **2raa8 – 2raa12** were measured at room temperature in ethanol solution within range 200 to 800 nm. The data is summarized in Table 2. UV-Vis spectrum for **2raa** showed 2 peaks (Figure 3) at 283 and 328 nm which attributed toπ to π* and n to π* transitions indicating the presence of benzene ring and amino C=N respectively [7].

Table 2. Electronic absorption spectra data of the hydrazone Schiff base 2raa and derivatives

| Compound | $\lambda_m$(nm) |
|---|---|
| **2raa** | 283, 328 |
| **2raa8** | 273, 375 |
| **2raa10** | 274, 375 |
| **2raa12** | 275, 375 |

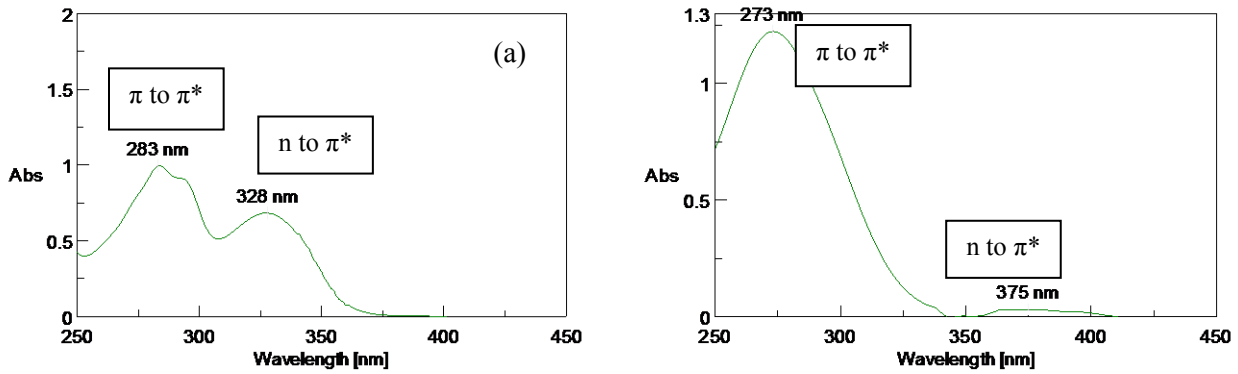

Figure 3. Electronic spectra of (a) parent compound (**2raa**), (b) derivative of Schiff base compound (**2raa8**)

Comparing the spectra of parent ligand and the derivatives, the peak of the derivatives shifted to a higher wavelength which is from 283 to 375 nm indicating the presence of long carbon chain in the moiety. It is known that the presence of electron donating group as substituent in aromatic molecule has significant effect on the absorption band in electronic spectra [8]. Long carbon chain is a donating group in which it decreased the energy gap between LUMO and HOMO in molecular orbital of azomethine C=N hence resulting in lower energy, increasing the wavelength as shown in the electronic spectra of the derivatives.

**Nuclear magnetic resonance spectroscopy**

Comparing the NMR spectra of starting material, 2-hydroxyacetophenone and etherified ketone, **2ra8 – 2ra12**, the presence long carbon chains in the **2ra8 – 2ra12** moiety were indicated by the presence of signals in range of 4.04 – 0.82 ppm [6] and disappearance of OH signal of hydroxyl group at meta position of starting material. Etherified ketones, **2ra8 – 2ra12** were reacted with benzhydrazide to form the derivatives of hydrazone Schiff base, **2raa8 – 2raa12** which were indicated by the presence of aromatic proton in the range of 7.56 – 6.97 ppm with the total number of nine protons [6] representing two benzene rings in the structure of the derivatives and also the presence of NH signal at 8.90 ppm [9]. The summary was tabulated in Table 3.

Table 3. Summary of significant $^{1}$H NMR spectral data for compounds

| Compounds | Chemical Shifts, $\delta$(ppm) | | | | |
|---|---|---|---|---|---|

**Antibacterial activities**

Disc diffusion method was used to evaluate the antibacterial properties of the hydrazone Schiff base compound, **2raa** and its long carbon chain derivatives, **2raa8 – 2raa12**. Gram positive bacteria, *Bacillus cereus* ATCC 33019 and gram-negative bacteria, *Escherichia coli* ATCC 35150 were used in this study. Compounds **2raa** and **2raa8 – 2raa12** were dissolved into the concentration of 0.16 to 0.020% using DMSO and the diameters of inhibition of the compounds were measured in mm unit. Inhibitions less than 10 mm is considered weak and insignificant, whereas more than 10mm is considered moderate and more than 16 mm is considered significant [10]. For *Bacillus cereus*, the derivatives of Schiff base, **2raa8 – 2raa12** showed better antibacterial properties than the parent compound (**2raa**) at all concentrations (Table 4).

Table 4. Results of antibacterial properties of compounds against *Bacillus cereus* ATCC 33019

| Compound | Diameter of Inhibition Zone (mm) | | | | |
|---|---|---|---|---|---|
| | Concentrations of Compounds in DMSO | | | | |
| | DMSO only | 0.16% | 0.08% | 0.04% | 0.02% |
| **2raa** | - | 10 | - | - | - |
| **2raa8** | | 15 | 12 | 11 | 10 |
| **2raa10** | | 15 | 10 | 10 | 10 |
| **2raa12** | | 11 | - | - | - |

The azomethine group of Schiff base compound is known to possess antibacterial properties as the group have the ability to form H bond with the intracellular components of the bacteria and interfere with the normal cell activity thus lead to the cell death [11]. The presence of long chain in moiety of the compound has increased the lipophilicity of the compound thus assist in the penetration through the peptidoglycan of the bacteria [6]. Synergistically, the effect of these two factors has enhanced the antibacterial properties of the compound. At the concentration of 0.16%, **2raa8** and **2raa10** showed better inhibition than **2raa12**. The antibacterial activity was found to increase with longer chain carbon until certain length where it reached cutoff effect where long chain no longer serves it purpose (as antibacterial agent) [6]. Hence, we can see that at 12 carbon compound namely **2raa12** has weaker inhibition compared to **2raa8** and **2raa10** at 0.16%. **2raa12** also showed insignificant inhibition at 0.02 – 0.08% concentration of compound. Meanwhile antibacterial screening against *Escherichia coli* showed that at all concentrations the incorporation of long chains into the compound (Table 5) has increased the antibacterial activities compared to the parent compound (**2raa**).

Table 5. Results of antibacterial properties of compounds against *Escherichia coli* ATCC 35150

| Compound | Diameter of Inhibition Zone (mm) | | | | |
|---|---|---|---|---|---|
| | Concentrations of Compounds in DMSO | | | | |
| | DMSO only | 0.16% | 0.08% | 0.04% | 0.02% |
| **2raa** | - | - | - | - | - |
| **2raa8** | | 11 | 10 | 10 | - |
| **2raa10** | | 16 | - | - | - |
| **2raa12** | | 16 | 14 | 12 | 11 |

## Conclusion

Hydrazone Schiff base compound and its long derivatives were successfully synthesized and characterized using $^{1}$H NMR, UV-Vis and FTIR. Antibacterial activities of the compounds were evaluated against *Bacillus cereus* and *Escherichia coli* using disc diffusion method where long carbon chain derivatives of hydrazone Schiff base (**2raa8 – 2raa12**) showed considerable antibacterial properties compared to the parent compound (**2raa**). The cooperative effect in between the ability of azomethine group of Schiff base compound to disrupt the normal processes of the bacterial cell by forming H bond with the intracellular components of the bacterial cell and the enhancement in the lipophilicity of the compound by the incorporation of long carbon chain into the moiety of the Schiff base compound that allow easy penetration through the peptidoglycan of the bacterial cell has increased the antibacterial properties of derivatives of the hydrazone Schiff base compound. This can be observed through the antibacterial activities result where the zone inhibition of Schiff base compound was increase upon incorporation of long carbon chain into the moiety of the compound.

**Abstract**

1-benzyl-3,3-dimethyl-5-methylenepyrrolidine-2,4-dione is an intermediate product produced in the synthesis towards the natural bioactive compound, zopfiellamide A. This compound was synthesized via four main steps including dimethylations, addition with $CuBr_2$, cyclization with benzylamine and reaction with formaldehyde. The corresponding intermediate was an α,ß-unsaturated ketone having *exo*-alkene group, and it was subjected to reduction using sodium borohydride and selected metal chlorides. In this study, the effect and the hydride transfer mechanism of sodium borohydride-metal chlorides system in the reduction of 1-benzyl-3,3-dimethyl-5-methylenepyrrolidine-2,4-dione was investigated based on the stereochemical outcome of the product.

**Keywords**: stereoselective, reduction, metal borohydride, exo-alkene

**Abstrak**

1-benzil-3,3-dimetil-5-metilenapirolidina-2,4-dion ialah produk perantara yang terhasil di dalam sintesis terhadap sebatian aktif semulajadi, zopfiellamide A. Sebatian ini telah disintesis melalui empat langkah utama termasuklah metilasi berganda, penambahan kepada kuprum bromida, pengkitaran dengan benzilamina dan tindak balas dengan formaldehid. Sebatian perantara ini merupakan keton α,ß-tidaktepu yang mempunyai kumpulan ekso-alkena, dan ia telah didedahkan kepada penurunan menggunakan natrium borohidrida dan logam klorida terpilih. Di dalam kajian ini, kesan dan mekanisma perpindahan hidrida oleh sistem natrium borohidrida-logam klorida di dalam menurunkan 1-benzil-3,3-dimetil-5-metilenapirolidina-2,4-dion telah dikaji berdasarkan stereokimia produk yang terhasil.

**Kata kunci:** stereoselektif, penurunan, logam borohidrida, ekso-alkena

## Introduction

Reduction is one of the important reaction in chemistry. Several functional groups such as aldehydes, ketones, carboxylic acids, esters, lactones, amides, lactams, imines and ammonium salts can be reduced by using an

appropriate reducing agent. Sodium borohydride ($NaBH_4$) is one of the reducing agent which offers good selectivity and have better solubility in most common organic solvents [2]. Its non-hazardous property allow its application in the efficient synthesis of (*R*)-salmeterol, which used to prevent bronchospasm in asthma patient [1]. It also have been used in industry to synthesized *d*-Biotin, also known as vitamin H, which is important additional nutrient for humans and animals [2].

Besides, $NaBH_4$ is also very versatile reducing agent. Its strength and selectivity can be altered by changing its countercation with other metal [3, 4]. For example, zinc-borohydride ($Zn(BH_4)_2$) can be prepared *in-situ* by adding $ZnCl_2$ into a THF slurry of $NaBH_4$ or to a glyme solution [5]. $Zn(BH_4)_2$ was known as a chemoselective reducing agent which capable of reducing ketones in the presences of enone [4, 5]. Its stereoselectivity was due to better coordinating ability of $Zn^{2+}$ lewis acid [4] via chelation-controlled [1, 5]. Meanwhile, similar reduction systems such as the $NaBH_4/CaCl_2$ reduction system, had been utilized in the reduction of phenacyl phenylglycinol derivatives, in which this reaction gave predominantly one diastereomers [1]. Another reducing reagent which offers excellent chemoselectivity is $Ce.Cl_3.7H_2O/NaBH_4$ which also known as Luche reagent. Davis et al. had used this reagent and was successfully reduced pyrrolidine enone to allylic alcohol in 83% yield [6].

In this study, 1-benzyl-3,3-dimethyl-5-methylenepyrrolidine-2,4-dione (**1**) was subjected to reduction using $NaBH_4$, with and without the presence of metal salts. The metal salts used in this study were $CaCl_2$, $ZnCl_2$, $MgCl_2$ and $MnCl_2$ respectively. $NaBH_4$/metal chloride reduction systems were produced by adding $NaBH_4$ to the reaction mixture containing these metal salts. The effectiveness and the stereochemical control of these reduction systems was mainly depends on the metals used. The stereochemical outcome of the product will reveal the influence and the effect of these metals in the reduction mechanism.

## Materials and Methods

### General

$^1H$ and $^{13}C$ Nuclear Magnetic Resonane (NMR) spectra were measured at 300 and 75 MHz, respectively. The NMR spectra were recorded in deuterated solvents on Bruker NMR 300 MHz, and the assignments were made on the basis of chemical shifts expressed in δ (ppm) units. Infrared spectra were recorded at Perkin Elmer instruments, Spectrum 2000 or Spectrum One, both in the spectral range of 4000 to 400 $cm^{-1}$. All samples were prepared using the KBr sampling method. Melting points were determined by either an Electrothermal melting point apparatus and were uncorrected. Polarimetry was performed using a Bellingham + Stanley Ltd ADP 410 Polarimeter with a cell of 10 cm in length and 4 mm internal diameter and the observed rotation was measured at 589 nm.

### General procedure for reduction using $NaBH_4$.

$NaBH_4$ (0.05 g, 1.57 mmol) was added in one portion into a cooled solution of 1-benzyl-3,3-dimethyl-5-methylenepyrrolidin-2,4-dione (**1**) (0.30 g, 1.31 mmol) in anhydrous methanol (30 ml), at 0 °C under nitrogen atmosphere. The mixture was stirred at 0 °C for four hours. The solvent was evaporated, and the residue was dissolved with DCM and partitioned against $NH_4Cl$ solution. The organic fraction was collected, washed with water, dried over anhydrous $MgSO_4$, filtered and concentrated in vacuum.

### General procedure for reduction using $NaBH_4$/metal chloride system.

Metal chloride (2.0 eq) was added into a stirred solution of 1-benzyl-3,3-dimethyl-5-methylenepyrrolidin-2,4-dione (**1**) (1.0 eq) in anhydrous methanol (20 ml). The mixture was stirred at room temperature under nitrogen atmosphere for 30 minutes. The mixture was then cooled to 0 °C and $NaBH_4$ (1.0 eq) was slowly added and stirred for another 30 minutes (except for $ZnCl_2$, the reaction was stirred for overnight). The solvent was evaporated and the doughy residue was extracted with DCM and partitioned against $NH_4Cl$ solution. The organic fraction was collected, washed with water, dried over anhydrous $MgSO_4$, filtered and concentrated in vacuum.

### (*R*)-(-)-1-Benzyl-3,3,5-trimethylpyrrolidine-2,4-dione (2 and its C5 epimer, 2a)

These products were obtained from the reduction using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems. The product was purified through column chromatography with hexane and ethyl acetate in 1:1 ratio.

**(*R*)-(+)-1-Benzyl-3,3,5-trimethylpyrrolidine-2,4-dione (2)**
This product was obtained from the reduction using $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ systems. The product was purified through column chromatography with hexane and ethyl acetate in 1:1 ratio.

## Results and Discussion

**Characterization study: (*R*)-(-)-1-Benzyl-3,3,5-trimethylpyrrolidine-2,4-dione**
The mixture was obtained as a white powder, m.p: 102.5 °C. IR v $cm^{-1}$: 3246 (OH stretch), 2927 (C-H stretch), 1658 (C=O), 1417 (C-C Ar stretch), 1101 (C-O stretch). Compound **2**; δH ($CDCl_3$, 300 MHz): 1.19 (3H, s, $CH_3$), 1.22 (3H, s, $CH_3$), 1.34 (3H, s, $CH_3$), 3.68 (1H, s, $CHCH_3$), 4.25 - 4.30 (1H, d, J = 15.9 Hz, CHHPh), 4.59 (1H, br s, OH enol), 4.74 – 4.79 (1H, d, J = 18.0 Hz, CHHPh), 7.23-7.32 (5H, m, Ar H). $^{13}C$ ($CDCl_3$, 75 MHz): 18.74 ($CH_3$), 23.39 ($CH_3$), 24.32 ($CH_3$), 42.00 ($CH_2Ph$), 42.89 (quat. C), 79.16 ($CHCH_3$), 87.56 (quat. C-alkene), 126.64, 126.86, 128.07 (Ar CH), 138.43 (quat. Ar C), 180.42 (C=O). C5 epimer, **2a**; δH ($CDCl_3$, 300 MHz): 1.13 (3H, s, $CH_3$), 1.24 (3H, s, $CH_3$), 1.26 (3H, s, $CH_3$), 3.85 (1H, s, $CHCH_3$), 4.26 – 4.31 (1H, d, J = 15.0 Hz, CHHPh), 4.59 (1H, br s, OH enol), 4.67 – 4.72 (1H, d, J = 15.0 Hz, CHHPh), 7.23-7.32 (5H, m, Ar H). $^{13}C$ ($CDCl_3$, 75 MHz): 18.35 ($CH_3$), 21.00 ($CH_3$), 23.82 ($CH_3$), 41.51 ($CH_2Ph$), 43.69 (quat. In this study, the reduction of 1-benzyl-3,3-dimethyl-5-methylenepyrrolidine-2,4-dione (**1**) was performed according to Fraga and Barreiro's method [3]. A reduction of (**1**), with $NaBH_4$ without metal chloride was served as a control reaction. The result obtained was used to evaluate the effect of metal chloride in the reduction mechanism. In this reduction, compound (**2**) was furnished as a white powder in 34% yield.

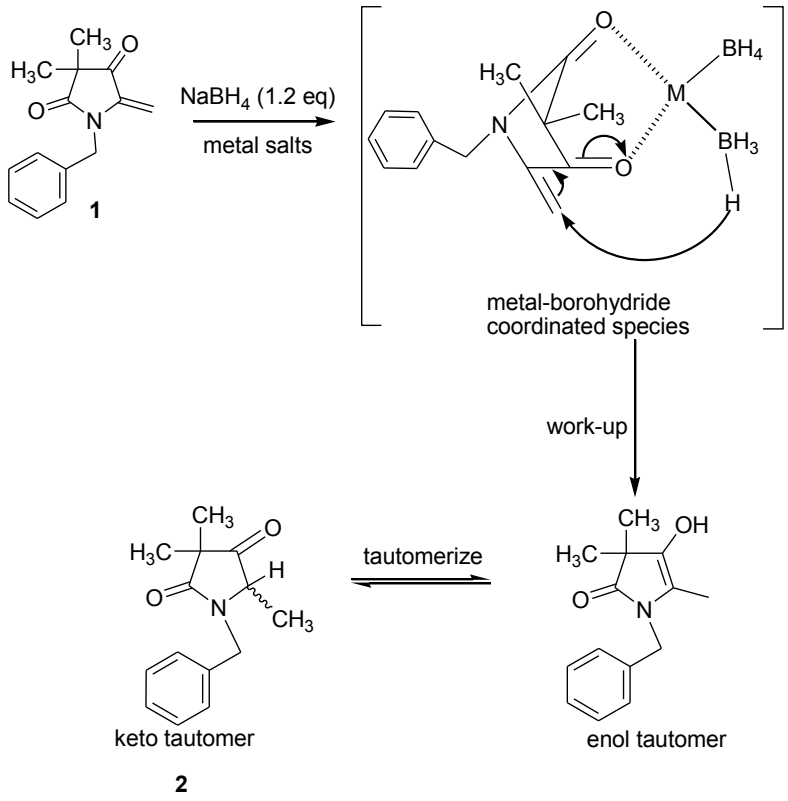
In the reduction using $NaBH_4$/metal chloride system, one portion of $NaBH_4$ was added to a solution containing (**1)** and one equivalent of anhydrous metal chloride, in anhydrous methanol. The mixture was stirred at 0 ºC for 30 minutes except for $ZnCl_2$, whereby the reaction was stirred for overnight. The products were purified through column chromatography and the results were presented in Table 1.

Table 1. Reduction of 1-Benzyl-3,3-dimethyl-5-methylenepyrrolidine-2,4-dione (**1**) using $NaBH_4$/metal chloride systems



| Condition | Yield (%) |
|---|---|
| $NaBH_4$, anh. $CaCl_2$, anh. MeOH (0 ºC, 30 minutes) | 62 |
| $NaBH_4$, anh. $MnCl_2$, anh. MeOH (0 ºC, 30 minutes) | 73 |
| $NaBH_4$, anh. $MgCl_2$, anh. MeOH (0 ºC, 30 minutes) | 45* |
| $NaBH_4$, anh. $ZnCl_2$, anh. MeOH (0 ºC, overnight) | 40* |

*Notes: *no repeating signals were observed in the NMR spectrum*

The results showed that the presence of these metal chloride did not affect the product outcome, instead had increased the yields of compound (**2**). In all cases, 1,4-addition product was predominate over 1,2-reduction product. The reduction systems employed had given a chemoselective product. The reduction occurred

chemoselectively at ß–carbon at C5 (*exo*-alkene) rather than at the carbonyl carbon at C3 position. Normally, isolated alkene did not undergo reduction with $NaBH_4$ due to lack of polarity, however, in this case, this enone group was activated by an electron withdrawing group present in this compound (carbonyl group). The delocalization of electrons through resonance increases the electrophilicity of this ß-carbon, enable the hydride (nucleophile) to mainly transfer to this position.

In terms of the reaction mechanism, the expected metal-borohydride coordinated species was involved during the hydride transfer, which led to the formation of product [3]. In this proposed reaction mechanism, $NaBH_4$ was reacted with metal chloride (as chelating agent) to form metal-borohydride coordinated complex. This complex had formed a chelation between both oxygen of the carbonyl at C4 and the oxygen of carbonyl amide at C2. Since the electrophilicity of the ß-carbon was increased, the hydride was transferred to this carbon. The usual work-up procedure was led to the formation of enol tautomer of compound (**2)**, which then tautomerized to its keto tautomer, (**2)** (refer to Scheme 1).

Scheme 1. Proposed reduction mechanism for $NaBH_4$/ metal chloride systems

Based on $^1H$ and $^{13}C$ NMR spectra, the reduction of prochiral compound (**1**) using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems showed poor stereochemical control compared to $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ reduction systems. The spectrum for reduction using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems, showed repeated signals, which indicates the presence of a mixture of compound **2** and its C5 epimer (**2a**). In Figure 1, two sets of signals (doublets of doublets) attributed to benzylic protons were observed; one set resonated at $\delta_H$ 4.25 – 4.30 and $\delta_H$ 4.74 – 4.78; and a second set resonated at $\delta_H$ 4.26 – 4.31 and $\delta_H$ 4.67 – 4.72 respectively. Two singlets which correspond to methine protons at C5 and C5'were resonated at $\delta_H$ 3.68 and 3.85. Repeating signals for methyl protons at C13, C14, C15, C13', C14' and C15'also appeared between $\delta_H$ 1.13 to 1.34. All 10 H's of aromatic protons for the mixture were observed between $\delta_H$ 7.22 – 7.30. The appearance of a broad signal at $\delta_H$ 4.59 was

indicated the presence of enol tautomer, in which the signal was corresponds to the hydroxyl proton at C4 (see Figure 1).

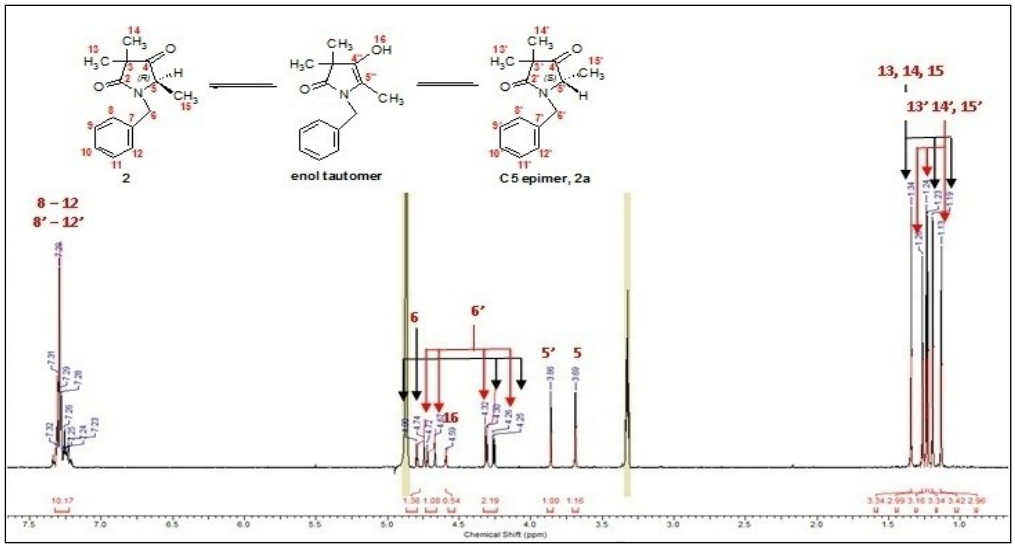


Figure 1. $^{1}$H NMR spectra for reduction using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems

The $^{13}$C NMR spectrum for reduction using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems in Figure 2 also show similar repeating pattern. The signals for methyl (at C13, C14, C15, C13',C14'and C15'), benzylic (C6 and C6') and methine (C5 and C5') carbons were observed between δ 18.35 to 24.32; δ 41.51 and 42.00; and δ 79.16 and 82.44 respectively. The enol's quatenary carbon (C5") was resonated at δ 87.56. Signals for aromatic protons also repeated around δ 126.63–138.65. In this spectrum, only two carbonyl carbon signals at C2 and C2', were observed. Two signals for carbonyl carbon at C4 and C4', does not appear in this spectrum. This might be due to rapid tautomerization process between keto and enol form of compound (**2**), which causes the signals hard to be detected. The enol's quaternary carbon (at C-5'") can be observed at δ 87.57.

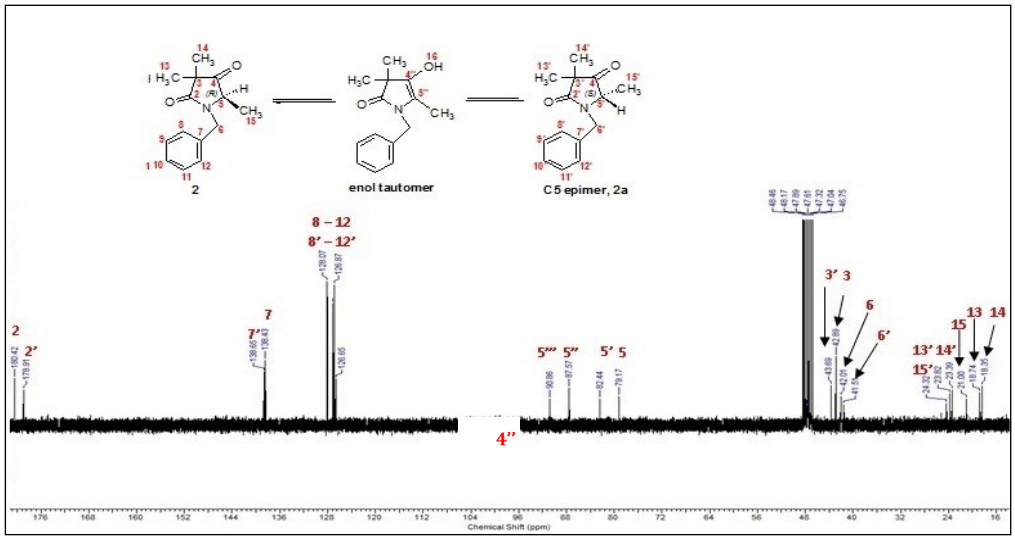

Figure 2. $^{13}$C NMR spectra for reduction using $NaBH_4$, $NaBH_4/CaCl_2$ and $NaBH_4/MnCl_2$ systems

Meanwhile, the reduction of prochiral compound (**1**), with $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ reduction systems, was resulted in a single compound (**2**) (stereoselective reaction). Both $^1H$ and $^{13}C$ NMR spectra in Figure 3 and 4, showed no repeated signals. This result concludes that, the presences of respective metal chloride in the reducing systems impart better stereochemical control in the reduction mechanism.

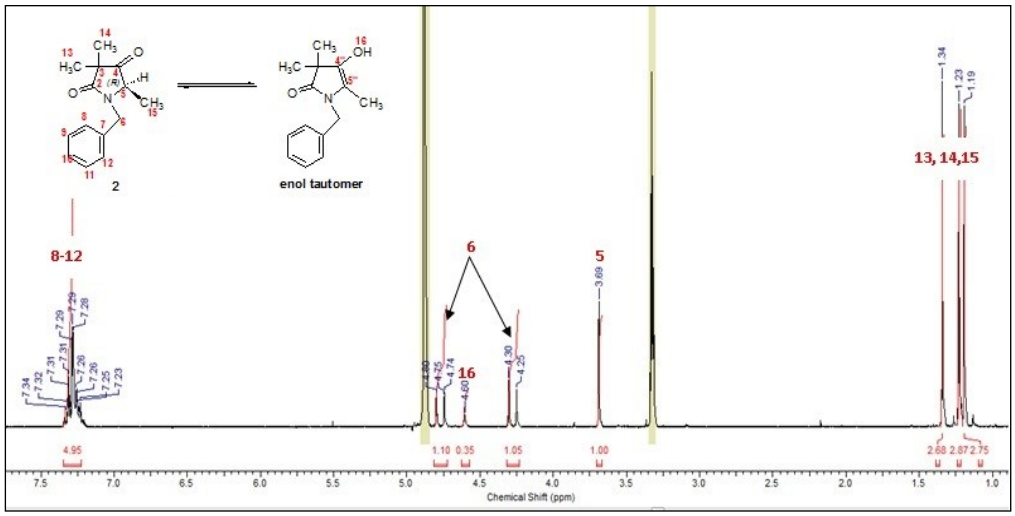

Figure 3. $^1H$ NMR spectra for reduction using $NaBH_4$, $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ systems

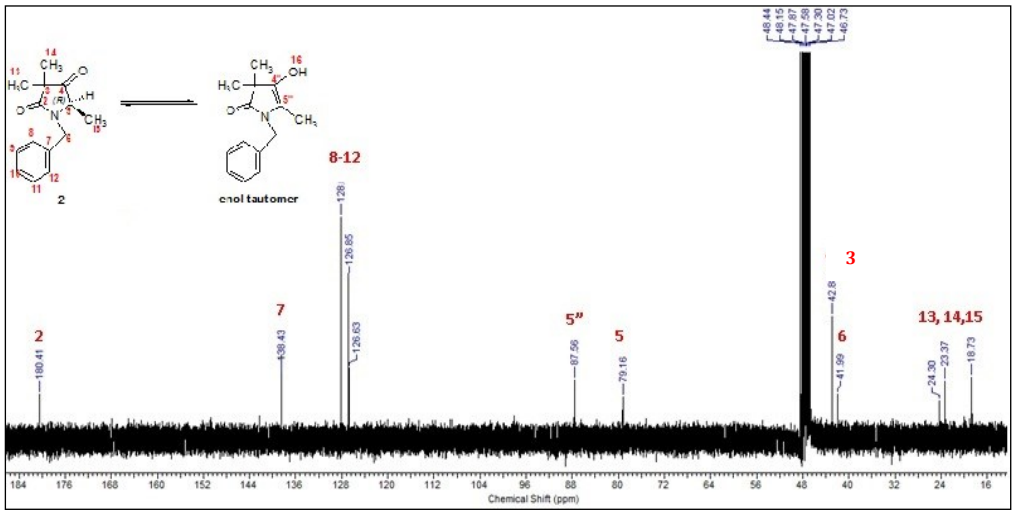

Figure 4. $^{13}C$ NMR spectra for reduction using $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ reduction system

The stereoselectivity of these reduction systems also can be explained in terms of the size and the chelation effect of the metal countercation used. In this study, bigger countercation ($Ca^{2+}$ and $Mn^{2+}$ is bigger than $Mg^{2+}$ and $Zn^{2+}$ respectively) resulted in a mixture as compared to smaller countercation. This might be due to the small size of countercations ($Mg^{2+}$ and $Zn^{2+}$) have better coordinating ability which imparts selectivity control during the hydride transfer mechanism [4]. This allows the hydride to transfer mainly on one side only (*si*-face) and produce compound (**2**). Meanwhile, big size of countercations cannot perfectly occupy (poor coordinating ability) certain position at a

certain time, and thus caused the hydride to transfer equally from both sides (*re*- or *si*-face). This led in a racemic mixture of compound (**2**) and its C5 epimer, (**2a**) (50:50 ratio based on $^1$H NMR spectra).

## Conclusion

The reduction of prochiral compound (**1**) using $NaBH_4$, $NaBH_4/CaCl_2$, $NaBH_4/MnCl_2$, $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ reduction systems, had resulted in a chemoselective reduction. However, only reduction using $NaBH_4/MgCl_2$ and $NaBH_4/ZnCl_2$ systems showed high stereoselectivity as the systems produced only a single compound. In the evaluation on the effect of metal chloride in the reduction mechanism, it can be deduced that big countercation has low stereochemical control and resulted in a mixture due to poor coordinating ability in comparison with small countercations.

## Acknowledgement

We would like to thank the Universiti Teknologi MARA (UiTM) for providing the facilities to conduct this research, and also International Islamic University Malaysia (IIUM) and Kementerian Pengajian Tinggi Malaysia for the fellowship.

**Abstract**

A series of azo derivatives (**1a-e**) were synthesized *via* coupling reaction with of overall yield 58 – 72% while aspirin-azo derivatives (**2a-e**) were prepared by esterification reaction of aspirin and azo derivatives (**1a-e**) with overall yield 38 – 75%. In this study, the structures of synthesized compounds were characterized using elemental analysis (CHN), nuclear magnetic resonance ($^{1}$H NMR and $^{13}$C NMR) and Fourier Transform Infrared (FTIR) spectroscopy. The synthesized compounds were tested on antibacterial activity against *Escherichia coli* ATCC 25922 and *Staphylococcus aureus* S48/81 *via* turbidimetric kinetic method. The azo derivative–substituted fluorine, **1d** showed the highest antibacterial activities against *Escherichia coli* ATCC 25922 and *Staphylococcus aureus* S48/81 compared with other synthesized compounds. However, synthesized aspirin–azo derivatives (**2a-e**) showed weak antibacterial activity against tested bacteria due to bulky molecular structure thus hindered the penetration into bacterial cell wall.

**Keywords**: aspirin, azo derivatives, turbidimetric kinetic, *Escherichia coli* ATCC 25922, *Staphylococcus aureus* S48/81

**Abstrak**

Satu siri terbitan azo **(1a-e)** telah dihasilkan melalui tindak balas gandingan dengan hasil keseluruhan 58 – 72% dan terbitan azo-aspirin **(2a-e)** telah disediakan melalui tindak balas esterifikasi aspirin dan terbitan azo **(1a-e)** dengan hasil keseluruhan 38 – 75%. Dalam kajian ini, struktur sebatian yang dihasilkan dicirikan menggunakan analisis unsur (CHN), resonans magnetik nukleus ($^{1}$H NMR dan $^{13}$C NMR) dan spektroskopi inframerah transformasi Fourier . Kesemua sebatian yang dihasilkan telah diuji pada aktiviti anti-bakteria terhadap *Escherichia coli* ATCC 25922 dan *Staphylococcus aureus* S48 / 81 melalui kaedah kinetik turbidimetrik. Terbitan azo tertukarganti fluorin **1d** menunjukkan aktiviti antibakteria tertinggi terhadap *Escherichia coli* ATCC 25922 dan *Staphylococcus aureus* S48/81 berbanding dengan sebatian lain. Walau bagaimanapun, terbitan azo aspirin **(2a-e)** menunjukkan aktiviti anti-bakteria yang lemah terhadap bakteria diuji disebabkan oleh struktur molekul yang besar itu telah menghalang penembusan ke dalam dinding sel bakteria.

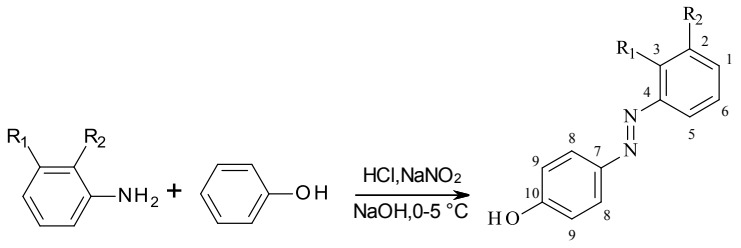
**Kata kunci**: aspirin, terbitan azo, kinetik turbidimetrik, *Escherichia coli* ATCC 25922, *Staphylococcus aureus* S48/81

## Introduction

Aspirin is a white crystalline weak acidic product that has analgesic and anti-inflammatory properties [1, 2]. It is also used to prevent cardiovascular disease and cancer. The compound has an antiplatelet effect by inhibiting the production of thromboxane, which under normal circumstances binds platelet molecules together to create a patch over damaged walls of blood vessels [3]. However, aspirin may cause some side effects such as vomiting and

stomach bleeding after prolonged usage [4]. Research on aspirin has been studied extensively. Chemical modification of aspirin and its derivatives have improved its pharmacological properties with less gastrointestinal toxicity [5]. Aspirin derivatives were also reported to apply many biological activities such as antibacterial [6], antithrombic [7], antiplatelet and anticancer properties [8].

Azo is a compound which consist of either an aryl or alkyl group functional group (R-N=N-R'). The most stable azo drivatives contain two aryl groups. The presence of N=N functional group is claimed to contribute to various applications in food [9], paints [10] and cosmetics [11]. In addition, azo derivatives have been reported to play important roles in many biological processes such as antibacterial [12], antifungal [13], antiviral [14] and anticancer activities [15], which stimulate the interest in the synthesis of a series compound containing aspirin with azo moiety.



In this paper, we report the synthesis of aspirin-azo derivatives **2a-e** by reaction of aspirin with azo derivatives **1a-e** *via* esterification. The preparation of halogenated azo derivatives **1a-e** was carried out *via* diazotiation followed by coupling reaction. The antibacterial activity of the synthesized azo derivatives **1a-e** and aspirin-azo derivatives **2a-e** against *Escherichia coli* ATCC 25922 and *Staphylococcus aureus* S48/81 have also been characterized.

**Materials and Methods**

Melting point was measured by Stuart SMP3 melting point apparatus and the elemental analysis was determined by flash EA1112 analyzer. IR spectra ($\nu$/cm$^{-1}$) were recorded on a Perkin Elmer GX spectrometer with potassium bromide pellet (KBr). $^{1}$H and $^{13}$C NMR spectra were recorded at 500 MHz on a JEOL.ECA NMR spectrometer.

**General method to synthesis of azo derivatives 1a-e**

The general method for synthesizing azo derivatives **1a-e** was shown in (Scheme 1). A mixture of HCl (2 M, 6 mL) and aniline derivatives (0.46 g, 5 mmol) was added with sodium nitrite solution (1 M, 2 mL) in water at 0 –5 °C slowly. Sodium hydroxide (0.4 g, 10 mmol) and phenol (0.47 g, 5 mmol) dissolved in water (10 mL) stirred and cooled to 0 – 5 °C. The diazo salt compound was added slowly into phenol solution at 0 – 5 °C and stirred for 40 minutes. The mixture was acidified by adding 2 M HCl. The precipitate formed was filtered and washed with cold water. The crude product was purified by crystallization from hot ethanol to give **1a-e**.

Scheme 1. Synthesis of azo derivatives **1a-e**

**General method to synthesis of aspirin-azo derivatives 2a-e**

The aspirin-azo derivatives **2a-e** can be synthesized from the reaction of aspirin and azo derivatives **1a-e** *via* esterification reaction (Scheme 2). Azo derivatives **1a-e**, (3 mmol) was dissolved in dichloromethane (20 mL) and added into the flask a solution containing acetylsalicylic acid (0.54 g, 3 mmol) in dichloromethane (20 mL) under ice batch. The mixture was added with dicyclohexylcarbodiimide (DCC) (0.62, 3 mmol) followed by N,N-

dimethyl-4-aminopyridine (DMAP) (0.37 g, 3 mmol). The reaction mixture was stirred for 4 hours at 0 – 10 ˚C and product formation was accompanied by thin layer chromatography (TLC) analysis using ethyl acetate/hexane (1:4). The white precipitate of by-product (dicyclohexylurea) was filtered off under suction. The filtrate was allowed to be evaporated under vacuum to form precipitate. The precipitate was purified by flash column chromatography on silica gel, using hexane as eluent. The product formed was recrystallized from hot ethanol to give **2a-e**.

**Antibacterial screening**

The antibacterial activities of the synthesized compounds were studied against *E. coli* and *S. aureus*. *Escherichia coli* was cultured on Luria–Bertani (LB) broth and incubated at 37 $^{o}$C for 24 hours with shaking at 250 rpm in order to be used as inoculums. Transmittances (T) were recorded in UV-Visible spectrophotometer. Erlenmeyer flasks containing 100 ml of culture medium added with 50 ppm, 80 ppm and 100 ppm concentrations of compounds and inoculated with 0.99 ml of inoculums and stirred in a culture chamber at 37 ºC with 180 rpm. Aliquots were extracted at 1 hour intervals for 6 hours and transmittances (T) were recorded in a UV-Visible spectrophotometer at 560 nm wavelength. T values were extrapolated to the number of cfu/ml (colony forming units/ml) for *E. coli* expressed in ln $N_t$. The antibacterial screening was repeated by replaced with *S. aureus* [16].

## Results and Discussion

**Characterization study**

The structures of **1a-e** and **2a-e** were confirmed by CHN elemental analysis, FTIR, $^{1}$H and $^{13}$C NMR spectroscopy. The FTIR spectra of **1a-e** and **2a-e** showed that the peak observed at 1491 – 1450 cm$^{-1}$ was associated to *v*(N=N). The peak observed at 1605 – 1583 cm$^{-1}$ was attributed to aromatic (C=C), while the peak at 764 – 749 cm$^{-1}$ and 918 – 752 cm$^{-1}$ were corresponded to *ortho*-substituted of halogen atom and *meta*-substituted of halogen atom, respectively [17]. In addition, **2a-e** showed that disappearance of *v*(O-H) peak at 3300 – 3000 cm$^{-1}$ and two new strong absorption peaks found at 1772 – 1732 cm$^{-1}$ indicated the presence of *v*(C=O) stretching of ester bond proved that the reaction was completed.

The $^{1}$H and $^{13}$C NMR spectroscopy were further confirmed the targeted structures of **1a-e** and **2a-e**. In the $^{1}$H NMR spectra of **1a-e** and **2a-e**, the aromatic protons were observed at δ 8.2 – 6.9 ppm. The $^{1}$H NMR spectra of **1a-e** showed the presence of OH group was resonated as singlet at δ 10.4 – 10.3 ppm (DMSO-$d_6$) and δ 5.8 – 5.6 ppm ($CDCl_3$), while $^{1}$H NMR spectra of **2a-e** showed the presence of -$CH_3$ appeared as singlet was observed at δ 2.28 –

2.26 ppm. The $^{13}C$ NMR spectra of **2a-e** revealed the -$CH_3$ at δ 20.8 – 20.7 ppm. Whereas, the C=O was observed at δ 169.5 – 162.0 ppm. Other the resonance of aromatic carbon **1a-e** and **2a-e** were observed at δ 163.5 – 95.6 ppm.

**Antibacterial screening**
The inhibition activity of **1a-e** and **2a-e** against *E. coli* and *S. aureus* are shown in Figure 1 and Figure 2, respectively. Most halogenated azo derivatives **1b-e** showed good antibacterial activities against *E. coli* and *S. aureus* at all concentration (50, 80 and 100 ppm). However, **2a-e** only showed good inhibition activity against bacteria at high concentrations (100 ppm). The effects of synthesized compounds tested at three different concentrations (50, 80 and 100 ppm) are further revealed by minimum inhibitory concentration (MIC) values. The MIC value of **1a-e** and **2a-e** were determined by extrapolating the concentration to zero growth rates of *E. coli* and *S. aureus* [16].

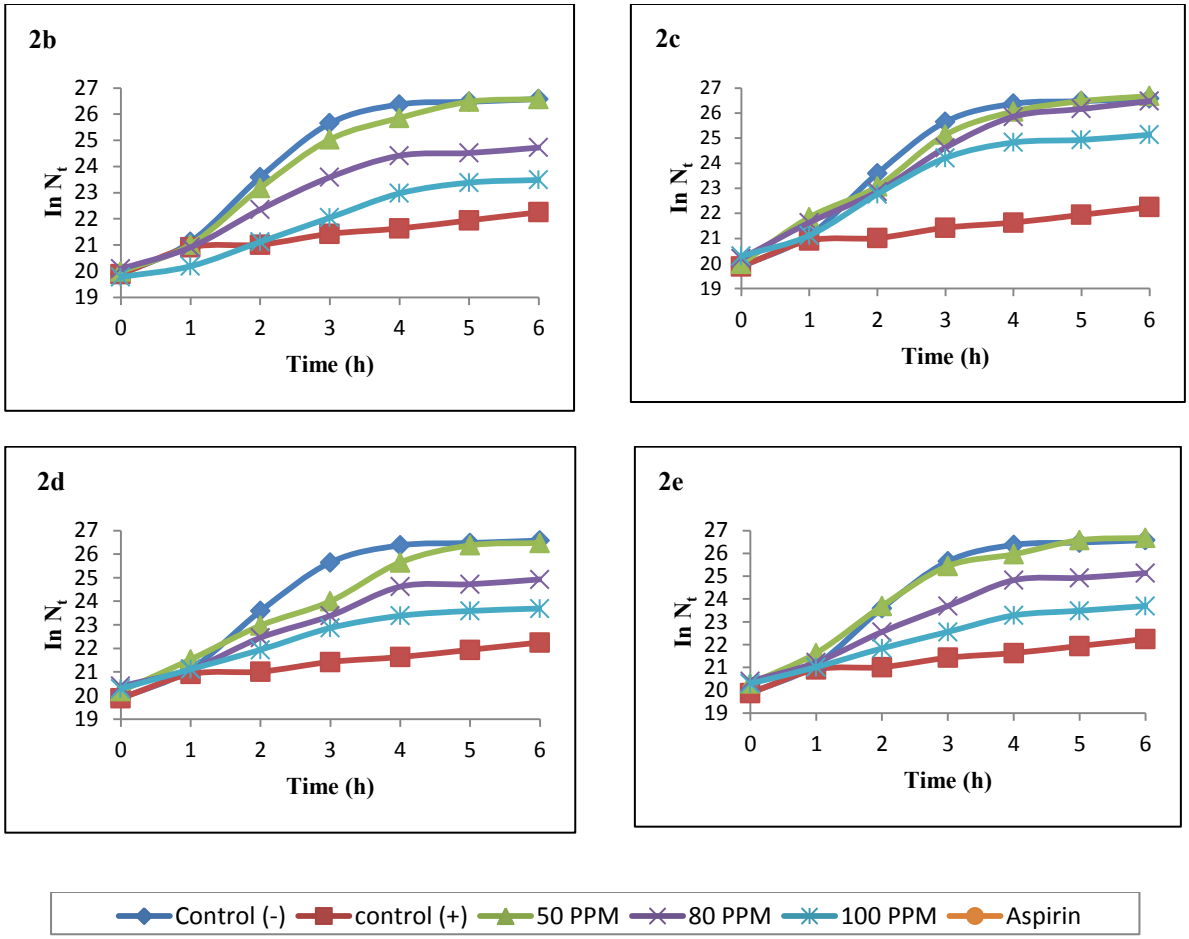

Figure 2. Inhibition activity of aspirin, **1a-e** and **2a-e** against *S. aureus* shown as In $N_t$ for *S. aureus* growth versus time

Based on the MIC values shown in Table 1, the MIC values showed that all halogenated azo derivatives **1b-e** exhibited very good bacteriostatic activities against *E. coli* and *S. aureus* compared to **1a** (without halogen substituent). All the synthesized halogenated azo derivatives **1b-e** demonstrated good inhibition against *E. coli* (MIC < 220 ppm) and *S. aureus* (MIC < 220 ppm), which indicated that these compounds are a potential antibacterial agent [18]. Among these compounds, **1d** (*ortho* fluorine atom substituent) gave the best inhibition with MIC values of 108 ppm and 132 ppm against *E. coli* and *S. aureus*, respectively. These results in agreement with Saeed et al. and Yarovenko et al. which reported that the halogen group and N=N played important roles in antibacterial activities [19, 20]. Furthermore, compounds consist of phenyl groups and halogen atoms have also revealed that those with more lipophilic character could easily penetrates the cell wall of microorganism [21, 22]. The azo derivatives **1b-e** consists of -N=N- group can be protonated under acidic condition to react with the phosphate group on the polysaccharide peptidoglycan layer of bacteria, which hinder the formation of cell wall [23, 24]. Patrick also reported that the halogenated compound was involved in inhibition of bacteria *via* interaction of halogen with receptor of enzyme [25]. In addition, The -N=N- and OH group in the synthesized halogenated azo derivatives **1b-e** interacts with active site on the enzyme of *E. coli* and *S. aureus* through hydrogen bond formation, thus inhibit the growth of bacteria [26].

For compound **2a-e**, only **2b** and **2d-e** exhibited good antibacterial activity against *E. coli* and *S. aureus* compared to **2a** (without halogen substituent) and aspirin. It is because the presence of halogen substituent and N=N in

molecular structure has contributed to antibacterial activities. The **2d** and **2e** substituted with fluorine and chlorine atoms, respectively at *ortho* position are more active to inhibit towards *E. coli* and *S. aureus* compared to compounds substituted with halogen atom at *meta* position. These results also revealed the same finding in which the halogen substituted at different position may have effect on the antibacterial activity as reported Lee et al. [27]. Furthermore, presence of more phenyl ring in molecular structure might also result in bulkiness. Therefore, it is more difficult to penetrate into bilayer of phospholipid *E. coli* and *S. aureus* [28].

Table 1. Minimum inhibitory concentration (MIC ppm) for compound **1a-e** and **2a-e**

| Compounds | MIC (ppm) | |
|---|---|---|
| | ***E. coli*** | ***S. aureus*** |
| Aspirin | >220 | >220 |
| **1a** | >220 | >220 |
| **1b** | 113.4 | 150.2 |
| **1c** | 111.3 | 139.0 |
| **1d** | 108.5 | 132.3 |
| **1e** | 117.3 | 138.3 |
| **2a** | >220 | >220 |
| **2b** | 180.9 | 194.1 |
| **2c** | > 220 | > 220 |
| **2d** | 156.3 | 199.5 |
| **2e** | 167.0 | 198.9 |
| Ampicillin (+) | 92.9 | 124.2 |

## Conclusion

In conclusion, there are two series of azo derivatives **1b-e** and aspirin-azo derivatives **2b-e** were synthesized and screened for their antibacterial activities. The results showed that all halogenated azo derivatives **1b-e** exhibited better antibacterial activities against both gram-negative bacteria and gram-positive bacteria when compared to all aspirin- azo derivatives **2b-e**. The esterification of aspirin with azo derivatives **1b-e** had increased the bulkiness of the molecular structure causing the steric hindrance, thus avoid the molecular structure from binding to the active site of bacteria. In addition, the bulky structure has caused difficulty to penetrate into the cell wall of bacteria. Azo derivatives **1d** bearing fluorine atom gave excellent antibacterial properties and gave the lowest MIC value due to the smaller size of fluorine.

**Abstract**

A series of hydrazone Schiff base (compounds **S**, **S8**, **S10** and **S12**) were synthesized by condensation reaction of salicylhydrazide with 3-hydroxybenzaldehyde, 3-(octyloxy)benzaldehyde, 3-(decyloxy)benzaldehyde and 3-(dodecyloxy) benzaldehyde, respectively. Herein, the addition of alkane numbers are reported using successful Williamson etherification method by reacting 3-hydroxybenzaldehyde with bromooctane, bromodecane and bromododecane, respectively. All compounds were characterised using Fourier Transform Infrared and $^1$H Nuclear Mangnetic Resonance spectroscopic. The compounds were assayed to antibacterial activity against Gram-positive and Gram-negative bacteria using *Bacillus cereus* and *Escherichia coli* by disc diffusion method. Interestingly, among the compounds tested **S8** showed a strong inhibition against *Escherichia coli* and none of the compounds tested show significant result against *Bacillus cereus*.

**Keywords**: 3-hydroxybenzaldehyde, Williamson etherification, hydrazone Schiff base, antibacterial activity

**Abstrak**

Satu siri bes Schiff hidrazon (sebatian **S**, **S8**, **S10** dan **S12**) telah disintesis mengunakan tindakbalas pemeluwapan oleh salisilhidrazida dengan 3-hidroksibenzaldehid, 3-(oktiloksi)benzaldehid, 3-(deciloksi)benzaldehid dan 3-(dodeciloksi) benzaldehid. Di sini, penambahan nombor alkana juga telah dilaporkan menggunakan kaedah pengeteran Williamson yang berjaya daripada tindak balas 3-hidroksibenzaldehid dengan bromooktana, bromodekana dan bromododekana. Semua sebatian telah dicirikan menggunakan spektroskopi inframerah transformasi Fourier dan $^1$H nukleus magnetik resonan. Sebatian yang terhasil telah diuji dengan aktiviti antibakteria terhadap bakteria Gram-positif dan Gram- negatif menggunakan *Bacillus cereus* dan *Escherichia coli* dengan kaedah cakera resapan. Menariknya, diantara sebatian yang telah diuji, **S8** menunjukkan perencatan yang kuat terhadap *Escherichia coli* dan tiada sebatian menunjukkan hasil yang ketara terhadap *Bacillus cereus*.

**Kata kunci**: 3- hidroksibenzaldehid, pengeteran Williamson, bes Schiff hidrazon, aktiviti antibakteria

## Introduction

Hydrazone Schiff base compounds have been widely reported regarding its effectiveness in biological activities including antibacterial [1], antifungal, antituberculosis [2], anticancer and antimalarial activities [3]. This is due to the presence of azomethine C=N group. The nitrogen atom of the schiff base contains a lone pair electron with $sp^2$ hybridised orbital that contributes to various biological and chemical properties [4]. In most cases, the structure of hydrazone Schiff base is the main factor in controlling the biological activites. As some reports demostrated that the antibacterial activity of some compounds enhanced by controlling the lipophilicity [5, 6], stereochemistry and the

nucleophilicity of the compounds [5]. Due to this reason, in order to increase the lipophilic ability of the compound which increasing the antibacterial property, Williamson etherification method was introduced to prolong the side chains of parent ligands by addition of C8, C10 and C12 alkyl chains in the compounds.

In this study, we herein report the synthesis, modification, characterization and antibacterial studies of hydrazone shiff base namely 3-hydroxybenzaldehyde salicylhydrazide, 3-(octyloxy)benzaldehyde salicylhydrazide, 3-(decyloxy)benzaldehyde salicylhydrazide and 3-(dodecyloxy)benzaldehyde salicylhydrazide.

## Materials and Methods

### Materials and characterizations

3-hydroxybenzaldehyde, salicylhydrazide, 1-bromooctane, 1-bromodecane and 1-bromododecane were obtained from Sigma Aldrich and Fluka. All chemicals and solvent were used as received without further purification. The infrared spectra were recorded using Thermo Scientific/Nicolet iS10 Fourier Transform Infrared spectrophotometer. The $^{1}H$ and $^{13}C$ NMR spectrum were recorded on a JEOL ECA-500 MHz NMR spectrometer and the chemical shift were reported relative to TMS and were referenced *via* residual proton NMR resonances of the appropriate diturated solvent (DMSO-$d_6$: 2.50 ppm).

### Etherification of 3-hydroxybenzaldehyde (T) to 3-alkoxybenzaldehyde (T8 – T12)

3-alkoxybenzaldehydes were prepared by a reported method with slightly alteration using 1-bromooctane, 1-bromodecane and 1-bromododecane [7]. The reaction was prepared by addition of ethanolic 3-hydroxybenzaldehyde (0.488g, 4 mmol) solution, anhydrous $K_2CO_3$ (1.035g, 7.5 mmol) and corresponding n-alkyl bromide (6 mmol) into the round bottom flask with present of KI and 20 ml of absolute ethanol as a solvent. The reaction mixture was heated under reflux for 20 hours and allowed to cool at room temperature. Then, the solution was transferred into separatory funnel and distilled water was added into the mixture and oily layer of 3-alkoxybenzaldehyde was formed. The mixture was extracted twice with diethyl ether (2 x 15 ml). Lastly, 5% NaOH solution (10 ml) was added into the mixture and distilled water was used to alter the mixture into pH 7. The oily ether extract was collected and dried under room temperature.

### Synthesis of 3-hydroxybenzaldehydesalicylhydrazide (S) and 3-alkoxybenzaldehydesalicylhydrazide (S8 – S12)

Salicylhydrazide (0.304g, 2 mmol) was dissolved in 20 ml of absolute ethanol in a round bottom flask with constant stirring. Ethanolic solution of 3-hydroxybenzaldehyde (**T**) or 3-alkoxybenzaldehydes (**T8 – T12**) (3 mmol) was then added dropwise into the mixture. The reaction mixture was refluxed with constant stirring for 20 hours and allowed to cool at room temperature. The precipitate formed was filtered and washed several times with ethanol and dried *in vacuo*.

### Antibacterial screening

Compounds **S**, **S8**, **S10** and **S12** were screened for their antibacterial property using disc diffusion method against *Bacillus cereus* and *Escherichia coli*. These bacteria were inoculated and incubated into Luria Bertani (LB) broth for 16 hours in an incubator at 37 °C. The culture was then diluted with a fresh LB broth and adjusted to 0.168 at wavelength of 550 nm in a UV-Vis spectrophotometer which represent 2.0 x $10^6$ (CFU/ml). A sterile cotton swab was lightly dipped into the culture and evenly inoculated into LB agar. After that, sterile 6mm paper disc was placed on agar in equal distance. Subsequently, 20 µl of compounds at 250 ppm in EtOH were dispensed individually to each of the disc and EtOH itself was tested to act as control. The agar plate was incubated at 37 °C for 24 hours. The presence of inhibition zone was recorded and measured in diameter (mm).

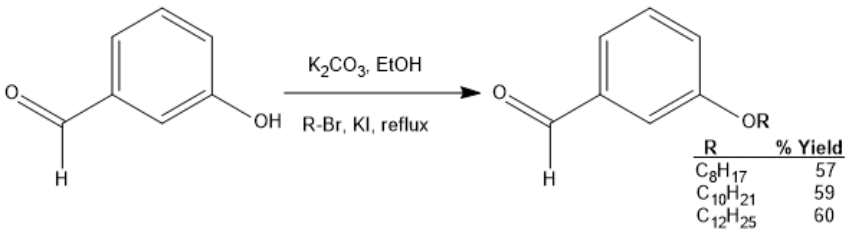
## Results and Discussion

### Characterization study: 3-octyloxybenzaldehyde (T8)

Colour: Oily yellowish brown. Yield: 57%. Main IR peaks ($cm^{-1}$): ν(C-H) aliphatic ($CH_2$) 2924, ν(C-H) alkanes ($CH_3$) 2854, ν(C=O) 1697, ν(C-O) 1260. $^{1}H$ NMR (DMSO-$d_6$, ppm): 9.96 (s, 1H, HC=O); 7.49 – 7.21 (m, 4H, $H_{aromatic}$); 4.02 – 3.99 (t, 2H, HC-O); 1.42 – 1.23 (m, 15H, $H_{alkanes}$): $^{13}C$ NMR (DMSO-$d_6$, ppm): 192.97 (HC=O); 159.20 (C-O); 137.65 – 113.59 (aromatic); 67.75 – 13.98 (aliphatic).

**3-decyloxybenzaldehyde (T10)**
Colour: Oily yellowish brown. Yield: 59%. Main IR peaks ($cm^{-1}$): ν(C-H) aliphatic ($CH_2$) 2922, ν(C-H) alkanes ($CH_3$) 2853, ν(C=O) 1697, ν(C-O) 1260. $^1$H NMR (DMSO-$d_6$, ppm): 9.95 (s, 1H, HC=O); 7.50 – 7.22 (m, 4H, $H_{aromatic}$); 4.01 – 3.98 (t, 2H, HC-O); 1.38 – 1.23 (m, 17H, $H_{alkanes}$): $^{13}$C NMR (DMSO-$d_6$, ppm): 192.93 (HC=O); 159.20 (C-O); 137.64 – 113.53 (aromatic); 67.73-13.96 (aliphatic).

**3-dodecyloxybenzaldehyde (T12)**
Colour: Oily yellowish brown. Yield: 60%. Main IR peaks ($cm^{-1}$): ν(C-H) aliphatic ($CH_2$) 2921, ν(C-H) alkanes ($CH_3$) 2852, ν(C=O) 1699, ν(C-O) 1260. $^1$H NMR (DMSO-$d_6$, ppm): 9.96 (s, 1H, HC=O); 7.49 – 7.24 (m, 4H, $H_{aromatic}$); 4.02 – 3.99 (t, 2H, HC-O); 1.39 – 1.21 (m, 19H, $H_{alkanes}$): $^{13}$C NMR (DMSO-$d_6$, ppm): 192.95 (HC=O); 159.20 (C-O); 137.64 – 113.54 (aromatic); 67.74 – 13.98 (aliphatic).



**3-hydroxybenzaldehydesallycylhydrazide (S)**
Colour: White fluffy paper-like structure. Yield: 98%. Main IR peaks ($cm^{-1}$): ν(NH) 3255, ν(O-H) 3059, ν(C=O) 1643, ν(C=N) 1611, ν(N-N) 1147. $^1$H NMR (DMSO-$d_6$, ppm): 8.36 (s, 1H, HC=N); 9.69 (s, 1H, NH); 11.84 (s, 2H, OH); 7.89 – 6.83 (m, 8H, $H_{aromatic}$): $^{13}$C NMR (DMSO-$d_6$, ppm): 148.77 (C=N); 157.74 (C-O); 135.43 –116.01 (aromatic).

**3-octyloxybenzaldehydesallycylhydrazide (S8)**
Colour: White needle shape crystal. Yield: 89%. Main IR peaks ($cm^{-1}$): ν(NH) 3246, ν(O-H) 3045, ν(C-H) aliphatic ($CH_2$) 2916, ν(C-H) alkanes ($CH_3$) 2846, ν(C=O) 1658, ν(C=N) 1627, ν(C-O) 1278, ν(N-N) 1145. $^1$H NMR (DMSO-$d_6$, ppm): 8.42 (s, 1H, HC=N); 10.28 (s, 1H, NH); 11.89 (s, 1H, OH); 7.92 – 6.98 (m, 8H, $H_{aromatic}$); 4.01 – 3.98 (t, 2H, HC-O); 1.41 – 1.25 (m, 15H, $H_{alkanes}$): $^{13}$C NMR (DMSO-$d_6$, ppm): 148.50 (C=N); 159.02 (C-O); 135.56 – 116.06 (aromatic); 67.54 – 14.00 (aliphatic).

**3-octyloxybenzaldehydesallycylhydrazide (S10)**
Colour: White granules. Yield: 92%. Main IR peaks ($cm^{-1}$): ν(NH) 3246, ν(O-H) 3049, ν(C-H) aliphatic ($CH_2$) 2918, ν(C-H) alkanes ($CH_3$) 2849, ν(C=O) 1658, ν(C=N) 1626, ν(C-O) 1278, ν(N-N) 1147. $^1$H NMR (DMSO- $d_6$, ppm): 8.41 (s, 1H, HC=N); 10.27 (s, 1H, NH); 11.88 (s, 1H, OH); 7.90 – 6.94 (m, 8H, $H_{aromatic}$); 4.01 – 3.98 (t, 2H, HC-O); 1.41 – 1.24 (m, 17H, $H_{alkanes}$): $^{13}$C NMR (DMSO- $d_6$, ppm): 148.53 (C=N); 159.03 (C-O); 135.56 – 116.01 (aromatic); 67.53 – 14.03 (aliphatic).

**3-octyloxybenzaldehydesallycylhydrazide (S12)**
Colour: White granules. Yield: 93%. Main IR peaks ($cm^{-1}$): ν(NH) 3246, ν(O-H) 3043, ν(C-H) aliphatic ($CH_2$) 2918, ν(C-H) alkanes ($CH_3$) 2847, ν(C=O) 1655, ν(C=N) 1625, ν(C-O) 1277, ν(N-N) 1148. $^1$H NMR (DMSO- $d_6$, ppm): 8.41 (s, 1H, HC=N); 10.27 (s, 1H, NH); 11.89 (s, 1H, OH); 7.92 – 6.93 (m, 8H, $H_{aromatic}$); 4.00 – 3.98 (t, 2H, HC-O); 1.41 – 1.22 (m, 19H, $H_{alkanes}$): $^{13}$C NMR (DMSO- $d_6$, ppm): 148.51 (C=N); 159.02 (C-O); 135.55 – 115.99 (aromatic); 67.52 – 14.01 (aliphatic).

**Spectroscopic studies: Etherification of 3-hydroxybenzaldehyde**
The yield of 3-(alkoxy)benzaldehyde from the reaction of 3-hydroxybenzaldehyde with 1-bromooctane, 1-bromodecane and 1-bromododecane, respectively were shown in Scheme 1. All figures shown were corresponding to T8 and S8, while the rest of the data were tabulated in Table 1 till Table 3.

The IR spectrum of **T8** in Figure 1 shows the disappearance of ν(-OH) peak compared to the IR spectrum of 3-hydroxybenzaldehyde at 3194 $cm^{-1}$ and the appearance of new peaks attributed to ν(-$CH_3$) alkyl chain in range of 2854 and 2924 $cm^{-1}$. The intensity of the peaks is depended on the length of an alkyl chain presence in the compounds; the longer alkyl chains the stronger intensity of the peak and *vice versa*.

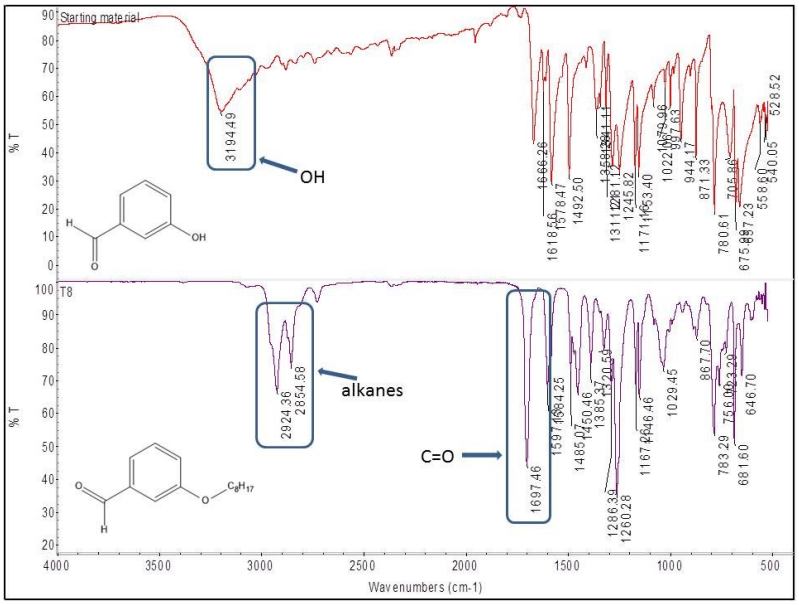

Figure 1. IR spectra of 3-hydroxybenzaldehyde (top) and T8 (bottom)

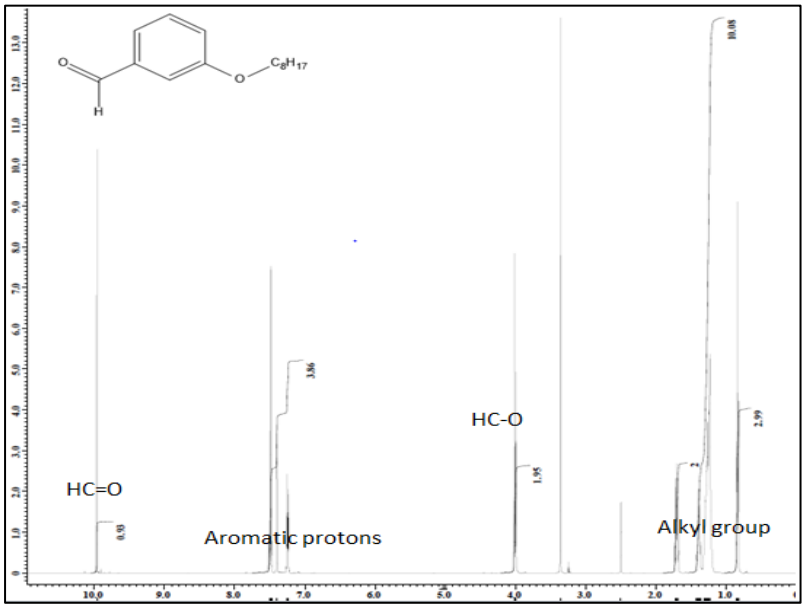
Similarly, the $^{1}$H NMR spectra of the three etherified products (i.e. $^{1}$H NMR spectrum of **T8** in Figure 2) showed the disappearance of $OH^{-}$ signal at 10.10 ppm and the existence of new proton signals for the alkoxy group at the high field region (δ: 1.00 – 4.00 ppm) has indicated the success of the etherification of 3-hydroxybenzaldehyde.



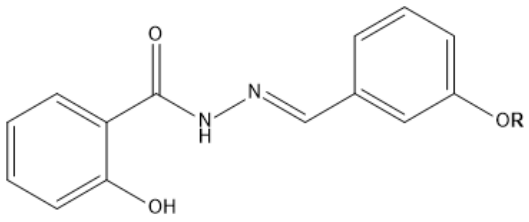


Figure 2. $^{1}$H NMR spectrum of T8

**Characterization of hydrazone Schiff base**
The yield of 3-(alkoxy)benzaldehydesalicylhydrazide were shown in Scheme 2.

| R | % Yield |
|---|---|
| H | 98 |
| $C_8H_{17}$ | 89 |
| $C_{10}H_{21}$ | 92 |
| $C_{12}H_{25}$ | 93 |

Scheme 2. Percentage yield of 3-(alkoxy)benzaldehydesalicylhydrazide

The IR spectrum of **S8** is shown in Figure 3. The disappearance of ν(C=O) peak in 3-(octyloxy)benzaldehyde at 1697 $cm^{-1}$ and appearance of new peaks at 1627, 3045 and 3246 $cm^{-1}$ was attributed to ν(C=N) stretching, ν(-OH) and ν(-NH) of **S8**, respectively.

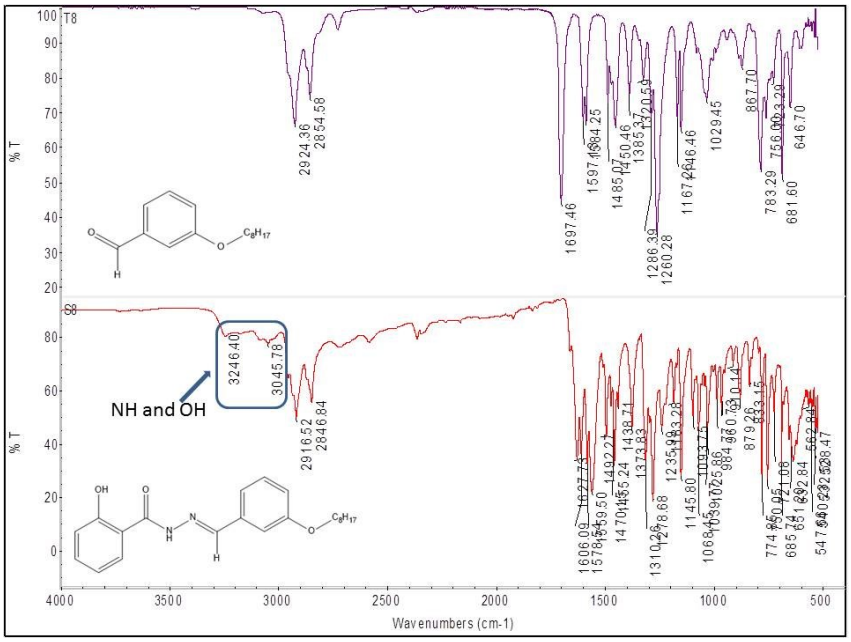

Figure 3. IR spectra of T8 (top) and S8 (bottom)

The $^1$H NMR spectrum of **S8** is shown in Figure 4. Similarly, the formation of **S8** can be represented by the deshielded of HC=N resonance at 8.42 ppm. This is due to the formation of C=N from C=O. In addition, the appearance of new peaks at 10.28 and 11.89 ppm confirmed the presence of NH and OH supporting the formation of **S8**.

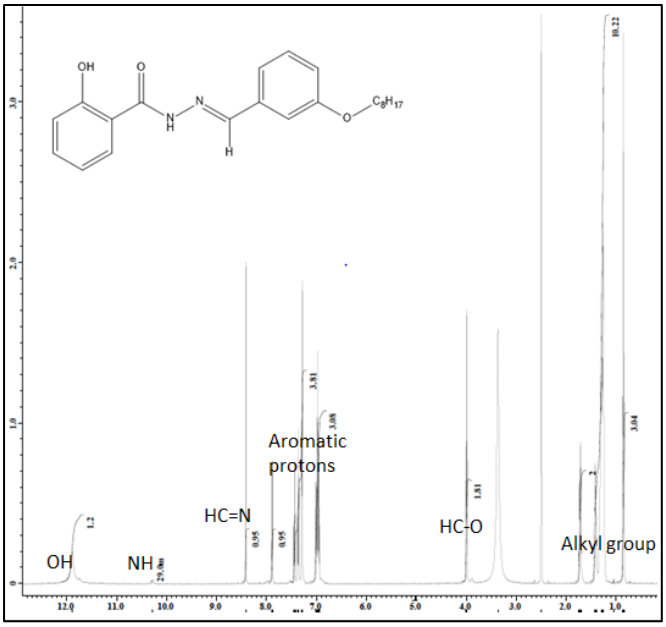

Figure 4. $^{1}$H NMR spectrum of **S8**

**Antibacterial screening**

The antibacterial activity of hydrazine Schiff base compounds **S**, **S8**, **S10** and **S12** were examined using disc diffusion method and the result were illustrated in Figure 5. The results show that, there is no significant inhibition of all the tested compounds to the activity of gram-positive bacteria represented by *Bacillus cereus*. On the other hand, there were strong inhibitions shown for the gram-negative bacteria, *Escherichia coli*. The increase of carbon chains in the structure has enhanced the inhibitory of bacteria activity. However, the activity showed slightly decrease as the length of carbon chain extended to C12. By these results, it is suggested that the moderate carbon chain size of lipophilic substituents might be vital for the optimal antimicrobial activity.

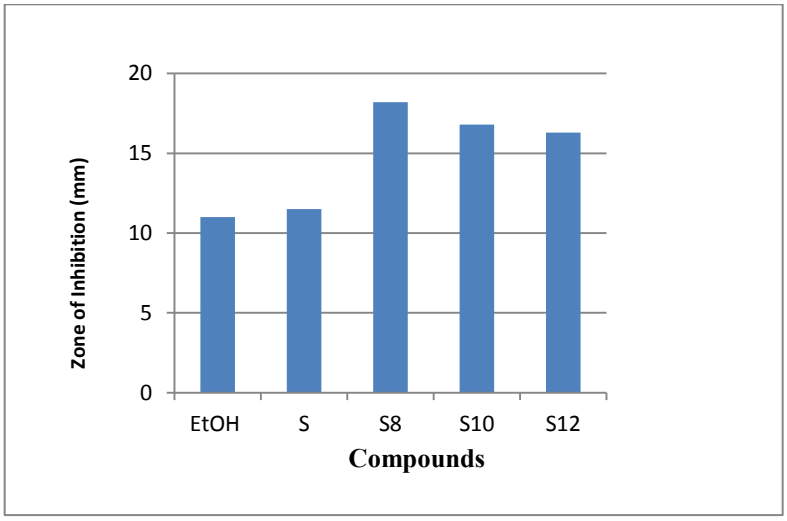

Figure 5. Antibacterial activity against *Escherichia coli*

## Conclusion

Hydrazone shiff base 3-hydroxybenzaldehyde salicylhydrazide (**S**), 3-(octyloxy)benzaldehyde salicylhydrazide (S8), 3-(decyloxy)benzaldehyde salicylhydrazide (**S10**) and 3-(dodecyloxy)benzaldehyde salicylhydrazide (**S12**) were successfully synthesised and characterized using FTIR, $^{1}$H NMR and $^{13}$C NMR. The presence of long carbon chain in the structure has enhanced the antibacterial activity which in good agreement with lipophilic effect. However, the result suggested that there is an optimum carbon chain number that give the highest inhibitory effect in antibacterial grow for gram-negative bacteria while non affect can be observed in gram-positive tested bacteria.

**Abstract**

Three-component Mannich reaction of ketones, aromatic aldehydes and aromatic amines was catalyzed by four Bronsted acidic ionic liquids comprising of iodide and borate at room temperature. Ionic liquid have been used as catalyst and solvent to produce some Mannich bases in high yield (75%) and shorter reaction time (20 minutes). Work up has been facilitated by simple extraction with water to recover ionic liquid for recycling up to four times without any significant loss in activity.

**Keywords**: Mannich bases, Bronsted acidic ionic liquids, 1-methylimidazole, 1,3-propane sultone, 1,4-butane sultone

**Abstrak**

Tindak balas tiga komponen Mannich iaitu keton, aldehid aromatik dan amina aromatik telah dimangkinkan oleh empat cecair ionik Bronsted berasid yang terdiri daripada iodida dan borat pada suhu bilik. Cecair ionik telah digunakan sebagai pemangkin dan pelarut untuk menghasilkan beberapa bes Mannich dengan hasil yang tinggi (75%) dan masa tindak balas yang lebih pendek (20 minit). Kerja pengekstrakan telah dipermudah dengan menggunakan air dan boleh dikitar semula sehingga empat kali tanpa sebarang kehilangan aktiviti yang penting.

**Kata kunci**: bes Mannich, asid Bronsted cecair ionik, 1-metilimidazol, 1,3-propana sulton, 1,4-butana sulton

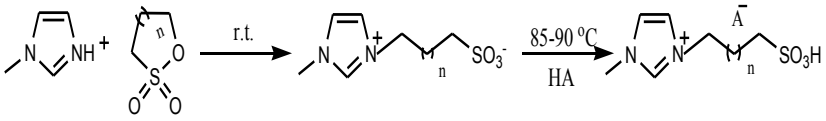
## Introduction

Multicomponent reactions have been proven to be an economic and facile approach for building of complex molecules in one synthetic step. A remarkable diversity can be achieved by varying the starting materials. Such appealing reactions offer an elegant course for synthesis of carbon-carbon and carbon-hetero atom linkages with high atom economy, simple methodology and high selectivity in one-pot procedure [1]. Mannich reaction is a fundamental method for a formation of β-amino carbonyl compounds of synthetic intermediates for natural product synthesis (alkaloids and polyketides) and in pharmaceutical industry [2]. The conventional catalysts for the synthesis of classical Mannich bases are mainly organic and mineral acids such as acetic acid [3], proline [4], p-dodecylbenzenesulfonic acid [5] and lewis acids [6]. These reactions conditions often lead to problems like difficulty in product separation, harsh reaction conditions, long reaction durations, toxicity and pollution [7]. Further development lead to the usage of other catalysts such as pTSA, BDMS, $HClO_4$-$SiO_2$, TMSCl, Amberlyst-15, carbon based solid acid, $AuCl_3$-$PPh_3$, $InCl_3$, silica supported sulphuric acid, $NbCl_5$, bismuth (III) chloride, sulfamic acid, boric acid, sucrose charsulfunic acid, $Zn(OTf)_2$, etc. [8]. The drawbacks include: large amount of

catalyst, expensive catalyst, high waste production, long reaction duration and ultimately low yield. [9]. Lanthanide triflate in acetonitrile or dichloromethane has also been reported for Mannich reaction catalysis [10].

In contribution to green chemistry, many studies reported on employing traditional volatile and flammable solvents to benign alternatives such as non-volatile solvent, supercritical system, aqueous media or solventless conditions. In this context, Mannich type reactions have also been reported in water [10]. In current years, ionic liquids (ILs) have been used as an environmentally benign solvents, efficient catalysts and a promising substitutes for volatile organic solvents and traditionally used acid/ base catalysts in construction of organic moieties [11, 12]. Use of organic solvents in reaction mixture usually leads to serious safety issues such as volatility, flammability and toxicity [12, 13]. The use of ionic liquids as reaction media offers a convenient solution to both solvent emission and catalytic recycling problems [10]. Beside high activity and selectivity, these versatile liquids are center of interest as they possess unique properties such as flexibility, high stability in air and water, easy separation and purification processes, reusability, non-volatility, non-flammability, noncorrosive nature, controlled immiscibility, low toxicity, low vapour pressure, low viscosities, high thermal and chemical stabilities [14-16]. Recently work on Mannich reaction is being carried out using ionic liquids [17, 18].

The present study emphasizes on employing ionic liquids as catalyst and solvents to overcome issues associated with traditional catalysts and organic solvents. In this approach, a green procedure has been proposed for synthesis of Mannich bases using acetophenone, aromatic aldehydes and anilines as starting materials. To the best of our knowledge, Mannich reaction catalyzed by ILs bearing imidazolium sultone as cation; and iodide and borate as anions are unprecedented. The reaction proceeded at faster rate with higher yield of desired Mannich bases using the synthesized ionic liquids. The effect of cations and anions in addition to the influence of additional carbon atom on sultone moiety was also been investigated.



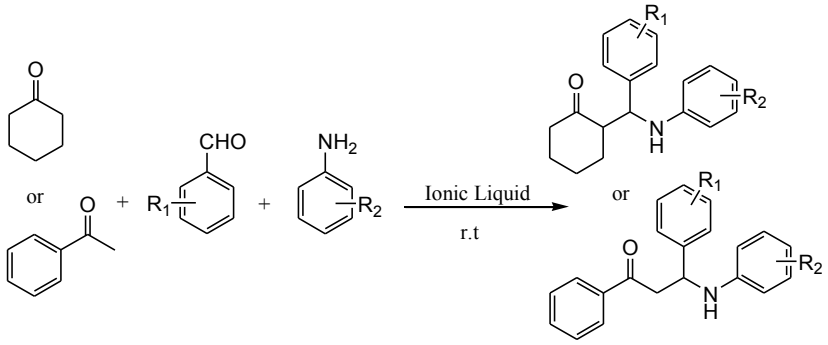
## Materials and Methods

### Chemicals

All the reacting molecules used such as 1,3-propane sultone, 1,4-butane sultone, *N*-methylimidazole, hydriodic acid, boric acid, acetonitrile, aromatic amines, aromatic aldehydes, acetophenone and cyclohexanone were purchased from Sigma Aldrich and used without any purification procedure. Melting points of the Mannich bases were determined in open capillaries and are uncorrected. NMR spectra were recorded on 400 MHz NMR Joel spectrometer using $D_2O$ and $CDCl_3$ as solvents. IR spectra were recorded in Nicolet FTIR spectrometer (400 – 4000 $cm^{-1}$).

### Synthesis of ionic liquids

The task specific ionic liquids have been synthesized by using an analogous method as reported in literature [19-21] with slight modifications. 1,3-propane sultone and 1,4-butane sultone were reacted with *N*-methylimidazole in equimolar ratio affording the respective zwitter ions that were then converted to ILs by acidification with two protic acids (Scheme 1). The corresponding ILs were used further without any purification.



where $A^- = I^-, B(OH)_4^-$, n= 1 and 2

Scheme 1. Reaction scheme for IL synthesis

### Mannich reaction: A typical procedure

Cyclohexanone (10 mmol), benzaldehyde (10 mmol), aniline (10 mmol) and 5 mmol of catalyst were taken in round bottom flask at 25 $^oC$ (Scheme 2) [22]. The completion of reaction was determined using TLC. For work up, some amount of water was added and extraction with ethyl acetate was done. The excess solvent was evaporated via rotary evaporator to afford solid product which was recrystallized from acetonitrile and dried under vacuum until

constant weight was obtained. At the end, the aqueous layer containing IL was vacuum dried at 70 °C to reuse ionic liquid for future use. The synthesized compounds were then characterized using IR and NMR. The spectral analysis along with physical data (melting points) was consistent with those reported in literature.

Scheme 2. Mannich reaction catalyzed by imidazolium based ionic liquids ($R_1$ and $R_2$ are mentioned in Table 4)

## Results and Discussion

The ionic liquids were synthesized by the reaction of methyl imidazole with 1,3-propane sultone and 1,4-butane sultone for preparation of Mannich bases. Spectral analysis confirmed the structure of synthesized ILs. these synthesized ILs were used to catalyze Mannich reaction using acetophenone/ cyclohexanone (10 mmol), benzaldehyde (10 mmol) and aniline (10 mmol) as model substrates at room temperature (Scheme 2).

The reaction mixture gradually turned to highly viscous material within 30 minutes. The reaction work up was done by addition of a small amount of water followed by extraction with ethyl acetate and finally evaporation of organic solvent. For purification, the synthesized Mannich bases were recrystallized from acetonitrile and the aqueous layer was further dried for recycling ionic liquid. Among the four protic ILs 75% of Mannich base was obtained as highest yield by 1-methyl-3-(3-sulfopropyl)-imidazolium borate ([mimps]HBO) in 20 minutes (Table 1).

Table 1. Effect of ionic liquid on yield of Mannich base[a]

| Entry | Catalyst | Solvent Used | Reaction Time (min) | Isolated Yield (%) |
|---|---|---|---|---|
| 01 | - | -, EtOH[b, c, d] | 120 | NR[a,b, c, d] |
| 02 | [mimps]I | -, EtOH[b, c, d] | 120 | NR[a,b, c, d] |
| 03 | [mimbs]I | -, EtOH[b, c, d] | 120 | NR[a,b, c, d] |
| 04 | [mimps]HBO | - | 20 | 75 |
| 05 | [mimbs]HBO | - | 30 | 69 |

[a] Reaction conditions: cyclohexanone (10 mmol), benzaldehyde (10 mmol), aniline (10 mmol), catalyst (5 mmol) r.t.
[b] yield in presence of solvent
[c] yield obtained at 60 °C
[d] yield obtained at 80 °C

The reaction with $I^-$ as anion, was also carried out with ethanol using same IL as catalyst using different temperatures but the results obtained were insignificant (Table 1). It was observed that IL based on propane sultone gave better yield than butane sultone based IL (entries 4 and 5 in Table 1). Furthermore it was also found that the IL formed from weak acid ($H_3BO_3$) gave better yield as compared to the IL which was formed from strong acid (HI).

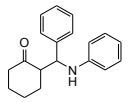
This observation might be rationalized on basis of pKa, which depicts that the reaction is catalyzed by conjugate bases ($I^-$ and $B(OH)_4^-$) of the protic acids (HI and $H_3BO_3$).

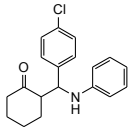
For determining the amount of IL used, the reaction of cyclohexanone (10 mmol), benzaldehyde (10 mmol), aniline (10 mmol) was catalyzed under variable amounts of [mimps]HBO at room temperature. It was found that the yields of the Mannich base was increased with the increase in the amount of [mimps]HBO (Table 2), where 5 mmol was found as an optimal amount.

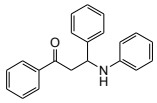
Table 2. Effect of amount of ionic liquid on Mannich reaction

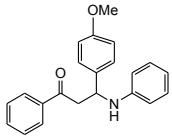
| Entry | Ionic Liquid (mmol) | Reaction Time (min) | Isolated Yield (%) |
|---|---|---|---|
| 01 | 0 | 24 h | 0 |
| 02 | 1 | 30 | 66 |
| 03 | 3 | 30 | 71 |
| 04 | 5 | 30 | 75 |
| 05 | 7 | 30 | 74 |
| 06 | 9 | 30 | 75 |

Mannich reaction was also conducted in polar and non-polar organic solvents to check the effect of solvent on the yield of product formed for estimation of the best reaction conditions. Herein the reaction of cyclohexanone, benzaldehyde and aniline was selected as standard reaction. It was found that the reaction in which no solvent was used gave the highest yield of 75% among the solvents selected showing that the ionic liquid may act as dual-reagent without need of any external solvent (Table 3).









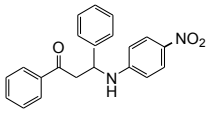


Table 3. Effect of ionic liquid/solvent on Mannich reaction[a]

| Entry | Ionic Liquid/Solvent | Isolated Yield |
|---|---|---|
| 01 | [mimps]HBO | 75 |
| 02 | [mimps]HBO/$H_2O$ | 70 |
| 03 | [mimps]HBO/$C_2H_5OH$ | 69 |
| 04 | [mimps]HBO/$CH_2Cl_2$ | 61 |
| 05 | [mimps]HBO/$C_6H_6$ | 39 |

[a] Reaction conditions: cyclohexanone (10 mmol), benzaldehyde (10 mmol), aniline (10 mmol), [mimps]HBO (5 mmol) r.t.

The Mannich reaction was further investigated with different aromatic aldehydes and anilines using [mimps]HBO. It was observed that aromatic aldehyde with electron-donating group produced higher yield of Mannich base as compared to that of electron withdrawing group (Table 4). In case of aromatic anilines, both electron withdrawing and electron-donating groups have been reported to be equally valuable for Mannich reaction [7]. The synthesis of Mannich bases was confirmed by physical and spectroscopic data and was found in good agreement with the previous reports.

Table 4. Preparation of –amino ketones using [mimps]HBO as catalyst

| Entry | $R_1$ | $R_2$ | H-Active Molecule | Product | Yield (%) | mp ($^oC$) (lit. mp) [ref] |
|---|---|---|---|---|---|---|
| 01 | H | H | $(CH_2)_5CO$ |  | 75 | 114 – 115 (115 – 116) [24] |
| 02 | 4-chloro | H | $(CH_2)_5CO$ |  | 73 | 133 – 134 (134 – 135) [25] |
| 03 | H | H | $C_6H_5CO$ |  | 75 | 168 – 169 (169 – 171) [26] |
| 04 | 4-methoxy | H | $C_6H_5CO$ |  | 74 | 150 – 151 151 – 152 [27] |
| 05 | H | 4-$NO_2$ | $C_6H_5CO$ |  | 72 | 184 – 186 183 – 185 [27] |

Regarding the reusability of ionic liquid, it was found that the IL could be successfully reused up to four cycles without considerable loss of activity (Table 5).

## Conclusion

Present methodology deals with a useful and effective way for synthesis of Mannich bases at room temperature in short reaction duration (20 minutes) and good yield (75%) using ILs as dual reagents. The reported synthetic method can be expected as an environmentally green procedure that might give valuable organic transformations by substituting conventional volatile, toxic and flammable organic solvents with ILs. Simple experimental and work up conditions along with reusability of IL can contribute a new method of green chemistry concept.

**Abstract**

*N*-glycans are biologically important oligosaccharides associated with the asparagine residue that may exist in protein-bound or unbound forms in all eukaryotes (including yeasts) and some bacteria. The- core structure of these oligosaccharides is based on the trimannosyl chitobiose structure resulting from cellular *N*-glycosylation. Preparative-scale amounts of these oligosaccharides are important for chemical, structural and functional studies due to their biological significance. Therefore, we explored a biochemical approach of oligosaccharide preparation using mutant-derived monoglucosylated lipid-linked oligosaccharides (LLOs) required for the assembly of *N*-linked glycoproteins and non-monoglucosylated free-oligosaccharides (fOSs) from misfolded *N*-linked glycoproteins using an *N*-glycosylation (*alg*) mutant of *Saccharomyces cerevisiae*. Oligosaccharide extracts of fOSs and LLOs from the *alg8 S. cerevisiae* mutant lacking the *ALG8* gene were profiled using fluorescence- and evaporative light scattering-based HPLC. LLOs did not produce accumulated levels of the target mutant- related monoglucosylated ($Glc_1Man_9GlcNAc_2$) at 100 ml scale. However, it was possible to detect truncated oligomannose (paucimannose) structures in the fOSs of the *alg8* mutant.

**Keywords**: *N*-linked glycosylation, *N*-glycans, Free oligosaccharides, Lipid-linked oligosaccharides, *Saccharomyces cerevisiae*

**Abstrak**

*N*-glikan merupakan oligosakarida yang penting dalam biologi yang bersekutu dengan residu asparagina yang hadir dalam keadaan terikat atau tidak terikat kepada protein dalam semua eukariot (termasuk yis) dan sesetengah bakteria. Struktur asas oligosakarida ini adalah berdasarkan struktur kitobiose trimanosa yang terhasil melalui pengglikosilan-*N*. Oligosakarida ini penting untuk kajian kimia, struktur dan fungsi disebabkan kepentingan biologinya. Oleh itu, kami telah mengkaji kaedah penyediaan oligosakarida dengan pendekatan biokimia menggunakan yis mutan (*alg*) *Saccharomyces cerevisiae* yang

menghasilkan monoglukosa oligosakarida terpaut-lipid (LLO) yang diperlukan dalam pengumpulan glikoprotein terpaut-*N* dan bukan-monoglukosa oligosakarida bebas (fOS) daripada glikoprotein terpaut-*N* silap lipatan. Ekstrak oligosakarida fOS dan LLO daripada mutan *alg8 S. cerevisiae* tanpa gen *ALG8* telah diprofil menggunakan KCPT-pendarfluor dan pengesan penyerakan cahaya sejatan. LLO didapati tidak menghasilkan sebatian sasaran monoglukosa ($Glc_1Man_9GlcNAc_2$) berkaitan-mutan pada skala 100 ml. Walau bagaimanapun, struktur fOS oligomanosa terpangkas (pausimanosa) boleh dikesan daripada mutan *alg8*.

**Kata kunci:** pengglikosilan terpaut-*N*, *N*-glikan, Oligosakarida bebas, Oligosakarida terpaut-lipid, *Saccharomyces cerevisiae*

## Introduction

Asparagine (*N*)-linked glycosylation is the most widespread form of modification found in secreted glycoproteins of all eukaryotes and some prokaryotes as part of the endoplasmic reticulum-associated degradation (ERAD) pathway [1]. These oligosaccharides are significant in various biological processes such as pathogenesis, development, fertility, protein biosynthesis and folding [2, 3]. The biosynthesis of these naturally occurring oligosaccharides begins in the endoplasmic reticulum (ER) with the assistance of the lipid carrier dolichol-pyrophosphate (Dol-PP) to form a lipid-linked triglucosylated high-mannose type oligomannose *N*-glycan. Subsequently, the Dol-PP lipid-linked oligosaccharide (LLO) is transferred co-translationally by oligosaccharyltransferase (OST) to an asparagine residue of a nascent polypeptide within N-X-S/T sequence (N = asparagine, X = any amino acid except proline, S = serine, T = threonine) to produce $Glc_3Man_9GlcNAc_2$ *N*-linked glycoproteins in the ER. Triglucosylated *N*-glycoproteins are further processed by ER glucosidases I and II to generate monoglucosylated $Glc_1Man_9GlcNAc_2$ and non-glucosylated $Man_9GlcNAc_2$ on partially folded proteins. Both these high-mannose type *N*-glycan structures play a critical role in ERAD-controlled protein folding via interaction with the molecular chaperones calreticulin and calnexin [4]. After the initial phase of biosynthesis and protein folding quality control in the ER, these oligomannoses will be trimmed for either further (1) expansion in the Golgi with other mannose or non-mannose units such as galactose, galactosamine, glucosamine, xylose and sialic acid for secretion as glycoproteins or (2) truncation as protein unbound oligosaccharides in the cytosol and lysosome. Therefore, the lipid-linked and protein-unbound *N*-glycans may represent a naturally occurring source for the scalable production of these oligosaccharides using a biochemical (mutant) approach as opposed to using chemical synthesis. In the ER, units of monosaccharides are linked to each other by the asparagine-linked glycosylation (*ALG) 1* to *14* genes encoding *N*-glycosylation enzymes. Mutations involving *ALG* genes will produce accumulation of the biosynthetically relevant *N*-glycan isomers. For example, absence of the *ALG8* gene that is responsible for the formation of $Glc_2Man_9GlcNAc_2$ will result in the accumulation of the $Glc_1Man_9GlcNAc_2$ *N*-glycan LLO [5]. Therefore, this study explored the production of high-mannose type *N*-glycans using the *alg8* mutant to obtain monoglucosylated and non-glucosylated *N*-glycans.

Among the many uses of obtaining sufficient quantity of *N*-glycans would be for structural/conformational studies such as to probe the critical role N-glycans play in the ERAD pathway [6]. Conformational studies of *N*-glycans is mainly based on NMR and molecular dynamics. The structural determination of glycans is beset by the limited spectral dispersion of 1D NMR ($^1H$ and $^{13}C$ nuclei). Although, using 2D NMR spectroscopy facilitates the process of resonance and linkage assignments, it is still tedious and time-consuming [7]. Isotope labelling especially $^{13}C$ and preparative-scale analysis of *N*-glycans can significantly reduce analytical time and allow higher dimensional 3D and 4D NMR experiments to be carried out as routinely done in protein NMR. Additionally, *N*-glycans can be used as valuable analytical standards or as natural substrates for enzyme assays. The preparative-scale production of glycans is also beneficial for the synthesis of glycoconjugates. For example, glycans can be employed in bioorthogonal click chemistry to tag relevant protein substrates for proteomics analysis combining metabolic engineering and mass spectrometry. These tags facilitate the discovery of biomarkers involved in disease development through the screening of disease-related glycans and glycoproteins [8].

Preparative amounts of *N*-glycans have been produced through total chemical synthesis, chemoenzymatic synthesis and isolation from natural sources [9, 10]. Total chemical synthesis is by far the most challenging especially for larger and/or conjugated glycans such as glycoproteins and glycolipids. *N*-glycans obtained from *N*-linked glycoproteins and LLOs as well as fOS have been analysed in cells. However, the preparative scale production of *N*-glycans in previous reports have been complicated by the enzymatic (PNGase/Endo-H-treatment) or chemical (hydrazinolysis-based) release of *N*-glycans from glycoproteins and tedious solvent-partitioning extractions steps

for LLOs [11]. Commercially obtained PNGase F is expensive, and hydrazine is an explosive hazard for sugar-release at the preparative-scale. Therefore, we investigated the use of LLOs and fOSs from a mutant *Saccharomyces cerevisiae* strain (*alg8*) as source of *N*-glycans to: (1) obviate the need for sugar release and tedious solvent extraction and (2) obtain target *N*-glycans i.e the use of the *alg8* mutant to obtain monoglucosylated structure(s) from LLOs and non-target *N*-glycans from fOSs.

## Materials and Methods

### Reagents

Yeast Nitrogen Base (YNB), selected amino acids, acid-washed glass beads, AG50W-X12 ($H^+$ form), AG2-X8 ($Cl^-$ form) and DEAE-cellulose were kindly gifted by the Oxford Glycobiology Institute, University of Oxford. Water was obtained from The Pacific UP6 TKA system was used to obtain pure water. Other materials were purchased from major vendors such as Sigma and Merck unless stated otherwise.

### Yeast strains and culture conditions

The *Saccharomyces cerevisiae* strains used in this study were BY4743 (MATa/α his3Δ1/his3Δ1 leu2Δ0/leu2Δ0 met15Δ0/MET15 lys2Δ0/LYS2 ura3Δ0/ura3Δ0) and YOR067C BY4743 (MATa/α his3Δ1/his3Δ1 leu2Δ0/leu2Δ0 met15Δ0/MET15 lys2Δ0/LYS2 ura3Δ0/ura3Δ0 Δ*alg8*::kanMX4) from Dharmacon, GE Healthcare. Both yeast strains were grown aerobically in Yeast Nitrogen Base (YNB) medium (100 ml) containing 2% (w/v) glucose and 2% (w/v) selected-amino acids (4 mg/ml histidine, 4 mg/ml uracil, 4 mg/ml methionine and 12 mg/ml leucine) in a rotary shaker (180 rpm) at 30 $^oC$.

### Extraction of LLOs

The LLOs were extracted using a previously described method [12]. The cell pellets were harvested by centrifugation (2500 rpm/ 1200 × *g*, 8 min; same parameters used for the rest of this protocol) and washed using phosphate-buffered saline (PBS) three times. Methanol (10 ml) was added and the cells were transferred into glass tubes (10 ml). Sonication was performed for 10 minutes using a water bath-type sonicator and dried under $N_2$ gas. A chloroform-methanol (2:1; 10 ml) solution was added into the tubes, sonicated, vortexed, centrifuged and the supernatant discarded. The cells were resuspended in methanol again, sonicated for 10 minutes and dried under $N_2$ gas. The chloroform-methanol extraction procedure was repeated, but this time using 10 ml water and subsequently chloroform-methanol-water (CMW) (10:10:3; 10 ml). The supernatants from the final centrifugation were collected for further LLO extraction. For LLO partial purification, each CMW extract was run through a DEAE-cellulose column pre-equilibrated with CMW. After sample loading, the column was washed using 10 bed volumes of CMW followed by 10 bed volumes of 3 mM acetic acid in CMW. Elution was carried out using 10 bed volumes of 300 mM $NH_4OAc$ in CMW. Chloroform (4.3 bed volumes) and water (1.2 bed volumes) were added into the collection tubes, vortexed and centrifuged which resulted in three phases. The upper layer was removed and the remaining layers (middle and lower) were dried using $N_2$ gas. For oligosaccharides released from LLOs, 2 ml of 0.1 N HCl in 50% isopropanol was added into the dried samples, vortexed, incubated for 1 hour at 50 $^oC$ and dried under $N_2$ gas. Butanol-saturated water (1 ml) was added, vortexed. After that, 1 ml of water-saturated butanol was added before centrifugation, and the lower phase was recovered after centrifugation and freeze-dried. The dried residues were resuspended in 1 ml water to which 200 µl of AG50W-X12 ($H^+$ form) was added, vortexed, and centrifuged. The supernatant was collected and added to 200 µl of AG2-X8 ($Cl^-$ form) that was vortexed and then centrifuged. The oligosaccharides released from LLOs were obtained from the recovered supernatant.

### Extraction of fOSs

fOSs were extracted by a previously described method [13]. Briefly, the harvest step was the same as LLO extraction, i.e. cells were recovered by centrifugation and the medium discarded. PBS buffer was added into the tube containing the cells and washed three times. Then, the cells were snap-frozen using liquid nitrogen for 10 seconds and thawed three times. One volume of lysis buffer (100 mM Tris-HCl, pH 7.4 containing 4 mM $MgCl_2$) and acid-washed glass beads were added into the tube, vortexed for 30 seconds (six times) and the cell debris removed by centrifugation. The supernatants were desalted by mixed-bed ion exchange column (0.1 ml of AG50W-X12 [$H^+$ form] over 0.2 ml AG8-X2 [$Cl^-$ form]), pre-equilibrated with 5 × 1 ml water, followed by loading and washing with 4 × 1 ml. The eluate was collected for further analysis.

**Phenol-sulfuric acid assay**

The concentration of oligosaccharides in the extracted fOS samples were determined using the microtiter phenol-sulfuric acid assay (PSA) instead of the conventional tube-based assay [14]. Three types of samples were prepared; blank, standard and samples. The blank was the solvent used for dissolving the standards and samples. A series of known glucose standard concentrations ranging from 0.05 to 1.0 mg/ml was prepared. For each 50 µl sample, 150 µl of concentrated sulfuric acid was added rapidly into a well of a 96-well microplate for maximum mixing. Immediately after acid-mixing, 30 µl of 5% phenol was added followed by incubation at 90 $^{o}$C for 5 minutes using a water bath. The plate was floated carefully to avoid any sample leakage. The plate was cooled for a few minutes and wiped dry to measure the absorbance at 490 nm ($A_{490nm}$) using a microplate reader.

**Carbohydrate fluorescence labelling**

The carbohydrates were labelled with 2-anthranilic acid (2-AA) as previously described [15]. For the labelling reaction, 30 mg of 2-AA was dissolved in 1 ml methanol containing 4% (w/v) sodium acetate trihydrate and 2% (w/v) boric acid, followed by the addition of 45 mg sodium cyanoborohydride addition. Labelling reagent (80 µl) was added to each sample (30 µl) and mixed well before incubation in a heating block for 80 $^{o}$C for 45-60 minutes. The reaction was cooled at room temperature and 1 ml of acetonitrile/water (97:3, v/v) was added. The labelled samples were then further purified using Discovery DPA-6S column pre-equilibrated with 1 column volume of acetonitrile water. The column was washed with 95% acetonitrile after sample loading and eluted with 2 × 0.75 ml of water which was collected.

**Carbohydrate analysis by HPLC-ELSD**

The unlabelled samples were analysed by HPLC (Dionex UltiMate 3000 LC System) using an XBridge™ amide column, 3.5 µm; 4.6 x 250 mm (Waters) coupled to an evaporative light scattering detector (ELSD) PS-ELS 2100 Ice (Polymer Laboratories) connected to nitrogen generator. The detector was set as follows: vaporisation temperature = 55 $^{o}$C; gas flow = 1.6 slm (standard litre per minute); light intensity = 100%; gain = 1.0; nebulisation = 30 $^{o}$C. Solvent A contained 20% 100 mM ammonium acetate, pH 3.85, in Milli-Q water and 80% acetonitrile. Solvent B contained 20% 100 mM ammonium acetate, pH 3.85, in Milli-Q water, 60% Milli-Q water, and 20% acetonitrile. Gradient conditions for carbohydrate analysis were as follows: time = 0 min (t = 0), 86% solvent A (0.8 ml/min); t = 6, 86% solvent A (0.8 ml/min); t = 35, 54.7% solvent A (0.8 ml/min); t = 37, 5% solvent A (0.8 ml/min); t = 39, 5% solvent A (0.8 ml/min); t = 41, 86% solvent A (0.8 ml/min); t = 60, 86% solvent A (0.8 ml/min) [15]. Samples were dissolved in Milli-Q water/acetonitrile (2:8, v/v) and injected using an autosampler (50 µl per injection).

**Carbohydrate analysis by HPLC-FD**

The 2-AA labelled samples were kindly analysed by the Oxford Glycobiology Institute, University of Oxford, United Kingdom using normal phase-HPLC with a 4.6 mm × 250 mm TSK gel-Amide 80 column (5 µm) (Anachem, Luton, Beds, U.K) as described previously [15]. The chromatography system consisted of Waters Alliance 2695 separations module and an in-line Waters 474 fluorescence detector (FD) set at Exλ 360 nm and Emλ 425 nm. Solvent A and B were prepared as described above for the HPLC-ELSD analysis. Gradient conditions for carbohydrate analysis were as follows: time = 0 min (t = 0), 86% solvent A (0.8 ml/min); t = 6, 86% solvent A (0.8 ml/min); t = 35, 54.7% solvent A (0.8 ml/min); t = 37, 5% solvent A (1 ml/min); t = 39, 5% solvent A (1 ml/min); t = 41, 86% solvent A (1 ml/min). Samples were injected in Milli-Q water/acetonitrile (2:8, v/v).

## Results and Discussion

**Yeasts growth**

Monoglucosylated structures of LLOs were expected to be accumulated with the deletion of the *ALG8* gene in the LLO biosynthesis pathway. However, fOS was produced through deglycosylation of misfolded glycoprotein by the enzyme PNGase F. This enzyme is known to be regulated in a growth-dependent manner [13]. Under standard culture and laboratory conditions, wild type *S. cerevisiae* reaches the stationary phase, approximately, after 6 days [16]. Based on this, larger fOSs ($Man_{7-9}GlcNAc_2$) were usually observed at the exponential phase and the presence of these glycans were much reduced after six days of culture [13]. Thus, we generated a growth curve for the parental and mutant yeast strains to harvest cells in the appropriate growth phase. Figure 1 shows the growth pattern of the parental and mutant strains of the yeasts for 4 days. The growth curve intercepted each other after 3 days of

culture the parental strain almost reached the stationary phase by day 3. However, mutant strain still increased after the third day and was expected to reach the stationary phase after 6 days as described previously. Hence, we decided to harvest the cells after 2 days because both yeasts showed a steady increase in growth and the larger glycans are accumulated in this phase.

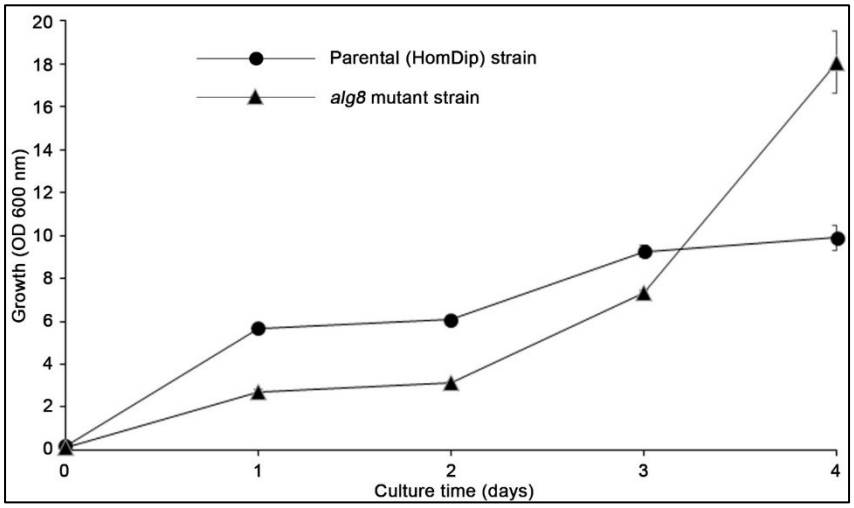

Figure 1. The growth curve of parental (HomDip) and *alg8* mutant strains

**Total concentration of carbohydrates in fOS extracts**

The total concentration of carbohydrates was determined using the PSA assay. A standard curve for quantification was generated using glucose. The linear equation generated from the standard curve shown to calculate sample concentrations was y = 1.115x - 0.008 ($R^2$ = 0.995) (Figure 2). The total oligosaccharide content of only the fOS samples were determined due to the negligible amounts of LLO extracted that were too little to be weighed (< 1 mg) and detection of very weak peaks by fluorescence-based HPLC. Comparison of between the fOS crude extracts of the parent and mutant strains showed that the concentration of carbohydrates was higher in the parent strain than the mutant strain. The values were also comparable to levels to the difference in OD readings measuring growth.

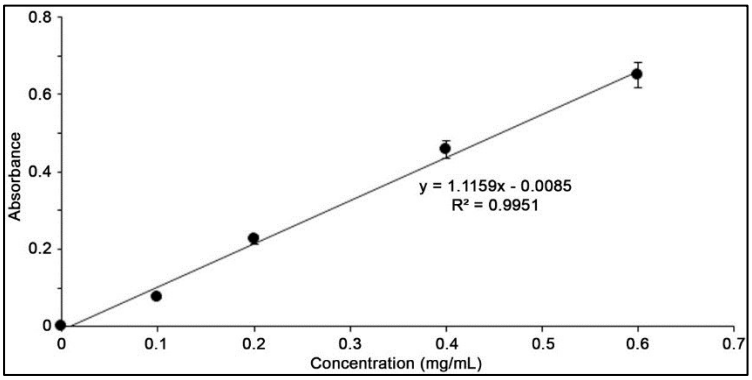

Figure 2. Standard curve of glucose for total carbohydrate content determination (PSA method)

Table 1. Crude samples total carbohydrate concentration of parental and mutant strains

| Samples | Concentration (mg/ml of cell lysate) |
|---|---|
| Parent strain (crude sample) | 2.83 |
| *alg8* mutant strain (crude sample) | 2.06 |

**Analysis of LLOs and fOSs with HPLC-ELSD and HPLC-FD**

HPLC analysis on the samples was carried out using ELSD and FD. The former mode of detection was universal and less sensitive whereas the latter was selective and highly sensitive. The dextran molecular weight ladder standard (0.1 mg/ml), LLOs and fOS extracted from parental and *alg8* mutant strains were analysed and shown in Figures 3 – 6. The HPLC-ELSD and FD chromatograms of the dextran ladder demonstrated good separation of peaks representing carbohydrates (glucose unit: GU) of difference sizes (ELSD: GU1 to GU12; and FD: GU1-GU13). Some of the HPLC-ELSD peaks were broad and slightly spilt. This is most probably a result of different configurations (α/β isomers) of the unlabeled sugar unit at the reducing end [17]. The 2AA-labelled fOS FD chromatogram showed a more complex profile of peaks than the unlabeled fOS ELSD chromatogram (Figures 3 and 5). fOS extract peaks appearing at lower retention times corresponding to ≤ GU3 were abundant in both the ELSD and FD chromatograms. In the FD chromatogram, these peaks were present at extremely high intensities exceeding the detection threshold of fluorescent detection (≥10 000 mV) (data not shown). The profiles suggested that ELS detection was not suitable (insensitive) for carbohydrate profiling on this scale of culture compared to fluorescence detection.

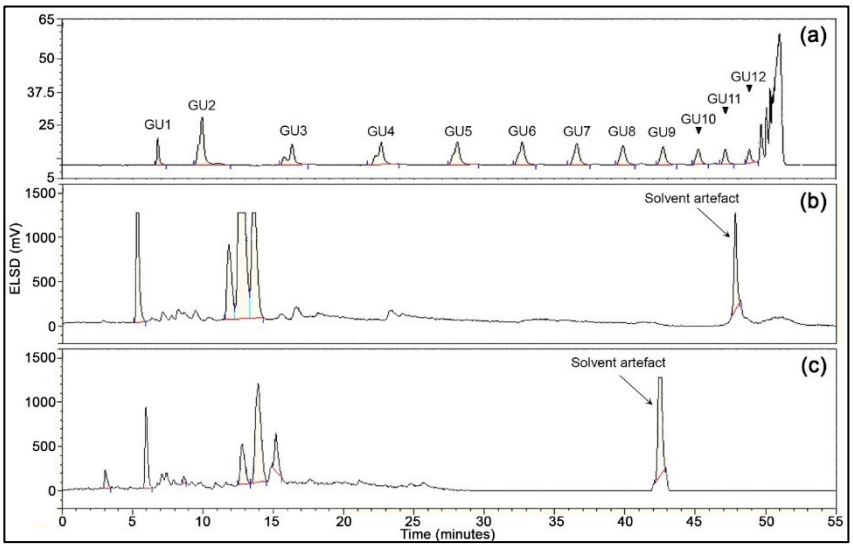

Figure 3. HPLC-ELSD analysis of (a) standard dextran and unlabeled fOS from (b) parental and (c) mutant strains

The major peaks in the HPLC profiles were more abundant in the parental strain. The common present in parent and mutant) abundant peaks present in both the parent and mutant may correspond to β-glucans associated with the cell wall of yeast have been extracted in fOS samples [18]. HPLC peaks were assigned using the glucose unit analysis method via the calculation of GU values calibrated to the dextran mixture standard for comparison to the values of known structures (Figure 6 and 7) [19, 20]. Based on this approach, two additional and abundant peaks with lower GU values were present in the *alg8* mutant. The additional peaks in the mutant had low GU values at 5.30 ($R_t$ = 23.0) and 6.47 ($R_t$ = 27.7) corresponding to the paucimannose *N*-glycans $Man_5GlcNAc_2$ and $Man_6GlcNAc_2$, respectively (Figure 5) [19, 20]. This is due to the truncation of free monoglucosylated $Man_9GlcNAc_2$ from

misfolded *N*-linked glycoproteins by glucosidse II and mannosidases in the ERAD pathway. For the two reported peaks, $Man_6GlcNAc_2$ was trimmed by α-1,2-mannosidase in ER to produce $Man_5GlcNAc_2$. In addition, the known absence of Endoglycosidase-H (Endo-H) in *S. cerevisiae* suggested that the glycan structures should be present with two GlcNAc units instead of one because, under normal circumstances, the presence of Endo-H will cleave chitobiose [21]. Our results show that the accumulation of fOSs from the lysate of *alg8 S. cerevisiae* mutant was more abundant than LLOs at the same scale of culture. Although LLOs did not show accumulation of the target *N*-glycan $Glc_1Man_9GlcNAc_2$, elevated levels of truncated oligomannose (paucimannose) *N*-glycans $Man_5GlcNAc_2$ and $Man_6GlcNAc_2$ were detected in fOSs using the *alg8* mutant.

## Conclusions

fOSs from *S. cerevisiae* afforded higher amounts of oligosaccharides than LLO at the same scale of culture (100 ml). Accumulation of the monoglucosylated $Glc_1Man_9GlcNAc_1$ and/or its mannose-truncated forms was not observed in the LLOs of the *alg8 S. cerevisiae* mutant. However, accumulation of truncated oligomannoses (paucimannoses) $Man_5GlcNAc_2$ and $Man_6GlcNAc_2$ was only observed in the fOS extract of the same mutant.

**Abstract**

Benzothiazoles are an important class of pharmaceutical drug with various therapeutic activities. In this work, an efficient and eco-friendly method of synthesizing of benzothiazole derivatives via ultrasonic probe irradiation was described here. Through the improved protocol, the benzothiazole derivatives were prepared with various benzaldehyde and 2-aminothiophenol. The yields were found to be in moderate to good yields, ranging from 65 – 83%. Among the advantages of this procedure as compared to the conventional methods of synthesizing benzothiazoles include simplicity in the procedure, solvent-, catalyst- free reaction and the improved protocol afforded compounds (**4a-4i**) within 20 minutes at room temperature. The current improved protocol could be extended for the synthesis of other bioactive heterocyclic compounds in future work.

**Keywords**: benzothiazole, ultrasound, solvent-free, catalyst-free.

**Abstrak**

Benzotiazola adalah kelas ubat farmaseutikal yang penting dengan pelbagai aktiviti terapeutik. Dalam kajian ini, satu kaedah yang efisien dan mesra alam bagi sintesis terbitan benzotiazola dengan menggunakan prob penyinaran ultrasonik dibincangkan. Melalui kaedah yang ditambahbaik, terbitan benzotiazola dapat disediakan melalui pelbagai benzaldehid dan 2-aminatiofenol. Peratusan hasil produk didapati dari sederhana hingga baik, iaitu antara julat 65 – 83%. Kelebihan protokol ini berbanding dengan kaedah – kaedah konvensional bagi sintesis terbitan benzatiazola, termasuk prosedur yang mudah, tanpa penggunaan pelarut, tanpa pemangkin dan protokol yang ditambahbaik menghasilkan sebatian (4a-4i) dalam masa 20 minit pada suhu bilik. Kaedah yang ditambahbaik kini boleh diperluaskan untuk sintesis sebatian heterosiklik bioaktif lain dalam kajian masa hadapan.

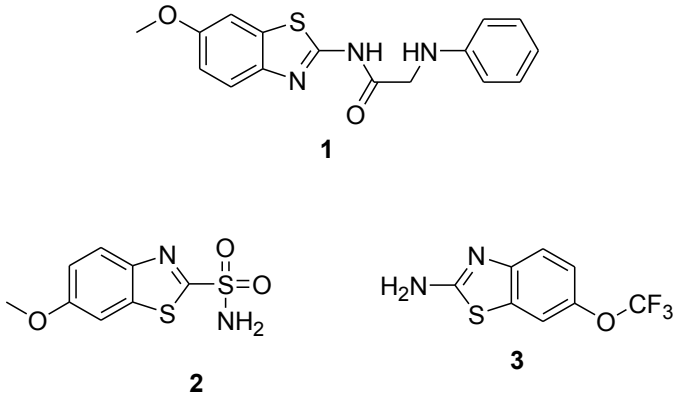
**Kata kunci:** benzotiazola, prob penyinaran ultrasonik, tanpa pengunaan pelarut, tanpa penggunaan pemangkin

## Introduction

Benzothiazoles belong to an important class of pharmaceutical drug that possesses many desirable biological activities, such as antibacterial [1], anticonvulsant [2], anticancer [3], antifungal [4], antimitotic [5], and antitumor [6] properties. Examples of pharmaceutical drugs that contain the benzothiazole moiety include frentizole **1** (an immunosuppressive agent) [7]; ethoxyzolamide **2** (a carbonic anhydrase inhibitor) [8] and riluzole **3** (a registered drug used to treat patients with amyotrophic lateral sclerosis) [9] (Figure 1). In the past, various synthetic pathways for the synthesis of benzothiazole and its derivatives have been reported, including the utilization of microwave

irradiation [10], reusable metal-based catalysis [11], utilization of rare earth based nanocatalyst coupled with ultrasound irradiation [12] and utilization of water in combination with ionic liquid system [13]. Although there is an effort to improve on the efficiency of benzothiazole synthesis, most of these reactions suffer from drawbacks such as less eco-friendly, long reaction time and use of additives in synthesizing benzothiazole derivatives [14]. To that end, method development in the search for a simple and efficient synthetic route for synthesizing bioactive compounds has always been one of the major challenges in organic synthesis research works.

Over the years, the application of ultrasound in chemical synthesis has been an attractive and efficient method, especially to overcome the low reaction rate in chemical synthesis [15]. For instance, a solventless ultrasound-mediated reaction for the synthesis of thiazolo[3,2-a]pyrimidine derivatives have been successfully carried out with good yields [16]. Besides, a shorter reaction time was reported on the production of 2,4,5-trisubstituted imidazoles using Selectfluor™ as catalyst with the employment of ultrasound technique [17]. A green synthesis of sulfonamides with the aid of a natural, efficient and reusable Natrolite nanozeolite catalyst under ultrasound irradiation was also disclosed recently [18]. The utilization of ultrasound in organic reactions can overcome poor mass transfer and interaction between reactants. Through this technique, tremendous amount of energies for chemical activation was supplied by the means of cavitation through bubbles formation, expansion and rupture, which led to a better interaction between reactants [19]. To date, a vast number of useful organic compounds have been generated by using the ultrasound method [20].



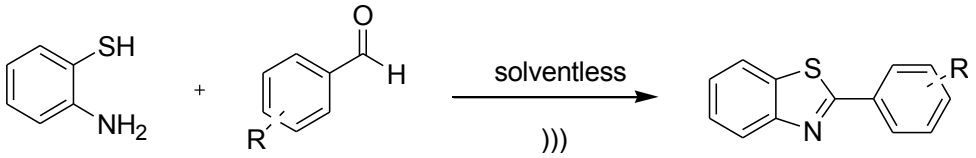


Figure 1. The benzothiazole drugs used for the treatment of various diseases. 1= frentizole. 2 = ethoxyzolamide and 3 = riluzole

In our continuous efforts to search for an efficient method for synthesizing bioactive heterocyclic compounds, herein, we reported on the synthesis of benzothiazole and their derivatives under ultrasound probe irradiation by using 2-aminothiophenol and benzaldehydes as starting materials (Scheme 1).

## Materials and Methods

### Materials and instrumentation

All the chemicals and solvents used in this study were of technical grade and were supplied by Merck, Acros Organics and HmbG® chemicals and were used without further purification. These chemicals include

benzaldehyde, 2-chlorobenzaldehyde, 3-chlorobenzldehyde, 4-chlorobenzaldehyde, 2-fluorobenzaldehyde, 4-fluorobenzldehyde, 4-bromobenzaldehyde, 4-isoporpylbenzaldehyde, 4-methoxybenzaldehyde, ethyl acetate, n-hexane and silica gel 60 (0.063-0.200 mm). The FT-IR spectra were recorded using Perkin Elmer 100 FT-IR spectrometer, in spectral range of 4000-400 cm-1. $^{1}$H and $^{13}$C-NMR spectra were recorded on Bruker Avance III 400 spectrometer, with deuterated chloroform as solvent at room temperature at 400 MHz. GC-MS analyses were carried out using Shimadzu QP2010SE. Normal phase GC-MS analysis used a Supelco fused silica capillary column (30 m × 0.25 mm i.d., 0.25 mm film thickness). The aliquot samples were injected directly onto GCMS with methanol as solvent. The oven was held at 50 °C for 5 min, subsequently heated at a gradient of 20 °C/min to 150 °C, 280 °C injector temperature; 100:1 split ratio and 1.0 mL/min flow.

**Synthesis procedure for benzothiazole derivatives 4a-4h.**
2-aminothiophenol (3.00 mmol) was added into benzaldehyde derivatives (3.00 mmol) and the mixture was irradiated under ultrasonic probe for 20 min. The crude product was then purified over silica gel column chromatography (Hexane: Ethyl acetate = 9.5:0.5, v/v) to afford the title compounds **4a-4h** except for compound **4i** which was purified with a different solvent system (Hexane: Ethyl acetate = 8.5:1.5, v/v) over silica gel column chromatography.

## Results and Discussion

**Physical and spectral data**
The spectroscopic data of the synthesized compounds **4a-4i** is as follows:

**(4a)** 2-phenylbenzothiazole
M.p: 112.0 $^{o}$C; IR (cm$^{-1}$): 3064.99, 1589.52-1433.53; $^{1}$H- NMR (ppm): 7.42 (t, 1H), 7.51-7.53 (m, 4H), 7.91-7.93 (d, *J*= 8.0 Hz, 1H), 8.14 (m, 3H); $^{13}$C- NMR (ppm): 122.09, 124.35, 125.48, 126.66, 127.60, 128.07, 130.19, 133.75, 136.06, 152.54, 167.30. GC-MS: m/z 211 [M]$^{+}$.

**(4b)** 2-(2-chlorophenyl) benzothiazole
M.p: 84.0 $^{o}$C; IR (cm$^{-1}$): 3067.21, 1586.06-1441.40, 750.09; $^{1}$H- NMR (ppm): 7.43-7.36 (m, 3H), 7.53-7.51 (m, 2H), 8.12 (d, *J*= 8.1 Hz, 1H), 8.21-8.23 (m, 1H) ; $^{13}$C- NMR (ppm): 121.3, 123.3, 125.4, 126,3, 127.2, 130.6, 131.5, 132.4, 132.5, 136.3, 152.4.4, 164.2 GC-MS: m/z 245 [M]$^{+}$.

**(4c)** 2-(3-chlorophenyl) benzothiazole
M.p: 97.0 $^{o}$C; IR (cm$^{-1}$): 3075.40, 1580.54-1430.01, 751.87; $^{1}$H- NMR (ppm): 7.51-7.34 (d, *J*= 8.0 Hz, 2H), 8.00 (d, *J*= 8.5 Hz, 2H) 8.05 (d, *J*= 8.1 Hz, 1H); $^{13}$C- NMR (ppm): 121.4, 123.4, 125.3, 126,4, 128.6, 129.0, 132.0, 135.1, 137.1, 154.3, 166.4. GC-MS: m/z 245 [M]$^{+}$.

**(4d)** 2-(4-chlorophenyl) benzothiazole
M.p: 117.0 $^{o}$C; IR (cm$^{-1}$): 3065.40, 1543.21-1421.34, 752.34; $^{1}$H- NMR (ppm): 7.21-7.15 (m, 2H), 7.39 (t, *J*= 7.5 Hz, 1H), 7.51 (t, *J*= 7.9 Hz, 1H), 7.86 (d, *J*= 7.9 Hz, 1H), 8.04-8.06 (m, 3H); $^{13}$C- NMR (ppm): 16.3, 121.4, 123.3, 125.4, 126.5, 129.2, 130.2, 135.2, 135.4, 154.3, 163.5, 166.0. GC-MS: m/z 245 [M]$^{+}$.

**(4e)** 2-(2-fluorophenyl) benzothiazole
M.p:67.0 $^{o}$C; IR (cm$^{-1}$): 3055.60, 1590.54-1434.68, 756.79; $^{1}$H- NMR (ppm): 7.21 (d, *J*= 7.5 Hz, 1H), 7.31 (d, *J*= 7.5 Hz, 1H), 7.31 (t, *J*= 7.8 Hz, 2H), 7.45 (m, 3H), 7.93 (d, *J*= 8.1 Hz, 1H), 8.11 (d, *J*= 8.1 Hz, 1H), 8.40, (t, *J*= 7.5 Hz, 1H) ; $^{13}$C- NMR (ppm): 116.3, 121.5, 123.4, 124.5, 124.6, 125.2, 126.2, 129.4, 132.0, 135.6, 152.4, 160.0, 162.1. GC-MS: m/z 229 [M]$^{+}$.

**(4f)** 2-(4-fluorophenyl) benzothiazole
M.p:100.0 $^{o}$C; IR (cm$^{-1}$): 3049.20, 1591.54-1484.22, 829.28; $^{1}$H- NMR (ppm): 7.21 (d, *J*= 7.5 Hz, 1H), 7.31 (d, *J*= 7.5 Hz, 1H), 7.31 (t, *J*= 7.8 Hz, 2H), 7.45 (m, 3H), 7.93 (d, *J*= 8.1 Hz, 1H), 8.11 (d, *J*= 8.1 Hz, 1H), 8.40, (t, *J*= 7.5 Hz, 1H) ; $^{13}$C- NMR (ppm): 116.3, 121.5, 123.4, 124.5, 124.6, 125.2, 126.2, 129.4, 132.0, 135.6, 152.4, 160.0, 162.1. GC-MS: m/z 229 [M]$^{+}$.

**(4g)** 2-(4-bromophenyl) benzothiazole
M.p:131.0 $^{o}$C; IR (cm$^{-1}$): 3005.60, 1604-1408.68, 689.79; $^{1}$H- NMR (ppm): 7.38 (t, *J*= 7.6 Hz, 1H), 7.51 (t, *J*= 7.5 Hz, 1H), 7.66-7.61, (m, 2H), 7.87 (d, *J*= 7.7 Hz, 1H), 7.94 (d, *J*= 8.7 Hz, 2H), 8.05 (d, *J*= 8.1 Hz, 1H) ; $^{13}$C- NMR (ppm): 121.4, 123.3, 125.2, 125,3, 126.4, 128.8, 132.1, 132.4, 135.1, 154.2, 166.5. GC-MS: m/z 288 $[M]^{+}$.

**(4h)** 2-(4-isopropylphenyl) benzothiazole
M.p: 119.0 $^{o}$C; IR (cm-$^{1}$): 2956, 2981, 1602.01-1484.00, 967.89; $^{1}$H- NMR (ppm): 1.25 (d, *J*= 7.3 Hz, 6H), 2.86 (m, 1H), 7.42-7.51, (m, 2H), 7.60-7.63 (m, 2H), 7.74-7.83 (m, 2H), 8.04-8.12 (m, 2H); $^{13}$C- NMR (ppm): 23.5, 34.1, 122.2, 122.5, 125.2, 125.4, 127.3, 128.2, 140.1, 149.0, 149.2, 153.1, 169.4. GC-MS: m/z 253 $[M]^{+}$.

**(4i)** 2-(4-methoxyphenyl) benzothiazole
M.p: 289.0 $^{o}$C; IR (cm$^{-1}$): 3382.00, 1613-1431.00, 811.00; $^{1}$H- NMR (ppm): 7.87-8.06 (m, 4H), 7.51 (t, *J*= 7.3 Hz, 1H), 7.38, (t, *J* = 7.4 Hz, 1H), 7.07 (d, *J*= 8.2 Hz, 2H), 3.8 (s, 3H); $^{13}$C- NMR (ppm): 55.3, 114.6, 122.2, 122.3, 125.1, 125.4, 126.3, 128.7, 134.1, 153.5, 161.6, 167.0. GC-MS: m/z 124.0 $[M]^{+}$.

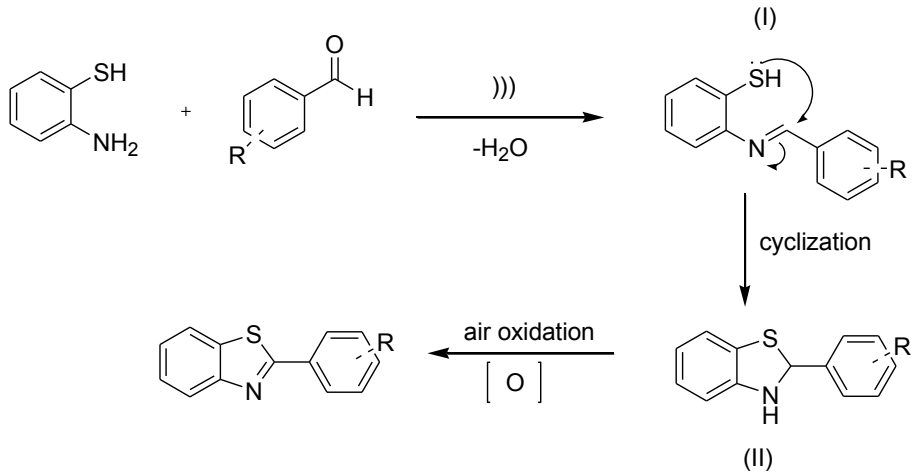
For the preliminary reaction, the optimized condition was determined by using a model reaction where 2-aminothiophenol and benzaldehyde were reacted in the presence of ultrasound probe irradiation to yield the corresponding product **4a**. Based on the preliminary study, the yield of **4a** has reached a plateau at 51 W power and the reaction yield was recorded at 83 % after 20 min of sonication (Table 1). The synthesis of other benzothiazole derivatives was repeated by using this optimized condition and the improved protocol was also employed for other comparative study.

The effectiveness of the improved protocol was also evaluated by comparing it with ultrasonic bath method and conventional heating method, using the synthesis of **4a** as the model reaction (Table 2). Under the ultrasonic bath method, there was no reaction occurred for the first 20 min at constant room temperature. While, after the reaction proceeded for 30 min, only less than 10 % yield of **4a** was recorded. The main reason for the low yield may due to inadequate heat energy produced in the reaction to agitate the reaction medium and thus required longer reaction time to produce compound **4a**. In contrast, the synthesis of **4a** under conventional heating method has recorded a 60 % yield when the reaction was heated under reflux with methanol as solvent for 6 h. Hence, it is evident that the ultrasound probe irradiation method under solvent- and catalyst-free condition gave the best yield as compared to the ultrasonic bath and conventional heating methods.

Table 1. The ultrasound yields of **4a** under solvent- and catalyst-free conditions

| Entry | Power (W) | Time (min) | Isolated Yield (%) |
|---|---|---|---|
| 1 | 46 | 5 | 60 |
| 2 | 48 | 10 | 70 |
| 3 | 50 | 15 | 73 |
| 4 | 51 | 20 | 83 |
| 5 | 51 | 25 | 83 |
| 6 | 51 | 30 | 83 |
| 7 | 53 | 25 | 83 |

Table 2. The yield of **4a** under ultrasonic bath irradiation and silent condition



| Time (min) | Isolated Yield (%) | |
|---|---|---|
| | Sonication | Conventional |
| 10 | 0 | - |
| 20 | 0 | - |
| 30 | 7 | - |
| 120 | - | 20 |
| 360 | - | 60 |

Next, we attempt to widen the scope of our study by synthesizing different substituted benzothiazole derivatives by using several electron-donating and electron-withdrawing benzaldehydes under solvent- and catalysts-free ultrasound probe irradiation. As indicated in Table 3, the condensation of different benzaldehydes and 2-aminothiophenol proceeded smoothly under the improved protocol and afforded the title compounds (**4a**-**4i**) in moderate to good yields (65 – 83%) within 20 minutes at room temperature. The electronic effect and the position of the substitution on the benzaldehydes were found to have negligible effect in the reactivity of the synthesis of benzothiazole derivatives (Table 3, **4b** -**4g** vs. **4h**-**4i**). The result of this study was congruent with a previous study on the synthesis of the benzothiazole derivatives using ammonium nickel sulfate in the presence of water assisted by ultrasound irradiation method [21]. The major advantages of this technique include short reaction time, solvent- and catalyst-free reaction condition and the final products were obtained in moderate to good yields in comparison to previous method [11, 12, 13].

Table 3. Isolated yields obtained for compounds **4a-4i**

| Entry | Product No. | R | Isolated Yield (%) | M. P ($^{o}$C) Observed | M. P ($^{o}$C) Reported |
|---|---|---|---|---|---|
| 1 | 4a | H | 83 | 112 | 112-114 [22] |
| 2 | 4b | 2-Cl | 70 | 84 | 84-85 [22] |
| 3 | 4c | 3-Cl | 65 | 97 | 97-98 [22] |
| 4 | 4d | 4-Cl | 65 | 117 | 115-117 [22] |
| 5 | 4e | 2-F | 69 | 67 | 67-68 [22] |
| 6 | 4f | 4-F | 66 | 100 | 98-100 [22] |
| 7 | 4g | 4-Br | 65 | 131 | 129-131 [22] |
| 8 | 4h | 4-$CH(CH_3)_2$ | 65 | 119 | 119 -120 [23] |
| 9 | 4i | 4-$OCH_3$ | 65 | 124 | 123-125 [22] |

A plausible mechanism for the formation of benzothiazole under the ultrasound probe irradiation is depicted in Scheme 2. Under the ultrasound probe irradiation, the nucleophilic attack of 2-aminothiophenol on the carbonyl of benzaldehydes led to the formation of intermediate (I). Subsequently, cyclization reaction occurred to yield the intermediate (II). The air oxidation of intermediate (II) furnish the end-products, which were the benzothiazole derivatives.

Scheme 2. A plausible mechanism for the synthesis of benzothiazole derivatives under ultrasound probe irradiation

## Conclusion

In conclusion, we have demonstrated a simple and efficient protocol for the synthesis of benzothiazole derivatives under ultrasound probe irradiation. The major advantages of this technique include short reaction time, solvent- and catalyst-free reaction condition and the final products were obtained in moderate to good yields. These traits have rendered this method as an alternative way for synthesizing benzothiazole derivatives. In the future, the use of ultrasound probe irradiation under solvent- and catalyst-free condition to synthesize useful bioactive heterocyclic compounds will be further explored in our laboratory.

**Abstract**

Four new thiourea derivatives namely 1-(2-aminophenyl)-3-(naphthlene-1-yl)thiourea, **3a**, *N*-(2-aminophenyl)-*N*-(1-naphthalenyl)thiourea, **3a'**, 1-(3-aminophenyl)-3-(naphthalene-1-yl)thiourea, **3b**, and 1,4-phenylene-bis[3-(*α*-naphthyl)thiourea], **3c** have been synthesized by the reaction of 1-naphthyl isothiocyanate, **1a** with 1,2-phenylenediamine, **2a**, 1,3-phenylenediamine, **2b,** 1,4-phenylenediamine, **2c**. The binding behavior of **3b** for mercury ion was evaluated by 'naked- eye', $^{1}$H Nucleus Magnetic Resonance, Fourier Transformation Infrared, and UV-Vis titration methods. Stoichiometry of the host-guest complexation of **3b** and mercury ion was found to be 1:1 by plotting molar-ratio curves.

**Keywords***:* synthesis, thiourea, sensing, mercury

**Abstrak**

Empat sebatian baru terbitan tiourea iaitu 1-(2-aminofenil)-3-(naftil-1-il)tiourea, **3a**, *N*-(2- aminofenil)-*N*-(1-naftilin-il)tiourea, **3a'**, 1-(3- aminofenil)-3-(naftilin-1-il)tiourea, **3b**, and 1,4-fenilin-bis[3-(*α*-naftil)tiourea], **3c** telah berjaya disintesis melalui tindak balas di antara 1-naftil isotiosianat, **1a** dengan 1,2-fenilenadiamina, **2a**, dan 1,3-fenilenadiamina, **2b** dan 1,4-fenilenadiamina, **2c**. Sifat kelakuan pengikatan sebatian **3b** terhadap ion merkuri dikaji dengan menggunakan kaedah mata kasar, $^{1}$H Resonan Magnetik Nukleus, Infra Merah Transformasi Fourier, dan juga pengtitratan Ultralembayung-Cahaya Nampak (UV-Vis). Stoikiometri kompleks 3b dan ion merkri ditemui pada nisbah 1:1 melalui lengkung nisbah molar yang telah diplot.

**Kata kunci**: sintesis, tiourea, penderia, merkuri

## Introduction

Thiourea, $SC(NH_2)_2$ is a compound that is analogous to urea ($CO(NH_2)_2$), where by the oxygen atom has been replaced with a sulfur atom. It has different properties compared to urea due to the difference in electronegativity between sulfur and oxygen [1]. Thiourea is one of the most important compounds used in relation to metallic electrodes [2]. It can absorb to a metal surface and in so doing block active sites [2]. It is also one of the most important industrial chemical products [3]. The presence of heavy metal ions in the environment is a large problem due to their acute toxicity. They are not biodegradable and harmful to human organs [4]. Among the variety of metal ions, mercury is hugely harmful because its compounds are widely spread in air, soil, and water also can subsequently bio-accumulate through the food chain [5].

Thioureas are also selective analytical reagents, especially for the determination of metals in the presence of other metal ions [6]. Thiourea derivatives with conjugated oxygen or nitrogen donor sites represent some of the most important chelating ligands in coordination chemistry and their metal complexes are useful for homogenous catalysis, chemical vapor deposition, supramolecular chemistry, redox sensing, magnetic materials and so on [7]. Copper is one of the important trace metals and has been used in complexes to disinfect human solids, liquids and also human tissues. The high concentrations of the metals in the environment are harmful and toxic to living organisms [8]. Mercury is very hazardous to the environment and living organisms. It can exist as either an inorganic or organic species in the environment. It can pass through biological membranes and can cause many dangerous conditions like cancer, brain damage and also motion disorder [9]. The thiourea compound can bind with metal ions to make a stable complex due to the sulfur atom's excellent donor properties [10]. Moreover, it is also extremely flexible as a ligand, either neutral, mono-anion or dianions that able to bind to metal center [11]. Metal complexes of thiourea are commonly semi organic materials, in which the organic and inorganic parts of complex confer the advantageous properties of both elements [12].

Thioureas show high biological activity where they act as corrosion inhibitors and antioxidants and are also the component of polymers. In 2006, researchers reported acyl thiourea derivatives are for a wide range of biological activities like bactericidal, fungicidal, herbicidal and insecticidal also possess regulating activity for plant growth [13]. In continuation of our research theme, herein we wish to report the synthesis and characterization of four thioureas based 1,2-, 1,3- and 1,4-phenylenediamine. The binding behavior of **3b** toward mercury ion was investigated by 'naked eyes', $^{1}$H NMR, FTIR and UV–vis titration method.

## Materials and Methods

### Chemicals

This research was using some chemicals such as 1,2-phenylenediamine (Sigma Aldrich), 1,3-phenylenediamine (Sigma Aldrich), 1,4-phenylenediamine (Merck), 1-naphthyl isothiocyanate (Sigma Aldrich), and solvent such as dimethyl sulfoxide (DMSO) and dichloromethane (DCM) from Fisher company. All the chemicals and solvents were used directly without any purification.

### Physical measurement

All reactions were performed under reflux condition. Chemicals and solvents were purchased from Sigma Aldrich and Acros and were used directly without further purification. The compound was analyzed using FTIR Perkin Elmer Model Spectrum GX in the range 400-4000cm$^{-1}$ using KBr method, $^{1}$H and $^{1}$C NMR spectrometer model Bruker Advance 400 MHz, Liquid Chromatography Mass Spectroscopy model Dionex/Bruker MicroToF Q and Ultraviolet visible (UV-vis) CARY Agilent 100.

### Synthesis of 1-(2-aminophenyl)-3-(naphthlene-1-yl)thiourea, 3a

A solution of 1-naphthyl isothiocyanate (0.185 g, 1.00 mmol) and 1, 2-phenylenediamine (0.054 g, 0.50 mmol) in 10 mL dichloromethane (DCM) was refluxed for 23 hours. The white precipitate was filtered out and the pure product was isolated (63 %, 0.092 g).

### Synthesis of N-(2-aminophenyl)-N-(1-naphthalenyl)thiourea, 3a'

A solution of 1-naphthyl isothiocyanate (0.093 g, 0.025 mmol) and 1-(2-aminophenyl)-3-(naphthlene-1-yl)thiourea (**3a**) (0.073 g, 0.025 mmol) in 20 mL DCM was refluxed for 24 hours. The white precipitate was filtered, and the pure product was isolated (85 %, 0.010 g).

### Synthesis of 1-(3-aminophenyl)-3-(naphthalene-1-yl)thiourea, 3b

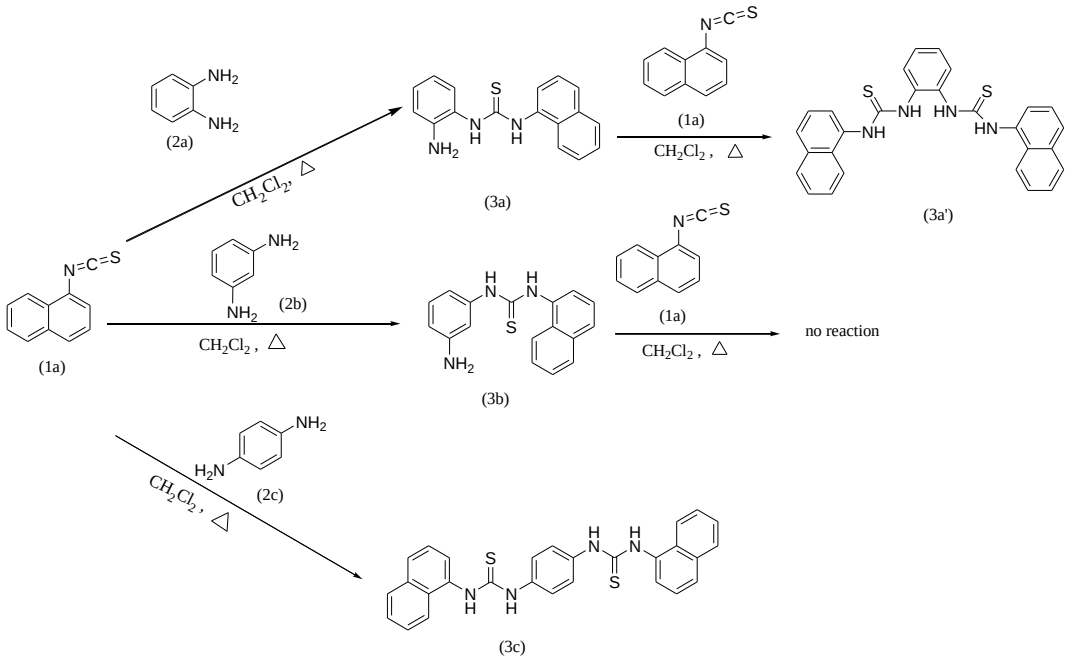
A solution of 1-naphthyl isothiocyanate (0.705 g, 2.00 mmol) and 1, 3-phenylenediamine (0.109 g, 1.00 mmol) in 20 mL dichloromethane (DCM) was refluxed for 24 hours. The white precipitate was filtered out and the pure product was isolated (82 %, 0.241 g).

**Synthesis of 1,4-phenylene-bis[3-(α-naphthyl)thiourea], 3c**

A solution of 1-naphthyl isothiocyanate (0.927 g, 5.00 mmol) and 1, 4-phenylenediamine (0.270 g, 2.50 mmol) in 20 mL dichloromethane (DCM) was refluxed for 28 hours. The white precipitate was filtered out and the pure product was isolated (95 %, 1.136 g).

**Binding behaviors for compound 3b towards selected metal salts**

The binding experiments were carried out using naked-eye method, FTIR, UV-Vis titration and $^1$H NMR titration. For naked-eye detection, stock solutions (1 x $10^{-3}$ M) of $Fe^{2+}$, $Pb^{2+}$, $Hg^{2+}$, $Ni^{2+}$, $Zn^{2+}$, $Ag^{+}$, $Cu^{2+}$, $Sn^{2+}$ ions and compound **3b** in dimethyl sulfoxide (DMSO) were prepared. 1.0 ml vial containing $Fe^{2+}$ and 1.0 ml of **3b** was mixed together in vials and shaken to ensure homogeneity. The color changes were observed and the data were collected. The experiment was repeated using $Pb^{2+}$, $Hg^{2+}$, $Ni^{2+}$, $Zn^{2+}$, $Ag^{+}$, $Cu^{2+}$, $Sn^{2+}$ ions.



For UV-Vis titrations, 10 ml stock solutions (1 x $10^{-3}$ M) of **3b** and selected metal ions (1 x $10^{-3}$ M) were prepared in DMSO as solvent. The screening of these solutions was conducted on a UV-Vis spectrophotometer. 200 µL of **3b** and 0-600 µL of the mercury ion solution were titrated and directly analyzed using UV-Vis spectrophotometer [5].

For the $^1$H NMR titrations, 300 µL of a stock solution of $Hg^{2+}$ (0 – 0.06 M) was added into 560 µL of stock solution of **3b** (0.03 M) and then was placed in an NMR tube. Both of solutions were in DMSO-$d_6$. The titration solutions were analyzed using $^1$H NMR spectroscopy [14].

For analysis using FTIR spectroscopy, the sample was prepared by using 0.03 M of compound **3b** and 0.03 M of $Hg(OAc)_2$, both in DMSO as solvent.

## Results and Discussion

Compound **3a, 3a', 3b** and **3c** were synthesized by the reaction of ethyl isothiocyanate **1a** with diamines **2a, 2b** and **2c** (Scheme 1).

LC-MS (ESI) m/z: calculate for $C_{28}H_{22}N_4S_2$ (M+$H^+$) (478.63), found (479.1) [17].

**Binding behaviors for 3b towards some selected metal ions**
For the visible observations, the most remarkable color change was observed in the presence of $Hg^{2+}$, $Cu^{2+}$, $Fe^{2+}$, and $Ag^+$ ions. The color changes before and after adding the metal salts into a solution of **3b** are seen in Figure 1 and Table 1. Based on the observation, the colorless solution became dark brown upon the addition of $Hg^{2+}$ (with acetate as counter ion). Next, the screening of **3b** with some selected metals in 2.0 ml solvent was carried out using UV-Vis spectroscopy (Figure 2). Based on the screening, $Hg^{2+}$ was found to show the highest absorption at 260 nm, together with new bands appearing at 305 nm and 370 nm which indicated strong binding behavior of **3b** towards the $Hg^{2+}$ ion. Due to this high affinity, the $Hg^{2+}$ ion was chosen for further titration studies using UV-vis and $^{1}$H NMR titrations.

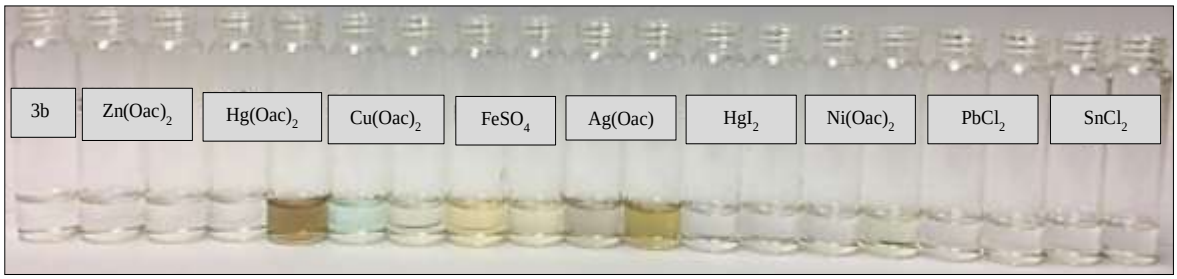

Figure 1. Color changes for naked-eyes sensor of 1-(3-aminophenyl)-3-(naphthalene-1-yl)thiourea, **3b** (1 x $10^{-3}$ M) towards selected metals (1 x $10^{-3}$ M)

Table 1. Color changes before and after adding the metal salts solution into the 1-(3-aminophenyl)-3-(naphthalene-1-yl)thiourea, **3b** solution

| **Metal salts** | **1-(3-aminophenyl)-3-(naphthalene-1-yl)thiourea, 3b (colorless)** |
|---|---|
| $Zn(OAc)_2$ (colorless) | Unchanged |
| $Hg(OAc)_2$ (colorless) | Dark brown |
| $Cu(OAc)_2$ (blue) | Light yellow |
| $FeSO_4$ (yellowish) | Light yellow |
| Ag(OAc) (light grey) | Brown |
| $HgI_2$ (colorless) | Unchanged |
| $Ni(OAc)_2$ (colorless) | Very light yellow |
| $PbCl_2$ (colorless) | Unchanged |
| $SnCl_2$ (colorless) | Unchanged |

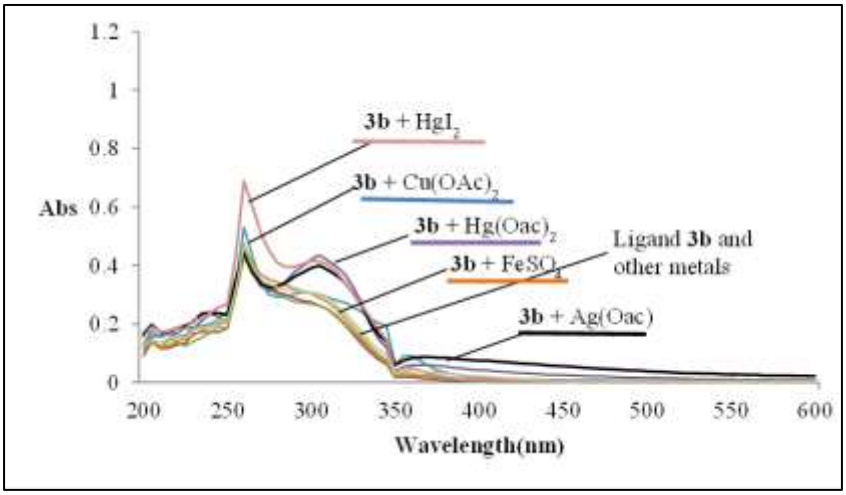

Figure 2. UV-Vis spectra of **3b** (1 x $10^{-3}$ M) with all metal ions (1 x $10^{-3}$ M) in DMSO as solvent

The titration studies of **3b** toward $Hg^{2+}$ ions were performed in DMSO. Figure 3 shows that upon the gradual addition of 25 µL equivalent of $Hg^{2+}$ ($1x10^{-3}$ M) to the 200 µL ligand solution ($1x10^{-3}$ M), new absorption bands at 305 nm and 370 nm appeared with increasing intensity. The absorbance maxima increased linearly with the concentration of $Hg^{2+}$ in a range of 0 – 1.0 M with a correlation coefficient of 0.99306 (Figure 4) after 10 readings. There was an isosbestic point at 280 nm which indicated that there were only two species present at equilibrium [18]. In addition, a new shoulder band appeared at 345 nm, something which relates to the intramolecular charge transfer (ICT) on the thiourea moiety of compound **3b**. The band at 370 nm shows a hyperchromic effect with an increasing amount of $Hg^{2+}$. Based on the UV-Vis titration, we were able to calculate the stoichiometry of the binding interaction between ligand **3b** and $Hg^{2+}$ through the molar-ratio curve method (Figure 4) [19]. The binding ratio of **3b**- $Hg^{2+}$ was 1:1 and the binding constant ($K_d$) was calculated using the nonlinear regression equation using Sigma Plot 12.0 software. The $K_d$ value of **3b**-$Hg^{2+}$ was 1.659 M.

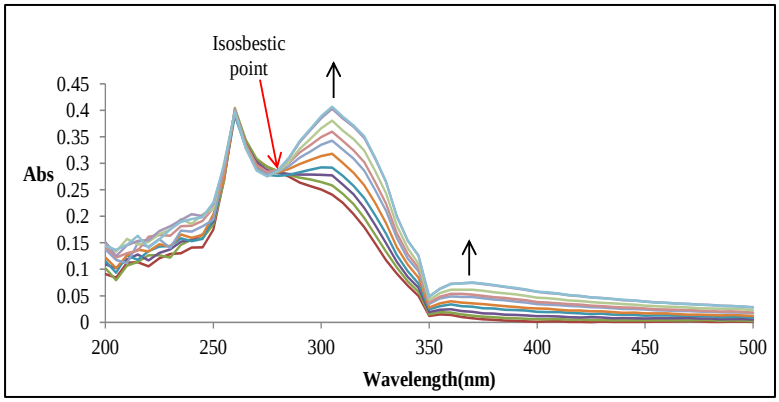

Figure 3. Changes in absorption spectra of **3b** (1 x $10^{-3}$ M) with increasing amount of $Hg^{2+}$ ions ($Hg(OAc)_2$) (1 x $10^{-3}$ M)

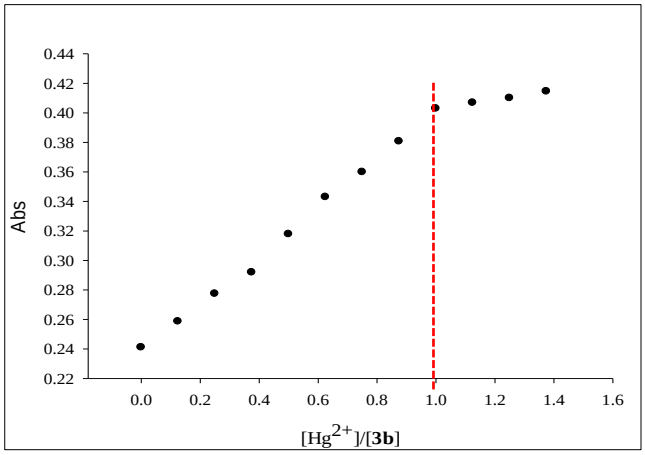

Figure 4. Variation of absorbance at 305 nm versus $[Hg^{2+}]/[\mathbf{3b}]$

To further study the binding behavior, $^1$H NMR titrations were performed in DMSO-$d_6$ (Figure 5). Protons for the two NH of compound **3b** were observed at 9.61 ppm and 9.59 ppm respectively. The integral of the peaks were both 2.00. After gradually adding the $Hg^{2+}$ solution (0 – 0.06 M), the size of the signals decreased and their integration value became less than 1. This was due to the strong interaction between **3b** and $Hg^{2+}$. In addition, the protons for

the $NH_2$ groups in the original spectra for compound **3b** were singlet, but in combination with $Hg^{2+}$ solution, the signal became broader and less intense (integration less than 1.00).

Next, the FTIR spectrum showed that the complex of **3b** and $Hg^{2+}$ showed a decreased intensity for both the CN and C=S groups, whilst a new peak appeared at 998 $cm^{-1}$ (Figure 6) [20]. This peak was due to the complexation of the $Hg^{2+}$ ion and the thiourea moiety. The peaks responsible for the $NH_2$ region disappeared due to the intramolecular charge transfer formed with the thiourea moiety. The proposed reaction mechanism of the **3b**-Hg interaction is shown in Figure 7.

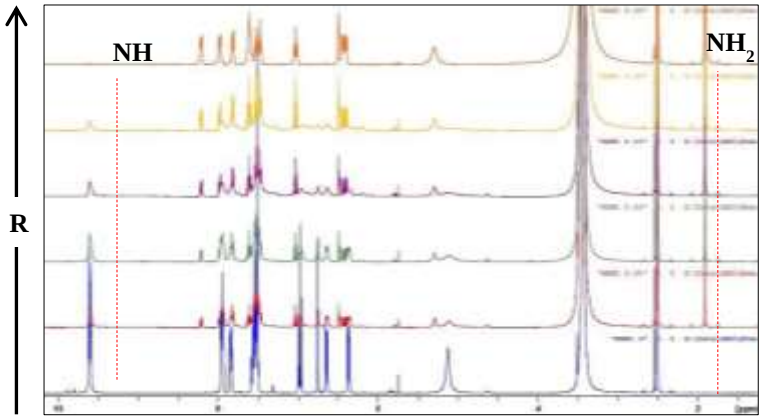

Figure 5. $^1H$ NMR titration of **3b** showing changes in the NH and $NH_2$ chemical shifts of the receptor **3b** (0.03M) with increasing amount of $Hg^{2+}$ (**R**) (0 - 0.06 M) in DMSO-$d_6$

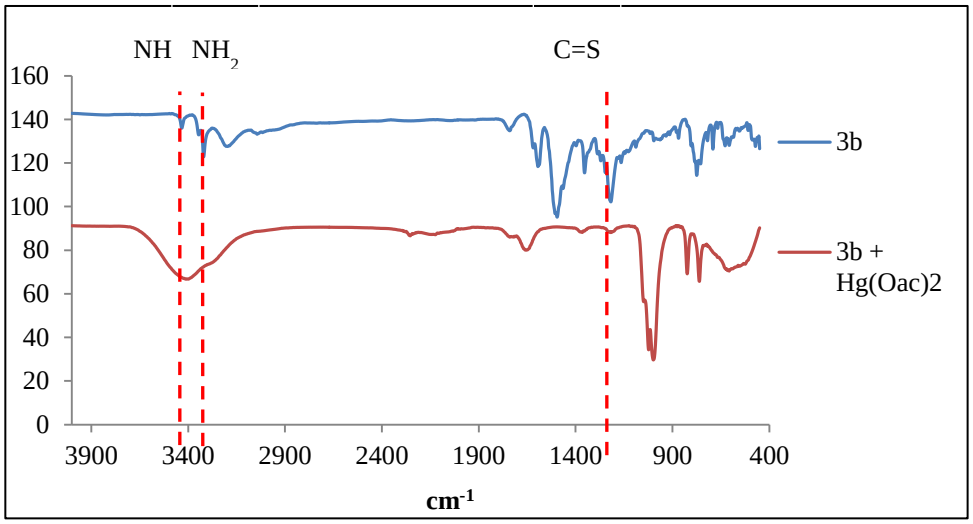

Figure 6. FTIR spectrum of compound **3b** with $Hg(OAc)_2$ solution.

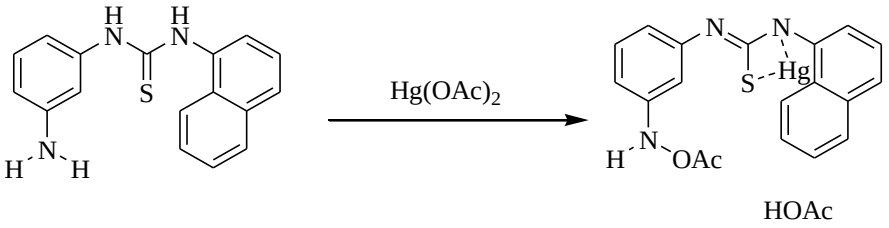

Figure 7. The proposed reaction mechanism of the **3b**-Hg interactions

## Conclusion

In conclusion, we have reported the synthesis of thiourea derivatives, 1-(2-aminophenyl)-3-(naphthlene-1-yl) thiourea (**3a**), N-(2-aminophenyl)-N-(1-naphthalenyl)thiourea (**3a'**), 1-(3-aminophenyl)-3-(naphthalene-1-yl) thiourea (**3b**), and 1,4-phenylene-bis[3-(α-naphthyl)thiourea] (**3c**). Using observation by naked eye, UV-vis titration, FTIR, and $^{1}$H NMR titration methods showed that the binding behavior of compound **3b** towards $Hg^{2+}$ afforded a complex with a 1:1 binding ratio. Future work will be aimed at using compound **3b** for sensor based applications whereby the fate of $Hg^{2+}$ can be tracked in the environment.

**Abstract**

Production of amino acid based vesicles using sonication method was employed to determine its encapsulation efficacy towards gadolinium(III) nanoparticles as potential drug carrier. The sonication process involved precursor namely sodium N-lauroylsarcosinate hydrate with 1-decanol to produce vesicle in 92 wt.% of water. Gadolinium(III) nanoparticle was then encapsulated into the vesicle system. The structure of $Gd_2O_2CO_3$ nanoparticles was confirmed by X-ray Diffraction technique (XRD). Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) spectroscopy indicates the presence of bonding that formed the vesicles. The size distribution of the obtained gadolinium encapsulated vesicle was examined using Transmission Electron Microscopy (TEM). It has been proven to be a potential nano-sized drug carrier.

**Keywords:** vesicles, encapsulation, gadolinium, sonication, drug carrier

**Abstrak**

Penghasilan vesikel berasaskan asid amino menggunakan kaedah sonikasi telah digunakan dalam menentukan pengkapsulan nanozarah gadolinium(III) yang berpotensi sebagai pembawa dadah. Proses sonikasi melibatkan prekursor natrium N-lauroylsarkosinat hidrat dengan 1-dekanol untuk menghasilkan vesikel dalam 92 wt.% air. Nanozarah gadolinium(III) kemudiannya dikapsulkan ke dalam sistem vesikel. Struktur nanozarah $Gd_2O_2CO_3$ telah disahkan menggunakan teknik pembelauan sinar-X (XRD). Spektroskopi transformasi infra merah Fourier (ATR-FTIR) menunjukkan kehadiran ikatan yang terbentuk ke atas vesikel. Taburan saiz yang nanozarah gadolinium terkapsul ke dalam vesikel dilihat menggunakan mikroskop elektron trasmisi (TEM). Ia telah terbukti berpotensi sebagai pembawa dadah bersaiz nano.

**Kata kunci:** vesikel, pengkapsulan, gadolinium, sonikasi, pembawa dadah

## Introduction

Nanomedicine is defined as a material used for specific diagnostic or therapeutic purposes in the scale range of 1-100 nanometers [1]. These therapeutic carriers have been increasingly used as drug delivery vehicles for the vast advantages that they offer due to their small size and versatility [2]. Gadolinium nanoparticles are very important as nuclear, phosphor, optical and electronic material [3-5]. Gadolinium is another new class of radiation sensitizers [6] because they could be easily viewed *in vivo* through the use of magnetic resonance imaging (MRI). MRI is a popular technique because it has a good soft tissue contrast [7] and high spatial resolution with non-invasive *in vivo* visualization [8]. In clinical use, the size of the nanoparticles has to be small to limit the toxicity due to poor renal clearance which is 6 nm, in order to allow complete and exclusive renal elimination after intravenous injection [9].

Vesicle has already been proven to be important as carrier system and for studying basic biology and medicine related to cell membranes [10]. Vesicle is a bilayer membrane structure consisting of a closed fluid chamber encapsulating aqueous solution [11, 12]. The vesicles were proven to have a good characteristic and potential as a drug delivery vehicles or carrier [13, 14]. In the present investigation, our goal is to encapsulate the gadolinium nanoparticles with amino acid based vesicle. The samples were characterized with various instruments such as transmission electron microscopy (TEM), Fourier transform infrared spectroscopy (FTIR) and X-ray diffraction (XRD).

## Materials and Methods

### Materials

Sodium N-lauroylsarconate with 95% purity was purchased from Across Organics (New Jersey, United States of America), 1-Decanol with 99% purity was purchased from Sigma-Aldrich and Nitric acid with 69.0 – 70.0% purity was purchased from J.T.Baker (Thailand). Gadolinium(III) oxide carbonate was purchased from Sigma-Aldrich with 99.8% trace metals basis. Deionized water was used to prepare all samples.

### Synthesis gadolinium(III) nitrate solutions

In order to obtain mixed assemblies, the required amount of $Gd_2O_2CO_3$ was dissolved in $HNO_3$ to form 5 mol/L concentration of nitrate solution. 0.1 ml nitrate solution was diluted with 500 ml deionized water. The pH of mixture was monitored and adjusted to pH 5 using deionized water. From this stock solution, only 0.08% of nitrate solution was used to synthesize amino acid based vesicles.

### Synthesis of control amino acid based vesicle

Amino acid based vesicles were prepared according to the sonication method as reported previously by Akter et al. [15] and Rosli et al. [13] with several modification. Sodium N-lauroylsarcosinate hydrate was mixed with 1-decanol in a test tube at a molar ratio of 1:2 in 92 wt.% of deionized water. The solution was sonicated for 15 minutes at room temperature using a bath sonicator. To obtain micro emulsion, the solution was vortexed for 5 minutes at 1400 rpm. The solution was then centrifuged for 15 minutes at the speed of 4200 rpm to obtain phase separation. The samples were left undisturbed for a few hours to achieve equilibrium.

### Synthesis of vesicle encapsulating gadolinium(III) nitrate nanoparticles

Vesicle encapsulating gadolinium (III) nitrate nanoparticles was synthesized using the same method used to synthesize control amino acid based vesicle with minor modification, in which the encapsulated gadolinium(III) nitrate nanoparticles was added to the deionised water prior to its addition with surfactant (SNLS and 1-decanol).

### Characterization study

To identify crystalline products, X-ray diffraction (XRD) pattern were collected on a Bruker D8 Advance, using Cu $K\alpha 1$ radiation (40 kV, 40 mA) with a wavelength 1.54060 in 2θ. Attenuated total reflectance infrared (ATR-FTIR) spectra in transmission mode were measured on a Perkin Elmer FTIR Spectrum 400 spectrometer in determining molecular confirmation using pressed KBr tablets in a mortar. The formations of vesicles were characterized using a transmission electron microscope (TEM, Bruker HT7700 electron microscope, operated at 120 kV).

## Results and Discussion

### X-ray diffraction

Based on the x ray diffraction patterns of powdered nanoparticle $Gd_2O_2CO_3$ in Figure 1, three dominant peaks of hexagonal $Gd_2O_2CO_3$ are observed. These peaks consist of peak 250 (at $2\theta \approx 31.8^o$), peak 175 (at $2\theta \approx 27.0^o$) and peak 115 (at $2\theta \approx 46.4^o$). These findings indicated that the nanocrystals consist of crystalline $Gd_2O_2CO_3$ with an excellent peak fitting (JCPDS no. 00-038-0680).

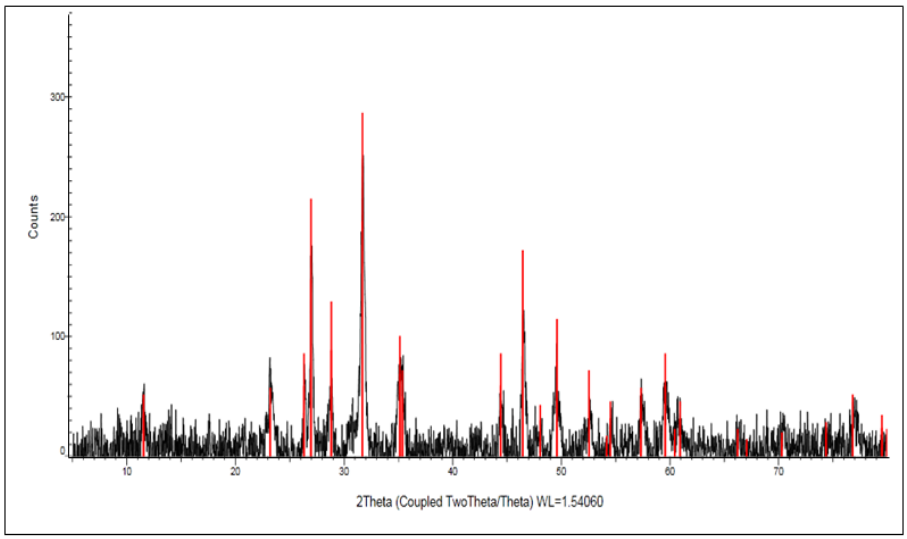

Figure 1. X-ray diffractograms of powdered $Gd_2O_2CO_3$ nanoparticles

**Fourier transform infrared spectroscopy**

The characterization of nanoparticles was performed using FTIR at a wavelength between 500 $cm^{-1}$ to 4000 $cm^{-1}$. The IR spectrum of $Gd_2O_2CO_3$ and $Gd(NO_3)_3$ nanoparticles are shown in Figure 2. The chemical bonds and functional group present in the characterized sample are as listed in Table 1. The peaks at 1100 and 860 $cm^{-1}$ represent carboxylic acids functional group (O-C) and (C-O-H) of $Gd_2O_2CO_3$, respectively. The alkene functional group of the $Gd_2O_2CO_3$ nanoparticles are also present at peak 1400 $cm^{-1}$ (=C-H & $=CH_2$ stretch). Furthermore, a (C-C) stretch (in-ring) of $Gd_2O_2CO_3$ appears as a very strong and sharp peak at 1490 $cm^{-1}$.

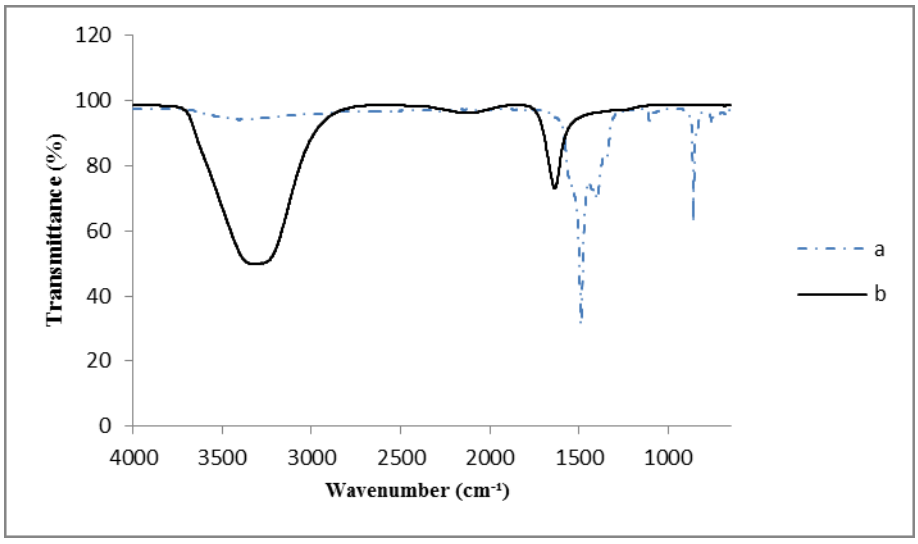

Figure 2. FTIR spectrum of (a) $Gd_2O_2CO_3$ powder and (b) $Gd(NO_3)_3$ solution.

Table 1. Vibrational mode assignment of $Gd_2O_2CO_3$ particles and $Gd(NO_3)_3$ solution

| Modes of vibration | Functional group | Wavenumber ($cm^{-1}$) | |
|---|---|---|---|
| | | $Gd_2O_2CO_3$ | $Gd(NO_3)_3$ |
| O-H stretch (wide,strong) | Hydroxyl | 3406.09 | 3330.65 |
| C≡N stretch | Nitriles | n.d | 2123.61 |
| C=O strecth (strong) | Amides | n.d | 1636.80 |
| H-C-H bend | Alkane | 1488.26 | n.d |
| C-O strecth | Ether | 1395.45 | n.d |
| C-N strecth | Aliphatic amines | 1104.94 | n.d |

n.d Not detected

Besides that, based on the spectrum obtained, C≡N stretch and C=O stretch of $Gd(NO_3)_3$ are also confirmed through the nitrile functional group (at wavelength 2123.61 $cm^{-1}$) and amide functional group (at wavelength 6136.80 $cm^{-1}$). However, these nitrile and amide functional group were not present in $Gd_2O_2CO_3$ compound as there is no use of nitrogen in the preparation of these compounds. The reaction of $Gd_2O_2CO_3$ and $HNO_3$ is shown in equation (1).

$$Gd_2O_2CO_3 + 6HNO_3 \rightarrow 2Gd(NO_3)_3 + 3H_2O + CO_2 \quad (1)$$

Before the synthesis and encapsulation of gadolinium(III) in the vesicle, 1-decanol and sodium N-lauroylsarcosinate hydrate were also characterized using FTIR. The spectrum of 1-decanol and sodium N-lauroylsarcosinate hydrate (SNLS) is shown in Figure 3. The chemical bonds and functional group present in the compound are listed as in Table 2.

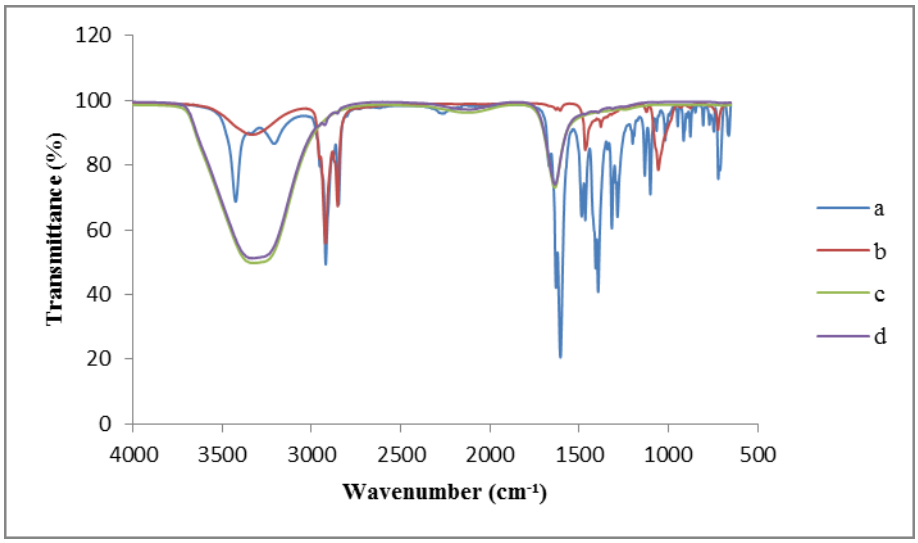

Figure 3. FTIR spectrum of (a) sodium N-lauroylsarcosinate hydrate, (b) 1-decanol, (c) gadolinium (III) nitrate solution and (d) vesicle solution.

Table 2. Vibrational mode assignment of sodium N-lauroylsarcosinate hydrate, 1-decanol, gadolinium (III) nitrate solution and vesicle solution

| Modes of vibration | Functional Group | Wavenumber ($cm^{-1}$) | | | |
|---|---|---|---|---|---|
| | | SNLS | 1-Decanol | $Gd(NO_3)_3$ | Vesicle |
| O-H stretch (wide, strong) | Hydroxyl | 3425.37 | 3341.79 | 3330.65 | 3340.40 |
| C=C-H asymmetric stretch | Alkenes | 3210.79 | n.d | n.d | n.d |
| H-C-H symmetric and asymmetric stretch | Alkanes | 2920.67 | 2922.26 | n.d | n.d |
| C-H bend | Alkanes | 1465.36 | 1465.79 | n.d | n.d |
| C-N stretch | Aliphatic amines | n.d | 1056.42 | n.d | n.d |

n.d Not detected

The strong and wide peak at 3500 – 3200 $cm^{-1}$ represent the O-H stretch from the alcohol group of decanol. Based on the modes of vibration in Table 2, the wavenumber of hydroxyl group for sodium N-lauroylsarcosinate hydrate (SNLS) is 3425.37 $cm^{-1}$ and 3341.79 $cm^{-1}$ for 1-decanol. The formation of vesicle from mixing of SNLS and 1-decanol at molar ratio of 1: 2 is confirmed through the present of strong and wide hydrogen bonding at the wavenumber 3340.40 $cm^{-1}$. Besides that, it is observed that there is a weak mode of asymmetric and symmetric stretch on the methyl group of SNLS and 1-decanol at peak of 2920.67 $cm^{-1}$ and 2922.26 $cm^{-1}$.

In the vesicle formation, strong hydrogen bond occurs between SNLS and 1-decanol. The schematic diagram for interaction between SNLS and 1-decanol is as shown in Figure 4 [15]. The amphiphilic molecules consist of a hydrophilic polar head and hydrophobic non-polar tail [16], which tend to form different structures when environmental changes occur. The nitrogen group also contributes to the formation of vesicles. Since the molecular geometry for nitrogen group is trigonal pyramidal is an evidence for the interaction of strong hydrogen bond which occurs between one SNLS molecule and two decanol molecules. The arrangement of surfactants in the vesicle formed between the interaction of SNLS and decanol in aqueous medium can be seen in Figure 5, in which the hydrophobic tail of surfactants is shielded from aqueous medium whereas the hydrophilic head is in full contact with the medium. Thus, a bilayer structure of vesicle is formed.

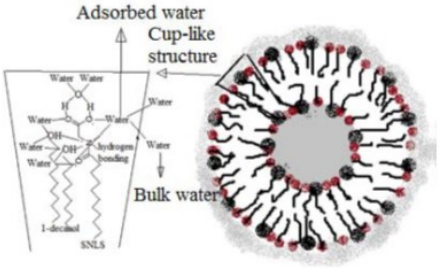

Figure 4. Schematic diagram of hydrogen bonding formation between sodium N-lauroylsarcosinate hydrate (SNLS) and 1-decanol [15] to form a vesicle

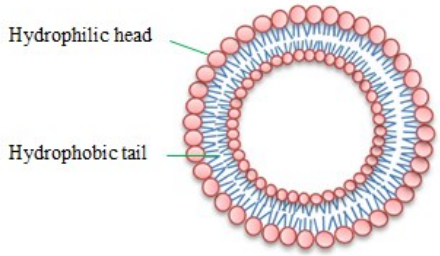

Figure 5. Bilayer structure of vesicle formed through the arrangement of amphiphile surfactants (SNLS and 1-decanol) in aqueous medium

The FTIR spectrum of encapsulated gadolinium(III) nitrate in the vesicle is shown in Figure 6. From the FTIR spectrum, the wavenumber 3500 – 3200 $cm^{-1}$ represent the strong stretch of O-H bond in all samples. In the vesicle encapsulating gadolinium(III) nitrate nanoparticle spectrum, it is observed that there is a slight shift in the O-H bond peak in comparison to the control vesicle and gadolinium(III) nitrate FTIR spectrum. The shift of O-H bond is possibly attributed by the attachment of gadolinium(III) nitrate on the OH group [17]. Besides that, the shift in the peak of gadolinium(III) nitrate nanoparticle was suspected to be encapsulated in the amino acid based vesicles. Further analysis on the morphology of both control vesicle and vesicle encapsulating gadolinium(III) nitrate nanoparticle could be obtained from the transmission electron microscopy (TEM) characterization.

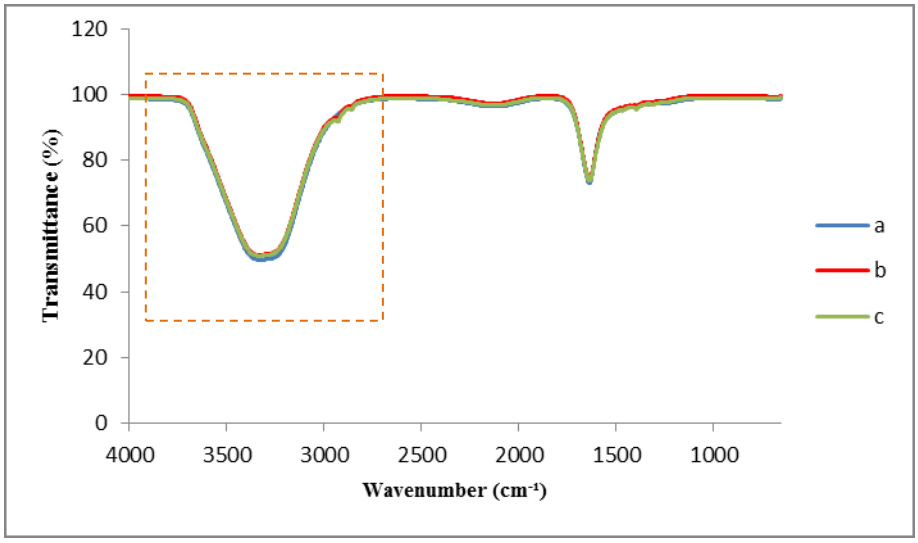

Figure 6. The FTIR spectrum (a) gadolinium(III) nitrate, (b) control vesicle and (c) vesicle encapsulating gadolinium (III) nitrate nanoparticle

**Transmission electron microscopy**

The morphology of synthesized vesicle and its size can be seen in Figure 7. From the TEM images, it is clearly shown that the control vesicle and vesicle encapsulating gadolinium(III) nitrate nanoparticle were formed through the spherical images of vesicle. The size of control vesicle ranged between 70 nm to 200 nm. Whereas, the size of vesicle encapsulating gadolinium nanoparticles ranged between 150 nm to 250 nm in diameter.

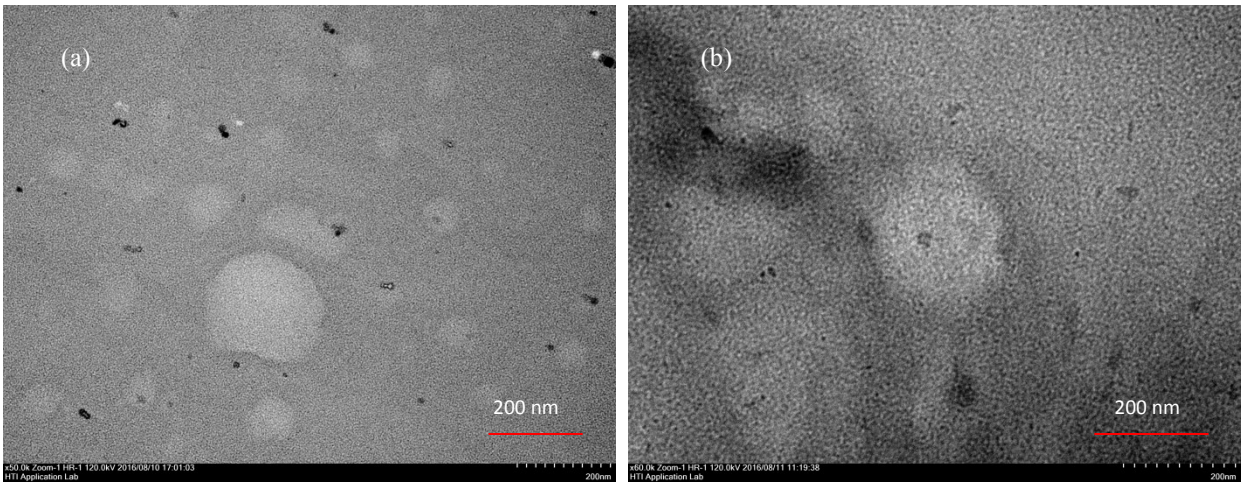

Figure 7. TEM micrograph shows the formation of (a) control vesicle and (b) vesicle encapsulating gadolinium(III) nitrate nanoparticle

Figure 8 shows the morphology of vesicle encapsulating gadolinium(III) nitrate nanoparticles which were stored for two weeks. A globular shape with a size of approximately 3 μm was observed. This shows that probably the synthesized vesicle is not suitable for storage and must be utilized directly after synthesized. This can only be further confirmed through stability test based on zeta potential using dynamic light scattering, which is currently on going.

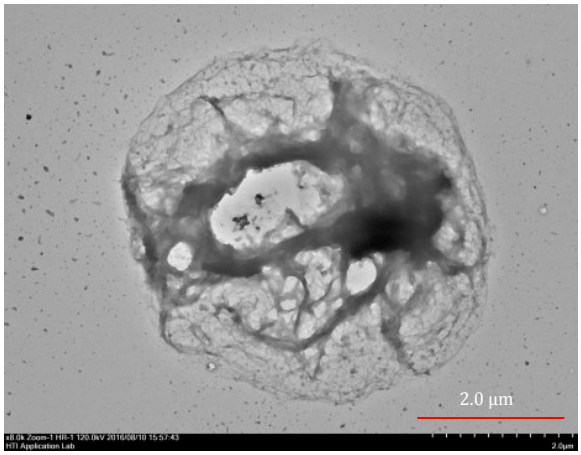

Figure 8. The globular shape was formed after vesicle encapsulating of gadolinium(III) nitrate nanoparticles was stored for two weeks

## Conclusion

Through this study, vesicle encapsulating gadolinium(III) nitrate nanoparticles was synthesized using sonication method. Through chemical molecular conformation and morphological characterization, it is proven that gadolinium(III) nitrate nanoparticles is encapsulated in vesicle. Therefore, this shows that the surfactant used in forming vesicle can be utilized in drug delivery, specifically in carrying encapsulated gadolinium(III) nanoparticle for medical purposes.

**Abstract**

Four diketopiperazine derivatives; cyclo(-Pro-Val) (**1**), (-)-cyclo(-Pro-Tyr) (**2**), (-)-cyclo(-Pro-Phe) (**3**) and (+)-cyclo(-Pro-Leu) (**4**) were isolated from the ethyl acetate extract of *Glaciozyma antarctica* PI12, a cold-adapted yeast that belongs to family Kriegeriales. The compounds were isolated by radial chromatography and thin layer chromatography techniques and the chemical structures were elucidated by infrared (IR), ultraviolet (UV), nuclear magnetic resonance (NMR) spectroscopy and mass spectrometry.

**Keywords:** *Glaciozyma antarctica* PI12, diketopiperazine, Kriegeriales

**Abstrak**

Empat terbitan diketopiperazin; siklo(-Pro-Val) (**1**), (-)-siklo(-Pro-Tir) (**2**), (-)-siklo(-Pro-Phe) (**3**) and (+)-siklo(-Pro-Leu) (**4**) yang dipencilkan daripada ektrak etil asetat *Glaciozyma antarctica* PI12, merupakan yis adaptasi sejuk yang terdiri dari famili Kriegeriales. Sebatian – sebatian terpencil telah diasingkan menggunakan teknik kromatografi pepejal dan kromatografi lapisan nipis dan struktur kimia dijelaskan oleh spektroskopi infra merah (IM), ultra lembayung (UL), resonans magnetik nuklear (RMN) dan spektrometri jisim.

**Kata kunci:** *Glaciozyma antarctica* PI12, diketopiperazin, Kriegeriales

## Introduction

Antarctica is a continent with extreme low temperature and nutrients, with high UV radiation, low water availabilities and frequent freeze-thaw cycle [1]. Therefore, the biology of Antarctica more than other continents, is dominated by microorganisms [2], with a high level of adaptation and able to withstand extreme condition [3]. However, temperature is one of major factors affecting the survival of microorganisms in Antarctica [4]. Cold adapted fungi that grow optimally at temperatures less than 15 °C and cannot grow above 20 °C are called "psychrophilic fungi or cold-adapted fungi" [5]. Since the 1960s, bioactive secondary metabolites have been isolated and structurally characterised from psychrophiles [6] such as bioactive non-ribosomal peptides (NRPs),

compounds derived from the NRP-synthetase that were developed into antibiotics i.e. bacitracin, polymyxin B and E [7].

*Glaciozyma antarctica* PI12 belongs to the family Kriegeriales [8] and was isolated from a marine environment in Antarctica [9]. Recently, this psychrophilic yeast was reclassified from *Leucosporidium antarcticum* to *Glaciozyma antarctica* PI12 [10] and has also been isolated from various locations in Antarctica [11, 12]. *Glaciozyma antarctica* PI12 was widely investigated in recent yearsin most antifreeze protein production and cold-active enzyme, including an extracellular serine proteinase [13]. The main objective of this paper is to describe the isolation and structure characterisation from psychrophilic yeast *G. antarctica* PI12.

## Materials and Methods

### Biological materials

The *G. antarctica* PI12 sample used was a gift from Prof. Dr. Nazalan Najimudin from Universiti Sains Malaysia in Penang, Malaysia. It was identified based on the biochemical characteristics and the sequence of the internal transcribed spacer (ITS) as well as the LSU rRNA (Accession numbers JX89896955 and JX896956) by the National Collection of Yeast Cultures, Norwich, UK. The strain was cultured on Tryptic Soy Agar for 10 days at 4 °C until a single colony was obtained [14]. The culturing of *G. antarctica* PI12 was conducted in collaboration with the Malaysia Genome Institute.

### Cultivation of yeast

10 µL of the *G. antarctica* PI12's glycerol stock was sub-cultured on the Yeast Extract-Peptone-Dextrose (YPD) agar with 50 µg/mL of ampicillin and 50 µg/mL of kanamycin at 12 °C until a single colony was obtained. Next, a starter culture of *G. antarctica* PI12 was prepared by inoculating a single colony of *G. antarctica* PI12 from the agar plate into 10 mL of YPD medium (50 mL falcon tube) with 50 µg/mL of ampicillin and 50 µg/mL of kanamycin. It was then cultured at 12 °C at 180 rpm until mid-log phase (OD600: 1.0 to 1.8) (5 days). Thirdly, a fixed amount ($10^6$ yeast cells/mL) of starter culture was inoculated into 50 mL of YPD medium (three 250 mL of conical flask were used) with two antibiotics, and then cultured at 12 °C at 180 rpm until stationary phase at day 14 [15].

### Extraction and isolation

The production culture was centrifuged (10,000 rpm, 4 °C, 5 min). The supernatant was filtered under vacuum to remove any cells that were not pelleted out and its pH was adjusted to 4.0. The supernatant was extracted thrice with ethyl acetate, and concentrated using a rotary evaporator. The ethyl acetate (EtOAc) extract (200.7 mg) of *G. antarctica* PI12 was subjected to radial chromatography (RC) with 1 mm thickness silica gel on a round glass plate and eluted with the mixtures of dichloromethane (DCM) and methanol (MeOH) with increasing polarity (started with DCM/MeOH, 9.6: 0.4). The eluates showing the same profile on thin layer chromatography (TLC) were combined to give three fractions (I-III). Purification of Fraction I (1-4) (29.7 mg) was carried out using RC with a silica gel plate of 0.5 mm thickness eluted with DCM and MeOH (9.2: 0.8) in 5% polarity increment to yield Compound **1** (1 mg). Purification of Fraction III (5-7) (48.8 mg) was conducted by utilising another RC with silica gel plate of 0.5 mm thickness. Elution with DCM and MeOH (8.4: 1.6) produced Compound **2** (1 mg), Compound **3** (1.5 mg), and Compound **4** (2 mg).

## Results and Discussion

### Characterization study

Cyclo(-Pro-Val) (**1**) is a white amorphous solid. ESI-MS $[M + H]^+$ at *m/z*: 197. IR $\bar{\upsilon}_{max}$ (ATR) $cm^{-1}$: 3191, 2956, 1640, 1453, 1110, 922. $^1H$ NMR (MeOD, 700 MHz) $\delta_H$ (ppm) and $^{13}C$ NMR (MeOD, 175 MHz) $\delta_C$ (ppm) data are tabulated in Table 1.

(-)-Cyclo(-Pro-Tyr) (**2**) is a white amorphous solid. $[\alpha]_D^{20}$ -43.1 (c 0.14, ethanol). ESI-MS $[M + H]^+$ ion at *m/z*: 261. IR $\bar{\upsilon}_{max}$ (ATR) $cm^{-1}$: 3248, 2927, 2853, 1747, 1658, 1449, 1252, 1174, 1114, 1017, 858. $^1H$ NMR (MeOD, 700 MHz) $\delta_H$ (ppm) and $^{13}C$ NMR (MeOD, 175 MHz) $\delta_C$ (ppm) data are tabulated in Table 1.

(-)-Cyclo(-Pro-Phe) (**3**) is a white amorphous solid. $[\alpha]_D^{20}$ -72 (c 0.7, methanol). ESI-MS $[M + H]^+$ ion at *m/z*: 169. IR $\bar{\upsilon}_{max}$ (ATR) $cm^{-1}$: 3357, 2956, 2108, 1647, 1449, 1318 and 1087. $^1H$ NMR (MeOD, 700 MHz) $\delta_H$ (ppm) and $^{13}C$ NMR (MeOD, 175 MHz) $\delta_C$ (ppm) data are tabulated in Table 1.

(+)-Cyclo(-Pro-Leu) (**4**) is a white powder. $[\alpha]_D^{20}$ +28.1 (*c* 0.032, ethanol). ESI-MS $[M + H]^+$ ion at *m/z*: 211. IR $\bar{\upsilon}_{max}$ (ATR) $cm^{-1}$: 3222, 2958, 2930, 2872, 1686, 1676, 1426, 1302, 1275, 1235, 1157, 1102, 1032, 996-919. $^1H$ NMR (MeOD, 700 MHz) $\delta_H$ (ppm) and $^{13}C$ NMR (MeOD, 175 MHz) $\delta_C$ (ppm) data are tabulated in Table 1.

Compound **1** was isolated as white amorphous solid. Its molecular formula was determined as $C_{10}H_{16}N_2O_2$, obtained by ESI–MS $[M + H]^+$ *m/z* 197. The IR spectrum showed the presence of carbonyl groups from amide (1640 $cm^{-1}$), and also saturated methylene groups at the range of 2956-2889 $cm^{-1}$. The $^{13}C$-APT NMR spectrum showed the location of ten signals representing two quaternary, three methines, three methylenes and two methyls carbons. The double bond equivalent (DBE) value of four indicated that this compound contained two double bonds and two cyclic aliphatic. The most deshielded carbons at $\delta_C$ 170.9 and 165.8 ppm were indicated as an asymmetrical carbonyl group. Three saturated non-equivalent methylenes signals at $\delta_C$ 28.3 (C-7), 22.4 (C-8) and 45.1 (C-9) were attributed to a pyrrolidine ring. A methine carbon at $\delta_C$ 58.7 ppm (C-6) was the specific of methine signal of diketopiperazine alkaloid and another one methine at $\delta_C$ 59.9 ppm (C-3) indicated the presence of a methine existed

between carbonyl and secondary amide while the two non-equivalent gem-dimethyls at $\delta_C$ 18.7 ppm (C-11) and $\delta_C$ 18.7 ppm (C-12) bound a saturated methine at $\delta_C$ 28.2 ppm (C-10).

Meanwhile, 12 proton signals representing 16 protons appeared in the $^1$H-NMR spectrum as shown in Table 1. Six of the signals came from the three non-equivalent methylenes proton at H-7, H-8 and H-9, forming a basic pyrrolidine ring. An aminated methine proton, H-6 ($\delta_H$ 4.11 ppm) resonated as a triplet, indicating that C-6 was adjacent to a methylene group (C-7). Another methine proton at H-10 ($\delta_H$ 2.32 ppm) was resonated as a multiplet, because it was bound to two non-equivalent gem-dimethyls at C-11 and C-12. Comparison of the $^1$H and $^{13}$C-APT NMR spectra of the compound suggested that it was Cyclo(-Pro-Val) (Fig. 1) [16]. Thus, the structure of Cyclo(-Pro-Val) (**1**) was previously isolated from *Aspergillus fumigatus* [17], *Pseudomonas aeruginosa* [18], and *Stenotrophomonas* sp. [19].

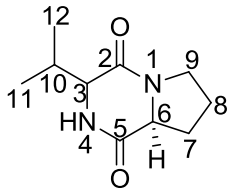

Figure 1. Chemical structure of compound **1**

Compounds **2** and **3** (Figure 2) were found in Fraction III as a UV absorbing spot, which stained to violet with anisaldehyde/sulphuric acid. The $^1$H NMR spectrum of Compound **2** showed two *ortho*-coupled signals at $\delta_H$ 7.05 (H-2', 6') and 6.79 (H-3', 5'), which pointed to an AA'-BB' system of a 1,4-disubstituted aromatic ring, as well as two signals at δ 4.37 and 4.05 for two methines attached to electron withdrawing substituents. The spectrum proton of Compound **2** showed also two doublet of doublets for an ABX system of a methylene group at $\delta_H$ 3.46 and 2.79 ($CH_2$-10), as well as three methylene multiplets ($CH_2$-7) ($\delta_H$ 2.33, 1.99) attached to a heteroatom and $CH_2$-8, 9 ($\delta_H$ 2.01, 1.93, 3.63, 3.57). The ESI mass spectra determined the molecular weight of Compound **2** as 261 Dalton by (+)-ESI mode. The structure was further confirmed as (-)-cyclo(-Pro-Tyr) (**2**) by comparison with an authentic sample and spectra from our collection [20]. (-)-cyclo(-Pro-Tyr) (**2**) was previously isolated from *Pseudomonas fluorescens* GcM5-1A [21], *Streptomyces* sp. H7372 and ML 1532 [22, 23], *Pseudomonas aeruginosa* [18] and *Lysobacter capsici* AZ78 [24]. The difference between Compound **2** and Compound **3** lay on C-4`, where Compound **2** had a hydroxy at C-4` (Figure 2).

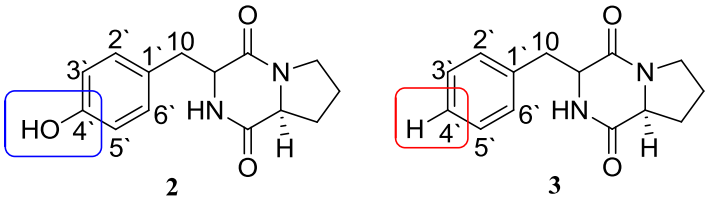

Figure 2. Structure of compounds **2** and **3**

From the spectroscopy data and comparison with the literature, compound **3** was confirmed as (-)-cyclo(-Pro-Phe) (**3**) [17] previously isolated from microbial sources, including *Streptomyces rochei* 87051-3 [16], *Streptomyces sudanensis*. A4.4 [25], *Tyridiomyces formicarum* [26], and *Alternaria alternata* [27].

(+)-Cyclo(-Pro-Leu) (**4**), $[\alpha]_D^{20}$ +28.1 (*c* 0.032, ethanol), was isolated as a white amorphous material with molecular formula $C_{11}H_{18}N_2O_2$, obtained by ESI–MS $[M + H]^+$ *m/z* 211. The IR spectrum showed bands attributed to the aliphatic carbons (2958, 2930, 2872 $cm^{-1}$) and amide (1686, 1676 $cm^{-1}$) functional groups. The $^1$H NMR spectrum

of compound **4** indicated the presence of three methines at H-3, H-6 and H-11; four methylenes at H-7, H-8, H-9 and H-10; and two non-equivalent dimethyls at H-12 and H-13 (Table 1). $^{13}$C NMR spectrum exhibited the presence of 11 carbon signals corresponding to two methyls, four methylenes, three methines and two quaternary carbons. The observation of the quaternary carbons at $\delta_C$ 167.1 (C-2) and 171.1 (C-5) suggested that these carbon signals were due to the carbonyl carbon of the amide groups. The DBE value of four indicated that this compound was containing two double bonds and two cyclic aliphatic. (+)-cyclo(Pro-Leu) (**4**) previously isolated from the Gram-negative Proteobacteria of *Burkholderia cenocepacia* and *Serratia marcescens* [28], *Alternaria alternata* [29], the bacteria *Pseudoalteromonas* sp. [30] and *Vibrio alginolyticus* [31].

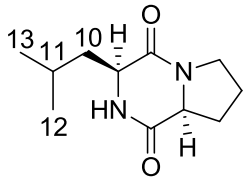

Figure 3. Structure of compounds **4**

## Conclusion

Four diketopiperazine derivatives, i.e. cyclo(-Pro-Val) (Compound**1**), (-)-cyclo(-Pro-Tyr) (Compound **2**), (-)-cyclo(-Pro-Phe) (Compound**3**) and (+)-cyclo(-Pro-Leu) (Compound**4**) were isolated and reported for the first time from psychrophilic yeast *G. antarctica* PI12. All the compounds reported in the present study were not subjected to further bioactivity studies due to insufficient amounts.

**Abstract**

Solvent extraction is a powerful separation technique in the preparation of nuclear grade thorium. In this study, monazite thorium concentrates produced from Malaysian monazite were used. Thorium was extracted from an aqueous nitric acid medium with TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene, respectively. Constant experimental conditions were used for the extraction in terms of the molarity of nitric acid, concentration of extractants in kerosene, organic/aqueous volumetric ratio, mixing time, and contact time between phases. The stripping process was carried out with distilled water. The determination of thorium and rare earth elements (REEs) in the monazite thorium concentrates and aqueous solutions were performed by using inductively coupled plasma mass spectrometry (ICP-MS). The concentrations of thorium in the thorium concentrate samples were in the range of 11.58 – 83.56%. Three stages of extraction and three stages of stripping were carried out for the extraction of thorium from the REEs in the nitrate solution. The results of the study showed that the thorium extraction efficiency was in the range of 60.96 – 99.75% using TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene. Thorium was stripped from the loaded TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene at an average stripping percentage of 89.04% and 75.75%, respectively. The stripped aqueous solutions were analysed, and it was shown that the thorium content was in the range of 29.49 – 91.28%. This study indicated that both extractants can be successfully used to recover thorium from REEs, but in order to increase the purification of thorium, the extraction and stripping process cycle should be increased.

**Keywords:** thorium, rare earth elements, solvent extraction, monazite thorium concentrate

**Abstrak**

Pengekstrakan pelarut adalah teknik pengasingan yang kuat digunakan untuk mengasingkan torium bergred nuklear. Dalam kajian ini, pekatan torium monazit yang dihasilkan daripada monazit Malaysia telah digunakan. Torium diekstrak daripada medium akues asid nitrik dengan TBP (30%) dalam kerosin dan Aliquat-336 (10%) dalam kerosin. Kondisi eksperimen digunakan iaitu molariti asid nitrik, kepekatan pengekstrak dalam kerosin, nisbah isipadu organik/akues, masa percampuran dan masa sentuhan antara fasa dikekalkan. Proses pelucutan dilakukan menggunakan air suling. Torium dan unsur nadir bumi (REEs) dalam pekatan torium monazit dan larutan akues ditentukan menggunakan spektrometri jisim plasma gandingan teraruh (ICP-MS). Kepekatan torium dalam sampel pekatan torium ditentukan adalah dalam julat 11.58 – 83.56%. Tiga peringkat pengekstrakan dan pelucutan dilakukan untuk mendapatkan torium dari REEs dalam larutan nitrat. Hasil kajian menunjukkan kecekapan pengekstrakan torium adalah dalam julat 60.96 – 99.75% menggunakan TBP (30%) dalam kerosin dan Aliquat-336 (10%) dalam kerosin. Torium telah dilucutkan daripada muatan TBP (30%) dalam kerosin dan Aliquat-336 (10%) dalam kerosin dengan purata peratus pelucutan masing – masing adalah 89.04% dan 75.75%. Larutan akues yang dilucutkan telah dianalisis dan menunjukkan bahawa kandungan torium adalah dalam julat 29.49 – 91.28%. Kajian ini menunjukkan bahawa kedua – dua pengekstrak boleh digunakan dengan berkesan untuk mendapatkan torium daripada REEs tetapi untuk meningkatkan kemurnian torium, pengekstrakan dan kitaran proses pelucutan harus dipertingkatkan.

**Kata kunci**: torium, unsur nadir bumi, pengekstrakan pelarut, pekatan torium monazit

## Introduction

High-purity thorium is required in nuclear technology applications. Nuclear grade thorium is obtained by several industrial processes such as solvent extraction, ion exchange and direct precipitation. Solvent extraction is a powerful separation technique compared to ion exchange and precipitation due to its speed, ease of operation and large throughput [1, 2]. The basis of thorium purification by solvent extraction depends on the solubility of thorium in water and organic solvents by forming complex ions, chalets and solvated species. The sequential transfer between the aqueous and organic phases leads to the purification of thorium.

The most common thorium extraction process is the extraction of thorium nitrate from a solution of nitric acid with TBP (tributyl phosphate) diluted with an aliphatic hydrocarbon such as kerosene or xylene/toluene to reduce the viscosity of the mixture [3]. The purified thorium nitrate, which can be used as a feed material to produce thorium compounds, is converted to thorium oxide or thorium tetrafluoride. Nuclear grade thorium nitrate is obtained with 99% thorium recovery by the solvent extraction process [4].

The extraction of thorium from monazite by solvent extraction was carried out with various organic solvents, e.g. the secondary amine, Adogen 283 [5], Aliquat-336 [6], TBP [7] and primene JM-T [8]. Sato studied the partition of thorium (IV) between aqueous sulphuric acid and solutions of di-(2-ethylhexyl)-phosphoric acid (DEHPA) in kerosene, and also between aqueous sulphuric acid and solutions of long-chain aliphatic amines [9, 10]. Several methods of stripping thorium and rare earths from solvents have been frequently performed. Furthermore, the optimum experimental conditions for the extraction of thorium from a number of elements have been determined in some studies, while the effects of the types and concentrations of the extractants, the settling time between phases, the types and concentrations of the stripping solutions, and the aqueous/organic volumetric ratio have been studied in detail [7, 8].

In this study, thorium concentrates were obtained from Malaysian monazite, which, according to a previous study, contains approximately 2% of thorium [11, 12], where a range of between 6.5 – 7.5% for thorium concentrations and 53.6 – 57.8% for rare earth oxides have also been documented in Malaysian monazite [13]. The objectives of this study were to extract thorium from REEs by TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene, and to determine the thorium purification percentage.

## Materials and Methods

### Materials

All the reagents and chemicals used in this work were of analytical grade, and the extractants used were TBP (tributyl phosphate), which was from Merck Schuchardt OHG, and Aliquat-336 (tricaprylmethylammonium chloride) from Alorich Chemistry. Both extractants were used without further purification. Kerosene, which was used as a diluent, was supplied by R&M Chemicals. Thorium nitrate was obtained from the nuclear science stockpile of Universiti Kebangsaan Malaysia (UKM), and distilled water was used in all the experiments for aqueous solutions**.**

### Solvent extraction procedure

The extraction and stripping experiments were performed using glass bakers and the magnetic stirrer, and then the separation of the organic/aqueous phases was done using a separatory funnel. The sample of Malaysian monazite used in this study was originally from *'amang'* factory in Perak, while the thorium concentrate was obtained from the selective precipitation of a sulphate leach solution of Malaysian monazite using ammonia at a pH of 1.8. Prior to that, the Malaysian monazite was initially processed using hot concentrated sulphuric acid (98%). The concentrations of thorium, uranium and REEs in the aqueous solutions were determined using ICP-MS (ELAN 9000 – Perkin Elmer SCIEX), and the concentration percentages of the elements were calculated from the total concentrations of the elements, which were in μg/g.

An aqueous solution of thorium was prepared by weighing about 0.10 g of thorium concentrate and dissolving it in 4 M of $HNO_3$ in a 100-ml volumetric flask at room temperature. A solution of thorium nitrate was prepared by dissolving 0.10 g of thorium nitrate in 4 M nitric acid in a 100-ml volumetric flask at a molarity of 1.85 x $10^{-3}$. TBP and Aliquat-336 were prepared by diluting 30% of TBP (v/v) in kerosene and 10% Aliquat-336 (v/v) in kerosene, respectively. The extraction experiments were carried out at room temperature.

Constant experimental conditions were maintained for each extractant, whereby the aqueous/organic volumetric ratio was 1:1, and the shaking and settling time was 10 minutes. About 5 ml. of the aqueous solution was mixed with 5 ml. of the organic solvents, and shaken for 10 minutes in bakers. The phases were allowed to settle, and were separated after 10 minutes in a separatory funnel. Three stages of extraction and three stages of stripping were carried out for the extraction of thorium from REEs in a nitrate solution. Each extraction experiment was triplicated.

The concentrations of thorium in the aqueous phase before and after the extraction were determined by ICP-MS, and the extraction percentage, E, was calculated from the distribution ratio, D, using equations 1 and 2, respectively as follows:

$$D = \frac{Co-C}{C}, \quad (1)$$

$$E\% = \frac{DVo}{DVo+Vaq}.100. \quad (2)$$

where $C_o$ and C are the thorium concentrations in the aqueous phase before and after the extraction, respectively, and $V_{aq}$ and $V_o$ are the volumes of the aqueous and organic phases, respectively [6, 7, 14].

The experimental conditions used for the stripping were similar to the conditions for extraction. Distilled water was used as the stripping solution to strip the thorium from the organic phase to the aqueous phase. The stripping percentage was calculated using the concentration of thorium in the aqueous phase after stripping and the concentration of thorium in the organic phase. The flowchart for the solvent extraction of thorium by TBP (30%) in kerosene and by Aliquate-336 (10%) in kerosene is illustrated in Figure 1.

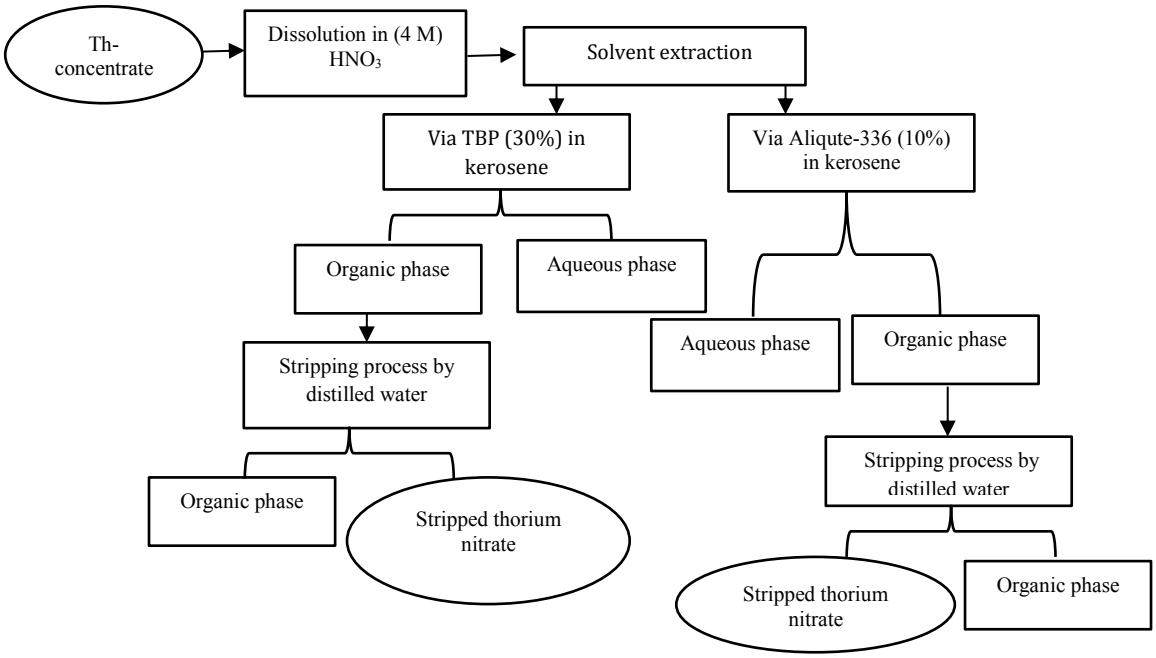

Figure1. Solvent extraction of thorium via TBP (30%) in kerosene and via Aliquate-336 (10%) in kerosene

## Results and Discussion

Monazite, which is a rare-earth and thorium phosphate mineral ((Ce, La, Nd, Th) $PO_4$), are the best primary sources of thorium. Monazite contains 2.5% of thorium and the concentrations of light rare earth elements (LREEs) are more than the concentrations of heavy rare earth elements (HREEs) [15, 16]. Furthermore, monazite concentrates usually contain 5.0 – 10.0% of thorium oxide ($ThO_2$), 0.2 – 0.4% of uranium oxide ($U_3O_8$), 55.0 – 60.0% of rare earth metal oxides, and 24.0 – 29.0% of phosphate ($P_2O_5$) [17].

The results of the analysis of eight monazite thorium concentrate samples are shown in Table 1. It was noticed that the thorium concentration was in the range of 11.58 – 83.56% in the monazite thorium concentrates and the uranium concentration was in the range of 0.04 – 0.63%, which was much lower than the concentrations of thorium and REEs. Meanwhile, the light rare earth elements (LREEs) were in high concentrations compared to the heavy rare earth elements (HREEs) because monazite is originally rich with LREEs and thorium. The Ce content was the highest among the LREEs, and its range was between 4.62 – 41.68%. The La, Nd and Pr contents were lower at 17.86%, 17.54% and 4.83%, respectively. In addition, the rest of the REE concentrations were less than 3.50%.

First, thorium was extracted from thorium nitrate solution dissolved in nitric acid by two extractants. The efficiency of the extraction of thorium by the two extractants is displayed in Table 2. The results indicated that under constant experimental conditions, both the TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene were able to successfully extract thorium from pure thorium nitrate solution with an extraction efficiency of 96.92 and 99.84%, respectively, and the extraction efficiency from the thorium concentrates was in the range of 60.96 – 99.75%. From the comparison between the two extractants, Aliquat-336 (10%) in kerosene was more efficient than TBP for the extraction of thorium, and achieved an average extraction efficiency of 95.47% from the thorium concentrates,

while the average extraction efficiency of TBP (30%) was 89.02%. Basically, the extraction of thorium depends on the stability of the thorium-ligand complex in the aqueous phase, and the solubility of the extracted thorium in the organic phase. The extractant type and concentration, mixing time, settling time and organic/aqueous volumetric ratio have an effect on the extraction of thorium.

Table 2. Extraction efficiency % of thorium using TBP (30%) in kerosene and Aliquat-336 (10%) in kerosene

| **Sample ID** | **TBP (30%)** | **Aliquat-336 (10%)** |
|---|---|---|
| | **E%** | **E%** |
| Pure thorium nitrate | 96.92 | 99.84 |
| Thc1 | 94.95 | 99.75 |
| Thc2 | 90.59 | 94.22 |
| Thc3 | 89.44 | 97.72 |
| Thc4 | 88.97 | 97.43 |
| Thc5 | 96.12 | 95.05 |
| Thc6 | 95.13 | 98.48 |
| Thc7 | 96.02 | 99.70 |
| Thc8 | 60.96 | 81.38 |

Furthermore, the stripping results showed that distilled water was a good stripper with TBP (30%) in kerosene and with Aliquat-336 (10%) in kerosene, and it was more successful in stripping thorium from loaded TBP than from loaded Aliquat-336 with an average stripping percentage of 89.04% and 75.75%, respectively (see Figure 2). However, the use of different strippers will increase the efficiency of the stripping, especially when the process involves Aliquat-336. The stripping process depends on the type of stripping agent, the concentration, mixing time, settling time and the organic/aqueous volumetric ratio.

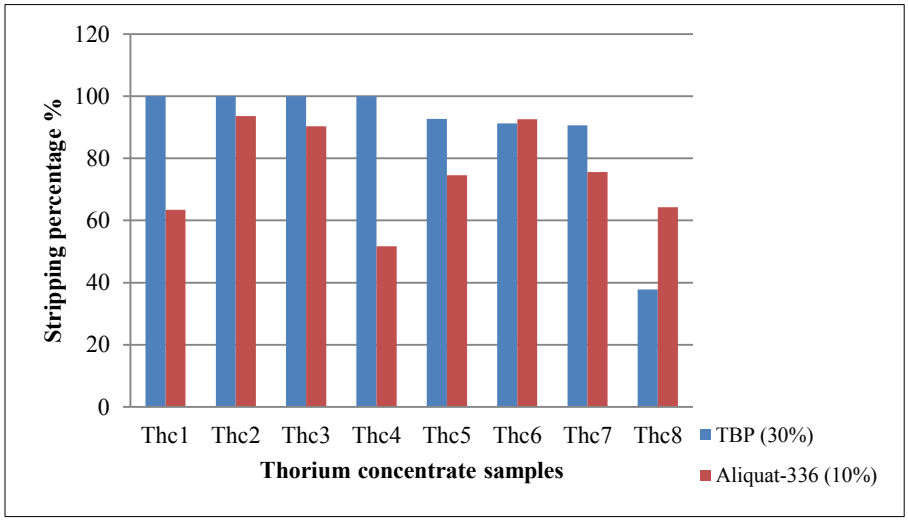

Figure 2. Stripping percentage of thorium by distilled water from loaded TBP (30%) in kerosene and Aliquate-336 (10%) in kerosene

The results of the analysis of the stripped aqueous solutions from loaded TBP and loaded Aliquat-336 for eight thorium concentrate samples are shown in Table 3. It can be seen the thorium purification range using TBP was good at approximately 30.65 – 91.28% compared to 29.49 – 86.90% for Aliquat-336. For uranium, slightly similar concentrations were shown using two extractants, while the REEs were high in the stripped solutions from Aliquat-336 compared to TBP. The study indicated that TBP was more efficient in the purification of thorium from REEs, and three stages of extraction and three stages of stripping were insufficient to obtain high-purity thorium. Therefore, the higher the number of cycles, the higher will be the level of purification.

## Conclusion

This study proved that pure thorium can be produced from monazite thorium concentrates by solvent extraction using TBP (30%) and Aliquat-336 (10%) in a nitric acid solution. Thorium was extracted successfully with an extraction efficiency in the range of 60.96 – 99.75% under constant experimental conditions. Aliquat-336 (10%) in kerosene was more efficient than TBP (30%) for thorium extraction, and achieved an average extraction efficiency of 95.47% compared to 89.02% with TBP (30%). Distilled water was able to strip thorium from TBP (30%) and Aliquat-336 (10%), and it was successful in the recovery of thorium, especially from TBP. Thorium purification of up to 91.28% was obtained in the stripped aqueous solutions. The results of this study indicate that both extractants can be used successfully to recover thorium from REEs, but to increase the purification of thorium, the number of extraction and stripping process stages should be increased.

**Abstract**

The calculation of spectral shifts in the UV-visible region, and the photostability of polyvinyl chloride membranes plasticized with 1-bromonaphthalene, dibutyl phthalate, dioctyl phthalate, *o*-nitrophenyl octyl ether and tricresyl phosphate, have been systematically investigated using the ZINDO/S method combined with stochastic molecular dynamics with the MMFF94 force field. A Langevin temperature bath was used for the thermostat and the simulation temperature was 298 K during the entire time of the simulation, which was set to 0.6 ns. These methods were employed to predict the molecular structure of the membranes. The absorption wavelengths and the HOMO and LUMO energies of membrane components are reported. In addition, the photostability of the membranes is discussed in the light of the absorption wavelength. Membranes plasticized with tricresyl phosphate and *o*-nitrophenyl octyl ether show less stability under the action of UV irradiation, as they absorb light with higher energy. Membranes plasticized with butyl and octyl esters of phthalic acid are more stable and show very similar behaviour. A membrane plasticized with 1-bromonaphthalene is likely to be the least sensitive to UV irradiation.

**Keywords**: polyvinyl chloride, membrane, molecular dynamics, excited state, photostability

**Abstrak**

Pengiraan anjakan spektra di dalam kawasan ultralembayung-cahaya nampak dan kestabilan foto bagi membran plastik polivinil klorida bersama 1-bromonaftalena, dibutil ftalat, dioktil ftalat, *o*-nitrofenil oktil eter dan tricresil fosfat telah secara sistematik telah dikaji mengunakan kaedah ZINDO/S gabungan molekul dinamik stokastik bersama medan daya MMFF94. Suhu rendaman Langevin telah diguna untuk termostat dan suhu simulasi ialah 298 K bagi keseluruhan masa simulasi, iaitu di tetapkan pada 0.6 ns. Kaedah ini dibangunkan untuk meramal struktur molekul membran berkenaan. Panjang gelombang serapan dan tenaga HOMO dan LUMO membran dilapor. Tambahan lagi, kestabilan foto bagi membran di bincang dari aspek panjang gelombang serapan. Membran plastik bersama tricresil fosfat dan *o*-nitrofenil oktil eter menunjukkan kestabilan yang rendah terhadap penyinaran UV sebagaimana ia menyerap cahaya pada tenaga yang tinggi. Membran plastik bersama butil dan oktil ester asid ftalik adalah lebih stabil dan menunjukkan sifat yang sama. Membran plastik bersama 1-bromonaftalena merupakan membran paling kurang sensitif terhadap penyinaran UV.

**Kata kunci:** polivinil klorida, membran, molekul dinamik, keadaan teruja, kestabilan foto

## Introduction

Ion-selective electrodes (ISEs) with plasticized membranes are widely used in analytical chemistry [1, 2]. ISEs can also be used in environmental analysis [3] and in clinical studies [4, 5]. The main advantages of using ISEs are:

short analysis time, high selectivity, sensitivity, reliability and reproducibility. Moreover, the electrodes in a potentiometer are relatively cheap and not cumbersome, which makes them suitable for use in the field.

Despite all these advantages, some disadvantages are also known, such as the drift in potential and the influence of interference ions [1]. Usually, errors are caused by changes in the membrane's characteristics during the operation of ISEs. The composition, homogeneity and lifetime of a membrane can change due to the leaching of the membrane's components, such as plasticizers or ionophores. Furthermore, degradation of polymeric compounds can be caused by ultraviolet irradiation. Near-UV radiation may be harmful to the plastics and plasticized plastic films [6-8]. The high-energy photons may cause a gradual degradation of the polymer or the plasticizer. Therefore, it is critical to identify the potential resistance properties of a membrane's materials, and to search for molecules that can withstand longer UV exposure. Even a small UV fraction may create major damage in the membrane via radical formation triggering photodegradation of the polymeric materials. This degradation causes a deviation in the conductivity of the ion-selective membrane and a deterioration in the membrane's physical and chemical properties. Therefore, from an application point of view, UV spectra and absorption energies must be considered as design parameters for the selection of materials in the construction of ISEs.

Quantum chemical calculation is a widely used method for the investigation of matter, especially in cases when direct physical measurements are not possible or too time-consuming. Computation and prediction of structure [9, 10], properties [11] and reactivity [12, 13] can readily be performed using various methods. The configuration interaction (CI) method is widely employed for the calculation of electronic spectra and photostability [14, 15].

In this work, we attempt to obtain a new insight into the photostability of five plasticized polymeric membranes. As model objects, we use polyvinyl chloride membranes plasticized with 1-bromonaphthalene (aBN), dibutyl phthalate (DBP), bis(2-ethylhexyl) phthalate also known as dioctyl phthalate (DOP), *o*-nitrophenyl octyl ether (NPOE) and tricresyl phosphate (TCP) [16, 17]. The absorption spectra obtained in this work will provide a valuable data set for other computational studies, and we will also use the data set as a basis for future experimental investigations.

## Materials and Methods

### Computational details

The simulations of the five systems were performed using stochastic molecular dynamics (MD) [18] with the MMFF94 force field [19]. The stochastic integrator uses a type of Langevin temperature bath for the thermostat, and the simulation temperature was 298 K. The total simulation time for each system was 600 ps, with 100 ps for equilibration and 500 ps as the sampling time. Snapshots were generated for each 10 ps period. The relaxation trajectory was obtained, with 50 snapshots for each system.

Using the snapshot geometries as input, the UV-Vis spectra of the five systems were calculated using the ZINDO/S method with the inclusion of all valence electrons [20]. The CI method in combination with the semi-empirical Hamiltonian enables the calculation of the absorption spectra of large organic systems. In the case of each membrane, we calculated a different number of first excited states, in such a way as to accurately describe the wavelength region above 200 nm. The average UV-Vis spectrum was obtained by overlapping all the spectra computed separately for each snapshot.

MD simulations were performed with the TINKER 7.1 package [21]. ZINDO/S calculations were performed with the program ORCA 3.0.3 [22]. The automatic computations for a group of snapshots were realized through the batch script. The Gabedit 2.4.9 program [23] was used to perform overlapping and visualization of the specified range of UV-Vis spectra. A VMD package [24] was used for calculation of the radial distribution function (RDF). Visualization of molecules and molecular orbitals was performed using the Jmol program [25].

## Results and Discussion

### Molecular dynamics simulation of modelled systems

Computations of PVC membrane parameters were performed on small systems that in our opinion can describe membranes in general reasonably well. Each simulated system (Table 1) was a small cluster of two molecules of plasticizer and one molecule of PVC polymer. This composition allows consideration of not only the polymer-

plasticizer interaction but also the interaction between plasticizer molecules. The PVC polymer was modelled as a linear molecule consisting of PVC monomers, $–CH_2$-CHCl-, and terminal H atoms. The size of the PVC molecule was different in each system to maintain the membranes' composition ratios of PVC to plasticizer at approximately 1:1.

Table 1. Simulated systems and their fundamental properties

| # | Number of $-CH_2$-CHCl- | Plasticizer:PVC Ratio (%) | Composition | Atoms | Formula | Weight (g/mol) |
|---|---|---|---|---|---|---|
| 1 | 6 | 52.35 : 47.65 | 2aBN+$PVC_6$ | 74 | $C_{32}H_{34}Br_2Cl_6$ | 791.138 |
| 2 | 8 | 49.93 : 50.07 | 2DBP+$PVC_8$ | 134 | $C_{48}H_{70}Cl_8O_8$ | 1058.689 |
| 3 | 12 | 50.95 : 49.05 | 2DOP+$PVC_{12}$ | 206 | $C_{72}H_{114}Cl_{12}O_8$ | 1533.107 |
| 4 | 8 | 49.34 : 50.66 | 2NPOE+$PVC_8$ | 131 | $C_{45}H_{70}Cl_8N_2O_6$ | 1018.671 |
| 5 | 12 | 49.49 : 50.51 | 2TCP+$PVC_{12}$ | 168 | $C_{66}H_{80}Cl_{12}O_8P_2$ | 1488.720 |

Figure 1 shows the change in total energy at a time during the MD simulation. The chosen integrator provides a reasonable numerical stability. Despite rounding errors and other numerical inaccuracies, the total energies of the systems are relatively well conserved. This shows relative stability and characterizes the chosen method as good enough to obtain reliable geometries. In addition, the thermostat is highly stable, with fluctuations mostly in ±5 K range, and only in a few steps was the deviation in temperature higher than 20 K. Intermolecular interaction energies, on the other hand, fluctuate considerably for each system during the simulation time. This behaviour can be explained in terms of the size of the system components. There is a huge number of possible conformers for these components, and this can cause huge deviations in intermolecular distances and large fluctuations in this type of interaction. Despite rounding errors and other numerical inaccuracies, the total energy of the system is very well conserved (Figure 1).

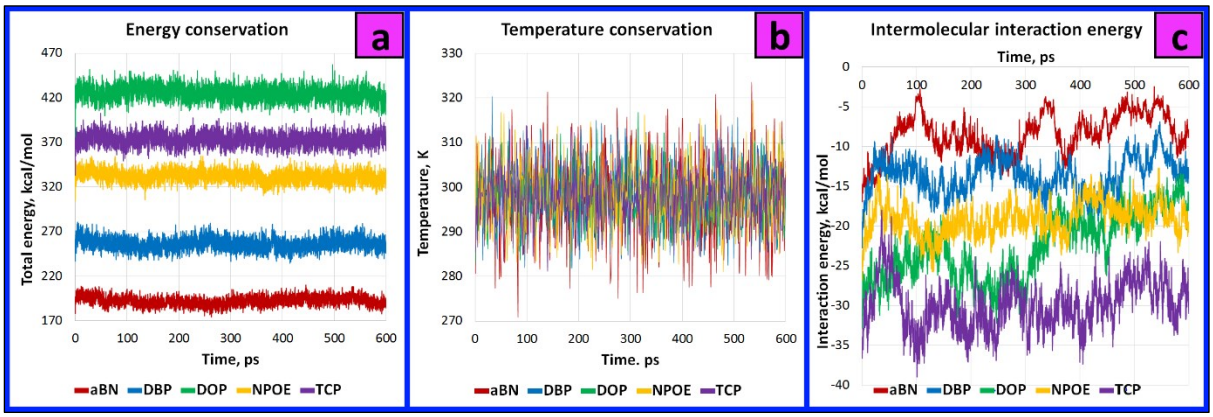

Figure 1. Characteristics of MD simulation (a) conservation of energy, (b) conservation of temperature and (c) intermolecular interaction energy

**1-bromonaphthalene-polyvinyl chloride system**

One of the snapshots of the HOMO and LUMO orbitals is shown in Figure 2. The HOMO of the aBN-PVC complex is located along the naphthalene ring and its energy is –8.00 eV. The LUMO of –0.81 eV is also located in the naphthalene ring. The HOMO–2 and HOMO–1, as well as the LUMO+1 and LUMO+2 of this system are focused on aromatic naphthalene moieties and, among others, also lie in the same energy regions of –9.24 eV, –8.28 eV, –0.71 eV and –0.39 eV respectively. This orbital distributions and energies are not unique to this specific

snapshot but are in general the same for all the generated structures. The RDF is also presented, showing that the average distance between plasticizer molecules and polymer molecules is about 3-15 Å, and the maximal value of the RDF distance during the simulation is 5-7 Å. The distance between 1-bromonaphthalene molecules during the simulation is generally in the range 4-7 Å.

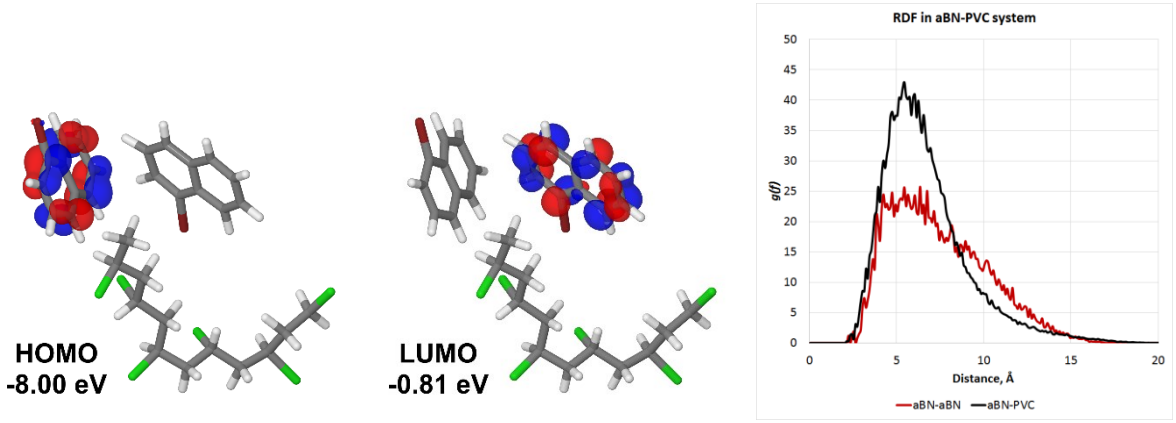

Figure 2. Snapshot geometry with HOMO, LUMO orbitals and RDF for average simulation trajectory of aBN-PVC system

**Dibutyl phthalate-polyvinyl chloride system**

The HOMO and LUMO orbitals of the DBP-PVC system are shown in Figure 3. The HOMO is located along the benzene ring of the phthalic acid fragment and its energy is –9.55 eV. The LUMO, with energy –1.15 eV, is also located on the benzene ring. The HOMO–2, HOMO–1, LUMO+1 and LUMO+2 energies of this system are –9.84 eV, –9.56 eV, –0.96 eV and –0.25 eV respectively. These are also focused on the aromatic phthalic acid moieties of different molecules of DBP. The distribution of orbitals and energies is characteristic for all generated snapshots of the DBP-PVC system. The RDF shows that the average distance between dibutyl phthalate molecules and polyvinyl chloride is in the range 3-17 Å, with the maximum RDF distance in the region of 5-7 Å.

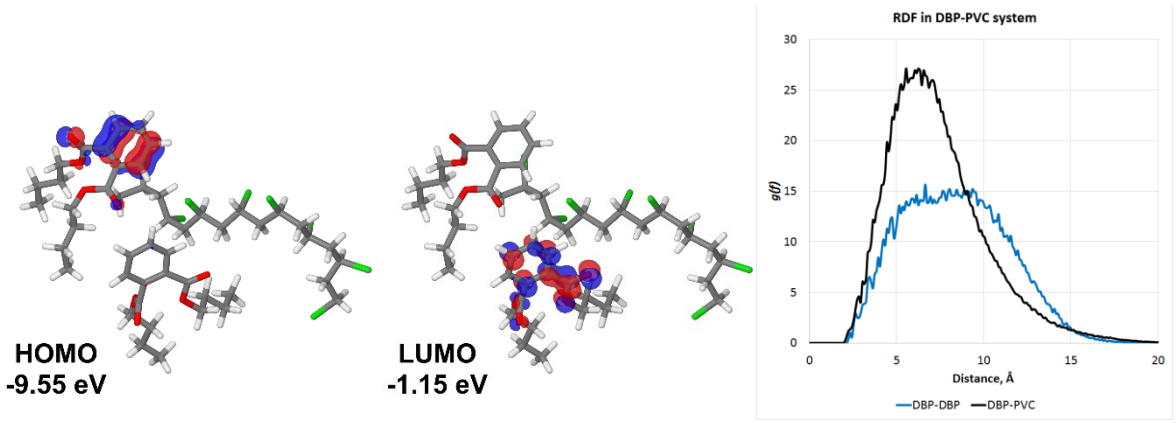

Figure 3. Snapshot geometry with HOMO, LUMO orbitals and RDF for average simulation trajectory of DBP-PVC system

**Dioctyl phthalate-polyvinyl chloride system**

Figure 4 represents the geometry of the DOP-PVC system. The RDF shows that average distance between dioctyl phthalate molecules and polyvinyl chloride is in the range 3-15 Å, with the maximum RDF distance in the region of

6-7 Å. The RDF for the distance between molecules of dioctyl phthalate has a maximum in the region of 5-10 Å. The frontal molecular orbitals can be characterized with the following values of energy: HOMO–2: –9.73 eV, HOMO–1: –9.59 eV, HOMO: –9.29 eV, LUMO: –1.04 eV, LUMO+1: –0.76 eV, LUMO+2: –0.32 eV. All frontier orbitals of the agglomerate are located along the benzene ring of the phthalic acid fragment, similarly to the DBP-PVC system. This can be explained by the similarity in structure and properties of DBP and DOP plasticizers.

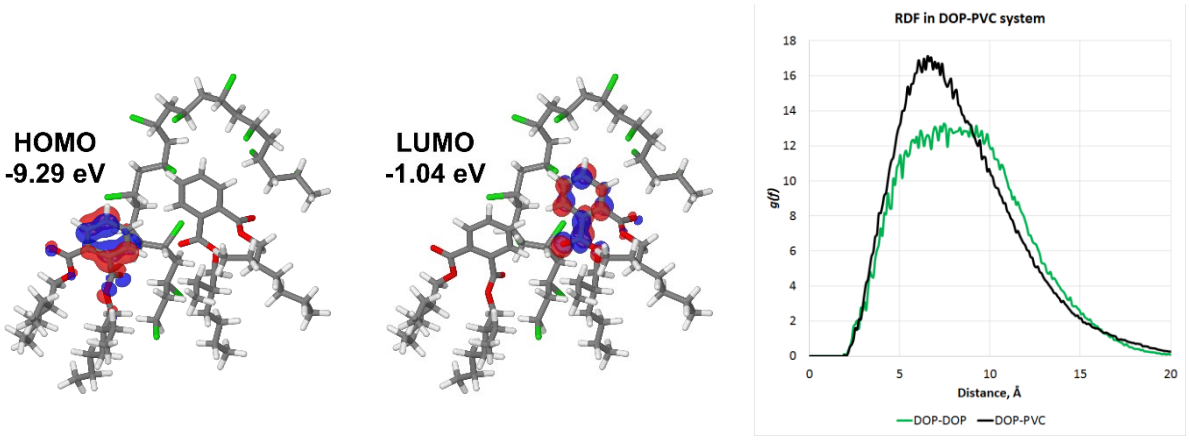

Figure 4. Snapshot geometry with HOMO, LUMO orbitals and RDF for average simulation trajectory of DOP-PVC system

**Nitrophenyl octyl ether-polyvinyl chloride system**

The geometry of the NPOE-PVC system, with HOMO and LUMO orbitals and RDF distances, is represented in Figure 5. During the MD simulation, the maximum distance distribution between NPOE molecules and PVC was about 5-8 Å with a total range of RDF distances of 3-15 Å and a distance between NPOE molecules of around 5-7 Å. The frontal molecular orbitals HOMO–2, HOMO–1, HOMO, LUMO, LUMO+1 and LUMO+2 were characterized by the following values of energy: –9.89 eV, –9.55 eV, –9.42 eV, –3.10 eV, –2.71 eV and –0.34 eV respectively. The HOMO is mostly localized on the phenyl ether moiety, whereas the LUMO is in the region of the nitro group. This is in good agreement with general knowledge about the reactivity of organic molecules.

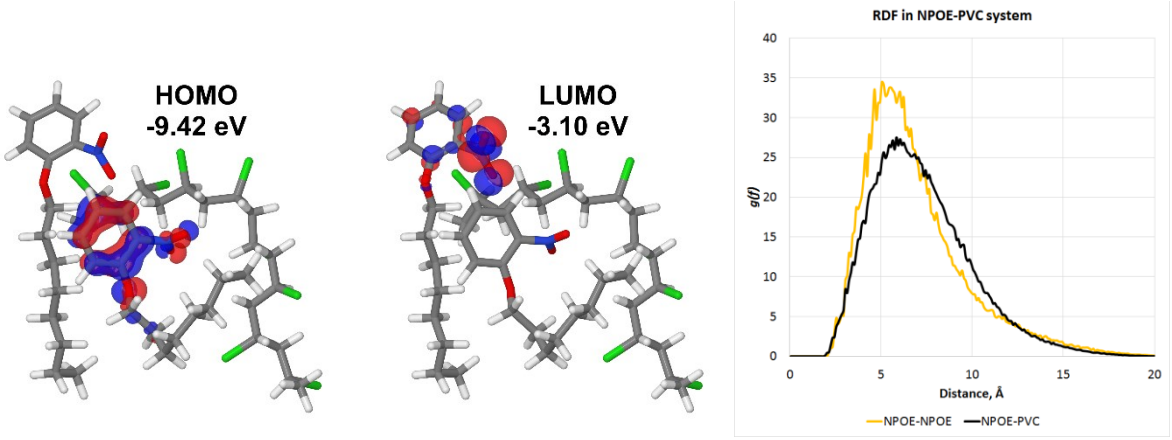

Figure 5. Snapshot geometry with HOMO, LUMO orbitals and RDF for average simulation trajectory of NPOE-PVC system

**Tricresyl phosphate-polyvinyl chloride system**

One of the snapshots of the HOMO and LUMO orbitals is shown in Figure 6. The HOMO of the TCP-PVC complex is located along the methyl phenyl rings of the TCP molecule and its energy is –8.59 eV. The LUMO of 0.07 eV is in the region of the CH-Cl bond of polyvinyl chloride. The HOMO–2 and HOMO–1 are focused on the aromatic moieties of the plasticizer molecules and lie in the same energy regions of –8.65 eV and –8.68 eV, whereas the LUMO+1 and LUMO+2 have energy values of 0.156 eV and 0.163 eV respectively and are located on the PVC molecule. This contrasts with all the other systems described here. To understand this behaviour, we analysed the partial atomic charges for each snapshot, and this showed the transport of a small amount of negative charge from TCP to the PVC chain. The average charge of TCP during the simulation is only –0.01, but this small difference explains the location of unoccupied orbitals and predicts that in the TCP-PVC system the polyvinyl chloride molecule will show more pronounced electrophilic properties. The RDF shows that the average distance between the phosphoric acid ester and the chlorinated polymer is about 3-15 Å, and the maximal value of the RDF distance during the simulation is 4-6 Å.

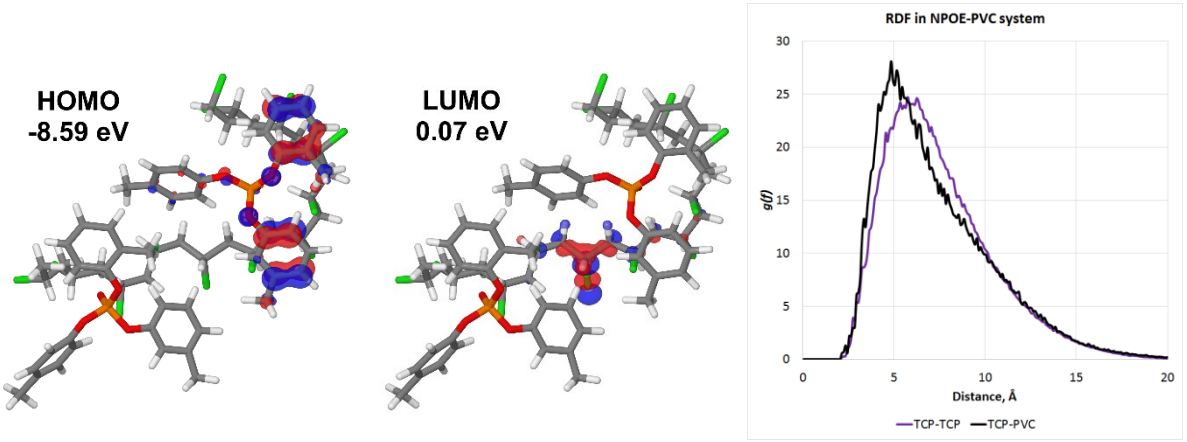

Figure 6. **Snapshot geometry with HOMO, LUMO orbitals and RDF for average simulation trajectory of TCP-PVC system**

**Photochemical stability**

In general, the absorption spectrum of a complex of polyvinyl chloride with a plasticizer molecule containing a phenyl ring is expected to show similarities to a non-substituted benzene molecule. The principal absorption bands in the plasticizer molecules are due to the $\pi \rightarrow \pi^*$ transitions in the benzene moieties. However, these benzene-like transitions are not the same in the modelled systems. This difference can be explained by the influence of another condensed phenyl ring in the 1-bromonaphthalene molecule or by the presence of different substituents and conjugation in the other plasticizers considered.

The detailed graph of the comparisons of the UV-Vis spectra computed using the ZINDO/S method is shown in Figure 7. Variations in the absorption spectra were observed for different plasticizer-polyvinyl chloride systems.

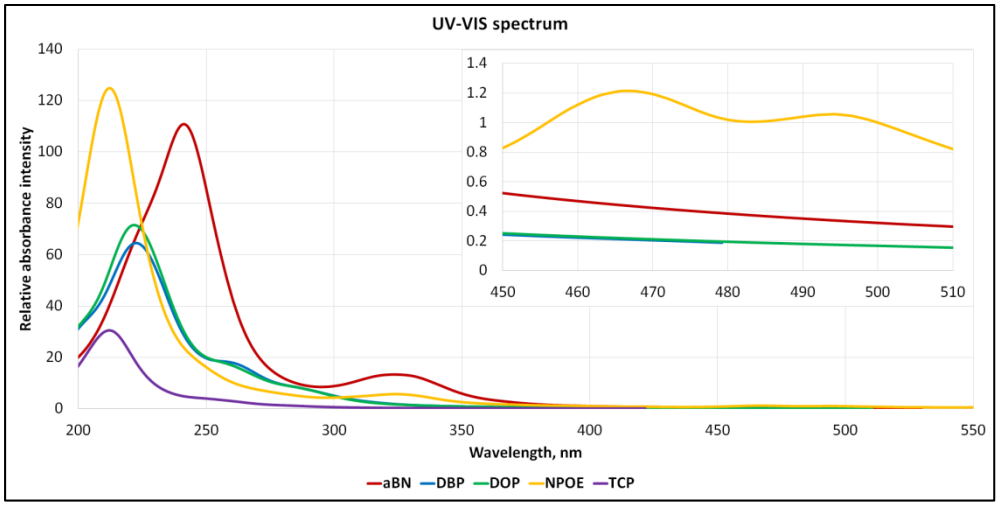

Figure 7. Average UV-Vis spectrum for five systems

**1-bromonaphthalene-polyvinyl chloride system**
In the UV region, three strong absorptions at 221.42 nm (λ1), 241.44 nm (λ2) and 323.45 nm (λ3) were observed. However, no absorption was observed in the visible region. The strongest band appears in the region of 200 nm to 296.05 nm, with an absorption maximum ($\lambda_{max}$) at 241.44 nm (λ2). The absorption band at 323.45 nm (λ3) is in general agreement with UV-Vis spectra of aBN from the NIST database [26]. Experimental data show that the multiple bands in the region of 256 – 320 nm, and the shift of about 30 – 50 nm could be explained by the influence of PVC and by computational error.

**Dibutyl phthalate-polyvinyl chloride system**
Figure 7 shows three prominent bands in the UV region with absorption maxima at 222.66 nm (λ1), 260.57 nm (λ2) and 284.78 nm (λ3) for DBP. The strongest band was observed from 200 nm to 244.44 nm with an absorption maximum at 222.66 nm (λ1). The absorption band at 284.78 nm (λ3) is in very good agreement with experimental UV-Vis spectra of DBP from the NIST database [27], which show bands at 277 nm and 286 nm.

**Dioctyl phthalate-polyvinyl chloride system**
Three strong absorption bands were observed for DOP in the UV region, with absorption maxima at 226.59 nm (λ1), 266.59 nm (λ2) and 284.94 nm (λ3) (Figure 7). The strongest band was observed in the region from 200 nm to 241.88 nm, with an absorption maximum at 226.59 nm (λ1).

**Nitrophenyl octyl ether-polyvinyl chloride system**
The absorption spectrum of the NPOE-PVC system (Figure 7) exhibits one strong and one weak absorption band in the UV region, with absorption maxima at 212.11 nm (λ1) and 324.16 nm (λ2) respectively. In addition, there are two very weak absorption bands in the visible region, with absorption maxima at 466.15 nm (λ1) and 493.88 nm (λ2). This is in a very good agreement with the fact that NPOE is itself yellow, and absorption in the visible region is very close to the predicted absorption.

**Tricresyl phosphate-polyvinyl chloride system**
Two strong absorption bands were observed for the TCP-PVC system in the UV region, with absorption maxima at 212.33 nm (λ1) and 249.16 nm (λ2) (Figure 7). One very weak absorption band at 279.08 nm (λ3) is also present. The strongest band was observed in the region from 200 nm to 240.08 nm with an absorption maximum at 212.33 nm (λ1).

## Conclusion

Calculations have been carried out on five plasticizer-polyvinyl chloride systems, to study their ultraviolet stability in the light of the shift of absorption wavelength with respect to the nature of the plasticizer. The electronic absorption spectra of plasticized membranes, except in the tricresyl phosphate-polyvinyl chloride system, show the strongest absorption band due to the transitions between the energy states HOMO–1→LUMO and HOMO→LUMO+1, which can be assigned as $\pi \rightarrow \pi^*$ transitions. This is due to the presence of two molecules of plasticizer in the systems described, and whereas the HOMO–1 and LUMO correspond to one phenyl/naphthyl ring, the HOMO and LUMO+1 correspond to a transition in another phenyl/naphthyl ring. In the case of the TCP-PVC system, the absorption bands mainly induce transitions of electrons from plasticizer molecules to the polymeric chain.

The principal absorption bands of membranes with TCP and especially with NPOE (considering the much higher relative absorption intensity) show that these membranes are less stable under the action of UV irradiation, as they absorb light with higher energy, causing the bonds to be more easily destroyed. DBP- and DOP-containing systems show very similar behaviour, and they are more stable than the two previously mentioned membranes. A membrane containing 1-bromonaphthalene as a plasticizer is likely to be the least sensitive to UV irradiation.

The methods described show good performance in the study of photostability, and this provides a basis for the future development of computer investigations and quantum chemical simulations in very complex and important objects such as synthetic membrane materials. Furthermore, the presented findings demonstrate that not all placticizers in membranes have the same stability, and therefore testing is needed in each case.

**Abstract**

The behavior of complex formation of Re(V) metal ion with azathioprine (AZ) and ceftriaxone (CE) as medicinal drugs has been investigated potentiometrically in 0.3 M hydrochloric acid. The stability constant of the prepared complexes has been determined and calculated at various temperatures. The obtained results showed that Re(V)-AZ system showed the formation 1:2, 1:3 and 1:4 complexes, while Re(V)-CE showed only 1:1 and 1:2 complexes. The complex formation suggests a successive displacement of the chloride molecules from the coordination sphere of the central ion by the AZ ligand. In addition, the effect of temperature on the complexes formation of Re(V) with AZ and CE was investigated. The entropy and enthalpy changes showed a favorable and exothermic process, respectively. The kinetic parameters of the formation complex process were calculated and discussed.

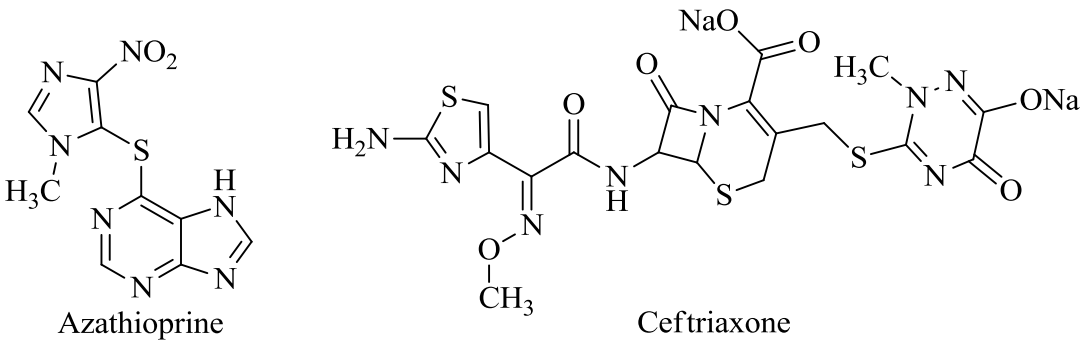
**Abstrak**

Tingkah laku penghasilan kompleks ion logam Re(V) dengan azatioprina (AZ) dan ceftriaxon (CE) sebagai ubat – ubatan telah dikaji secara potentiometri dalam 0.3 M asid hidroklorik. Pemalar kestabilan terhadap kompleks yang dihasilkan telah ditentukan dan dikira pada pelbagai tahap suhu. Hasil yang diperoleh menunjukkan bahawa sistem Re(V)-AZ mempamerkan penghasilan kompleks 1:2, 1:3 dan 1:4, sementara Re(V)-CE mempamerkan hanya kompleks 1:1 dan 1:2. Penghasilan kompleks mencadangkan satu anjakan molekul klorida berturut-turut dari lingkungan koordinasi ion tengah oleh ligan AZ. Di samping itu, kesan suhu pada pembentukan kompleks Re(V) dengan AZ dan CE telah dikaji. Perubahan entropi dan entalpi menunjukkan proses yang baik dan eksotermik. Parameter kinetik proses penghasilan kompleks turut dikira dan dibincangkan.

**Kata kunci:** rhenium(V), ubat, potentiometri, penghasilan kompleks, pemalar kestabilan



## Introduction

The stability of complexes with medicinal drugs plays a major role in their biological and chemical activities. This is due to that, the medicinal drugs have various functional groups, which can bind to metal ions present in the human body [1, 2]. The azathioprine (AZ) is an immunosuppressive drug used in organ transplantation and autoimmune diseases [3 – 5] while the ceftriaxone (CE) is effective against a wide variety of Gram-positive and Gram-negative bacteria [6 – 9]. Very few works investigated the stability constant and thermodynamic parameters (ΔG, ΔH and ΔS) of Re-Az and Re-CE complexes at different temperatures. The complex formation behavior of AZ with various metal ions has been studied by the potentiometric titration method [10]. AZ is found to form 2:1

complexes with Co(II), Cu(II) and Ni(II), in the stability order of Cu(II) > Ni(II) > Co(II). The effect of various divalent cations on the encapsulation efficiency of gellan gum and to probe the underlying mechanisms responsible for drug loading efficiency. Spherical beads containing AZ were prepared from deacetylated gellan gum by ionotropic gelation method [11]. The anti-rheumatic studies on AZ have also involved its Cu(II) complexes as the possible active form and the stoichiometry and the stability constants of AZ metal complexes, even with that of Cu(II), have been determined [12].

CE is evaluated as a corrosion inhibitor for carbon steel alloys in the presence of 0.5 M hydrochloric acid (HCl) at different concentrations, i.e., 10-50 ppm and different temperatures [13]. Studies of the mechanism, kinetics and thermodynamic constants of VO(II) and Cu(II) complexes with CE in the pH range of 2 – 5 at temperatures of 303, 313, 323 and 333 K, using reversed phase HPLC and ion exchange HPLC were reported [14]. CE degradation in aqueous solution was studied at 310 and 353 K in acidic, basic and neutral conditions. Stability constants of Re(V) metal complexes with selected medicinal drugs adenosine, isoniazid and metformin hydrochloride have been determined using a pH metric titration technique in aqueous HCl at different temperatures and an ionic strength of 0.2 M [15]. The process of complex formation of Re(V) ion with 2-mercapto-pyridine was investigated potentiometrically by evaluating formation the equilibrium and stability constants of the metal complex at the temperature range of 273-338 K [16].

In the present study, the formation equilibrium investigations were extended to the stoichiometry and stability constants of complex formation of AZ and CE (Scheme 1) with Re(V) metal ion in aqueous HCl at different temperatures. Moreover, the kinetic parameters of the complex formation were determined and discussed.

## Materials and Methods

### Materials

Potassium perrhenate ($KReO_4$) and iodine were purchased from Aldrich and Fluka, respectively. $KReO_4$ was converted to $K_2ReOCl_5$ precursor according to the method reported elsewhere [17]. The concentration of metal ion solution was determined spectrophotometrically at wavelength (λ) of 480 nm. A pure AZ and CE drugs were purchased from the local market (El-Nasr Pharm. Chem. Co., Egypt), potassium iodide and HCl (36.4%) was purchased from BDH.

### Titration method

Potentiometric titrations were performed using a R3003 voltage comparator. A platinum plate was used as an indicator electrode. The redox system consisting of AZ and CE was created by oxidizing a small portion of the initial drugs in 0.3 M HCl with 0.1 N iodine solution (0.5 mL). The stepwise complexes of Re(V) with AZ and CE were studied using the Bjerrum method [18, 19]. For this purpose, the redox system consisting of the drugs (0.04192 mol/L) and its oxidized form titrated with a $K_2ReOCl_5$ solution (0.0799 mol/L) in 0.3 M HCl. The

equilibrium ligand concentration ([L]) and the formation function ($\bar{n}$) at each titration point was calculated using the equations (1) and (2) [20, 21], respectively:

$$\log [L] = \frac{E_I - E_i}{1.9837x10^{-4}\,T} + logC_L^l + \frac{1}{2}\, log\frac{V_I}{V_T} \quad (1)$$

$$\bar{n} = \frac{C_L^l - [L]}{C_M} \quad (2)$$

where, $E_I$ and $E_i$ are the initial equilibrium potentials of the system in the absence of metal ion and at the current titration point, $C_L^1$ is the drug initial concentration of, $V_I$ and $V_T$ are the initial and total volumes, respectively, T is the temperature in K and $C_M$ is the concentration of metal ion at each titration point.

The stepwise stability constants (log $K_i$) of the complexes were calculated at half-integer values of the degree of formation. Thus, a large equilibrium constant indicates a highly stable complex. The overall stability constant (βi) defined as the following equation 3 [22]:

$$\log \beta_i = \log K_1 + \log K_2 + \log K_3 \ldots\ldots + \log K_i \quad (3)$$

The log $K_i$ of the complexes was calculated at 288, 298, 308 and 318 K.

The complex formation thermodynamic characteristics such as: enthalpy (ΔH), Gibb's free energy (ΔG) and entropy (ΔS) are a fundamental important properties of understanding of the various factors such as electronic and steric effects, solute-solvent interactions that may influence on the complexes [23]. The thermodynamic parameters of the metal ion complexes at 288, 298, 308, and 318 K were studied. The complex degree of formation was obtained according to the equations (4) and (5) [24, 25]:

$$\boldsymbol{\Delta G = \Delta H - T\Delta S} \quad (4)$$

$$\boldsymbol{\log\, K_i = \frac{-\Delta H}{2.303\,R} + \frac{1}{T} \times \frac{\Delta S}{2.303\,R}} \quad (5)$$

where, R is the ideal gas constant (8.314 J/K mol). ΔH and ΔS were obtained from the intercept and slope of the plot of log $K_i$ against 1/T.

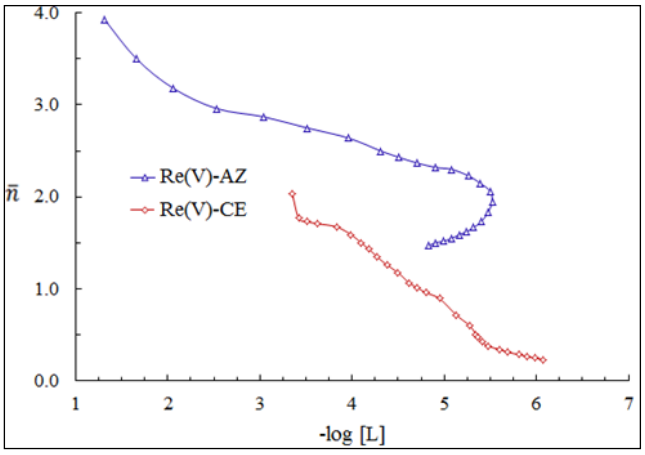
## Results and Discussion

### Potentiometric titration

The metal ion in solution excites as combined with ligands or chelating groups instead of isolated form, giving rise to complexions or coordination compounds. The obtained titration data were analyzed and then stability constant values were calculated [26]. The experimental data show that the equilibrium potential of the redox system increases in the process of potentiometric titration as the metal ion volume increases. During the titration, no precipitates were formed indicating that there is no tendency to form hydroxide complexes [27]. Intense coloration was observed, which indicated the complexes formation. The formation curves were plotted between $\bar{n}$ and -log [L]. The coordination process in the systems Re(V)-AZ and Re(V)-CE in 0.3 M HCl at various temperatures were characterized by the formation curves as displayed in Figure 1.

Re(V) exists in solutions and solids as octahedral species [28, 29]. In this study, the obtained complexes of Re(V) with AZ and CE have a coordination number of six [30, 31]. AZ is considered as neutral and monodentate ligand and the coordination bonds occur between the lone pair of sulfur atom and Re(V) [32]. The Re(V)-AZ system has a maximum value of $\bar{n}$ = 4, this indicates the formation 1:2, 1:3 and 1:4 complexes. While about 1:1 complex has not formed. The complex formation suggests a successive displacement of the chloride molecules from the coordination sphere of the central ion by the AZ and CE ligands [33]. The maximum value of $\bar{n}$ in the Re(V)-CE system was 2, this shows the formation of 1:1 and 1:2 complexes. On the other hand, CE loses one sodium atom and becomes anionic. In case of 1:1 complex, Re(V) unit is coordinated by a mono anionic O,O-bidentate unit of CE ligand, one

CE and three halogens, with Re(V) center in a distorted octahedral environment. The halide ligands are in *cis* positions to each other [34, 35]. The proposed mechanism of the Re(V)-CE complex formation process 1:1 and 1:2 ratios according to the following reaction (Scheme 2). The estimated log $K_i$ values of Re(V) complexes with AZ and CE at different temperatures are listed in Table 1.



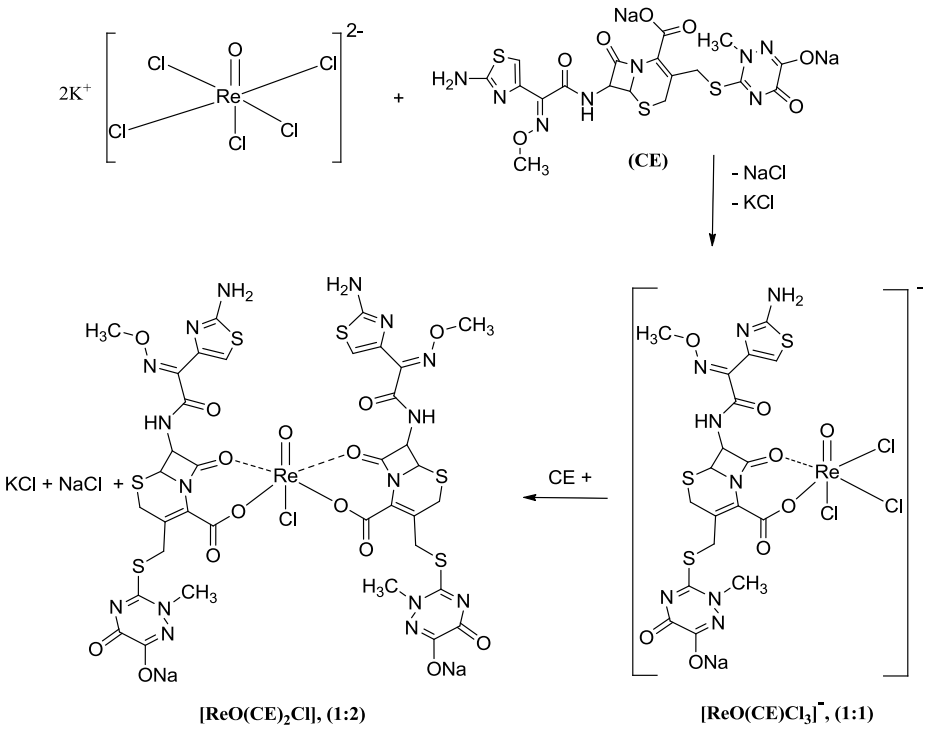


Figure 1. Formation curves of Re(V) complexes with AZ and CE in 0.3 M HCl at 318 K

Scheme 2. The chelation between the $[ReOCl_5]^{2-}$ and CE

Table 1. Stepwise stability constants of Re(V) complexes in 0.3 M HCl

| T (K) | Re(V)-AZ | | | | Re(V)-CE | | |
|---|---|---|---|---|---|---|---|
| | log $K_{2AZ}$ | log $K_{3AZ}$ | log $K_{4AZ}$ | log $\beta_{iAZ}$ | log $K_{1CE}$ | log $K_{2CE}$ | log $\beta_{iCE}$ |
| 288 | 5.93 | 5.30 | 1.82 | 13.05 | 6.66 | 4.95 | 11.61 |
| 298 | 5.84 | 5.13 | 1.77 | 12.72 | 6.34 | 4.67 | 11.01 |
| 308 | 5.32 | 4.66 | 1.72 | 11.63 | 6.11 | 4.33 | 10.44 |
| 318 | 4.91 | 4.31 | 1.66 | 10.84 | 5.35 | 4.10 | 9.45 |

It is observed from Table 1 that, the temperature increase leads to decreasing in log $\beta_i$ values for both AZ and CE. It could be seen from data in all the cases that the differences between $K_1$, $K_2$, $K_3$ and $K_4$ values are found to be high which indicate the formation of the stepwise complex. The value of the ratio of log $K_1$/log $K_2$ or log $K_2$/log $K_3$ is positive in all the cases. This implies that there is no steric hindrance to the addition of a secondary ligand molecule [36]. This is due to the statistically effective and statistically coordination of a second molecule is difficult when compared to the first due to the availability of less number of coordinating sites on the metal ion for the second ligand [37].

**Complexes thermodynamic**

The chemical species in the reaction undergo a change in their concentrations, at the same time. The Gibb's free energy is a function of the concentrations of reactants and products. Entropy is a measure of energy that is unavailable for useful, chemical work. The entropy of an individual species is always positive and tends to be larger for gases than for solids, and for more complex molecules than for simple molecules. The thermodynamic parameters values of Re(V)-AZ and Re(V)-CE complexes have been calculated from the temperature dependent data given in Table 1.

The thermodynamic data were plotted as the values of equilibrium constants (log $K_i$) versus the reciprocal of temperature (1/T) as shown in Figures 2 and 3 for AZ and CE complexes, respectively. All the thermodynamic parameters of the stepwise stability constants of the complexes are given in Table 2.

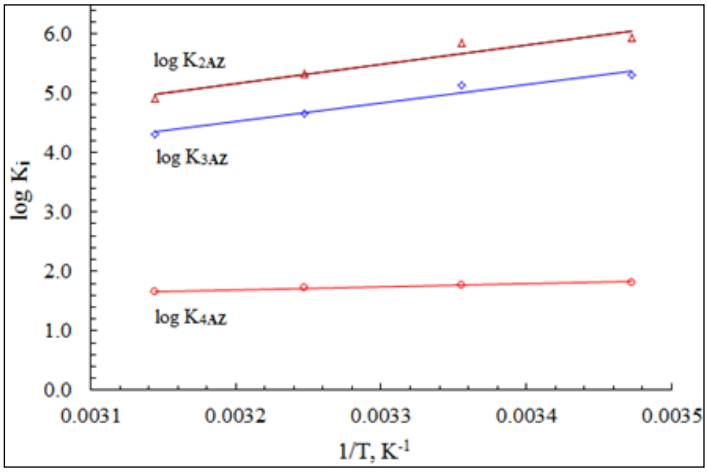

Figure 2. The relations between the values of equilibrium constants (log $K_i$) versus the reciprocal of temperature (1/T) of Re(V)-AZ complexes: log $K_2$ corresponds to $[ReO(AZ)_2Cl_3]$; log $K_3$ corresponds to $[ReO(AZ)_3Cl_2]^+$ and log $K_4$ corresponds to $[ReO(AZ)_4Cl]^{2+}$ species

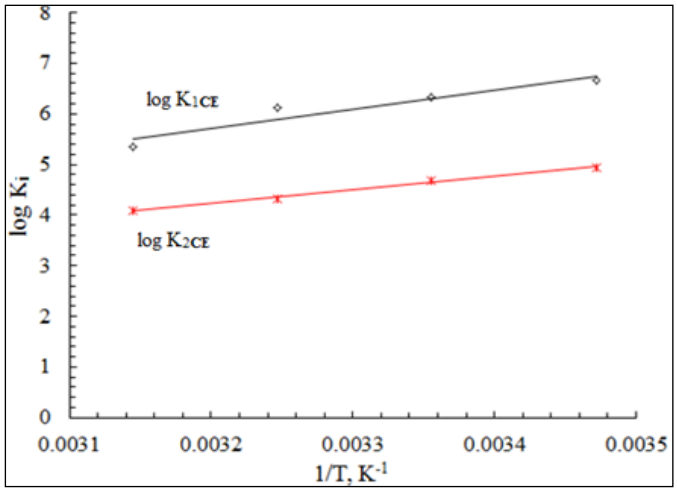

Figure 3. The relations between the values of equilibrium constants (log $K_i$) versus the reciprocal of temperature (1/T) of Re(V)-CE complexes: log $K_1$ corresponds to $[ReO(CE)Cl_3]^-$ and log $K_2$ corresponds to $[ReO(CE)_2Cl]$ species

Table 2. Thermodynamic parameters of Re(V) complexes with AZ and CE in 0.3 M HCl

| **Species** | **– ΔG (kJ/mol)** | **– ΔH (kJ/mol)** | **ΔS (J/K mol)** |
|---|---|---|---|
| $[ReO(AZ)_2Cl_3]$ | 32.32 | 62.36 | –100.78 |
| $[ReO(AZ)_3Cl_2]^+$ | 28.58 | 60.07 | –105.66 |
| $[ReO(AZ)_4Cl]^{2+}$ | 10.08 | 92.76 | 2.71 |
| $[ReO(CE)Cl_3]^-$ | 35.99 | 72.40 | –12.18 |
| $[ReO(CE)_2Cl]$ | 26.51 | 50.70 | –81.60 |

The stepwise formation constants of complexes of the type $ML_n$ (where $M$ is the metal, $L$ is the ligand and $n$ is the number of ligands) decrease in magnitude as $n$ increases. This may be partly explained in terms of the entropy factor. In the case of the formation of octahedral complexes of Re(V)-AZ, the reaction between $K_2[ReOCl_5]$ and AZ involves three successive reactions as the following equations (6-8).

$$K_2[ReOCl_5] + 2AZ \leftrightharpoons [ReO(AZ)_2Cl_3] + 2KCl \quad (6)$$

$$[ReO(AZ)_2Cl_3] + AZ \leftrightharpoons [ReO(AZ)_3Cl_2]Cl \quad (7)$$

$$[ReO(AZ)_3Cl_2]Cl + AZ \leftrightharpoons [ReO(AZ)_4Cl]Cl_2 \quad (8)$$

In equation (6), the two ligands ($n$ = 2) can go into two cites out of five of $K_2[ReOCl_5]$. For equation (8), $n$ = 4 and the fourth ligand can go into one of two sites of $K_2[ReOCl_5]$. This means that there is more randomness in the first step than the fourth one, so ΔS is more positive (2.71), ΔH is more negative (-92.76) and log $K_2$ > log $K_4$ [38]. In addition, there is a dramatic increase in ΔS for adding two compared to adding four monodentate AZ ligands (-100.78 to 2.71 J/K mol) which changed from negative (unfavorable) to positive (favorable). Using the equilibrium constant for the complex formation of Re(V)-CE where the one and two bidentates ligand replace the monodentates chloride ions, it has been found the ΔS decrease (-12.18 to -81.60). The negative change in ΔS indicates a highly solvated metal complex and indicated that the formation of these complexes was entropy favored [39, 40]. ΔH

change for the complexes suggests that all the complexation reactions releasing heat have a negative value (exothermic), favorable at a lower temperature. The metal-ligand binding process is enthalpy driven and metal-ligand bonds are strong [41]. The sign of ΔG indicates the direction in which a reaction moves to reach its equilibrium position. The complexation reactions are thermodynamically favorable when its enthalpy decreases and its entropy increase. Substituting the inequalities $\Delta H < 0$ and $\Delta S > 0$ into the previous equation (4) shows that complexation reactions are thermodynamically favorable and spontaneous when ΔG is negative [42]. Similar trend was obtained for Re(V) with another ligand [38].

**Distribution diagrams**

Mole fractions are commonly used to calculate the concentrations of the individual complexes based on the formation constants. Mole fractions of a form of the complex compressed as the ratio of the concentration of the complex to the total concentration of the metal ion. The distribution diagrams were drawn in the titration where the Re(V) to ligands, mole ratio was 1:1, 1:2, 1:3 and 1:4 at 318 K (Figure 4). It was obtained using Microsoft Excel calculations [43] and the concentration of total metal ions (0.0799 mol/L) was set as 100%.

In Figure 4, the species $[ReO(AZ)_2Cl_3]$ for the system Re(V)-AZ reached a maximum of 2.9%. The second species $[ReO(AZ)_3Cl_2]^+$ and $[ReO(AZ)_4Cl]^{2+}$ reached a maximum of 85.3% and 96.6%, respectively. For Re(V)-CE system, it reached a maximum of 67.5% and 99.89% for $[ReO(CE)Cl_3]^-$ and $[ReO(CE)_2Cl]$ species, respectively. The analysis of the temperature-dependent distribution function shows that the yield of the complexes decreases with increasing the temperature. The analysis of the distribution curves provides the possibility to elucidate the predominance region for some complex depending on temperature and concentration. These results were used to develop optimal methods for the preparation of Re(V) metal ion complexes with AZ and CE in 0.3 M HCl.

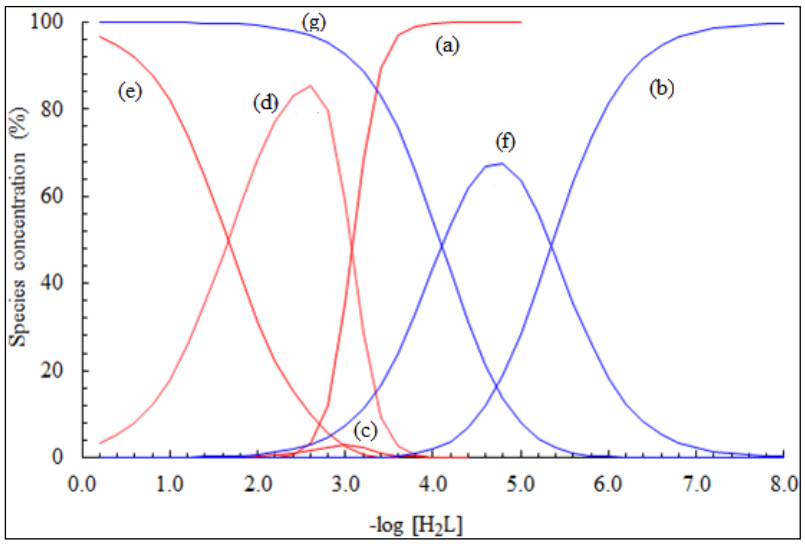

Figure 4. Distribution curves of Re(V) complexes with AZ and CE at 318 K for $[ReOCl_5]^{2-}$ (a) and (b), $[ReO(AZ)_2Cl_3]$ (c), $[ReO(AZ)_3Cl_2]^+$ (d), $[ReO(AZ)_4Cl]^{2+}$ (e), $[ReO(CE)Cl_3]^-$ (f) and $[ReO(CE)_2Cl]$ (g)

## Conclusion

The potentiometric study investigated the behavior of complex formation of Re(V) metal ion with azathioprine (AZ) and ceftriaxone (CE). AZ is a neutral and monodentate ligand and the coordination bonds occur between the lone pair of sulfur atom with Re(V). Re(V)-AZ system has a maximum value of $\bar{n}$ of 4, this showed the formation 1:2, 1:3 and 1:4 complexes. The complex formation suggests a successive displacement of the chloride molecules from the coordination sphere of the central ion by the AZ ligand. The maximum value of $\bar{n}$ in the system of Re(V)-CE was 2, this showed the formation 1:1 and 1:2 complexes. The CE is losing one sodium atom and becomes anionic

ligand. The increasing amount coordinated molecules AZ and CE and the temperature the values log $K_i$ decreases. There is a dramatic increase ΔS for adding two compared to adding four monodentate AZ ligands (-100.78 to 2.71 J/K mol) which change from negative (unfavorable) to positive (favorable). The enthalpy change (ΔH) for the complexes suggests that all the complexation reactions releasing heat have a negative ΔH (exothermic), favorable at low temperatures. ΔG indicates the direction in which a reaction moves to reach its equilibrium position. The above mentioned parameters and results will be useful in understanding the biological behavior of these complexes in the biological applications.

# SINTESIS $MnO_2$ NANOBUNGA POROS MENGGUNAKAN TEMPLAT SILIKA-APTES

## (Synthesis of Porous $MnO_2$ Nanoflower using Silica-APTES Template)

**Abstrak**

Tujuan kajian ini dilakukan adalah untuk menyediakan $MnO_2$ poros nano yang mempunyai bentuk nanobunga untuk digunakan sebagai penjerap pewarna sintetik komersial (remazol merah, eriokrom hitam dan metilena biru). Permukaan bahan silika yang telah diubahsuai dengan 3-aminopropil trietoksisilana (APTES) digunakan dalam proses sonokimia pada suhu bilik dengan kehadiran 0.1M $KMnO_4$ untuk menghasilkan komposit silika-$MnO_2$ dan seterusnya $MnO_2$ bersaiz nano selepas proses penyingkiran templat dilakukan. Spektrum FTIR menunjukkan kehadiran getaran $MnO_2$ dalam julat 400 – 600 $cm^{-1}$. Analisis jerap-nyahjerap $N_2$ menunjukkan $MnO_2$ tulen memiliki liang yang bersifat mesoporos 51.9 Å (± 1.4), manakala luas permukaan $MnO_2$ ialah 123.6 $m^2/g$. Penjerap $MnO_2$ nanobunga yang diperolehi menunjukkan kebolehan menjerap pewarna eriokrom hitam dan metilena biru sahaja. Kedua-dua isoterma penjerapan eriokrom hitam dan metilena biru oleh $MnO_2$ menepati ciri-ciri model Langmuir.

**Kata kunci**: sonokimia, logam oksida, jerapan

**Abstract**

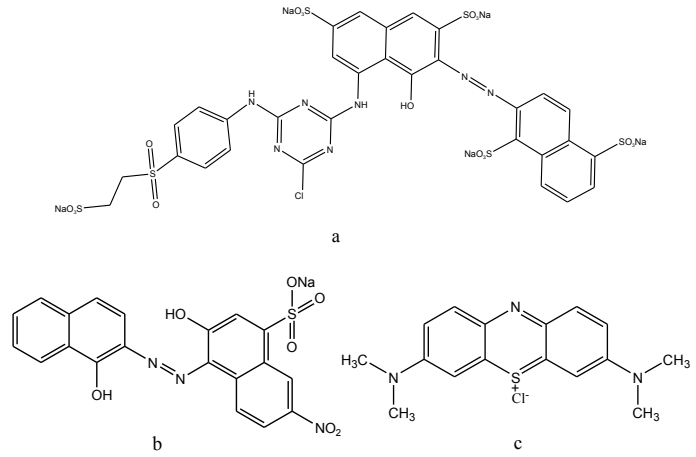
The aim of this study is to prepare porous $MnO_2$ nanoflower to be used as an adsorbent for commercial synthetic dyes (remazol red, eriochrome black and methylene blue). The modified surface of the silica with 3-aminopropyl triethoxysilane (APTES) was used in sonochemical process at room temperature in the presence of 0.1M $KMnO_4$ to produce composite silica-$MnO_2$ and later nano-$MnO_2$ after removal of the template. FTIR spectra indicate the presence of $MnO_2$ vibration in the range of 400 – 600 $cm^{-1}$. $N_2$ sorption-desorption analysis showed pure $MnO_2$ is mesopores with the value of 51.9 Å (± 1.4), while the $MnO_2$ surface area is 123.6 $m^2/g$. $MnO_2$ nanoflower adsorbent obtained demonstrate the ability to adsorb dye eriochrome black and methylene blue only. Both adsorption isotherms of eriochrome black and methylene blue by $MnO_2$ meet the characteristics of Langmuir model.

**Keywords**: sonochemical, metal oxides, adsorption

## Pengenalan

Semenjak beberapa tahun kebelakangan ini, sintesis pelbagai logam oksida bersaiz nano menarik perhatian para saintis kerana partikel bersaiz nano mempunyai sifat – sifat yang unik seperti pemangkinan, mekanik, elektronik, magnet, aktif kimia dan sifat optik disebabkan oleh kesan saiznya yang kecil dan luas permukaan yang besar [1-3]. Sintesis logam oksida boleh dilakukan dengan pelbagai kaedah seperti elektrokimia, hidroterma, tindak balas keadaan pepejal, gelombang mikro dan banyak lagi [2, 4 - 9]. Mangan dioksida merupakan salah satu logam oksida

yang digunakan secara meluas sebagai bahan asas dalam pembuatan elektrod dan diaplikasikan dalam pengoksidaan mangkin terpilih. Mangan dioksida banyak digunakan dalam degradasi azo, aplikasi kapasitor elektrokimia dan pemangkinan [10 - 13].



Pewarna organik mempunyai banyak kegunaan dan diaplikasikan dalam bidang pengeluaran dan pemprosesan. Namun, kewujudan sebatian pewarna organik dalam efluen memberikan kesan buruk terhadap alam sekitar. Terdapat 100 000 pewarna komersial yang dihasilkan dan pengeluarannya adalah lebih daripada 700 000 tan setahun [14]. Di Malaysia, menurut sumber industri berjadual (sisa pepejal), industri tekstil hanya menyumbang kira-kira 0.1%. Walau bagaimanapun, jumlah sisa berjadual oleh industri tekstil meningkat sebanyak satu kali ganda iaitu daripada 744 tan (2007) kepada 1559 tan pada tahun 2009 [15]. Pewarna organik sintetik yang dihasilkan biasanya menggunakan bahan kimia yang toksik dan bersifat karsinogenik terhadap ekosistem akuatik dan kehidupan manusia amnya [16, 17]. Kewujudan pewarna organik sintetik di dalam efluen merupakan satu perkara yang tidak diingini. Terdapat beberapa kaedah yang telah dikaji iaitu rawatan secara kimia, biologi dan fizikal. Rawatan secara fizikal iaitu penjerapan dikatakan sebagai satu teknik yang sangat baik dalam rawatan air buangan daripada industri tekstil. Teknik fizikal menarik perhatian saintis kerana kebolehannya menyingkirkan bahan pencemar yang terlalu stabil bagi kaedah biologi. Teknik fizikal seperti penjerapan pewarna dengan menggunakan penjerap logam oksida telah banyak dilakukan [11, 18 - 23].

Objektif kajian ini dilakukan adalah untuk mensintesis $MnO_2$ bersaiz nano menggunakan kaedah sonokimia dengan cara yang mudah dimana templat silika-APTES dicampurkan dengan $KMnO_4$ dan tindak balas dilakukan dalam bekas rendaman ultrasonik pada suhu bilik. Produk yang diperolehi digunakan sebagai penjerap dalam ujian penjerapan pewarna remazol merah, eriokrom hitam dan metilena biru.

## Bahan dan Kaedah Kajian

### Bahan kimia

Bahan jerap yang digunakan ialah pewarna reaktif remazol merah (C.I. 239, tulen 99%), pewarna berasid eriokrom hitam (C.I. 14645, tulen 99%) dan pewarna bes metilena biru (C.I. 52015, tulen 99%) yang diperolehi daripada R & M Chemicals (Rajah 1). Semua bahan kimia lain yang digunakan dalam kajian ini seperti APTES (tulen 98%), silika (tulen 99%), toluena (tulen 99.5%), $KMnO_4$ (tulen 99%) dan NaOH (tulen 98%) diperolehi daripada Sigma Aldrich tanpa dilakukan penulenan terlebih dahulu.

Rajah 1. Struktur molekul sebatian pewarna (a) remazol merah, (b) eriokrom hitam dan (c) metilena biru

### Sintesis bahan poros nano-$MnO_2$

Sintesis $MnO_2$ dilakukan seperti yang telah dilaporkan oleh Hasan et al. [24]. $MnO_2$ yang diperolehi mempunyai morfologi seperti bentuk nanobunga. Refluks dilakukan terlebih dahulu dengan mencampurkan 5 mL APTES ke dalam kelalang bulat (250 mL) yang mengandungi 0.5 g silika dengan kehadiran 50 mL pelarut toluena. Refluks

dilakukan bertujuan mengubahsuai permukaan silika yang hidrofobik kepada hidrofilik dengan memasukkan kumpulan $NH_2$. $MnO_2$ diperolehi dengan melakukan proses sonokimia terhadap templat silika-APTES (12j) dengan kehadiran 5 mL larutan $KMnO_4$ (0.1M). Tindak balas sonokimia dilakukan selama 6 jam pada suhu bilik untuk menghasilkan komposit silika-$MnO_2$. Hasil tindak balas yang diperolehi dituras menggunakan penapis vakum yang menggunakan kertas turas bersaiz 0.45 µm dan dibilas sebannyak tiga kali dengan air nyahion (50 mL setiap kali) sebelum dikeringkan pada suhu 105 ºC selama 9 jam. Setelah kering, proses penyingkiran templat silika keatas mendakan yang diperolehi seterusnya dilakukan dengan merendam hasil yang diperolehi ke dalam 20 mL larutan NaOH (2.0 M) selama 24 jam. Hasil yang diperolehi, iaitu $MnO_2$ tulen dibilas dengan kaedah yang sama seperti sebelum proses penyingkiran templat dilakukan dan dikeringkan pada suhu yang sama.

**Penyediaan larutan pewarna**
Setiap larutan stok pewarna yang berkepekatan 1000 ppm disediakan dengan mencampurkan 1000 mg serbuk pewarna ke dalam 1000 mL air nyahion. Bekas yang berisi larutan pewarna dibalut dengan pembalut aluminium dan disimpan di tempat yang gelap untuk mengelakkan penguraian foto.

**Pencirian penjerap**
Ciri permukaan sampel yang telah dikeringkan terlebih dahulu dianalisis menggunakan mikroskop imbasan elektron (FESEM) daripada jenama Merlin Compact. Ciri-ciri keporosan dan luas permukaan penjerap $MnO_2$ nanobunga ditentukan melalui ujian jerap-nyahjerap $N_2$ menggunakan Micromeritic ASAP 2020 pada -196 ºC. Analisis FTIR dilakukan untuk mengenalpasti getaran kumpulan MnO yang hadir pada nisbah sampel: serbuk KBr (0.5:1) menggunakan alat FTIR berjenama Perkin Elmer model Spectrum BX. Imbasan dilakukan dalam julat 4000 – 400 $cm^{-1}$.

**Ujian penjerapan**
Ujian penjerapan pewarna remazol merah (anionik), eriokrom hitam (anionik) dan metilena biru (kationik) oleh penjerap yang telah disediakan dilakukan menggunakan kaedah kelompok. Sebanyak 0.2 g penjerap seperti bahan pemula (templat silika, silika-APTES dan komposit silika-$MnO_2$) dan $MnO_2$ digunakan dalam ujian penjerapan pewarna dalam tempoh masa sehingga selama 120 minit pada suhu bilik dan pH asal larutan. Perbezaan keamatan serapan setiap pewarna sebelum dan selepas ujian penjerapan diukur menggunakan UV-Vis. Peratus penyahwarnaan dikira menggunakan persamaan di bawah:

$$\% \text{ Penyahwarnaan} = \frac{A_o - A_t}{A_o} \times 100 \quad (1)$$

dimana $A_o$ dan $A_t$ masing-masingnya adalah nilai serapan yang diukur pada panjang gelombang maksimum ($\lambda_{mak}$) kepekatan awal larutan pewarna dan nilai serapan pada waktu *t*. Jumlah bahan jerap yang terjerap pada keadaan keseimbangan, $q_e$ (mg/g) dikira menggunakan persamaan seperti berikut:

$$Q_e = \frac{(C_o - C_e)}{W} \times V \quad (2)$$

dimana $C_o$ adalah kepekatan awal dan $C_e$ adalah kepekatan keseimbangan (mg/L). V adalah isipadu pelarut (L) dan W adalah berat penjerap yang digunakan (g).

**Isoterma penjerapan**
Isoterma penjerapan dilakukan bagi mengkaji potensi penjerapan diantara penjerap dan bahan jerap. Mod isoterma penjerapan yang perlu dikenalpasti ialah Langmuir, Freundlich dan Temkin. Mod Langmuir menentukan hanya satu tapak aktif yang boleh memegang satu molekul bahan jerap, penjerapan berlaku pada tapak homogen penjerap dan interaksi di antara spesis terjerap tidak berlaku. Persamaan linear Langmuir adalah seperti berikut :

$$\frac{C_e}{} = \frac{1}{} + \frac{C_e}{}$$

$$Q_e = Q_{max}b \quad Q_{max} \tag{3}$$

dimana $Q_e$ (mg/g) dan $C_e$ (mg/L) masing-masingnya adalah kapasiti pewarna yang terjerap pada penjerap dan kepekatan pewarna pada keadaan keseimbangan. Manakala mod Freundlich pula menjangkakan penjerapan berlaku pada permukaan yang mempunyai tenaga penjerapan yang berbeza. Persamaan Freundlich adalah seperti berikut:

$$Q_e = K_F C_e^{1/n} \tag{4}$$

dimana $K_F$ ialah pemalar yang terlibat dengan kapasiti penjerapan dan $1/n$ ialah parameter empirik yang menerangkan keheterogenan permukaan atau intensiti penjerapan. Persamaan linear Freundlich adalah seperti berikut:

$$\ln Q_e = \ln K_F + 1/n \, (\ln C_e) \tag{5}$$

Mod Temkin pula menjangkakan haba penjerapan semua molekul berkurang secara linear dengan liputan yang terhasil disebabkan oleh interaksi bahan jerap. Persamaan linear Temkin adalah seperti berikut:

$$Q_e = B \ln A + B \ln C_e, \qquad B = RT/b_T \tag{6}$$

dimana $B$ (J/mol) ialah pemalar yang berkait dengan haba penjerapan dan $A$ (L/g) ialah pemalar pengikat keseimbangan yang merujuk kepada tenaga pengikatan maksimum. $R$ dan $T$ masing-masingnya ialah pemalar gas universal (8.314 J/mol/K) dan suhu pada 298K, manakala $b_T$ ialah pemalar isoterma Temkin.

Sebanyak 50 mL pewarna eriokrom hitam dan metilena biru yang berkepekatan 10 mg/L dicampurkan dengan 0.2 g penjerap $MnO_2$ nanobunga dan eksperimen dilakukan pada suhu bilik pada pH asal larutan pewarna. Selepas tempoh masa tertentu (15, 30, 60, 90 dan 120 minit). 5 mL larutan dikeluarkan dengan menggunakan picagari yang hujungnya disambung dengan penapis membran nilon (0.45 µm). Larutan yang dikeluarkan diukur nilai serapannya pada $\lambda_{max}$ setiap pewarna menggunakan spektrofotometer UV-Vis pada panjang gelombang ($\lambda_{max}$ eriokrom hitam dan metilena biru masing-masingnya ialah 540 dan 664 nm).

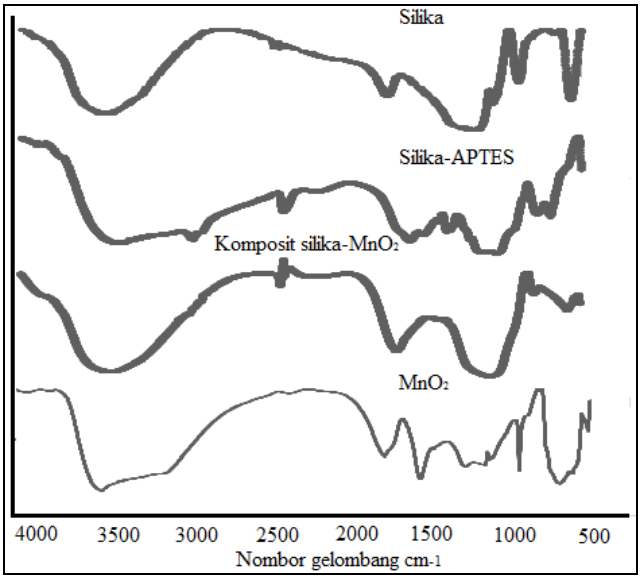
**Kinetik penjerapan**

Terdapat dua model kinetik penjerapan yang biasa diaplikasi dalam ujian penjerapan pewarna iaitu model tertib pertama *pseudo* dan tertib kedua *pseudo*. Model tertib pertama *pseudo* diaplikasikan pada peringkat awal proses penjerapan. Persamaan model tertib pertama *pseudo* ialah:

$$\ln (Q_e - Q_t) = \ln Q_e - K_1 t \tag{7}$$

dimana $Q_e$ dan $Q_t$ masing-masingnya ialah kuantiti pewarna yang terjerap (mg/g) pada keseimbangan dan masa tertentu, $t$ (min), $K_1$ ialah pemalar kadar keseimbangan penjerapan tertib pertama *pseudo* ($min^{-1}$). Persamaan model tertib kedua *pseudo* ialah:

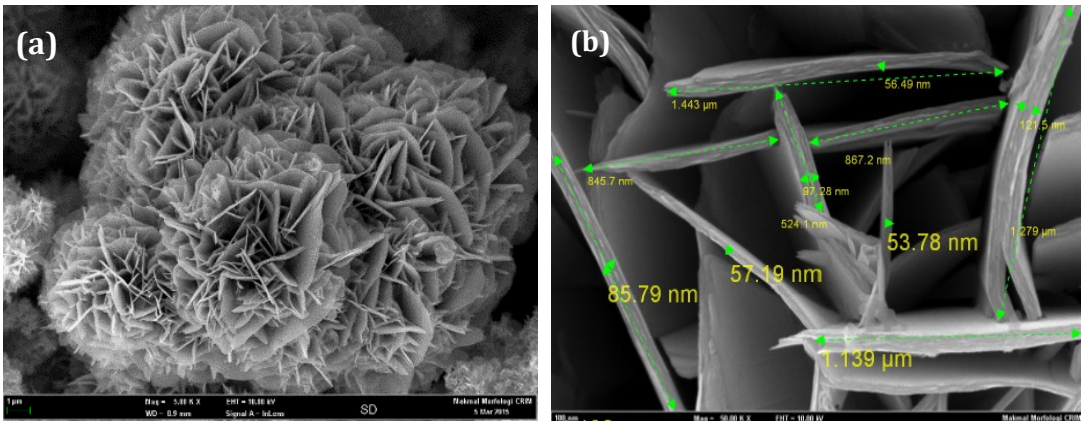
$$\frac{t}{Q_t} = \frac{1}{K_2 Q_e^2} + \frac{t}{Q_e} \tag{8}$$



dimana $K_2$ (g/mg/min) ialah pemalar kadar keseimbangan tertib kedua *pseudo*, $Q_e$ (mg/g) ialah kapasiti penjerapan maksimum, dan $Q_t$ (mg/g) ialah kapasiti penjerapan pada masa tertentu, $t$ (min).

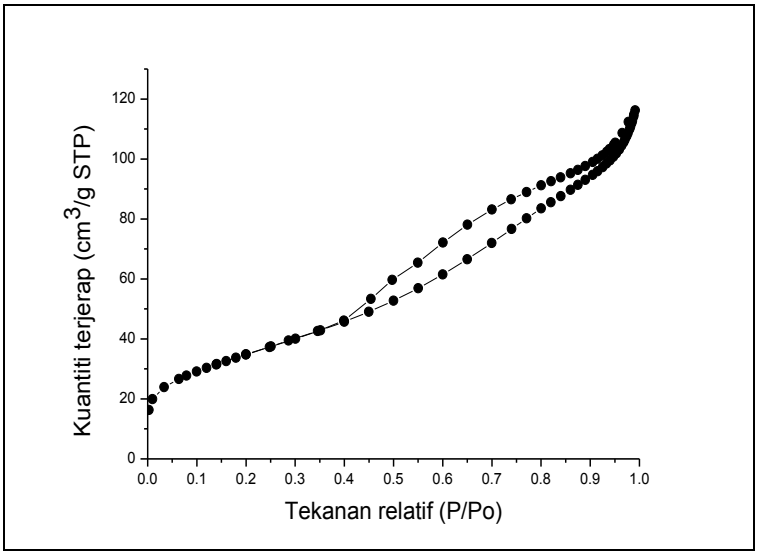
Ujian kinetik penjerapan dilakukan dengan menggunakan 50 mL pewarna eriokrom hitam dan metilena biru yang berkepekatan 10 mg/L yang dicampurkan dengan 0.2 g penjerap $MnO_2$ nanobunga dan eksperimen dilakukan pada suhu bilik dan pH asal larutan pewarna. Selepas tempoh masa tertentu (15, 30, 60, 90 dan 120 minit), 5 mL larutan dikeluarkan dengan menggunakan picagari yang hujungnya disambung dengan penapis membran nilon (0.45 µm). Larutan yang dikeluarkan diukur nilai serapannya menggunakan spektrofotometer UV-Vis pada $\lambda_{max}$ setiap pewarna.

**Keputusan dan Perbincangan**



Keberhasilan pengubahsuaian permukaan templat silika dengan APTES dapat diperhatikan dalam spektrum FTIR seperti yang ditunjukkan dalam Rajah 2. Spektrum FTIR silika menunjukkan kehadiran jalur pada 3467 $cm^{-1}$, dimana ini merupakan getaran regangan kumpulan OH yang terikat kepada kumpulan silikon [25]. Manakala jalur pada 1650 $cm^{-1}$ menunjukkan bengkokan kumpulan silanol [25]. Pada jalur 1079 $cm^{-1}$, menunjukkan wujudnya getaran regangan tidak simetri bagi Si-O-Si dalam $SiO_2$, getaran regangan Si-O-Si wujud pada jalur 975 dan 800 $cm^{-1}$, dan getaran bengkokan wujud pada jalur 471 $cm^{-1}$ [25, 26]. Selepas refluks dilakukan, spektrum silika-APTES menunjukkan kehadiran jalur baru di dalam kawasan 3290-3000 $cm^{-1}$ dimana ini merujuk kepada kehadiran getaran regangan kumpulan $NH_2$. Ini membuktikan berlakunya pengikatan antara kumpulan aminopropil dengan silika. Selain itu juga, mod getaran regangan dan bengkokan kumpulan alifatik $CH_2$ masing-masingnya wujud pada jalur 2936 dan 2832 $cm^{-1}$ manakala getaran bengkokan $NH_2$ bagi $SiO_2$-$NH_2$ wujud pada jalur 1574 $cm^{-1}$ [25]. Selepas tindak balas sonokimia, terdapat beberapa jalur baru yang wujud dalam spektrum FTIR komposit silika-$MnO_2$. Jalur 463 $cm^{-1}$ menunjukkan kehadiran getaran Mn-O dan Mn-O-Mn bagi unit $MnO_6$ oktahedron dan jalur pada 3445 dan 1653 $cm^{-1}$ masing-masingnya menunjukkan getaran regangan dan bengkokan kumpulan OH daripada molekul air [27]. Jalur 1067 $cm^{-1}$ menunjukkan kehadiran getaran bengkokan kumpulan OH pada permukaan logam [28].

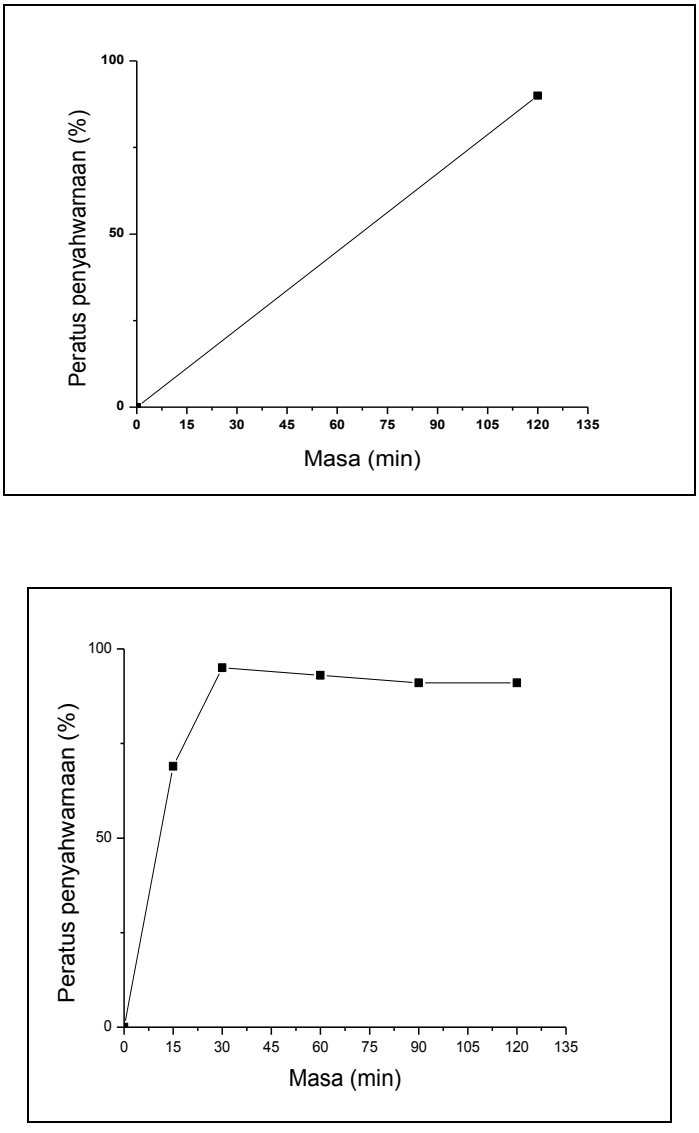
Selain itu juga, terdapat perbezaan antara spektrum FTIR dimana jalur getaran regangan dan bengkokan kumpulan alifatik $CH_2$ yang wujud pada jalur 2936 dan 2832 $cm^{-1}$ serta getaran bengkokan $NH_2$ bagi $SiO_2$-$NH_2$ yang wujud pada jalur 1574 $cm^{-1}$ sebelum tindak balas sonokimia tidak lagi kelihatan dalam spektrum selepas tindak balas. Ini membuktikan berlakunya pengikatan diantara mangan oksida dan atom nitrogen. Selepas penyingkiran templat dilakukan, spektrum FTIR $MnO_2$ menunjukkan kehadiran getaran Mn-O dan Mn-O-Mn bagi mangan oksida pada nombor gelombang 500 – 800 $cm^{-1}$ [29], dimana getaran Mn-O dan Mn-O-Mn bagi $MnO_2$ ialah 602 $cm^{-1}$. Jalur pada 1468 dan 1405 $cm^{-1}$ wujud selepas proses penyingkiran templat dilakukan kerana spektrum FTIR komposit silika-$MnO_2$ tidak menunjukkan kehadiran jalur ini. Kehadiran jalur ini mungkin disebabkan oleh kumpulan getaran bengkokan OH daripada NaOH yang terikat pada permukaan mangan oksida selepas proses penyingkiran templat dilakukan. Selain itu juga, jalur pada 3467 – 3445 $cm^{-1}$ menunjukkan regangan OH bagi molekul air, jalur pada 1645 – 1695 dan 850 $cm^{-1}$ masing-masingnya menunjukkan getaran bengkokan OH dan getaran bengkokan luar satah OH daripada molekul air, manakala jalur pada 1021, 1186 dan 1068 $cm^{-1}$ merupakan getaran bengkokan OH yang terikat kepada atom Mn [28].



Rajah 2. Spektrum FTIR silika, silika-APTES, komposit silika-$MnO_2$ dan $MnO_2$ nanobunga

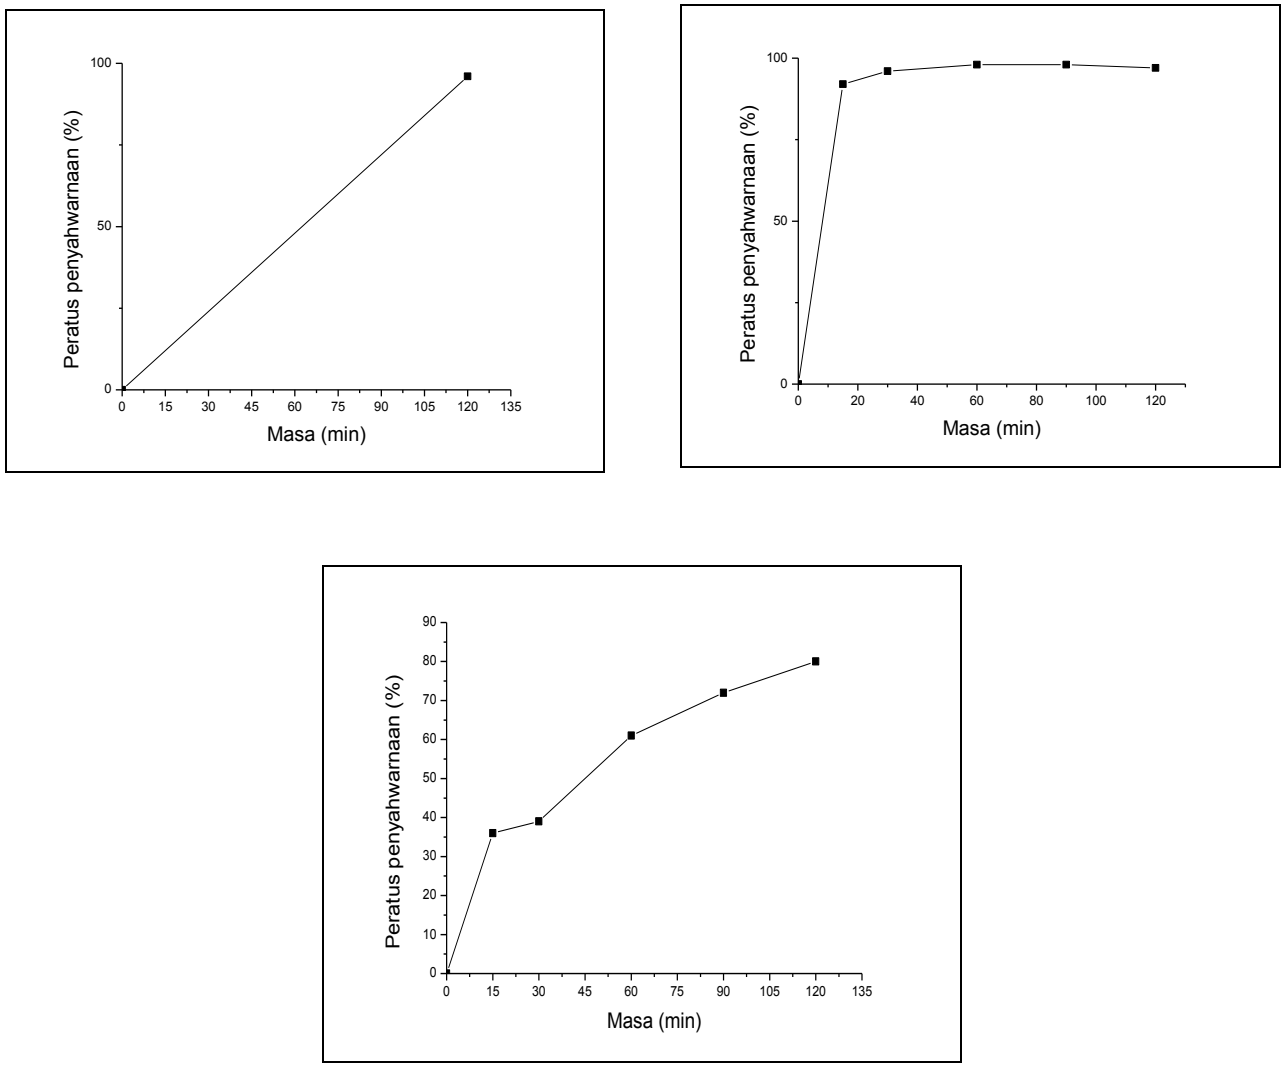
Imej SEM bagi penjerap $MnO_2$ adalah seperti yang ditunjukkan dalam Rajah 3 dimana ia menunjukkan morfologi nanobunga yang mempunyai panjang yang tidak sekata iaitu lebih daripada 100 nm dan mencapai 1.5 µm, manakala ketebalannya dalam julat 53 – 122 nm. Rajah 4 menunjukkan graf isoterma jerap-nyahjerap $N_2$ bagi $MnO_2$ yang menunjukkan ia memiliki isoterma jenis II dan IV. Menurut Asouhidou [30], isoterma jenis II merujuk kepada penjerap bukan poros atau makroporos, dimana penjerapan lapisan mono dan lapisan berganda berlaku tanpa had. Isoterma jenis IV pula merujuk kepada bahan mesoporos [31, 32]. Penjerap $MnO_2$ memiliki gelung histeresis jenis $H_3$ dimana pada tekanan relatif (P/Po) yang tinggi, ia tidak mempunyai had penjerapan dan mempunyai liang berbentuk celah. Penjerap ini menunjukkan sifat liang mesoporos dengan saiz liang ialah 51.9 Å (± 1.4). Tambahan lagi penjerap ini menunjukkan luas permukaan yang agak tinggi 123.6 $m^2/g$.

Rajah 3. Mikrograf FESEM $MnO_2$ nanobunga



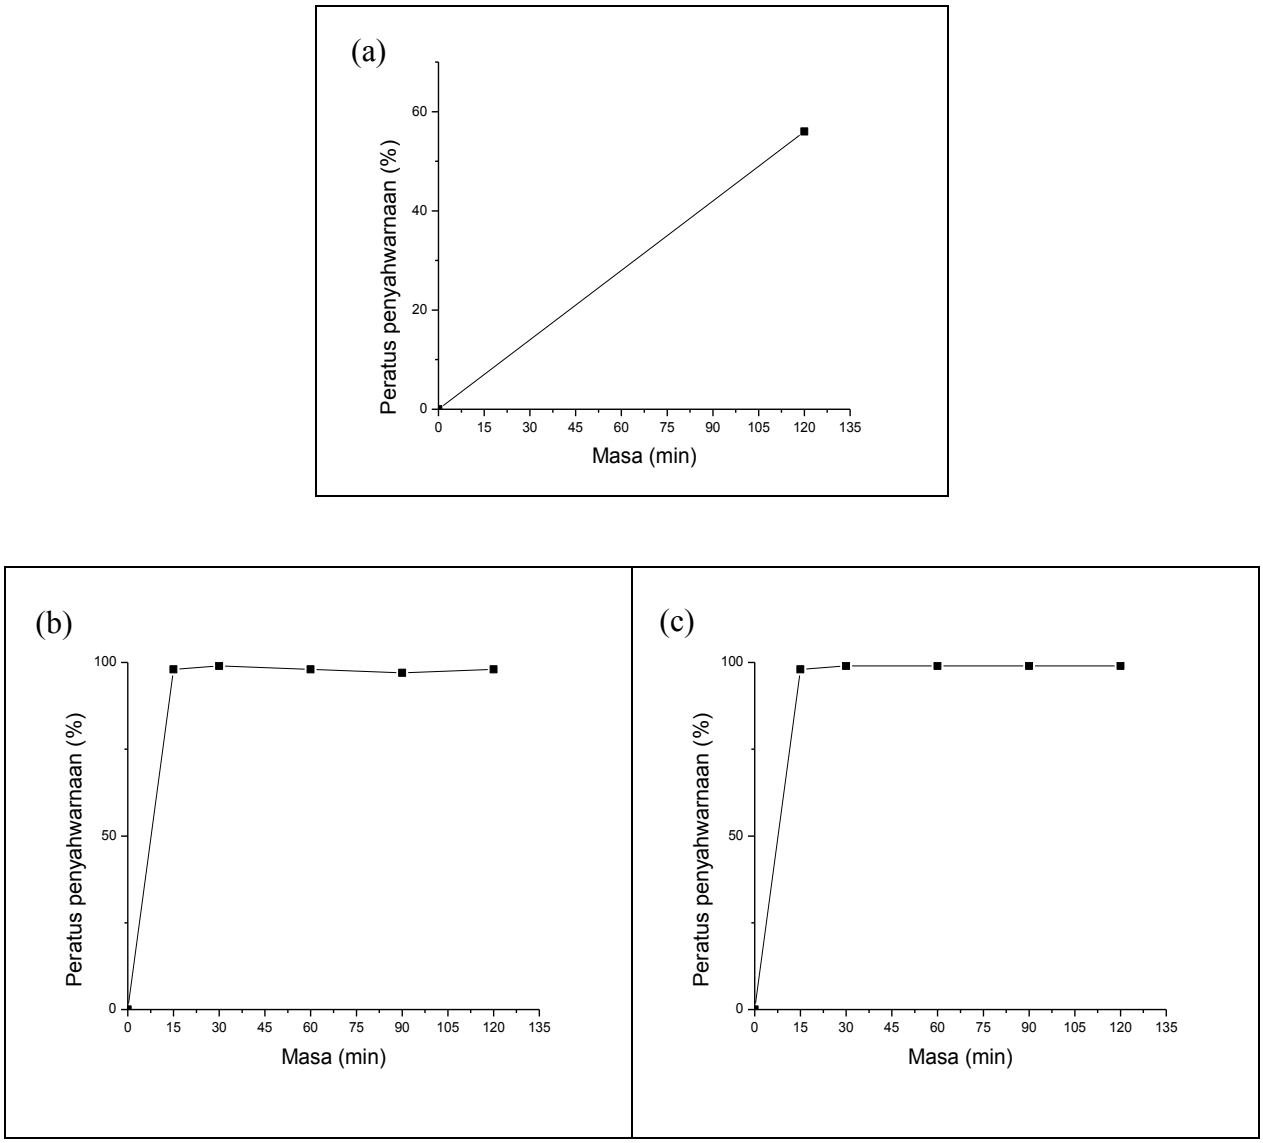
Rajah 4. Graf isoterma jerap-nyahjerap $N_2$ $MnO_2$

Rajah 5 menunjukkan peratus penyahwarnaan pewarna remazol merah oleh penjerap silika-APTES dan komposit silika-$MnO_2$. Tiada penjerapan yang berlaku pada penjerap silika dan $MnO_2$. Perkara ini berlaku kerana silika adalah bersifat hidrofobik dan kumpulan OH yang terikat pada atom logam Mn bagi $MnO_2$ adalah sangat banyak menyebabkan berlakunya peningkatan persaingan antara kumpulan OH dan spesis sulfonat ($SO_3^-$). Ciri – ciri



hidrofobik silika menunjukkan ia kalis air kerana struktur dan sifat kimia yang dimilikinya. Apabila air dicampurkan dengan silika, partikel ini menghalang air daripada meresap masuk ke dalam teksturnya. Air hanya bersentuhan dengan hujung partikel lapisan luar bahan. Disebabkan kekurangan daya tarikan, silika menolak molekul air [27].

Peratus penyahwarnaan pewarna reaktif remazol merah adalah sangat tinggi apabila penjerap silika-APTES (90%) dan komposit silika-$MnO_2$ (95%) digunakan. Di sini dapat diperhatikan penjerapan pewarna reaktif remazol merah oleh penjerap komposit silika-$MnO_2$ adalah lebih cepat berlaku berbanding dengan silika-APTES. Penjerap silika-APTES mengambil masa selama 120 minit untuk penyahwarnaan sebanyak 90% tetapi komposit silika-$MnO_2$ mengambil masa 30-40 minit sahaja. Perkara ini berlaku disebabkan oleh perbezaan mekanisme penjerapan yang berlaku pada permukaan penjerap. Mekanisme penjerapan pewarna oleh silika-APTES adalah disebabkan oleh pembentukan ikatan hidrogen manakala penjerapan yang berlaku pada komposit silika-$MnO_2$ adalah disebabkan daya tarikan elektrostatik.



Rajah 5. Penjerapan pewarna reaktif remazol merah oleh (a) silika-APTES dan (b) komposit silika-$MnO_2$

Rajah 6 menunjukkan peratus penyahwarnaan pewarna eriokrom hitam oleh penjerap silika-APTES, komposit silika-$MnO_2$ dan $MnO_2$. Peratus penyahwarnaan pewarna eriokrom hitam oleh silika-APTES, komposit silika-$MnO_2$ dan $MnO_2$ pada minit ke 120 masing-masingnya ialah 96, 97 dan 80%. Perbezaan peratus penjerapan disebabkan oleh mekanisme penjerapan yang berlaku. Mekanisme penjerapan yang berlaku antara eriokrom hitam dengan penjerap silika-APTES ialah ikatan hidrogen manakala penjerapan antara eriokrom hitam dengan penjerap komposit silika-$MnO_2$ adalah disebabkan luas permukaan mangan dioksida yang menyediakan tapak penjerapan dan daya tarikan elektrostatik yang terbentuk antara permukaan penjerap yang bercas negatif dan molekul pewarna yang bercas positif. Penjerapan semakin berkurang apabila penjerap $MnO_2$ digunakan. Hal ini sedemikian kerana permukaan penjerap $MnO_2$ dipenuhi oleh kumpulan OH yang hadir semasa proses penyingkiran templat silika, oleh itu berlaku persaingan antara kumpulan sulfonat daripada eriokrom hitam dan kumpulan OH pada permukaan penjerap $MnO_2$ yang menghadkan bilangan molekul bahan jerap terjerap.

Rajah 6. Penjerapan pewarna anionik eriokrom hitam oleh (a) silika-APTES, (b) komposit silika-$MnO_2$ serta (c) $MnO_2$

Rajah 7 menunjukkan peratus penyahwarnaan pewarna metilena biru oleh penjerap silika-APTES, komposit silika-$MnO_2$ dan $MnO_2$. Peratus penyahwarnaan bagi silika-APTES, komposit silika-$MnO_2$ dan $MnO_2$ pada minit ke 120 masing-masingnya ialah 56, 98 dan 99%. Perbezaan peratus penyahwarnaan adalah disebabkan oleh mekanisme penjerapan yang berbeza. Mekanisme penjerapan pewarna metilena biru oleh penjerap silika-APTES adalah ikatan hidrogen, manakala mekanisme penjerapan metilena biru oleh penjerap komposit silika-$MnO_2$ dan $MnO_2$ adalah disebabkan oleh daya tarikan elektrostatik yang terbentuk antara permukaan penjerap yang bercas negatif dan sebatian pewarna yang bercas positif [33].

Rajah 7. Penjerapan pewarna kationik metilena biru oleh (a) silika-APTES, (b) komposit silika-$MnO_2$ dan (c) $MnO_2$

Secara kesimpulannya, penjerapan oleh penjerap $MnO_2$ hanya berlaku terhadap pewarna eriokrom hitam (anionik) dan metilena biru (kationik) sahaja. Tiada penjerapan berlaku terhadap remazol merah (anionik). Perkara ini berlaku disebabkan kehadiran banyak kumpulan OH pada permukaan penjerap $MnO_2$ yang menghalang penjerapan kumpulan $SO_3^-$ sebatian pewarna pada permukaan penjerap. Sebaliknya pula berlaku terhadap pewarna eriokrom hitam. Walaupun eriokrom hitam terdiri daripada pewarna anionik, namun penjerapan pada permukaan penjerap boleh berlaku. Hal ini sedemikian kerana penjerapan eriokrom hitam pada permukaan penjerap $MnO_2$ disebabkan oleh daya tarikan elektrostatik antara kumpulan $^-OH$ dan $^+NO_2$ sebatian pewarna. Perkara yang sama juga berlaku terhadap pewarna metilena biru. Penjerapan yang berlaku pada permukaan penjerap $MnO_2$ disebabkan oleh daya tarikan elektrostatik antara kumpulan $^-OH$ dan $S^+$ sebatian pewarna.

**Mod isoterma penjerapan**

Mod isoterma penjerapan dipilih berdasarkan nilai pekali korelasi, $R^2$. Nilai $R^2$ merupakan kuantiti yang memberikan kualiti bagi kuasa dua terkecil kepada data asal dimana nilai $R^2$ adalah 1 atau menghampiri 1. Penjerapan eriokrom hitam dan metilena biru oleh $MnO_2$ menepati mod Langmuir dimana masing-masingnya mempunyai nilai $R^2 = 0.9788$ dan 0.9147. Parameter setiap model penjerapan isoterma ditunjukkan dalan Jadual 1.

**Model kinetik penjerapan**

Model kinetik yang dikaji ialah tertib pertama *pseudo*, tertib kedua *pseudo*, tertib kedua dan resapan intrazarah model Weber-Morris. Model kinetik penjerapan dipilih berdasarkan nilai pekali korelasi, $R^2$. Penjerapan eriokrom hitam dan metilena biru oleh penjerap $MnO_2$ masing-masingnya menepati model tertib pertama *pseudo* dan Weber-Morris dengan $R^2 = 0.7482$ dan 0.9902. Parameter model kinetik penjerapan ditunjukkan seperti yang diringkaskan dalam Jadual 2.

Jadual 1. Parameter mod isoterma penjerapan eriokrom hitam dan metilena biru oleh penjerap $MnO_2$

| Model Isoterma | Pembolehubah | Bahan Jerap | |
|---|---|---|---|
| | | Eriokrom Hitam | Metilena Biru |
| Langmuir | $Q_{max}$ ($mgg^{-1}$) | 0.7564 | 3.5804 |
| | $Q_{max}$ b ($Lg^{-1}$) | -0.7268 | 54.3478 |
| | $R^2$ | 0.9788 | 0.9147 |

## Kesimpulan

Dalam kajian ini, $MnO_2$ nanobunga berjaya disintesis menggunakan kaedah mudah sonokimia dengan mencampurkan templat silika-APTES dan larutan $KMnO_4$. Produk yang diperolehi mempunyai luas permukaan yang agak tinggi iaitu 123.4 $m^2/g$ dan memiliki sifat liang mesoporos dimana saiz liangnya ialah 51.9 (±1.4) Å. Ujian penjerapan pewarna sintetik organik oleh penjerap $MnO_2$ menunjukkan penjerapan hanya berlaku terhadap eriokrom hitam dan metilena biru sahaja. Penjerapan pewarna oleh $MnO_2$ disebabkan oleh daya tarikan elektrostatik. Isoterma penjerapan menunjukkan penjerapan eriokrom hitam dan metilena biru oleh $MnO_2$ menepati mod Langmuir. Kinetik penjerapan menunjukkan penjerapan eriokrom hitam oleh $MnO_2$ menepati model tertib pertama *pseudo* manakala penjerapan metilena biru oleh $MnO_2$ menepati resapan intrazarah model Weber-Morris.

## Penghargaan

Pengarang menghargai sumbangan yang diberikan oleh geran FRGS/2/2013/SG01/UKM/01/1 dalam menjalankan penyelidikan ini. Selain itu juga, ribuan terima kasih diucapkan kepada Universiti Kebangsaan Malaysia terhadap ruang dan instrumen yang disediakan.

**Abstract**

A simple and efficient method called dispersive liquid–liquid microextraction based on solidification of floating organic droplets (DLLME-SFO) method coupled with gas chromatography flame ionization detector (GC-FID) was developed for the extraction of methylparaben (MP) in cosmetics. In the optimized DLLME-SFO method, a mixture of n-hexadecane (70 µL) as an extraction solvent and methanol (0.25 mL) as a disperser solvent was rapidly injected into a 5 mL sample solution (pH 6) containing 4 % (w/v) NaCl. After 4 minutes of centrifugation at 4000 rpm, the mixture was separated into two phases with the fine droplets of n-hexadecane floating at the top of the sample solution. Then, the test tube was placed in an ice bath for cooling and solidification purposes. The solidified extract was transferred into a small vial where it melted and injected into GC-FID system. The DLLME-SFO method gave a good linearity over the concentration range from 0.1 – 8 µg/mL with coefficient of estimation ($r^2$) from 0.9996. The method also provides a low limit of detections (LODs) which is 0.0048 µg/mL. Methylparaben was detected in both samples at the concentration level of 0.06 µg/mL for sample 1 and 0.42 µg/mL for sample 2 respectively.

**Keywords:** dispersive liquid–liquid microextraction, solidification of floating organic droplets, gas chromatography flame ionization detector, methylparaben, cosmetic

**Abstrak**

Kaedah yang senang dan berkesan iaitu pengekstrakan mikro cecair-cecair serakan berdasarkan pemejalan organik terampai (DLLME-SFO) berganding dengan kromatografi gas dengan dengan pengesan nyala pengionan (GC-FID) telah dihasilkan bagi penentuan metilparaben dalam alatan kosmetik. Dalam kaedah DLLME-SFO yang telah dioptimumkan, campuran n-heksadekana (70 µL) sebagai pelarut pengekstrak dan metanol (0.25 mL) sebagai pelarut penyebar disuntik segera ke dalam 5 mL larutan sampel (pH 6) yang mengandungi 4% (w/v) NaCl. Selepas pengemparan selama 4 min pada 4000 rpm, campuran terpisah kepada dua fasa di mana titisan halus n-heksadekana terapung di atas larutan sampel. Kemudiannya, tabung uji diletakkan di dalam rendaman ais untuk penyejukan dan pemejalan. Ekstrak yang beku dimasukkan ke dalam vial di mana ia mencair dan disuntik ke dalam sistem GC-FID. Kaedah DLLME-SFO memberikan kelinearan yang baik untuk kepekatan diantara, 0.1 – 8 µg/mL dengan pekali penentuan ($r^2$) 0.9996. Kaedah ini juga menunjukkan had pengesanan (LODs) rendah iaitu 0.0048 µg/mL. Metilparaben telah dikesan dalam kedua-dua sampel pada tahap kepekatan 0.06 µg/mL untuk sampel 1 dan 0.42 µg/mL untuk sampel 2.

**Katakunci:** pengekstrakan mikro cecair-cecair serakan, pemejalan organik terampai, gas kromatografi pengesan pengionan nyala, metilparaben, kosmetik

## Introduction

A preservative is a natural or man-made chemical that is added to several types of products, for example foods, pharmaceuticals, paints, biological samples, wood, beverages and others. It is used to prevent decomposition or any undesirable chemical changes due to microbial activities; hence, products last longer and are safe for use [1, 2]. Hirose and coworkers [3] stated that these preservatives act as either antimicrobials or antioxidants which they will either inhibit the activity of or kill the bacteria, molds, insects and other microorganisms. Antimicrobials are to prevent the growth of molds, yeasts and bacteria while antioxidants keep the products from becoming rancid or developing black spots [4]. They suppress the reaction when the products come in contact with oxygen, heat, and some metals.

Parabens or ester of p-hydroxybenzoic acid are extensively used in formulations of personal care products due to having neutral pH, no perceptible odor or taste, and no discoloration or hardening effect [5]. Generally, parabens are stable in the air, and are resistant to hydrolysis in hot and cold water as well as in acidic solutions ($1 \leq pH < 7$). Despite their benefits, a controversy surrounds the discussion the effect of commonly used parabens, methylparabens (MP), which can cause side effects on consumers and organoleptic alterations in the cosmetics. The studies revealed that the use of parabens may cause cancer, genotoxicity and breast cancer [6, 7, 8]. Parabens are also reported to have side effects on males as it may decrease the reproduction potential, cause infertility and cause skin cancer diseases such as malignant, melanoma and contact eczema. Recently, the use of preservatives in consumer products has been the subject of criticism because of their possible side-effects on human health. According to European Union (EU) and USA legislation, 0.4% (w/w) of single paraben concentration and a maximum of 0.8% (w/w) for the mixture of parabens is allowed in a cosmetic product [9, 10].

There is no doubt that legislation lags behind the market. Numerous amounts of paraben-free cosmetic products have been marketed in recent years. Labels on these products usually claim 0% parabens or paraben-free cosmetics. However, the lack of specific regulation facilitates labeling fraud. Their widespread use makes parabens a group of chemicals to be controlled from an analytical point of view. Information about some analytical methods published for paraben determination can be found in the book edited by Salvador and Chisvert [11] and a review paper by Wang and Liu [12]. Liquid-liquid extraction (LLE), solid phase extraction (SPE), solid-phase microextraction (SPME), and matrix-solid phase dispersion (MSPD) coupled with either gas chromatography (GC) or high performance liquid chromatography (HPLC) have been critically examined for the identification of MP in cosmetics [13-15]. In a conventional LLE there are many well-known drawbacks and limitations, the most important of which are the large volumes of samples and extraction solvents required, and consequently the large amount of wastes generated, as well as the low preconcentration on samples.

Dispersive liquid-liquid microextraction (DLLME) has been introduced for the analysis of organic compounds, inorganic analytes and various types of analytes from different matrices such as water, tissue, biological fluids, and food matrices. DLLME is a miniaturized LLE using microliter volumes of extraction solvent, which is based on the equilibrium distribution process of the target analytes between sample solution and extraction solvent. This method offers simplicity of operation, rapidity, low cost, high recovery, high enrichment factor, and environmental benignity with wide application prospects in trace analysis [16, 17]. In conventional DLLME, the density of extraction solvent should be higher than water. The high density extraction solvents, being mostly halogenated, are generally hazardous to laboratory personnel and are not often compatible with reversed phase high performance liquid chromatography (HPLC).

Recently, a new microextraction method was developed, which is DLLME integrated with the solidification of a floating drop (DLLME-SFO) [18]. In DLLME-SFO, the extraction solvent was collected on the top of the test tube and was then cooled by inserting it into an ice bath for 5 minutes. The solidified extraction solvent was transferred into a suitable vial and immediately melted at room temperature; then it was finally injected into a suitable instrument.

In this work, we present a new application of DLLME-SFO in the extraction of MP in cosmetic creams and separation using GC-FID. In addition, the sample treatment step was employed for the extraction of target analyte in cosmetic creams before DLLME-SFO and thus reducing the matrix effect.

## Materials and Methods

### Chemicals and reagents

Methylparaben standard, 1-undecanol, 1-dodecanol, and *n*-hexadecane were supplied by Sigma-Aldrich (Buchs, Switzerland). HPLC grade of methanol, acetonitrile, and acetone were obtained from Fisher Scientific (UK). Sample pH was adjusted by the addition of diluted sodium chloride from Merck (Darmstadt, Germany). 100 mg $mL^{-1}$ solution was prepared by dissolving analyte in methanol and stored in the refrigerator at 4 ºC before use. This stock solution was diluted with methanol to prepare a series of working solutions. Deionized water was prepared by the use of a Millipore Milli-Q (Milford, MA, USA) reagent water system. pH value was measured using a Cyberscan 510 pH meter; a Hettich (Oxford, UK) model EBA 20 centrifuge was used for phase separation. Two different local cosmetic sunblock's were used as real samples.

### GC conditions

Gas chromatographic (GC-15A, Shimadzu, Japan) analysis was performed with a split or splitless injector system, and a flame ionization detector was used to determine methylparaben. A SPB-50 capillary column (30 m x 0.22 mm i.d., 0.25µm film thickness) was used for chromatographic separation and ultra-pure helium (99.99%, Air products, UK) was used as the carrier gas. The injection port was held at 270 $^{o}$C in the splitless mode with a purge time of 45s. The oven temperature was programmed as follows: initial temperature 130 $^{o}$C (held for 1 min), from 130 $^{o}$C to 230 $^{o}$C at the rate of 10 $^{o}$C/min, and finally held at 230 $^{o}$C for 2 minutes. The FID temperature was maintained at 270 $^{o}$C. Hydrogen gas for FID was generated by a hydrogen generator (OPGU-1500S, Shimadzu, Japan) at a flow rate of 40 mL/min. The flow rate of air for FID was 300 mL/min.

### Sample preparation

Sunblock cream samples (5g) were dissolved into 2:8 mL methanol and deionized water before 1 mL of concentrated HCl was added into the solution and exposed to sonication for 10 minutes. Then, the solution was diluted to 150 mL with deionized water, adjusted to pH 6.0, and then subjected to DLLME-SFO extraction.

### DLLME-SFO procedure

Aqueous solution (5 mL) containing methylparaben (3.0 µg/mL) was placed in a 10-mL test tube. A mixture of *n*-hexadecane (70µL) and methanol (0.25 mL) was rapidly injected into the sample solution using a syringe. A cloudy suspension resulted from dispersion of fine droplets of *n*-hexadecane in the sample solution was then separated by centrifugation for 4 minutes at 4000 rpm. After centrifugation, the test tube was directly put into an ice bath for 5 minutes to solidify the floated *n*-hexadecane. After 5 minutes, the solidified solvent was collected using a small spatula and transferred into a conical vial, where it melted rapidly at room temperature. The floating extraction phase was collected using a microsyringe and 1µL was injected for GC-FID analysis.

## Results and Discussion

### Peak identification

In the GC-FID analysis, methylparaben was detected and eluted at 10.9 minutes (Figure 1). Generally, the area under the peak is directly proportional to its concentration.

### Optimization of DLLME-SFO method

To determine the optimized extraction conditions, the peak area of MP was used to evaluate the extraction efficiency under different conditions. Six parameters were critically examined; types of extraction solvent and disperser solvent, volumes of extraction solvent and disperser solvent, effect of salt concentration and sample pH.

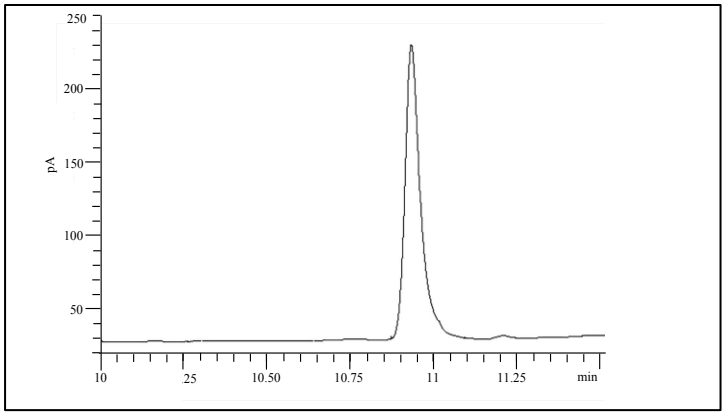

Figure 1. GC-FID chromatogram of MP at concentration 0.5 µg/mL

**Selection of extraction solvents**

An extraction solvent is crucial in the optimization of DLLME-SFO conditions. To achieve the optimum results, the extraction solvent must meet several criteria: high affinity for analytes, lower density than water, low solubility in aqueous solution, low melting point and volatility (Table 1), and perform a good chromatographic behavior [19]. In this study, 1-undecanol, 1-dodecanol, and *n*-hexadecane were tested in DLLME-SFO extraction (Figure 2). The results revealed that *n*-hexadecane showed better extraction efficiency compared to 1-undecanol and 1-dodecanol. Thus, it was selected as an extraction solvent and used in further experiments.

Table 1. Boiling point, melting point and density of extraction solvents [20]

| Extraction Solvent | Boiling Point ($^oC$) | Melting Point ($^oC$) | Density ($g/cm^3$) |
|---|---|---|---|
| 1-Undecanol | 243 | 13-15 | 0.8298 |
| 1-Dodecanol | 98 | 22-24 | 0.8309 |
| *n*-hexadecane | 287 | 18 | 0.7700 |

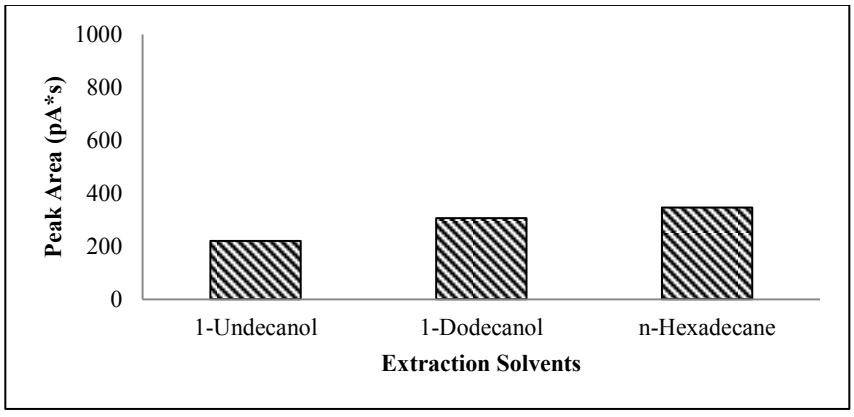

Figure 2. Effect of extraction solvent on extraction efficiency for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant 70 µL; volume disperser solvent (methanol) 0.25 mL; extraction time 1 min; centrifugation 4000 rpm × 4 min; no salt added

**Selection of disperser solvents**

The miscibility of disperser solvent in diluted cosmetic solution and extraction solvent is one of the criteria that should be considered in order to enable the *n*-hexadecane to be dispersed as a fine particle in aqueous phase to form a cloudy solution (water/disperser solvent/extraction solvent). In such a case, the surface area between extraction solvent and aqueous phase can be definitely large, thus increasing the extraction efficiency [21]. Thereby, acetone, methanol, and acetonitrile were selected for this purpose of study. A series of experiments were conducted by using a mixture of 70 *n*-hexadecane and 0.25 mL of each disperser solvent (Figure 3). According to the obtained results, methanol was selected as the most suitable disperser because of the formation of a cloudy state with very fine droplets and high recovery of analyte.

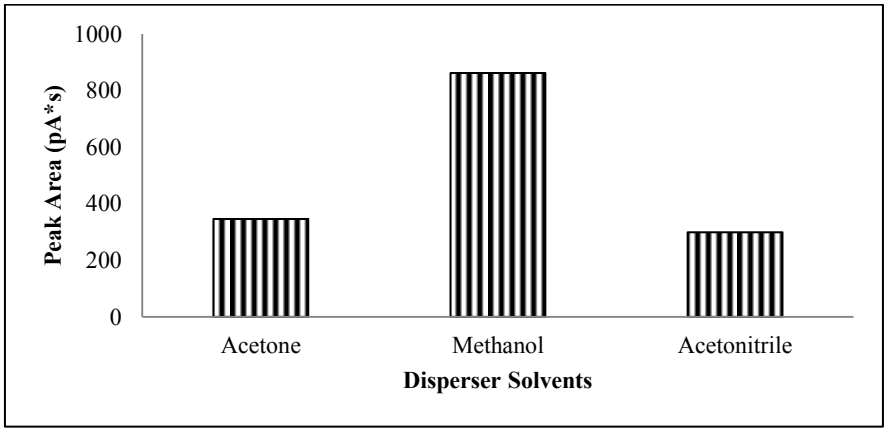

Figure 3. Effect of disperser solvent on extraction efficiency for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant (*n*-hexadecane) 70 µL; volume disperser solvent 0.25 mL; extraction time 1 min; centrifugation 4000 rpm × 4 min; no salt added

**Effect of volume of extraction solvent**

To study the effect of extraction volume on extraction efficiency in DLLME-SFO method, different volumes of *n*-hexadecane (60, 70, and 80 µL) containing 0.25 mL method were tested. Based on the results in Figure 4, the extraction recoveries decreased when the volume of *n*-hexadecane increased to 80 µL. This is due to the increasing volume of floating phase, and hence lessen the concentration of MP in *n*-hexadecane (dilution factor occurred). Therefore, 70 µL of *n*-hexadecane was chosen as the optimum volume for extraction solvent.

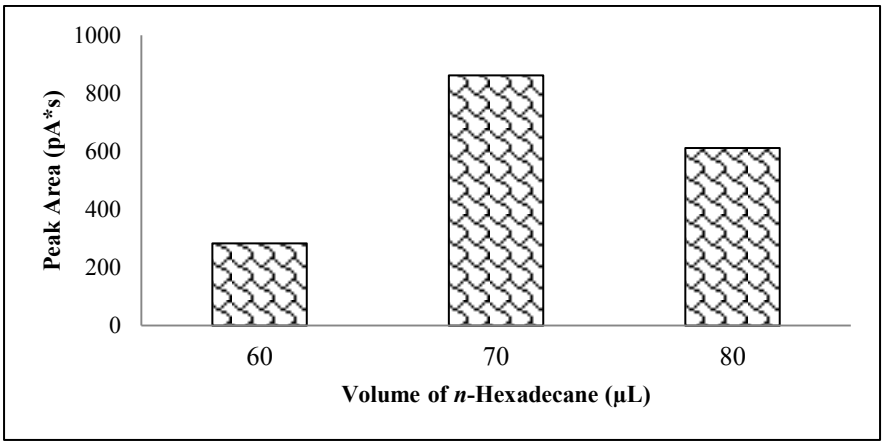

Figure 4. Effect of extraction solvent (*n*-hexadecane) volume for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant (*n*-hexadecane) 60 - 80 µL; volume disperser solvent (methanol) 0.25 mL; extraction time 1 min; centrifugation 4000 rpm × 4 min; no salt added

**Effect of disperser solvent volume**

The volume of disperser solvent directly affects the formation of cloudy solution (sample solution/disperser solvent/extraction solvent), volume of floated phase, and the degree of dispersion of extraction in aqueous phase and subsequently the overall extraction efficiency. To study the effect of disperser solvent volume on the extraction efficiency in DLLME-SFO method, different volumes of methanol (0.15, 0.25 and 0.50 mL) containing 70 µL of *n*-hexadecane were tested. According to the results in Figure 5, recovery of the analyte increased with the increasing volume of methanol up to 0.25 mL. This may be due to the increasing interaction of MP in water with the increasing volume of methanol. On the other hand, with a large volume of methanol, the solubility of analytes in aqueous phase increased; thus decreased the extraction efficiency. Finally, 0.25 mL of methanol was selected as the volume of disperser solvent in subsequent experiments.

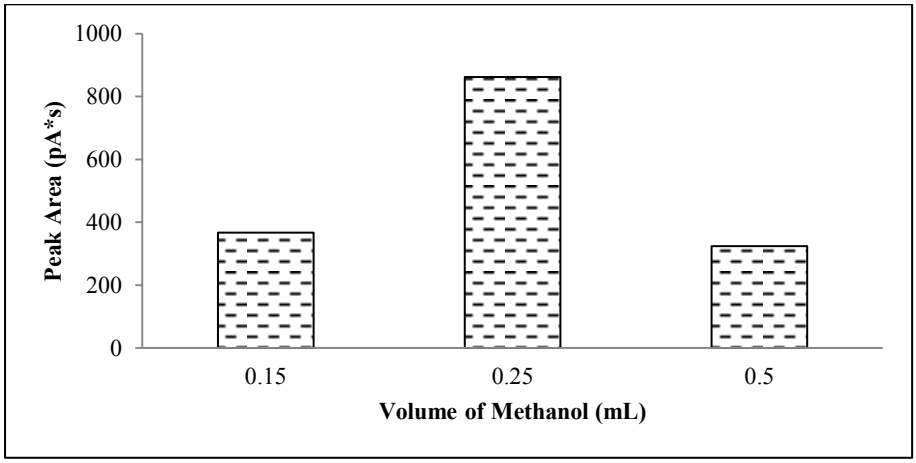

Figure 5. Effect of disperser solvent (methanol) volume for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant (*n*-hexadecane) 70 µL; volume disperser solvent (methanol) 0.15 - 0.25 mL; extraction time 1 min; centrifugation 4000 rpm × 4 min; no salt added

**Effect of salt concentration**

The function of adding a salt (NaCl) into the sample solution is to increase its ionic strength, decrease the solubility of the analytes in the sample solution and enhance the extraction efficiency [22, 23]. The concentration of salt used in this study was varied between 0 and 8% (w/v) and the effect on the extraction efficiency was investigated. According to the results in Figure 6, the peak areas of MP started to increase with the increasing amount of the NaCl concentration from 0 to 4%. However, with the addition of NaCl to 6%, it shows a dramatic decrease in extraction efficiency and a slight decrease when 8% NaCl was added. This phenomenon can be described regarding the salting-out effect happened in DLLME-SFO. Upon the addition of more than 6% of NaCl, the transportation of the analyte to the extraction solvent is dropped due to the increase of sample viscosity. By increasing the salt concentration, the diffusion of analyte towards organic solvent becomes more difficult; thus, 4% of NaCl was used in next experiments.

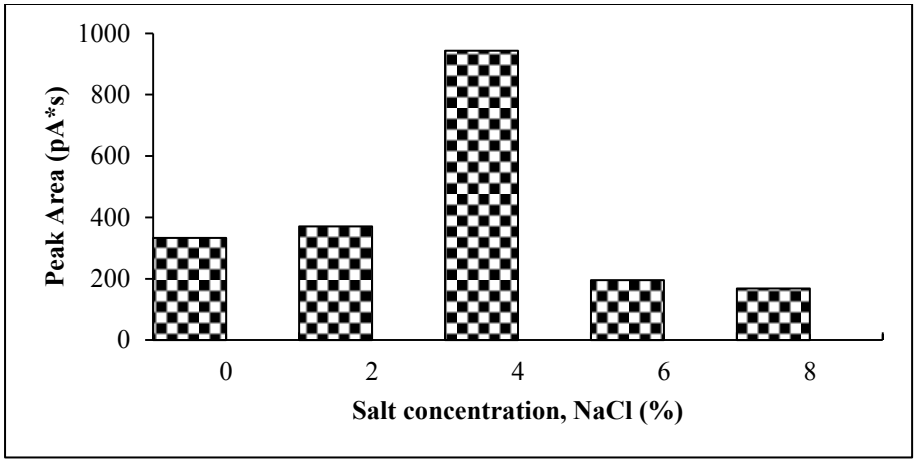

Figure 6. Effect of NaCl for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant (*n*-hexadecane) 70 µL; volume disperser solvent (methanol) 0.15 - 0.25 mL; extraction time 1 min; centrifugation 4000 rpm × 4 min

**Effect of sample pH**

The pH values of samples can affect the ratio of ionic form to molecular form of the analytes, especially for the analytes which are weak acid or weak alkali. According to Soni et. al. [4], at higher pH values (≥ pH 8), methylparaben is in ionic form and the hydrolysis will occur and make it less to be extracted into organic solvent. Therefore, methylparaben should be extracted at pH values lower than its pKa value (methylparaben, pKa = 8.2) which is less than pH 8. Hence, the pH that was investigated in this study is in the range of 3–7 by adding appropriate sodium hydroxide or hydrochloric acid to the samples. The results illustrated in Figure 8 demonstrate that the optimum extraction efficiency of MP in DLLME-SFO was obtained at pH 6.0.

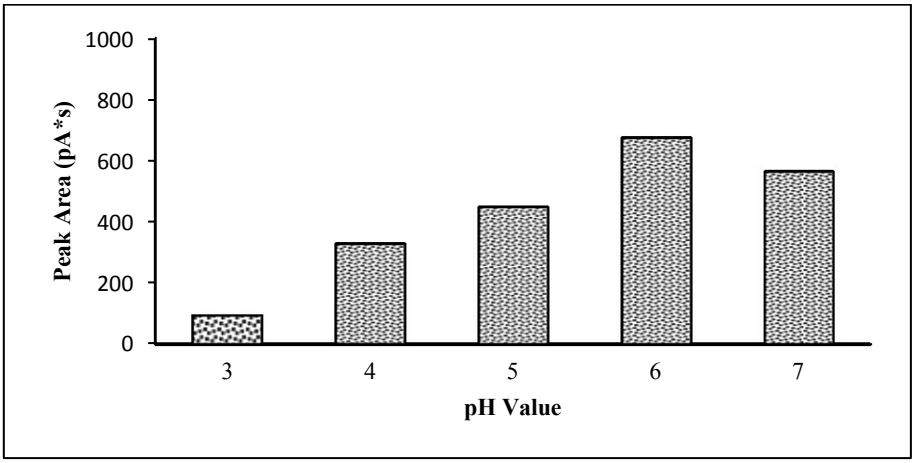

Figure 7. Effect of sample pH for DLLME-SFO of MP. Concentration of MP 3.00 µg/mL; volume of sample 5 mL (pH 6); volume extractant (*n*-hexadecane) 70 µL; volume disperser solvent (methanol) 0.25 mL; NaCl (w/v) 4%; extraction time 1 min; centrifugation 4000 rpm × 4 min

**Method validation and real sample analysis**

The optimized DLLME-SFO conditions which is 70 µL of *n*-hexadecane as extraction solvent, 0.25 mL of methanol as disperser solvent, 4% of NaCl, and pH 6 of sample solution was carried out for the extraction validation in the range of 0.1 – 8 µg/mL. The results showed good linearity and acceptable LODs as summarized in Table 2.

Table 2. Correlation coefficients, LOD and LOQ of samples using GC-FID for DLLME-SFO

| Paraben | Linear Range (µg/mL) | Correlation coefficients, $R^2$ | LOD (µg/mL) | LOQ (µg/mL) |
|---|---|---|---|---|
| Methylparaben | 0.1 – 8 | 0.9996 | 0.082 | 0.272 |

To investigate matrix effects and applicability of the technique on cosmetic samples, the final experiments were carried out on two different brands of sunblock labeled as Sample 1 and Sample 2. These samples were handled exactly according to the steps described in the sample preparation procedure and each sample was carried out with triplicate extraction. According to the chromatograms in Figure 8, MP was detected in both samples at the concentration of 0.06 µg/mL (Sample 1) and 0.42 µg/mL (Sample 2), respectively.

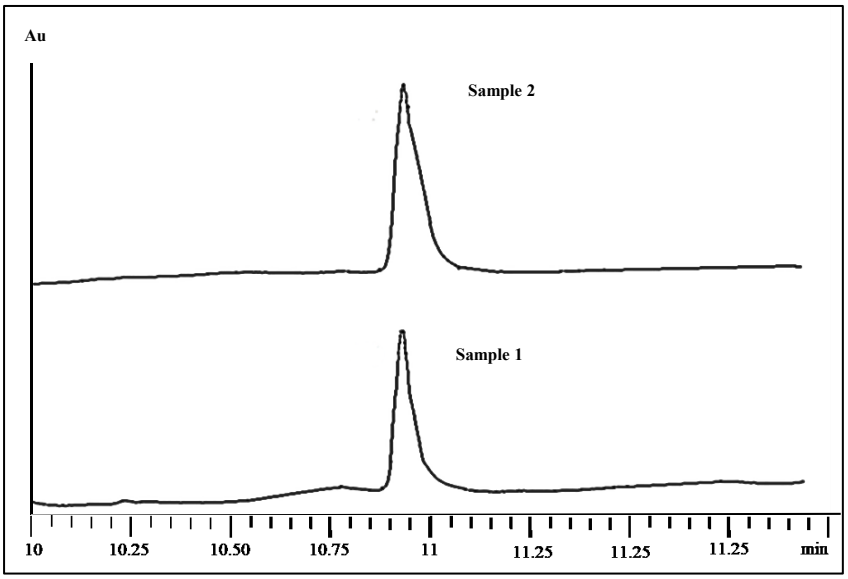

Figure 8. GC-FID chromatograms of DLLME-SFO extracts of Sample 1 and Sample 2

## Conclusion

This study has demonstrated the successful application of DLLME-SFO technique coupled with GC-FID for the determination of methylparaben in cosmetic samples. This method proved to have a high precision and requires a shorter extraction time with a low volume of the lower toxicity of extraction solvent. It is convinced that DLLME-SFO possesses a great potential in the rapid preconcentration of analyte and provides good linearity over the investigated concentration range. Since this is the first time we reported the application of DLLME-SFO in an analysis of methylparaben, with satisfactory results, the system could readily be applied to determine other parabens from different and complex sample matrices, using different analytical instruments. Combination with other microextraction techniques is suggested to enhance the extraction efficiency and sample preconcentration. In addition, simplicity, ease of operation and less consumption of organic solvents are the additional advantages of the method.

# SENSORY EVALUATION AND QUANTITATIVE ANALYSIS OF MINERAL AND HEAVY METAL CONTENT OF PROTEIN SUPPLEMENT INCORPORATED WITH HERBAL EXTRACT

## (Penilaian Rasa dan Analisa Kuantitatif Kandungan Mineral dan Logam Berat bagi Makanan Tambahan Protin Digabungkan dengan Ekstrak Herba)

**Abstract**

Calories-dense products promote weight gain through its healthy ingredients. The incorporation of herbs increased the product's benefit with antioxidant, anti-cancer and anti-aging properties. In this study, the comparison between herbal and non-herbal (commercial products) protein supplements were determined. The sensory evaluation of the protein supplements were done via 9-point hedonic scale. The mineral contents and undesirable toxic metals in the the product were also analysed using Inductively Coupled Plasma-Mass Spectrometry (ICP-MS). The score of hedonic scale indicated that the sweetness and bitterness of the herbal protein supplement were significantly different compared to the commercial products. All samples showed differences in the mineral contents where the herbal protein supplement contributed the highest content of magnesium (Mg) 3643.7 µg/kg, sodium (Na) 8192.3µg/kg and ferum (Fe) 180.7 µg/kg. The ICP-MS analysis result showed traces of heavy metals (cadmium, arsenic, plumbum, mercury) were 1.10 µg/kg, 0.03 µg/kg, 3.00 µg/kg and 5.07 µg/kg, respectively. These results confirmed that the concentrations of heavy metals in the product has not exceeded the maximum standard limit of regulation in Malaysia for Cd (0.3 mg/kg), As (5 mg/kg), Pb (10 mg/kg), and Hg (0.5 mg/kg). Hence, the results might be useful to define the new formulations of these highly consumed protein supplement with health benefits for atheletes.

**Keywords**: protein supplement, mineral content, heavy metal content, hedonic scale

**Abstrak**

Produk-produk padat kalori menggalakkan penambahan berat melalui ramuan-ramuan sihatnya. Penambahan herba meningkatkan kebaikan produk seperti ciri-ciri antioksida, anti-kanser dan anti-penuaan. Di dalam kajian ini, perbandingan di antara makanan tambahan protein berherba dan tidak berherba (produk komersil) telah diperolehi. Ujian rasa terhadap makan tambahan protin ini telah dilakukan melalui 9-titik skala hedonik. Kandungan mineral dan logam toksik yang tidak dikehendaki di dalam produk turut dianalisa menggunakan Spektrometri Jisim-Plasma Ganding Secara Aruhan (ICP-MS). Skor skala hedonik menujukkan kemanisan dan kepahitan makanan tambahan berprotin berbeza secara ketara berbanding produk-produk komersil. Semua sampel menunjukkan perbezaan di dalam kandungan mineral, di mana makanan tambahan protin berherba menyumbang kandungan tertinggi untuk magnesium (Mg) 3643.7 µg/kg, sodium (Na) 8192.3 µg/kg dan ferum (Fe) 180.7 µg/kg. Analisa keputusan ICP-MS menunjukkan kandungan logam berat (kadmium, arsenik, plumbum, merkuri) adalah 1.10 µg/kg, 0.03 µg/kg, 3.00 µg/kg dan 5.07 µg/kg setiap satunya. Hasil ini mengesahkan kepekatan logam berat tidak melebihi piawaian kadar maksimum peraturan Malaysia untuk Cd(0.3 mg/kg), As (5 mg/kg), Pb(10 mg/kg), and Hg (0.5 mg/kg). Oleh itu, keputusan yang

diperolehi mungkin berguna untuk menterjemah formulasi-formulasi baru yang banyak digunakan bagi makanan tambahan protin yang bermanfaat kepada kesihatan untuk atlet.

**Kata kunci:** makanan tambahan protin, kandungan mineral, kandungan logam berat, skala hedonik

## Introduction

The Malaysian sports nutrition industry benefited a 2% value of compound annual growth rate (CAGR) in 2014. Sports nutrition products in Malaysia will continue to have a strong sales demand specifically for men [1]. The increasing number of sports nutrition outlets in major shopping malls will also facilitate sales growth of wide ranges of sports nutritions. Protein supplement, specifically protein shakes is one of the examples of a sport nutrition drink. The protein supplement is added to the diet, mainly as is it contain vitamins, minerals, amino acids, herbs or botanicals, metabolites/constituents/extracts or a combination of any of these ingredients [2]. Sportperson prefers protein supplement as it easy to be prepared as a drink. The protein supplement is also able to speed up the recovery of strained muscles. These features are particularly important for athletes, bodybuilders, or people who need to gain muscle mass and strength while losing fat [3, 4].

The main ingredients used in protein supplement are whey protein, branch chain amino acid (BCAA), sweeteners, creatine, and glutamine. Consuming whey protein is a healthy way to add more protein in the daily diet. The whey protein is a quality protein source; that is absorbed and utilized efficiently by the human body [5]. The whey protein can be digested quickly and performs rapid delivery of amino acid to muscle cell which serves as a building block to increased muscle growth [6]. Meanwhile, the use of beta-alanine is to promote delay in muscle fatigue after workout with regard to the increasing levels of carnosine in intra-muscular. For synergistic effect, creatine is added in order to increase muscle volume and promoting lean body mass as well as increased in post-workout recovery [7]. Apart from that, glutamine promotes durability when connected to high muscle usage [8]. The intake of glutamine allows a person to be actively involved in exercises in longer period and with less fatigue [9].

Currently, there are a lot of protein supplements available in the market which can be used as directed. However, a lot of protein supplements which are commercially available may contain andro-steroids and most of the products are high level in sugar content. Andro-supplements acts like a steroid once it is metabolized by the body and therefore can pose similar kinds of health risks as steroids. The andro-supplements claim to be converted into testosterone in the body to help improve muscle mass. However, in 2004, the U.S. Food and Drug Administration (FDA) declared the andro- supplements are illegal, citing safety concerns [10].

The incorporation of herbs in the formulation of protein supplement is targeted to support a healthy lifestyle while contributing to the growth and maintenance of lean muscle mass. By adding the herbs in the ingredient such as *Eurycoma longifolia* (TA*)* may give a significant effect to sportperson for a long-lasting endurance during performing activities. The *Tongkat Ali* itself can act naturally as andro-supplement, which helps to boost the energy and increases stamina during the workout and/or activity. In parallel, it also promotes wellness with reference to its chemical components which are rich in phytonutrients [11]. Simultaneously, *Tribulus terristeris* has been used to enhance overall health, support healthy libido function and amplify muscle tone [12]. The *Safed muesli (Chlorophytum borivilianum)* is used as an energy booster and generally strengthens body immune system. The addition of herbal extract is also ideal for those who is lacking in consuming vegetables due to rich in vitamins and mineral [13].

Minerals plays an important role to support the metabolism of all living creatures [14]. Mineral contents such as selenium, zinc and copper are essential to maintain the metabolism of the human body; the optimal function for cell growth, healing and the activity of many metabolic processes [15]. Meanwhile, heavy metals such as cadmium, arsenic, lead and mercury can lead to adverse effects, although they are only present in small quantity [16]. Regular consumption of protein supplement may contribute to an increase intake of both mineral and heavy metal contents by the human body [17]. Therefore, it is necessary to give a guideline of the average amount to be consumed safely by the consumers. Contamination of heavy metals in the supplements during preparation and/or the use of heavy metal in the supplements itself is increasing especially when dealing with plants [18, 19]. This contamination might

result in serious health hazards such as dysfunction of kidney and symptoms of chronic toxicity [20, 21] when over consumed.

The innovation of products with healthy ingredients of *Eurycoma longifolia*, *Tribulus terristris* and *Chlorophytum borivilianum* with less sugar content is highly favourable to the sports industry. With balanced combination of fats, proteins, carbohydrates and minerals content, it will help sport persons such as athletes, body builders, and gym-goers to increase muscle size in a healthier way. Since the incorporation of the herbs are relatively new in the market, this study would provides information on the safety guideline of protein supplements with focus on essential mineral content and evaluate the level of heavy metal in the protein supplement. Commercial products of protein supplements were also analysed for its mineral and heavy metal content for comparison. The sensory attributes such as bitterness, sweetness, aftertaste, appearance and overall acceptability were also identified for use in future product formulation.

## Materials and Methods

### Ingredients formulation

The guidelines for the ingredients for the initial product formulation as well as the method of preparation were obtained from a commercial protein supplement. The ingredients chosen for this research were focused on developing the best formulation, with less sugar content and high in essential mineral including protein content. The ingredients of the formulations were obtained from health store at Taman Universiti, Skudai, Johor. Three commercial products categorized as food supplement were purchased for comparison purposes and labeled as sample CML 1, CML 2 and CML 3.

### Preparation of formulated protein supplement

The main herbs used in this product were prepared as follows; *Tongkat Ali* powder were prepared from extracted root part using water with the ratio (1:8 w/v) and then spray dried using spray dryer (Gea Niro, Italy). The spray dried parameter used were as follows : air inlet temperature at 160 °C, feed temperature at 25 °C, air pressure at 17.91 psi and feed flow rate at 4.86 mL/min. The parameter used was at the optimum condition. All other ingredients which formulated were then mixed together using fine grinder until homogenized. The prepared sample were sealed, packed and stored at room temperature for further required test.

### Mineral content and heavy metal analysis: Digestion procedures

For the digestion of the samples, a representative of 0.5 – 1 gram of dry weight sample is digested with 1 mL of 60% analytical grade Nitric acid (Sigma Aldrich, Germany) and ultrapure water (Hitachi, Japan). The digestate was heated using a hot plate under boiling temperature until white vapour appeared. The sample was then diluted with ultrapure water until it reaches a 100-mL final volume. The sample is filtered using 0.25 nylon syringe filter and ready for Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) injection.

For the precise quantification of heavy metal and mineral contents, calibration against synthetic standards was used before running the sample. 1000 µg/kg multi-element standard was used from Perkin Elmer standard solution and diluted to 10, 20, 30, 50 µg/kg and 25 µg/kg as Quality Control (dissolved with 1% nitric acid (Sigma Aldrich, Germany)) for mercury determination Gold (Au) standard solution was used with same concentrations. The data acquisition was done by ICP-MS Software (ELAN 6100, Perkin Elmer).

### ICP-MS instrumentation

The ICP-MS (ELAN 6100, Perkin Elmer) was used for heavy metal and mineral content analysis in the samples. The instrument was setup via an integrated all lines system including; 1000 Watts Inductively Couple plasma radio-frequency (ICP RF) Power. Other conditions were set as follows; plasma flow, auxiliary flow and nebulizer flow, at 15 L $min^{-1}$, 1.5 L $min^{-1}$ and 0.47 L $min^{-1}$, respectively. The samples were introduced after an initial delay of 25 seconds. Afterward, the samples were pumped at the rate of 10 rpm and 25 seconds rinse time. The concentrations were read within 5 seconds for each replicates and an instrument stabilization time of 15 seconds was allowed between the samples.

**Sensory analysis: Subjects**

Fifty subjects consisting of volunteers (comprising of 26 men and 24 women) from University Teknologi Malaysia (UTM) have taken part in the sensory evaluation session. They were led by an experienced facilitator and lasted for 10 minutes. They were given instructions and the objective of the sensory evaluation. The explanation included descriptions of the attributes and their implied acceptability in the two samples; commercial product (CML 1) and formulated protein supplement product (FMD 1). These protein supplements were purposely developed as to compare with the commercial samples.

The attributes generated from the participants included sweetness, bitterness, aftertaste, appearance and overall preference. All five sensory attributes were measured using the 9-point hedonic scale. The scale values ranged from 'Like extremely' to 'dislike extremely', corresponding to the highest and lowest scores of '9' to '1', respectively.

**Sample preparation for sensory evaluation**

Only one of the commercial products was chosen as a comparison with the formulated protein supplement product. The samples were labeled with 3-digit random number and samples were presented simultaneously. Purified water was used to clean the palate. The order of the presentation was balanced and randomised to eliminate contrasting effect and positional bias.

**Statistical analysis**

The sensory scores for the protein supplement were subjected to the analysis of variance (ANOVA) to determine if there were statistically significant ($P \leq 0.05$) preferences in sensory attributes [22]. Tukey's test was used to determine which of the formulation was higly preferred [23, 24].

## Results and Discussion

**Mineral and heavy metal content**

The results of mineral content and heavy metal analysis are presented in Table 1 and Table 2, respectively. Table 1 shows the mineral analysis of CML 1, CML 2, CML 3 and FMD 1. In general (Table 1) sodium and magnesium were the two major components presenet in all of the samples, and followed by ferum. The results obtained for sodium (8192.3 µg/kg), magnesium (3643.7 µg/kg) and ferum (180.7 µg/kg) for formulated protein supplement (FMD 1) were higher compared to the commercial products. Magnesium significantly contributed to the digestive and kidney health level while sodium is important as it isrelated to cardio activities [25]. Ferum is important for its protein transport activities specifically related to the circulatory of blood to the cells [26]. The results obtained from the formulated protein supplement showed a presence of 42.6 µg/kg of zinc, 23.6 µg/kg of manganese, 18.3 µg/kg of chromium, 16.9 µg/kg of copper and 2 µg/kg of selenium. These result was also comparable to the commercial products. Based on the ASEAN Guideline for herbal supplement, the daily dietary intake for adults are as follow; 350 mg of magnesium, 20 mg of ferum, 15 mg of zinc, 3.5 mg of manganese and selenium at 0.2 mg. All of these minerals play an important role in our body as it is related to bioavailability and physiological action where they act as a co-factor in metabolic processes [27].

Table 1. Mineral components of commercial and formulated protein supplement in µg/kg

| Minerals Contents | Protein Supplements | | | |
|---|---|---|---|---|
| | CML 1 | CML 2 | CML 3 | FMD 1 |
| Sodium | 953.3 | 1116.7 | 2645.9 | 8192.3 |
| Ferum | 74.4 | 134.6 | 106.7 | 180.7 |
| Magnesium | 1342.6 | 1378.2 | 2309.8 | 3643.7 |
| Selenium | 0.4 | 0.3 | 0.6 | 2.0 |
| Zinc | 52.6 | 36.0 | 63.8 | 42.6 |
| Manganese | 13.3 | 22.8 | 30.4 | 23.6 |

Table 2. Heavy metals of commercial products and herbal protein supplements in μg/kg

| Heavy Metal contents | Protein Supplements | | | |
|---|---|---|---|---|
| | CML 1 | CML 2 | CML 3 | FMD 1 |
| Plumbum | 2.42[a] | 1.49[a] | 5.87[ab] | 3.00[a] |
| Arsenic | 0.03[a] | 0.05[a] | 0.02[a] | 0.03[a] |
| Mercury | 5.12[a] | 4.80[a] | 5.01[a] | 5.07[a] |
| Cadmium | 0.56[a] | 1.00[ab] | 0.61[a] | 1.10[ab] |
| Chromium | 10.6[a] | 10.0[a] | 7.0[a] | 18.3[ab] |
| Cuprum | 11.2[a] | 15.2[a] | 20.4[ab] | 16.9[a] |

*Means in rows and columns with different superscripts differ ($p \leq 0.05$).

The results obtained in Table 2 refer to the presence of heavy metal content of all protein supplements. In general, mercury, plumbum, cadmium, and arsenic were detected in all samples; however, at a lower detection limit. Based on the National Pharmaceutical Control Bureau (Ministry of Health, Malaysia), the guideline for maximum level permitted for metal contaminant in food product, are as follow; mercury (≤ 0.5 ppm), cadmium (≤ 0.3 ppm), plumbum (≤ 10 ppm), arsenic (≤ 5.0 ppm), chromium (0.5 mg) and copper (2 mg). Plumbum (Pb), cadmium (Cd), arsenic (As) and mercury (Hg) are considered as toxic to human body, therefore, their daily intake via supplements has been restricted. Limitation of intakes of As, Cd, Hg, and Pb were assessed with respect to the safety levels described by various national and public health organizations [28].

**Acceptance of the formulation**

A sensory analysis was carried out at a lab-scale test to verify whether the addition of *Tongkat Ali* herbs would affect the acceptance of the product. In general protein supplement added with herbs was accepted as there is no significant difference compared to the commercial protein supplement where the score were 3.43 and 3.46, respectively as in Table 3. The sensory scores of sweetness, bitterness, aftertaste, appearance and overall acceptability assigned by the panellists were presented in Figure 1. It was observed that the sweetness, bitterness and appearance score were significantly different at ($p \leq 0.05$) as in Table 3. Meanwhile, it was observed that the aftertaste score was not significantly different at ($p \leq 0.05$). The sweetness of the protein supplement needs to be addressed since consumers tend to reduce food intake when they consumed high glucose products. Glucose in solution would be expected to pass rapidly to the small intestine and stimulate the satiety hormones including CCK [29] and polypeptide YY [30]. As a result, this may increase the possibilities of lacking other important nutrients which in turn might increase the risk to health problem. The aftertaste attributes is one of the important attributes as this will affect consumers to like or dislike the products. The component which could also contribute to bitter aftertaste are low-calorie products such as saccharin and acesulfame-K [31]. The low sensory score for the bitterness of the formulated protein supplement was probably because of *Tongkat Ali* powder extract added in the formulation. This bitter tastes in the protein supplement is probably mainly due to the eurycomanone compound in *Tongkat Ali*. Eurycomanone is one of the phytochemical compounds which can be found in *Tongkat Ali* extract and was identified as one type of quassiniods which responsible for the bitter taste [32].

Table 3. Mean sensory scores for protein supplements

| Sensory Attributes | Formulation | |
|---|---|---|
| | Commercial (CML 1) | Formulated (FMD 1) |
| Sweetness | 3.62[a] | 3.07[ab] |
| Bitterness | 3.00[a] | 3.43[ab] |
| Aftertaste | 3.87[a] | 3.67[a] |
| Appearance | 3.83[ab] | 4.03[ab] |
| Overall | 3.43[a] | 3.46[a] |

[ab] There are statistically significant preferences (P ≤0.05) of one sample over the other(s) with respect to the particular sensory attributes if values in the same row carry different superscripts; that is if calculated t-value > tabulated t-value.

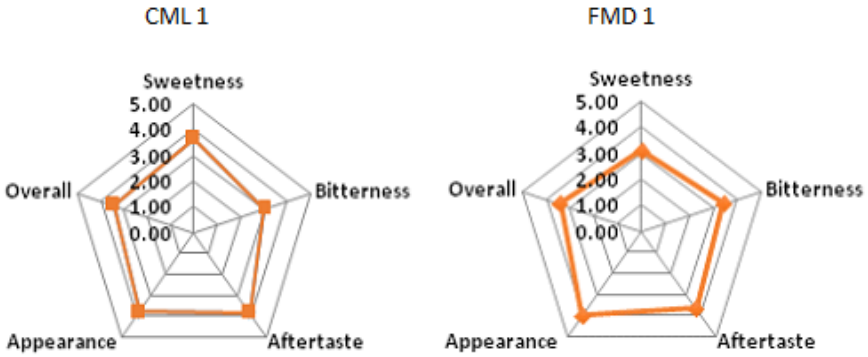

Figure 1. Comparison of sensory attributes for commercial (CML 1) and formulated (FMD 1) product of protein supplements

## Conclusion

Based on the overall results, incorporation of herbal powder significantly affected the bitterness and sweetness of protein supplement products. The addition of herbs in the protein supplement is also important as it increased the mineral intake which is good to promote a healthy diet. Based on the result obtained, protein supplement added with *Tongkat Ali* satisfactorily contribute to nutritional values if compared to other products available in the market. Since there is no significant difference between commercial and formulated product in overall acceptability of the products, it may be concluded that this formulated product may have the potential to be commercial.

**Abstract**

In this paper, we report molecularly imprinted $TiO_2$ inorganic film ($MITiO_2$) and PVDF/$TiO_2$ composite film ($MIPTiO_2$) as sensors for the detection of parathion methyl (PTM), a simulant of chemical threat agent (CTA) using quartz crystal microbalance (QCM). PTM was used as a molecular template for the imprinting of the sensor film. The $MITiO_2$ showed a greater response ($\Delta f$ 19 Hz) to 9.88 μM of PTM than that ($\Delta f$ 2 Hz) of the $MIPTiO_2$. The ratios of $TiO_2$/template and PVDF/$TiO_2$/template were optimized. Time for the UV degradation of the template was also optimized. $MITiO_2$ sensor shows good potential for the detection of CTA, other chemical and biochemical pollutants.

**Keywords**: molecularly imprinted polymer, quartz crystal microbalance, sensor, $TiO_2$, parathion methyl

**Abstrak**

Dalam kajian ini, kami melaporkan $TiO_2$ filem tak organik ($MITiO_2$) dan filem komposit PVDF/$TiO_2$ ($MIPTiO_2$) molekul tercetak sebagai sensor untuk mengesan paration metil (PTM), yang merupakan ejen bahan kimia berbahaya (CTA) menggunakan penimbang mikro kristal kuarza (QCM). PTM telah digunakan sebagai templat molekul untuk peneraan filem sensor. $MITiO_2$ menunjukkan tindak balas yang lebih besar ($\Delta f$ = 19 Hz) pada kepekatan 9.88 μM daripada PTM berbanding $MIPTiO_2$ ($\Delta f$ = 2 Hz). Nisbah $TiO_2$/templat dan PVDF/$TiO_2$/templat telah dioptimumkan. Masa untuk degradasi UV bagi templat juga telah dioptimumkan. Sensor $MITiO_2$ menunjukkan potensi yang baik untuk mengesan CTA, serta bahan kimia yang lain dan bahan pencemar biokimia.

**Kata kunci**: polimer molekul tercetak, penimbang mikro kristal kuarza, sensor, $TiO_2$, paration metil

## Introduction

Chemical threat agents (CTA) are toxic synthetic chemicals that can be dispersed in various forms like gas, liquid, aerosol or adsorbed to solid particles [1]. CTA were deployed in war to kill or incapacitate the enemy. Nerve agents are among the most potent of all reported CTA. Nerve agents like Sarin, Tabun and Soman act as inhibitor irreversibly binding to the enzyme acetylcholinestearase, an enzyme that normally destroys and stops acetylcholine, a neurotransmitter. Inhibition of the enzyme would lead to an accumulation of acetylcholine, producing a perpetual

excited state in the nerve (e.g. constant muscle contraction) [2]. The critical effects of this would be the paralysis of the respiratory muscles and inhibition of the respiratory centre in the central nervous system, leading to death of the victim by asphyxiation within minutes [3]. Due to their high toxicity, imperceptibility to senses and rapid action, administration of antidote to victims exposed to such chemicals were often carried out too late. In addition, these CTAs are potential weapons of choice for terrorist organizations that could threaten national security [4]. Thus, there is a need for a highly sensitive and selective sensor to be developed for the detection of such CTAs as a preventive measure.

Various analytical methods had been used in the military and civil agencies for the detection of CTA such as liquid chromatography and gas chromatography [5, 6]. Although these methods are advantageous in terms of having a low limit of detection, they are usually not selective. One selective new method is based on molecular imprinting polymers (MIPs). MIP polymers are synthesized when monomers are polymerized in the presence of template molecules (Figure 1). The functional groups in the monomers would orient toward their counteracting functional groups in the template via forces of interactions like hydrogen bonding, van der Waals interaction and dipole-dipole interactions etc. [7]. Subsequent cross-linking of the polymer would hold the template molecule in place. Upon removal of the template molecules, the remaining cavities that retained the molecular configuration of the template would act as highly specific molecular recognition sites [8].

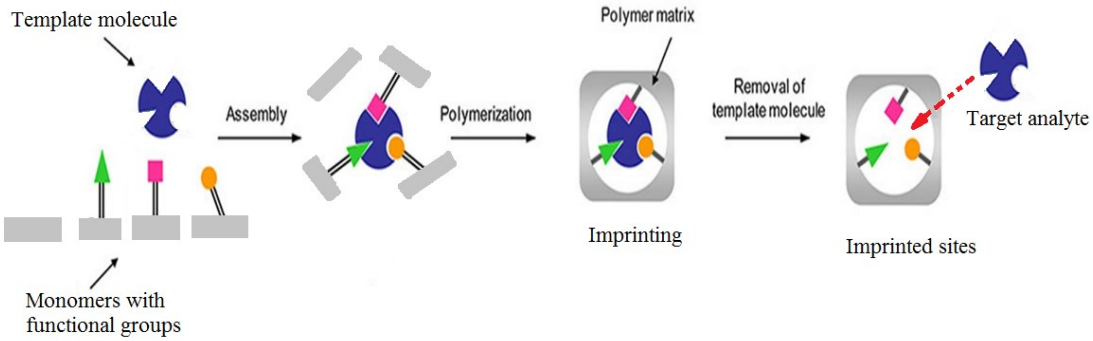

Figure 1. Illustrative formation of molecularly imprinted polymer sensor

A MIP sensor on gold coated AT cut quartz could be coupled with mass sensitive devices such as QCM for the detection of target analyte molecules. A QCM flow cell consists of two electrodes where the MIP sensor sits in between. Resonance frequency of the quartz based sensor with applied voltage is sensitive to mass change. Binding of target analyte molecules onto the molecular cavities on the MIP would lead to an increase in mass which is reflected by a proportional drop in its resonance frequency [9,10,11]. The relationship between change of resonance frequency and change of mass for a QCM sensor could be described by the Sauerbrey equation (eq. 1):

$$\Delta f = -\frac{2f_0^2}{A\sqrt{\rho_q \mu_q}}\Delta m \quad (1)$$

where $\Delta f$ is the frequency change (Hz), $f_0$ is the resonant frequency (Hz), $\Delta m$ is the mass change (g), A is the coated area ($cm^2$), $\rho_q$ is the density of quartz ($g/cm^3$), $\mu_q$ is the shear modulus of quartz ($g/cm\ s^2$).

Hydrophobic PVDF (-($CH_2CF_2$)-) has high affinity to hydrophobic analyte molecules. The polarity of PVDF enables dipole-dipole interaction in addition of Van der Waals interaction with the template molecule. These characteristics, in addition to its chemical and thermal stability, enable PVDF a suitable candidate as the polymer of MIP. PVDF has high affinity to hydrophobic molecules but low affinity to hydrophilic molecules. Therefore, it will be good to include some hydrophilic materials into PVDF so that the final composite sensor could be optimized to bind to both hydrophobic and hydrophilic molecules. $TiO_2$ particles with enriched surface hydroxyl groups could

bind to hydrophilic molecules. In addition, with UV irradiation it could photocatalytically degrade template and analyte molecules which facilitate the template removal and cleaning after analysis. $TiO_2$ particles could be prepared from titanium butoxide ($Ti(OBu)_4$). Upon exposure to moisture, $Ti(OBu)_4$ rapidly undergoes hydrolysis to form $TiO_2$ nano crystals. When $Ti(OBu)_4$ was used alone the rapid formation of the $TiO_2$ particles neighboured the template molecules enabled specific recognition sites to be formed on the MIP [12]. PTM, commonly found in pesticides, was chosen as the template due to its lower toxicity than real CTAs and structure similarity to organophosphorous CTAs like sarin (Figure 2).

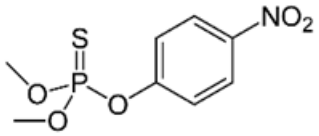

Figure 2. Molecular structure of parathion methyl

Template removal to form MIP is one of the critical and difficult steps. Extra chemicals introduced for template removal may destroy the newly formed molecular cavities. Without extra chemicals introduced, photodegradation have advantages in keeping the molecular cavities not touched with other chemicals during template removal. PTM has been reported to undergo photolysis in the presence of sunlight or more specifically, ultraviolet (UV) light [13]. In addition, metal oxides like titanium dioxide ($TiO_2$) that exhibits high photocatalytic activity have been shown to be able to decompose CTA simulants completely into inorganic products under UV light [14]. Upon absorption of UV light, positively charged holes and negatively charged electrons are generated and these two species can then initiate redox reactions via the generation of reactive species like hydroxyl radicals and superoxides [15]. Therefore, either alone or together with PVDF, photocatalytically active $TiO_2$ could assist the template removal during MIP preparation and sensor post-cleaning after analysis. Here we report molecularly imprinted $TiO_2$ inorganic film and PVDF/$TiO_2$ composite film as sensors for the detection of PTM using QCM. Removal of template molecules was completed through their photocatalytic degradation by the surrounding $TiO_2$ particles under UV irradiation.

## Materials and Methods

### Materials

Polyvinylidene difluoride powder (M.P. 155 – 160 °C) was from Alfa Aesar (Ward Hill, MA). Titanium(IV) butoxide ($Ti(OBu)_4$, reagent grade 97%) was from Sigma Aldrich (St. Louis, MO, USA). Parathion-methyl ($C_{10}H_{14}NO_5PS$, 99.5%) was from Chem Service Inc. (West Chester, PA, USA). N,N-dimethylformamide ($C_3H_7NO$, reagent grade 99.5%) was from Merck (Darmstadt, FR, Germany). Tetrahydrofuran ($C_4H_8O$, reagent grade 99.7%) was from VWR International (Singapore). $TiO_2$ nanoparticles (12 nm) were synthesized according our previously reported sol-gel method from the hydrolysis of $TiOSO_4$ in an alcohol and water mixture [16].

### Preparation of molecularly imprinted PVDF/$TiO_2$ composite sensor (MIP$TiO_2$)

A certain quantity of PVDF powder and PTM were dissolved in DMF. And then $TiO_2$ particles were dispersed into the transparent PVDF/PTM/DMF solution with 10 minutes of sonication. Mass ratios of PVDF, $TiO_2$ nanoparticles and PTM in the ad-mixture were 5:5:1, 2:2:1 and 1:1:1 respectively for different sensors. 20 µL of the ad-mixture was applied onto the gold coated surface of the AT cut quartz crystal chip. After dry at room temperature, the chip was wetted by 700 ppm of potassium bromate aqueous solution and irradiated with monochromatic 365 nm UV light (100 W, mercury lamp, 18 mW/cm$^2$) for a certain period of time for the template degradation. The photocatalytic degradation of parathion methyl was reported before [17, 18]. After template removal the sensor was rinsed with DI water for several times before use.

### Preparation of molecularly imprinted $TiO_2$ film sensor (MI$TiO_2$)

$Ti(OBu)_4$ was used for the preparation of MI$TiO_2$. Due to $Ti(OBu)_4$ sensitive to moisture in air, it was necessary to avoid prolonged exposure of $Ti(OBu)_4$ to the air during the preparation procedures. The reaction vials to be used were first blown with nitrogen gas for 3 minutes to dispel adsorbed moisture on the wall. Then a certain quantity of

$Ti(OBu)_4$ was added into one of the vials and rapidly capped to avoid substantial entry of moisture. THF was then added to the $Ti(OBu)_4$ and the vial was sonicated for 5 minutes to obtain a homogenous solution. Similar procedure was applied when preparing a PTM/THF solution. Then PTM/THF solution was added into $Ti(OBu)_4$/THF solution and mixed well. Subsequently, the mixture was topped up with THF such that the ratio of the total mass (g) of $TiO_2$ and PTM to volume (mL) of THF was 3/1000. Different molar ratios of $TiO_2$/PTM 10:1, 5:1, 2:1 and 1:1 were used to prepare different sensors. The final solution mixture was further sonicated for 5 minutes. 20 μL of the ad-mixture was placed onto the gold surface of quartz chip. When exposure to air, $Ti(OBu)_4$ hydrolyzed to form $TiO_2$ nanocrystallines wrapping PTM template molecules. $Ti(OBu)_4$ hydrolysis process was completed at room temperature after overnight. After complete hydrolysis, the chip was wetted by DI water and irradiated with monochromatic 365 nm UV light (100 W, mercury lamp, 18 $mW/cm^2$) for a certain period of time for the template degradation. Once template molecules were removed, the sensor was rinsed with DI water for a few times and then was ready for use.

**Preparation of non-imprinted polymers (NIP)**

NIPs of PVDF/$TiO_2$ composite and pure $TiO_2$ were prepared using similar procedures but without including template PTM molecules. They were named as PVDF/$TiO_2$ NIP and $TiO_2$ NIP, respectively.

**Evaluation of sensors**

Evaluation of the sensors were conducted using a Q-Sense E4 QCM Analyzer (Biolin Scientific) consisting of a QE 401 Electronics Unit, a QCP 401 Chamber Platform and 4 QFM 401 Flow Modules. The MIP$TiO_2$ and MI$TiO_2$ sensor chips were mounted onto the flow modules and fitted onto the platform in the temperature-controlled chamber with the liquid inlet and outlet tubes connected. The resonance frequencies of the sensor chips were first measured to ensure that with the thickness of the MIP films their resonance frequencies were still within the detection range of QCM. With the chamber's temperature maintained at room temperature (25°C), the liquid flow was started. Deionized water was first introduced into the flow module at 50 μL/min for 5 minutes before increasing to 100 μL/min. Measurement of the frequency change was then started. DI water flow was continued until the frequency has stabilized before PTM analyte solution was introduced. The flow of analyte solution was continued from for about 1.5 hours until the resonance frequency has stabilized before switching to DI water rinsing for 30 minutes. The frequency change was taken at the $70^{th}$ minute after analyte introduction.

## Results and Discussion

**Template removal**

When $TiO_2$ is activated by UV light, holes ($h^+$) are formed in the valence band and electrons ($e^-$) in the conduction band of $TiO_2$. Photogenerated holes and electrons further react with water and oxygen to produce hydroxyl and superoxide radicals. The photocatalytic degradation of PTM was reported before [17, 18]. PTM reacted with hydroxyl radicals to produce paraoxon methyl, which further reacted with hydroxyl radicals to generate p-nitrophenol, hydroquinone, carboxylic acids and other intermediates to final $CO_2$ gas and phosphate ions. To enhance photocatalytic degradation of PTM, electron acceptor bromate was added as an additive. Electron acceptors like $BrO_3^-$ ions removed photogenerated electrons from the conduction band resulting in better electron-hole separation and so photocatalytic efficiency (equation 2) [15]:

$$BrO_3^- + 2H^+ + 2e^- \rightarrow BrO_2\cdot + H_2O \quad (2)$$

Based on previous reports, $TiO_2$ UV photocatalytic degradation of organophosphorous compounds like PTM and diethylphosphoramidate was carried out in the presence of suspended $TiO_2$ particles in an aqueous solution and the time taken for complete photodegradation of these molecules required at least a few hours [14, 18].

**Non-imprinted polymers (NIP)**

PVDF/$TiO_2$ NIP and $TiO_2$ NIP showed some baseline response to 9.88 μM of PTM solution. Mass ratio 1/1 of PVDF/$TiO_2$ was used for the PVDF/$TiO_2$ NIP. Their resonance frequency changes are listed in Table 1. $TiO_2$ NIP had a frequency change of 4.0 Hz, which was lower than that (8.0 Hz) of PVDF/$TiO_2$ NIP although both were low enough as background baseline. Lower NIP response was preferred because lower baseline could enhance detection sensitivity.

Table 1. Response of PVDF/$TiO_2$ NIP and $TiO_2$ NIP to 9.88 μM of PTM solution

| Name of NIPs | Frequency Changes Δf (Hz) |
|---|---|
| PVDF/$TiO_2$* | 8.0 |
| $TiO_2$ | 4.0 |

* Mass ratio of PVDF to $TiO_2$ was 1/1

**MIP$TiO_2$ sensor**

Figure 3 shows the changes of resonance frequency (Δf) of MIP$TiO_2$ sensors with different ratios of PVDF/$TiO_2$/PTM responding to 9.88 μM of PTM aqueous solution before and after template removal. Before template removal MIP$TiO_2$ sensor with 1/1/1 ratio of PVDF/$TiO_2$/PTM in the preparation as-mixture had higher response to PTM than the other two sensors with lower PTM percentage, which could be due to the interactions between template PTM molecules and analyte PTM molecules. However, after template removal by UV irradiation, responses of all the three sensors greatly decreased which could be attributed to two reasons. The first reason was that after UV irradiation, $TiO_2$ may exhibit both natural and permanent superhydrophilicity [19 – 21]. Natural superhydrophilicity was reversible and mainly induced by heating effect of UV light, which dispelled some moisture molecules from $TiO_2$ surface and then the leftover hydrogen bonded moisture molecules spread out thermodynamically to compensate the decrease of surface tension due to the partial loss of water molecules. Permanent superhydrophilicity based on natural superhydrophilicity was mainly attributed to the stabilization layer such as outer $SiO_2$ layer [21] or the PVDF layer in our case to stabilize surface hydroxyl groups. The second reason could be attributed to the appearance of some hydrophilic functional groups on the surface of PVDF after UV irradiation with the existence of $TiO_2$ [22, 23]. Therefore, after template removal by UV irradiation, the sensor surface was highly likely very hydrophilic and so have very weak interaction with hydrophobic PTM molecules, resulting in low response to PTM.

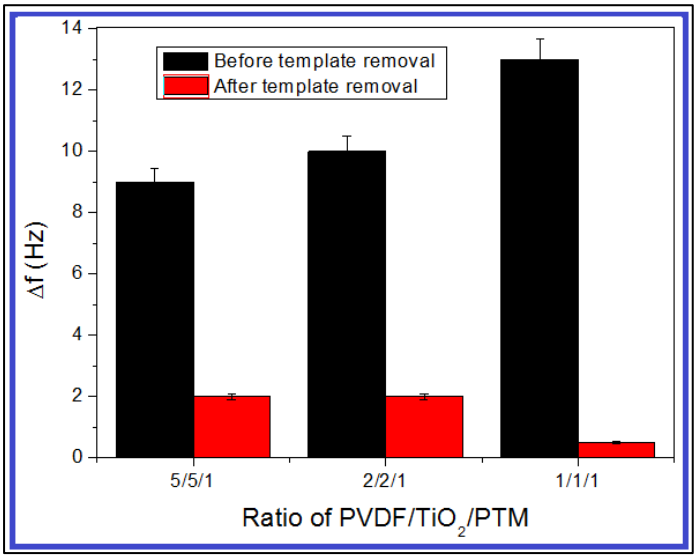

Figure 3. Changes of resonance frequency (Δf) of MIP$TiO_2$ sensors with different ratios of PVDF/$TiO_2$/PTM responding to 9.88 μM of PTM aqueous solution before and after template removal

**$MITiO_2$ sensors**

Figure 4 shows that $MITiO_2$ sensor with $TiO_2$/PTM ratio of 10/1 after template removal had an Δf value of 11.0 Hz responding to 9.88 μM of PTM solution, which was higher than the 4.0 Hz of $TiO_2$ NIP. This demonstrated that PTM molecular cavities were likely imprinted in the $MITiO_2$ sensor. Figure 5 shows the changes of resonance frequency (Δf) of $MITiO_2$ sensors with different ratios of $TiO_2$/PTM responding to 9.88 μM of PTM solution before and after template removal. After template removal, $MiTiO_2$ sensors had higher response to PTM than those before template removal. When ratio of $TiO_2$/PTM was 5/1, the $MITiO_2$ sensor reached the highest response to PTM. When the percentage of template molecules in the preparation ad-mixture was too high, the formed $TiO_2$ film after template removal could easily collapse due to insufficient $TiO_2$ quantity in the film.

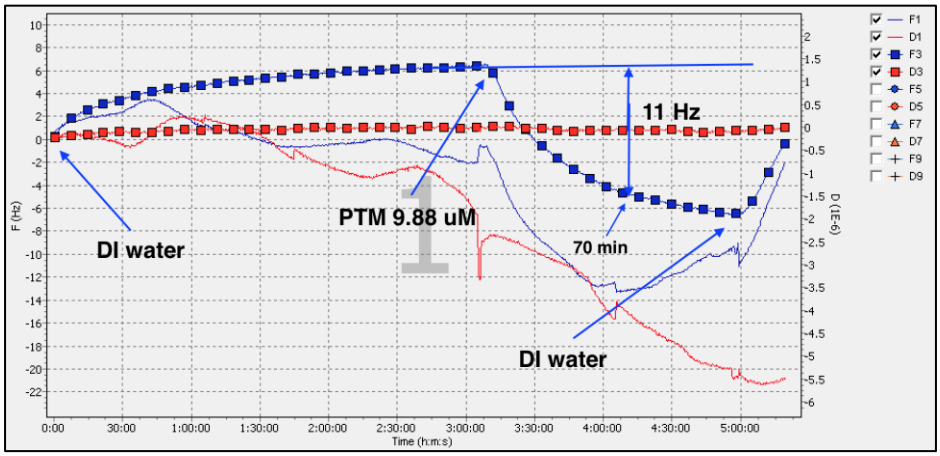

Figure 4. Change of resonance frequency (3rd overtone, i.e. the blue line with squares) of a $MITiO_2$ sensor after template removal; $TiO_2$: PTM = 10:1. The 1st fundamental frequency (the blue line without squares) was not stable and so could be ignored. Red lines were changes of resonance dissipation that were not discussed here.

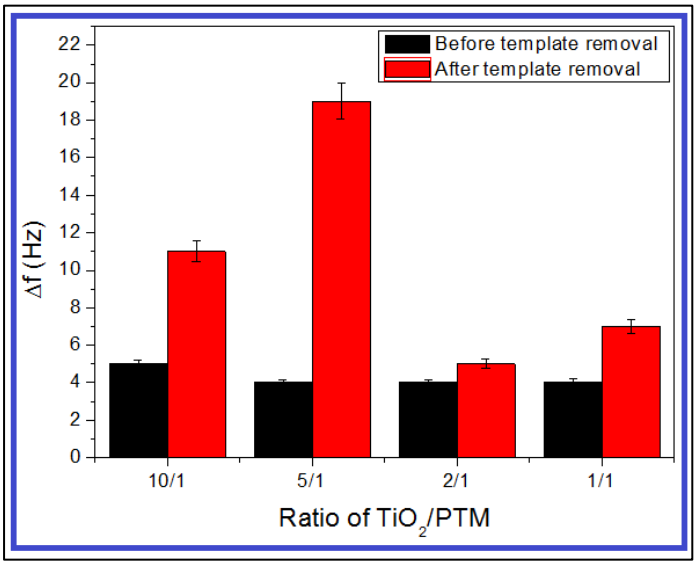

Figure 5. Changes of resonance frequency (Δf) of $MITiO_2$ sensors with different ratios of $TiO_2$/PTM responding to 9.88 μM of PTM solution before and after template removal by UV irradiation for 18 h

Figure 6 shows the changes of resonance frequency (Δf) of $MITiO_2$ sensor with 5/1 ratio of $TiO_2$/PTM with different UV irradiation time during template removal corresponding to 9.88 μM of PTM solution. With longer UV irradiation up to 36 hours, the sensor' response to PTM became weaker than that with only 18 hours of UV exposure. Superhydrophilicity of $TiO_2$ after UV exposure may explain this phenomenon. With 18 hours of UV irradiation, the superhydrophilicity of $TiO_2$ surface may reach a certain level but still could interact with hydrophobic PTM analyte molecules [19 – 21]. With further UV irradiation to 36 hours, the superhydrophilicity of $TiO_2$ surface continuously enhanced to a high level so that hydrophobic PTM analyte molecules had very weak interactions with $TiO_2$, resulting in poor response. Figure 7 further shows that $MITiO_2$ sensor had much higher response to PTM than non-imprinted $TiO_2$ (NIP).

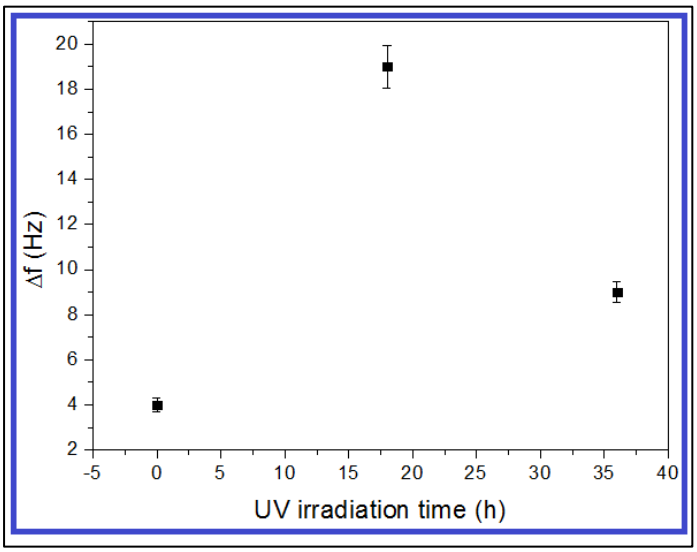

Figure 6. Changes of resonance frequency (Δf) of $MITiO_2$ sensor with 5/1 ratio of $TiO_2$/PTM with different UV irradiation time during template removal responding to 9.88 μM of PTM solution

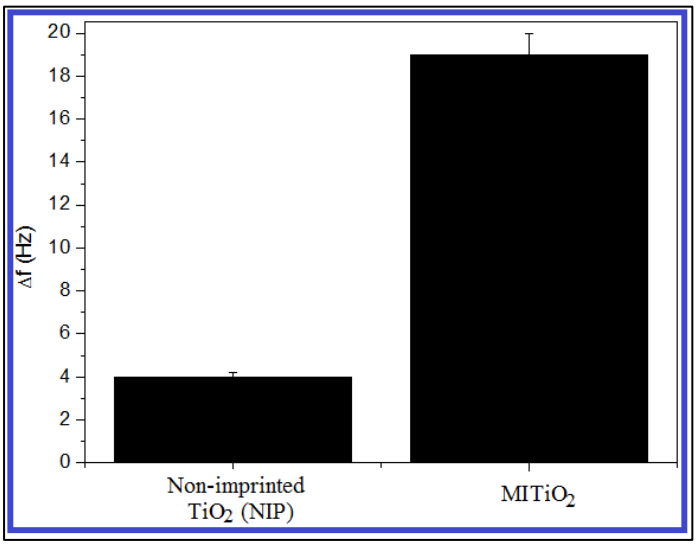

Figure 7. Changes of resonance frequency (Δf) of Non-imprinted $TiO_2$ (NIP) and $MITiO_2$ sensor with 5/1 ratio of $TiO_2$/PTM in the ad-mixture responding to 9.88 μM of PTM solution

## Conclusion

Molecularly imprinted PVDF/$TiO_2$/PTM ($MIPTiO_2$) and $TiO_2$/PTM ($MITiO_2$) sensors were prepared and evaluated for the detection of parathion methyl, a simulant of chemical threat agents. Template PTM molecules were removed via photocatalytic degradation under UV irradiation with the existence of photocatalytically active $TiO_2$ nano crystals. Here we demonstrated that molecular cavities of PTM were formed inside the $MITiO_2$ sensor after PTM template molecules were removed. $MITiO_2$ with a 5/1 mass ratio of $TiO_2$/PTM in the ad-mixture showed promising sensing ability towards PTM analyte molecules after template removal. 18 h of UV irradiation time for template removal was sufficient while 36h was too long that superhydrophilicity of $TiO_2$ dominated and repelled the hydrophobic PTM analyte molecules resulting in lower response to PTM. Molecularly imprinted $MITiO_2$ sensors were suitable for the detection of CTAs and their simulants, such as PTM, with a good sensitivity. However, molecularly imprinted polymers $MIPTiO_2$ were not sensitive enough to be as sensors for CTAs and their simulants, possibly due to the incompatibility between hydrophobic PVDF and hydrophilic $TiO_2$.

**Abstract**

In this study, newly developed copper modified CN composites were prepared and tested as a fluorescence sensor for detection of nitrate ions ($NO_3^-$). The structure and chemical properties of CN and copper modified CN composites were investigated via X-ray diffraction (XRD), Fourier transform infra-red (FTIR), diffuse reflectance ultraviolet-visible (DR UV-Vis) and fluorescence spectroscopies. Three emission sites represented as C=N, C=O and C-N moieties were suggested to contribute as sensing sites in CN and copper modified CN composites. The sensing capabilities of CN and copper modified CN composites toward $NO_3^-$ in the range of 300 to 1800 µM were determined via a quenching technique. The quenching efficiencies ($K_{SV}$) of CN and copper modified CN composites were obtained from the Stern-Volmer plot. Among three emission peaks of CN, C=N sites were found to be the most sensitive site having the strongest interaction with $NO_3^-$. By addition of Cu(0.5 mol%), the $K_{SV}$ of CN was improved from 2.11 x $10^{-4}$ to 5.27 x $10^{-4}$ $\mu M^{-1}$. This study showed that with the addition of copper as modifier, the performance of CN can be improved and the composite can be used as potential fluorescence sensor for the detection of $NO_3^-$.

**Keywords:** copper modified carbon nitride, fluorescence sensor, nitrate ion

**Abstrak**

Dalam kajian ini, karbon nitrida terubah suai kuprum yang baru telah disediakan dan diuji sebagai sensor pendafluor untuk mengesan ion nitrat ($NO_3^-$). Struktur dan sifat kimia bagi CN telah disiasat melalui pembelauan sinar-X (XRD), transformasian infra-merah Fourier (FTIR), spektroskopi pantulan serakan ultralembayung-cahaya nampak (DR UV-Vis) dan spektroskopi pendafluor. Tiga tapak pelepasan diwakili sebagai moiti C=N, C=O dan C-N telah dicadangkan untuk menyumbang sebagai tapak penderiaan CN dan komposit CN terubah suai kuprum. Keupayaan penderiaan CN dan komposit CN terubah suai kuprum terhadap $NO_3^-$ dalam lingkungan 300 hingga 1800 µM telah ditentukan melalui teknik pelindapan. Kecekapan pelindapan ($K_{SV}$) bagi CN dan komposit CN terubah suai kuprum telah diperoleh daripada plot Stern-Volmer. Di antara tiga tapak pelepasan CN, tapak C=N telah ditemui menjadi tapak yang paling sensitif dan mempunyai interaksi paling kuat dengan $NO_3^-$. Dengan penambahan Cu(0.5 mol%), nilai $K_{SV}$ bagi CN telah bertambah baik daripada 2.11 x $10^{-4}$ kepada 5.27 ×$10^{-4}$ $\mu M^{-1}$. Kajian ini menunjukkan bahawa dengan penambahan kuprum sebagai pengubahsuai, prestasi CN boleh ditingkatkan dan komposit tersebut boleh digunakan sebagai potensi sensor pendafluor untuk mengesan $NO_3^-$.

**Kata kunci:** karbon nitrida terubah suai kuprum, sensor pendafluor, ion nitrat

## Introduction

Nitrate ($NO_3^-$) is a widespread contaminant of groundwater which can be easily detected in the environment and cause hazard to human health. The $NO_3^-$ is largely used for food preservative, drinking water and fertilizing agents [1, 2]. Excessive consuming of food and drinking water containing high level of $NO_3^-$ can cause severe risk to human health especially infants. Human may metabolize $NO_3^-$ in blood and finally transform it into carcinogenic nitrosamine causing the condition known as methemoglobinemia or also called as baby blue syndrome [3, 4]. In addition, it has been reported that the healthy human urine range of $NO_3^-$ is in the range of 300 to 1800 μM [5]. Therefore, determination of $NO_3^-$ is an important aspect to human health and environment. Griess reagent has been used widely for detection of $NO_3^-$ ion. Basically, Griess reaction involved several steps starting from reduction of $NO_3^-$ to $NO_2^-$ ion by using vanadium (III) chloride [6]. The mixture was subsequently reacted with sulfanilamide and *N*-(1-naphtyl) ethylenediamine to produce pink coloured azo dye product which strongly absorbed light at 540 nm [5, 7-9]. However, it presents several disadvantages such as using high concentration of hazardous reagent in the reaction, complicated detection procedure and cannot be reused [10]. Thus, development of reusable and sensitive sensor for detection of $NO_3^-$ ion is highly required.

Recently, carbon nitride (CN) has become a current interest because of its unique properties such as non-toxicity, low cost, high photoluminescence intensity [11] and good photostability [12]. CN is a graphite like layered material where *s*-triazine ($C_3N_3$) or tri-*s*-triazine ($C_6N_7$) units connected with amino groups (-NH/$NH_2$) are held together through hydrogen bonds between the amino groups [13, 14]. The principal application of the CN in the environment is mainly in photocatalysis for photodegradation of environmental pollutants [15, 16], while only few studies have been reported on its application in optical detection of environmental pollutant [17-22]. For instances, the CN has been reported to act as fluorescence sensor for detection of $Cu^{2+}$ and $Fe^{3+}$ ions [16-18] and *N*-Nitrosopyrrolidine [19]. Recently, metal-free CN was used as a fluorescence chemical sensor for detection of $NO_3^-$ [23]. Unfortunately, CN alone still has low sensitivity towards the detection of the $NO_3^-$. Therefore, further investigation is still required to improve the performance of the CN.

The objective of this study is to design a sensitive sensing material based CN by improving the sensing sites of the CN for detection of the $NO_3^-$. In order to improve the sensing sites of the CN, copper species was used as the modifier. Copper based material has attracted a great interest due to its low cost as compared to noble metals such as Au, Pt, or Pd. It has been reported that the amino groups from the CN can interact with copper ion to form a stable complex due to the strong coordination force between the amino group and copper ion [24]. Herein, this study reported the modification of the CN by using copper species prepared by impregnation followed by a reduction method. The synthesized composites were demonstrated to show better sensing performances towards the $NO_3^-$.

## Materials and Methods

### Material preparation

CN was prepared by using urea ($CON_2H_4$, Sigma-Aldrich, 98%) as precursor via thermal polymerization technique at 823 k for 4 hours [21, 25]. As for the preparation of composites, certain amount of $Cu(acac)_2$ ($Cu(C_5H_7O_2)_2$, Merck, 99.99%) was dissolved in ethanol and mixed with CN via an impregnation process. The mixture was heated up to 363 K until all the ethanol was evaporated. The obtained solid was underwent thermal hydrogenation process at 473 K for 2 hours under hydrogen flow of 5 ml/min to produce copper species modified CN composites. Composites were denoted as Cu(*x*)/CN composites where *x* showed the mol ratio of Cu to CN, which were fixed at 0.1 and 0.5 mol%. As a reference, the $Cu(acac)_2$ was heated under thermal hydrogenation process at 473 K or 2 hours to obtain Cu metal.

### Characterizations

Properties of CN and Cu(*x*)/CN composites were investigated by several instruments. The structure of the CN and its composite was identified by using powder X-ray difractometer recorded with a Bruker D8 Advanced using Cu Kα irradiation (λ = 1.5406 Å). The surface area of CN and its composites was confirmed by using Brunauer-Emmett-Teller (BET) equation obtained from a Quantachrome NOVA TOUCH $LX^4$. The functional groups present in the CN and its composites were recorded by using a Nicolet iS50 spectroscopy by mixing the samples with potassium bromide as a pellet. The diffuse reflectance UV-Visible (DR UV-Vis) spectra were recorded by using

Shimadzu UV-Vis spectrophotometry (UV-2600) in the range of 250 – 800 nm. The emission spectra were determined via JASCO FP-8500 fluorescence spectrophotometer at room temperature.

**Quenching test**

The interactions between the CN and its composites with $NO_3^-$ were studied via fluorescence spectroscopy at room temperature. The quenching tests were carried out by exposing various concentrations of $NO_3^-$ in the range of 300 to 1800 μM onto the CN and its composites. The various concentrations of $NO_3^-$ (10 μL) were introduced into the sample (0.05 g) and the emission spectra were measured at excitation wavelengths of 277, 320 and 370 nm. The interaction between the samples and the $NO_3^-$ can be observed from the changes in the emission intensity measured at each excitation wavelength and evaluated from the Stern-Volmer plot.

## Results and Discussion

**Characterization of CN and Cu(x)/CN composites**

To investigate the chemical structure and optical properties of CN and its composites, XRD, FTIR, DR UV-Vis and fluorescence spectroscopies measurements were performed. The XRD patterns of CN and its composites are given in Figure 1. The XRD pattern of the prepared Cu metal is also shown as a reference. Cu metal gave three obvious peaks at $2\theta$ of 44.3, 50.4 and 74.1° as the characteristics of copper (0) species (JCPDS no. 00-004-0836), which pattern was virtually the same as the reported one [26]. On the other hand, the CN exhibited two diffraction peaks at $2\theta$ of 13.10 and 27.30°, corresponding to in-planar repeating units and the distance between the nitride pores, respectively [20, 23, 27-30]. The Cu(*x*)/CN composites showed similar diffraction patterns to those of the CN, suggesting that the added Cu might be too low to be detected by XRD or the Cu was highly dispersed on the CN.

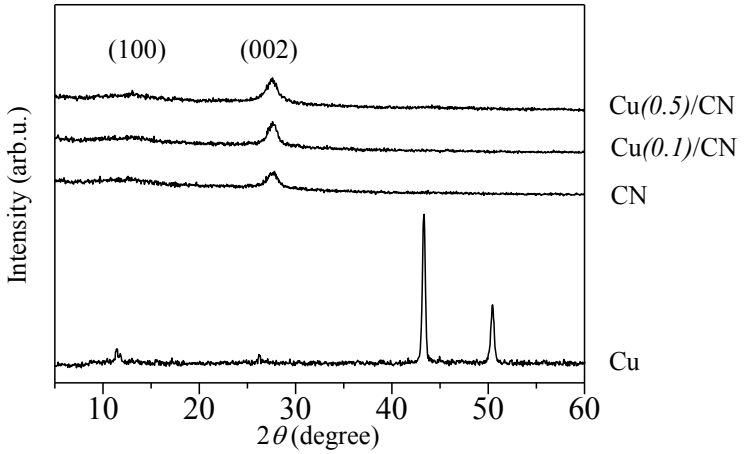

Figure 1. XRD patterns of Cu, CN and Cu*(x)*/CN composites

The FTIR spectra of CN and the Cu*(x)*/CN composites are shown in Figure 2. The CN showed vibration bands at around 3300 – 3400 $cm^{-1}$ that can be attributed to the overlapping bands of primary and secondary amine, *v*(N-H) and *v*(O-H) groups [21-24, 31-35]. The stretching modes of *v*(C-N) heterocycles were observed at 1200 –1700 $cm^{-1}$, while the heterocyclic tri-*s*-triazine ($C_6N_7$) was found at around 809 $cm^{-1}$. Even though the presence of amino groups in the synthesized CN is difficult to be analysed by FTIR spectroscopy, it has been reported by XPS analysis [31]. It was obvious that the Cu(*x*)/CN composite exhibited almost similar peaks to those of the CN, which indicated that the structure of CN was kept to be almost the same even after addition of copper species on the samples, similar to other reported literatures [24, 32].

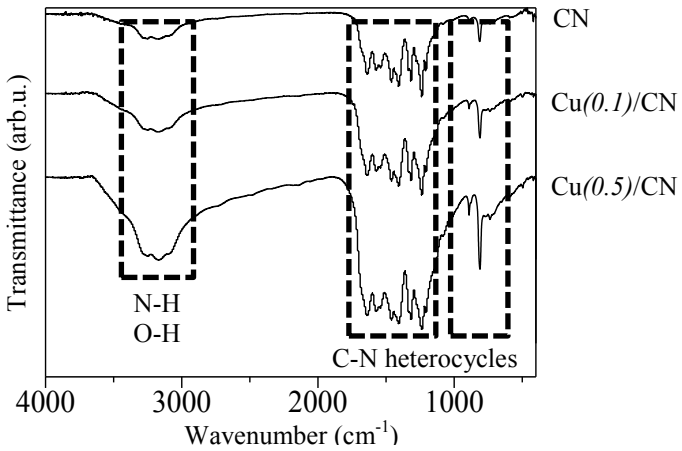

Figure 2. FTIR spectra of CN and Cu*(x)*/CN composites

Figure 3 shows $N_2$ adsorption-desorption isotherms of CN and its composites. It was obvious that they exhibited type III isotherm, which referred to nonporous solids. There were no change occurred on the isotherm when the Cu species were added onto the samples, suggesting that the added copper species did not affect the physical properties of the CN. The BET specific surface areas of CN, Cu *(0.1)*/CN, and Cu *(0.5)*/CN were measured to be 91, 93 and 56 $m^2g^{-1}$, respectively. Addition of 0.1 mol% of Cu did not affect much the specific surface area, but the addition of 0.5 mol% of Cu significantly decreased the specific surface area. The decrease in the surface area has been also reported when $Cu(acac)_2$ was dispersed on the CN [32].

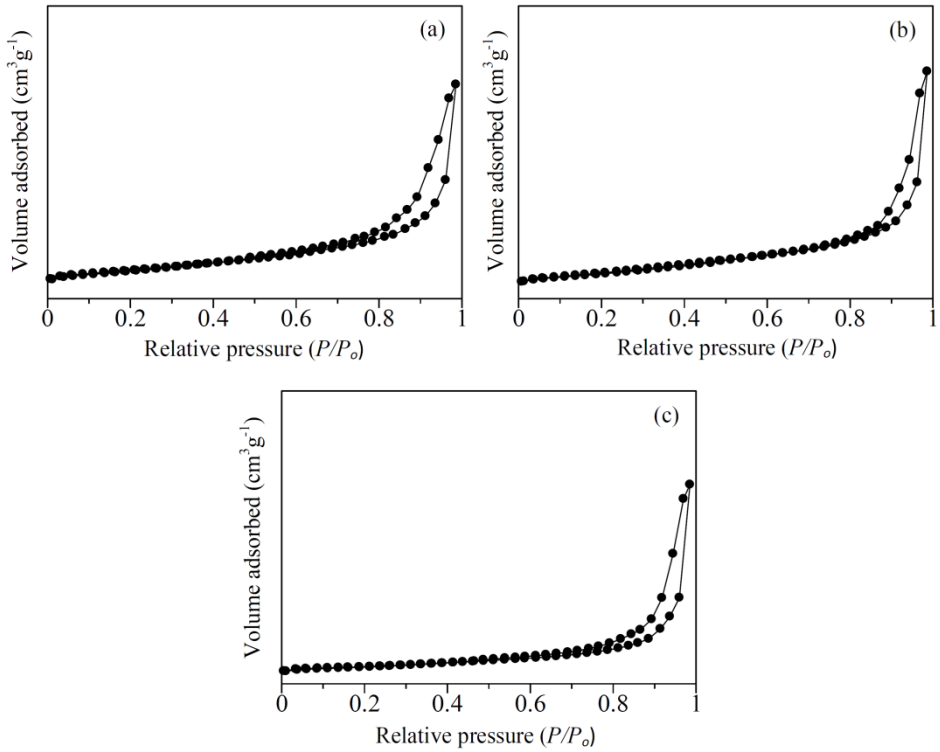

Figure 3. $N_2$ adsorption-desorption of (a) CN, (b) Cu*(0.1)*/CN and (c) Cu*(0.5)*/CN composites

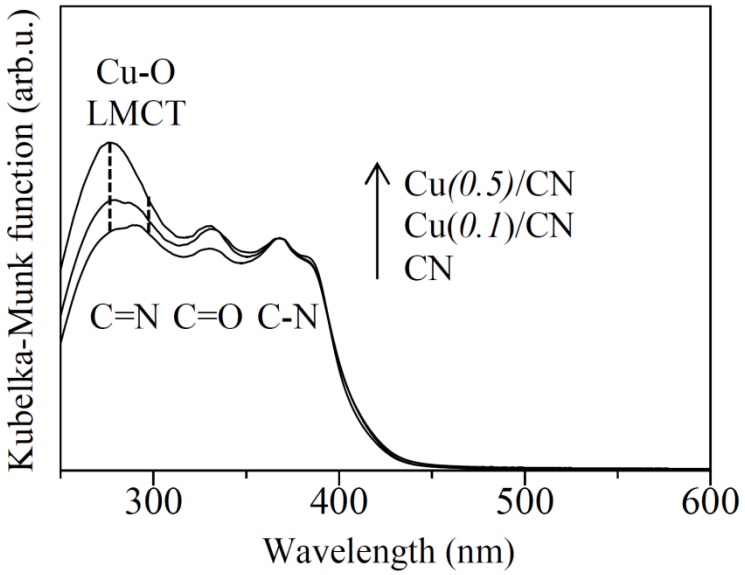

Figure 4. DR UV-Vis spectra of CN and Cu*(x)*/CN composites

The optical properties of CN and its composites were investigated by DR UV-Vis spectroscopy. As shown in Figure 4, CN and its composites exhibited three strong absorption bands at 277, 320 and 370 nm. The peak at 277 nm was corresponded to C=N groups ($\pi$-$\pi$*) in the conjugated aromatic triazine ring [20, 23, 31, 32], while the peak at 320 nm would be related to the presence of C=O moiety ($\pi$-$\pi$* and $n$-$\pi$*) due to the low condensation during the polymerization process of urea [30, 32, 36]. The peak at 370 nm was originated from the C-N terminal moiety ($n$-$\pi$*) [20, 23, 31, 32]. The Cu($x$)/CN composites also gave similar absorption peaks to the CN, but with increased absorption peak intensities below 350 nm. The increase was more prominent for Cu*(x)*/CN composite with higher Cu loading amount. This would be the evidence of the presence of Cu on the samples since the peaks were contributed from the ligand to metal charge transfer (LMCT) transition between Cu and oxygen species in the composites [37].

The fluorescence properties of CN and Cu*(x)*/CN composites were studied by using fluorescence spectroscopy. Similar to the DR UV-Vis spectra, CN and its composites also shows three excitation peaks at 277, 320 and 370 nm, which referred to C=N, C=O and C-N terminal groups, respectively. On the other hand, only one emission peak was observed when CN and its composites were excited at 277, 320 or 370 nm [23]. As can be seen in Figure 5 (a), the intensity of the excitation spectra of the composites decreased with the increase in the loading amount of Cu species. This is believed due to certain interactions occurred between Cu species and CN. The same phenomenon also can be monitored from the emission spectra of CN and its composites at 455 nm for all excitation wavelengths, as can be seen in Figure 5 (b), (c) and (d), which illustrates the emission spectra of CN and its composites when excited at 277, 320 and 370 nm, respectively.

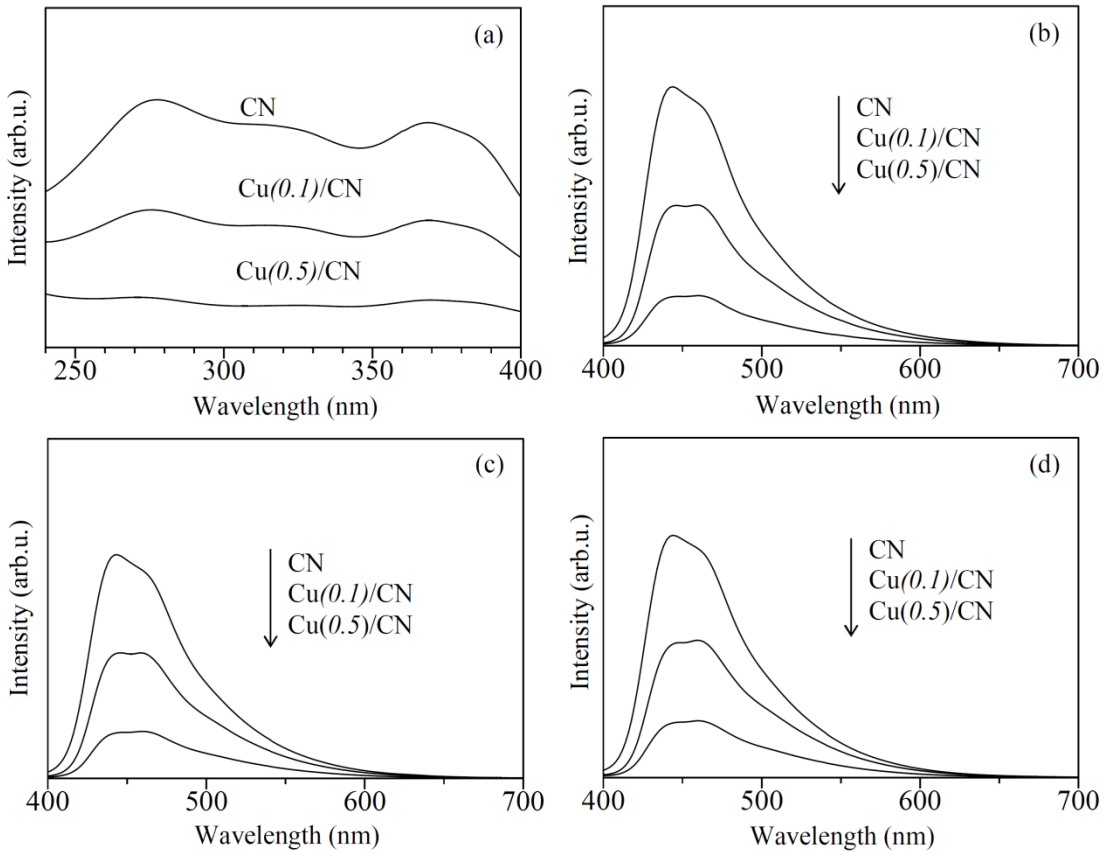

Figure 5. (a) Excitation spectra of CN and Cu*(x)*/CN composites monitored at emission wavelength of 455 nm, and emission spectra of CN and Cu*(x)*/CN composites monitored at excitation wavelengths of (b) 277, (c) 320 and (e) 370 nm

**Sensing performance of CN and Cu(*x*)/CN composites toward $NO_3^-$ ion**

The fluorescence responses of CN and its composites to various concentrations of $NO_3^-$ (300-1800 µM) were studied by using a quenching technique. Since the CN and its composites have three emission sites, which are C=N, C=O and C-N terminal groups, it is important to determine which emission site has the strongest interaction to $NO_3^-$. Figure 6 shows the emission spectra of CN at 277, 320 and 370 nm before and after addition of various concentrations of $NO_3$. Based on the spectra, it is clearly seen that the intensity of CN decreased with the increase of the $NO_3^-$ concentration at all sensing sites, suggesting that the $NO_3^-$ ion interacted with C=N, C=O and C-N terminal sites and acted as a quenching agent to deactivate the emission sites of the CN. It is believed that there is an electrostatic interaction between the CN and its composites with $NO_3^-$ due to different charge between the sensing sites of the sensor samples and the $NO_3^-$ [38]. The same phenomena also can be observed for Cu*(0.1)*/CN and Cu*(0.5)*/CN samples, which spectra are shown in Figures 7 and 8, respectively.

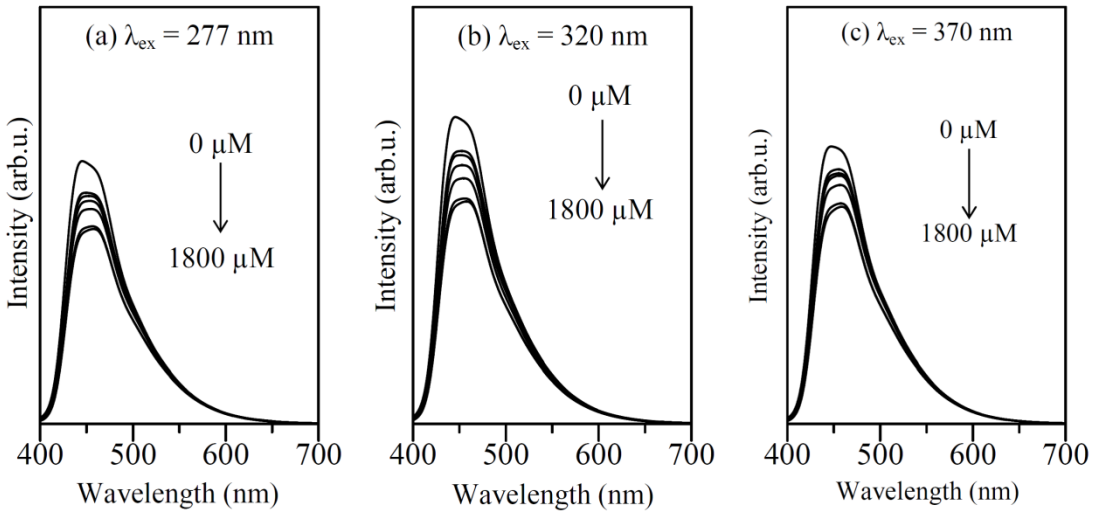

Figure 6. Emission spectra of CN in the absence and presence of $NO_3^-$ with various concentrations, monitored at excitation wavelength of (a) 277, (b) 320 and (c) 370 nm

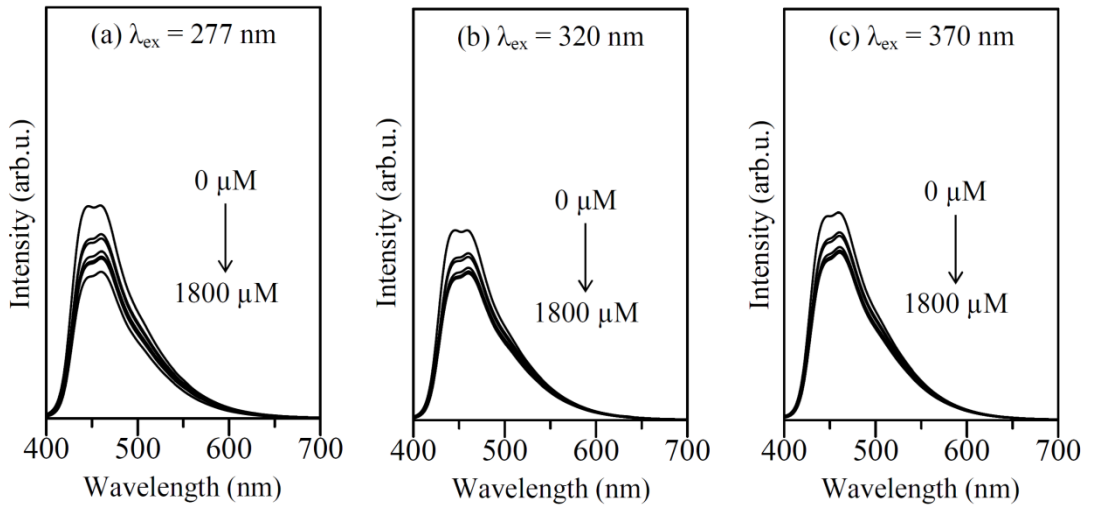

Figure 7. Emission spectra of Cu *(0.1)*/CN in the absence and presence of $NO_3^-$ with various concentrations, monitored at excitation wavelength of (a) 277, (b) 320 and (c) 370 nm

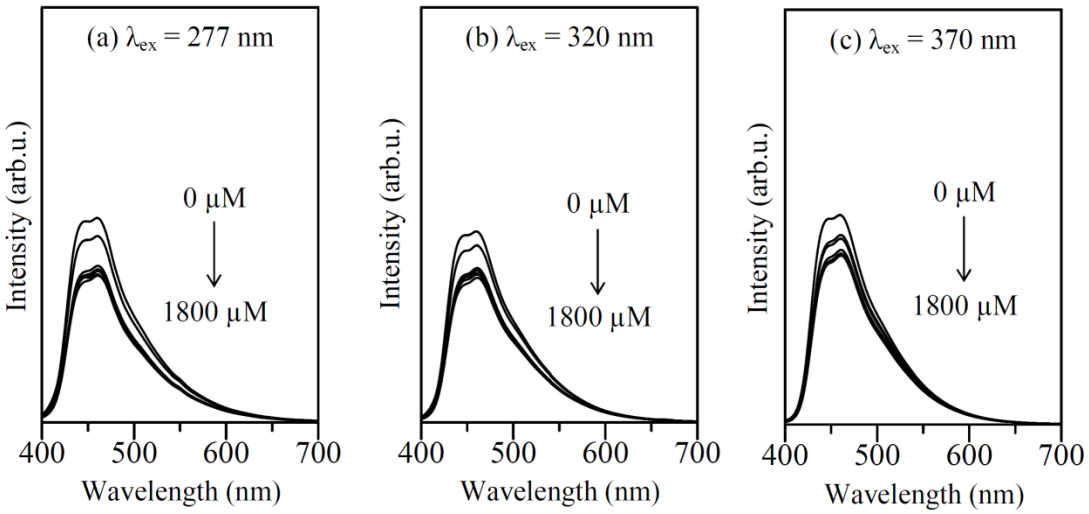

Figure 8. Emission spectra of Cu *(0.5)*/CN in the absence and presence of $NO_3^-$ with various concentrations, monitored at excitation wavelength of (a) 277, (b) 320 and (c) 370 nm

In order to determine the most sensitive sensing sites on the CN and its composites, quenching efficiencies at each sensing sites of the samples need to be calculated. The quenching efficiencies of the sensor can be determined by the relationship between the reduced intensity and the added concentration of $NO_3^-$, which is reflected by the Stern-Volmer equation:

$$I_0/I = K_{SV}[Q] + 1 \quad (1)$$

where $I_0$ is the fluorescence intensity of sensor in the absence of quencher ($NO_3^-$) and $I$ is the fluorescence intensity of sensor in the presence of quencher ($NO_3^-$), $K_{SV}$ is the Stern-Volmer constant which measures the efficiency of quenching and [$Q$] is the concentration of $NO_3^-$.

Among the three sensing sites of the CN and its composites, which are C=N, C=O and C-N terminal groups, the C=N showed the strongest interaction between the samples and the $NO_3^-$ ion. The Stern-Volmer plots of the CN and Cu*(x)*/CN composites for the C=N sites monitored at excitation wavelength of 277 nm are shown in Figure 9. The CN gave almost linear plot to sense $NO_3^-$ ion up to 1800 μM. On the other hand, the Cu *(0.1)*/CN composite and the Cu(*0.5*)/CN composites gave a linear plot up to 1500 and 900 μM, respectively. When the added concentration was higher than these concentration levels, saturation was observed and this was more prominently observed on the Cu(*0.5*)/CN. The addition of Cu was found to give lower concentration range detection, which may be caused by the blocking of the sensing sites by the added Cu species. However, it is clear that the addition of Cu improved the quenching efficiency of the CN. The calculated $K_{SV}$ values of CN, Cu(*0.1*)/CN and Cu(*0.5*)/CN composites at excitation wavelength of 277 nm were $2.11 \times 10^{-4}$, $2.50 \times 10^{-4}$ and $5.27 \times 10^{-4}$ $\mu M^{-1}$, respectively, as summarized in Figure 10. Although detection range on the Cu(*0.5*)/CN composite was lower, obviously the Cu(*0.5*)/CN composite showed almost twofold higher $K_{SV}$ value as compared to the unmodified CN. It is revealed that the presence of copper species improved the performance of CN for the detection of $NO_3^-$ ion. Therefore, it can be concluded that Cu(*x*)/CN composites were potential to be used as a fluorescence sensor for detection of $NO_3^-$ ion.

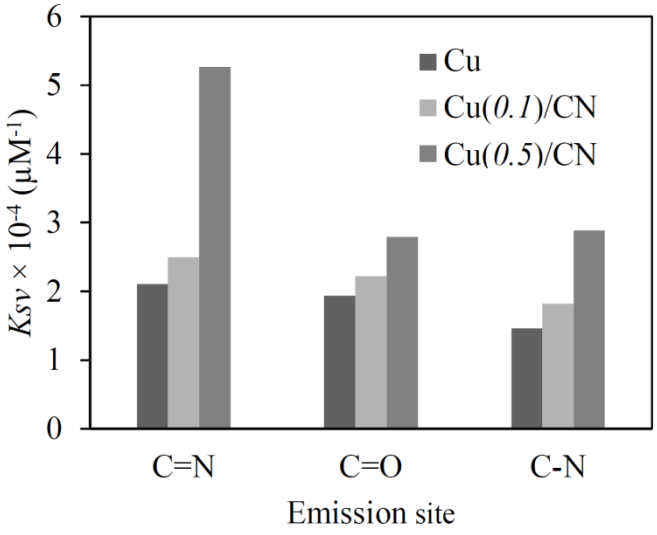

Figure 10. The $K_{SV}$ values for CN and Cu(*x*)/ CN for all the emission sites

## Conclusion

The CN was successfully synthesized via a thermal polymerization technique, while the Cu*(x)*/CN composites were prepared by impregnation of copper species, followed by thermal reduction process. XRD patterns and FTIR spectra did not show any changes, suggesting that the structural properties of CN were not influenced by the addition of copper species onto CN. On the other hand, the DR UV-Vis spectra showed the presence of copper species in the composites in the area below 350 nm, which was due to the LMCT between the copper species and CN. The CN and Cu*(x)*/CN composites exhibited three emission sites, which are C=N, C=O and C-N sites. Among all these emission sites, the C=N site showed the most favorable sensing site for detection of $NO_3^-$ ion. The quenching efficiencies were represented by the $K_{SV}$ values, which values for CN, Cu*(0.1)*/CN and Cu*(0.5)*/CN composites were 2.11 ×$10^{-4}$, 2.50 ×$10^{-4}$ and 5.27 ×$10^{-4}$ µ$M^{-1}$, respectively. Modification with copper species (0.5 mol%) onto the CN improved the quenching efficiency up to two times higher than the unmodified CN. This work clearly demonstrated that the Cu*(x)*/CN composites can be used as a potential fluorescence sensor for detection of $NO_3^-$ ion.

**Abstract**

Organophosphorus compounds (OPs) as important components of insecticides, pesticides, and chemical threat agents (CTA), have become more and more serious threats to the environment. Real-time monitoring of the threats is an urgent demand for environmental safety. The molecular imprinting polymer (MIP) technique is an attractive method for the generation of polymer-based molecular "memory" for a present target or group of target molecules. In this work, we integrate a novel MIP with quartz crystal microbalance (QCM) to build a simple sensor to selectively monitor OP in water samples in real-time. The MIP system was built up by polymerization of methacryalic acid (MAA) with divinylbenzene (DVB), initiated with 2,2'-azobis(2-methylpropionitrile) (AIBN) in presence of target. The polymer was characterized with FT-IR. Using parathion as a representative template, the MIP was coated on QCM by casting a semi-polymerized solution. The sensor could detect parathion in wide range from 290 ppb to 29 ppm. This sensor is stable, easy to prepare which can be reused and has the potential to be applied other analytes, which are threats to the environment.

**Keywords:** organophosphorus compounds, molecular imprinting polymer, quartz crystal microbalance, parathion

**Abstrak**

Sebatian organofosforus (OPs) adalah kompenen penting bagi racun serangga, racun mahkluk perosak dan agen kimia berbahaya yang telah menjadi ancaman kepada alam sekitar. Pemantauan terhadap ancaman ini telah meningkat berdasarkan kepada keselamatan alam sekitar. Teknik polimer molekul tercetak (MIP) adalah kaedah yang menarik molekul berasaskan polimer yang mempunyai sasaran terhadap molekul tertentu. Dalam kajian ini, MIP tulen bersama penimbang mikro kristal kuarza (QCM) telah disepadu untuk menghasilkan sensor mudah bagi pemantauan terpilih kehadiran OP di dalam sampel air bagi siutuasi sebenar. Sistem MIP telah dibangunkan berdasarkan pempolimeran asid metakrialik (MAA) dan divinilbenzena (DVD), dimulakan dengan kehadiran 2,2'-azobis(2-metilpropionitril)(AIBN) sebagai sasaran. Polimer telah dicirikan menggunakan FT-IR. Menggunakan parathion sebagai templat, MIP disadur ke atas QCM melalui teknik saduran larutan separa polimer. Sensor berupaya mengesan parathio pada julat yang besar dari 290 ppb hingga 29 ppm. Sensor ini adalah stabil, mudah disediakan, dimana boleh diguna semula dan berpotensi untuk diaplikasi terhadap analit lain yang mengancam alam sekitar.

**Kata kunci:** sebatian organofosforus, polimer molekul tercetak, penimbang mikro kristal kuarza, parathion

## Introduction

Pesticides including insecticides are widely used in agriculture activities to provide more food productivity. As important components of pesticide and chemical threat agent (CTA), many organophosphorus compounds (OPs) are generally neurotoxic to all animal and human as cholinesterase inhibitors.[1-3] As shown in Figure 1, a typical organophosporus compound has a phosphorus atom with P=S or P=O bond and phosphate groups. Over-use of OPs has become more and more serious threats to the environment and human health. For example, natural water can be easily contaminated by OPs because it is widely spread and highly fluid, which would result in severe environmental and human health concerns. The residual OPs in food are another traditional problem, which is highly related to human health. To evaluate and control the contamination of OPs in environment, food or other places, many efforts were made on the development of different analytic methods in the last decades, which include chemosensor [4], capillary electrophoresis [5], immunoassay[6] and chromatography-mass spectrometry. Among these methods, the most popular methods are GC and HPLC or in tandem with mass spectrometer [7]. These methods normally are expensive, complex and require skilled personnel to operate. In addition, for trace analysis of complex samples, pre-treatments including separation and enrichment steps are generally required [8].Therefore, sensitive, fast, reliable and easy-handling methods are of great demand.

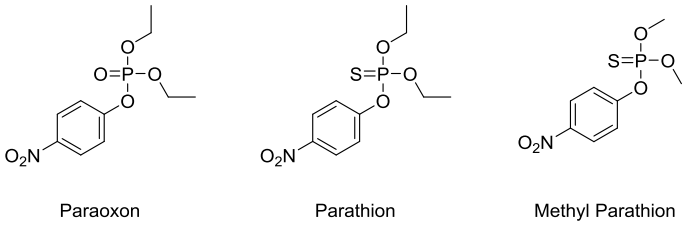

Figure 1. Structures of paraoxon, parathion and methyl parathion

Molecularly imprinted polymer (MIP) has grown fast in the last decades. MIP technique becomes an attractive method to construct of polymer-based molecular recognition elements for a preset target or a group of target molecules. The so-called artificial "enzyme" or "antibody", MIP has many applications, such as separation,[9] sensor [10] and immunoassay [11]. For example, MIPs have been used in selectively separation and enrichment of OPs from complex samples [12, 13]. MIPs have also been reported to make a sensor for Ops detection using electrochemical method by coating the MIPs on electrode [14]. This technique has many advantages including easy preparation, cost-effect, high stability, high affinity and high selectivity [15, 16].

Based on the piezoelectric properties of quartz crystals, the quartz crystal microbalance (QCM) is suitable for trace analysis, as a very sensitive pressure- and mass-sensing device. However, QCM itself has no selectivity. Therefore, different functional materials or chemicals were immobilized on the crystal surface to offer the desired selectivity. According to the well-known Sauerbrey equation, the frequency change of QCM, $\Delta f$, is proportional to the mass of the absorbed target of interest. Therefore, QCM-based sensor has been applied to many research fields, such as vapour analysis and biological analysis [17-19]. For example, an antibody against *A. hydrophila*, which is a bacteria of pathogen, was immobilized on QCM and the mass of target bacteria attached was monitored [20].

Parathion, also known as Folidol, is an organothiophosphate pesticide, which is widely used in agriculture and has high toxicity [21]. In this study, by combination of the sensitivity of QCM and the selectivity of MIP, we have developed a novel on-line biosensor for detection of parathion in water sample.

## Materials and Methods

### Instrument and device

QCM-D experiments were performed on a Q-Sense E4 QCM-D instrument (Q-Sense AB, Västra Frölunda, Sweden) with an AT-cut gold-coated quartz crystal (Model: AC5AP14, Diameter:14.0 mm, Jiaxing JingKong Electonic Co. Ltd, China), which has a response frequency of 5 MHz. All data were recorded at room temperature (25 $^{o}$C). Sauerbrey's equation has been established for the AT-cut gold-coated quartz crystal:

$$\Delta f = -2 f_0^2 . (\rho_q \mu_q)^{-1/2} \Delta m / A \quad (1)$$

$\Delta f$ is frequency shift (Hz) due to the mass change on the crystal, $f_0$ is the resonant frequency (Hz) of the original crystal, $\rho_q$ is the density of quartz crystal (2.648 g. $cm^{-3}$), $\mu_q$ is the shear modulus ($2.947 \times 10^{11}$ $g \cdot cm^{-1} \cdot s^{-2}$) and A is the active electrode area ($cm^2$).

**Chemicals**
Parathion, methacryalic acid (MAA), divinylbenzene (DVB), 2,2'-azobis(2-methylpropionitrile) (AIBN), sulphuric acid (98%), Hydrogen peroxide (30%, w/w) and ethanol (AR grade) are purchased from commercial vendors. Ultra-pure water was processed by Q-POD® ultrapure water dispenser (Merck Millipore) to reach a resistivity of 18.2 MΩ.cm.

**Sample preparation**
The stock solution of parathion was prepared in ethanol. Then the aqueous solution of samples (100 µM, 50 µM, 10 µM, 1 µM, 100 nM and 0 nM) was diluted with ultra-pure water in gradient.

**Sensor fabrication**
Firstly, QCM was soaked in piranha solution (9 mL of conc. sulphuric acid (98%) and 3 mL of hydroperoxide (30%)) for 5 minutes. Then, the crystal was washed thoroughly with ultra-pure water until the water was neutral (pH = 7). It was subsequently flushed with nitrogen flow followed by air-drying for few hours. After cleaning, the crystal is ready for coating without any other treatment.

In a 1.5 mL Eppendorf tube, to a solution of ethanol (178.2 µL), parathion (11.8 µL, 0.34 M), MAA (10.0 µL) and DVB (50.0 µL) was added 1.0 mg of AIBN. The mixture was mixed by vortex for few minutes and bubbled with nitrogen for 5 minutes. Then the sealed tube was incubated at 60 $^oC$ in water-bath for 10 minute until the mixture turned to be slightly muddy. 10.0 µL of the semi-polymerized solution was casted on the gold surface of QCM. The QCM was incubated in oven at 60 $^oC$ overnight to make sure the polymerization was complete. Non-imprinted polymer coated-QCM (NIP@QCM) was prepared in the same way without the template molecule. The sensor was soaked in 30 mL of ethanol with gentle shaking. The solvent was renewed every 6 hours for 4 times. Then the sensor was stored in ultra-pure water with gentle shaking for 1 day.

**Characterization of MIP and NIP**
The polymer (MIP or NIP) in the tube was soaked in ethanol under the same conditions to remove unreacted reagents and target and then dried in vacuum oven. The dried polymer (1 part) was mixed with dried KBr (100 parts). The mixture was ground and the resulted powder was pressed to a transparent pellet. FT-IR spectroscopy was obtained with an ALPHA FTIR Spectrometer (Bruker). The characteristic peaks for the MIP ($cm^{-1}$) included: 3018 (alkene), 2960 (alkane), 2925 (carboxylic acid), 1700 (C=O); NIP ($cm^{-1}$): 3019 (alkene), 2960 (alkane), 2926 (carboxylic acid), 1699 (C=O).

**Analytical procedure**
The detection procedure was monitored on-line with flow rate of 50 µL after the sensor was prepared and installed properly, followed by few pulses of maximum flow rate to remove air bubbles. After each analysis, desorption step was performed in ethanol (30 mL) with gentle shaking. The solvent was renewed every 6 hours for 4 times. Then the sensor was stored in ultra-pure water with gentle shaking for 1 day.

## Results and Discussion

**Design strategy and sensor fabrication**
The design of the sensor is shown in Figure 2a. In the first step, after necessary processes of QCM, the MIP was coated onto the gold electrode surface of the quartz crystal by free radical polymerization. The polymer system includes 4 parts: 1) MAA as functional monomer is used to build the framework of MIP and the carboxylic acid is served as the recognition element via hydrogen-bonding donor; 2) DVB as a cross-linking reagent is used to reinforce the stability of the rigid framework which contributes to the solid "memory" of MIP. DVB also

contributes to recognition by spatial hindrance and hydrophobic interaction to those hydrophobic domains of target including π-π interaction; 3) AIBN is used as initiator; 4) Parathion as the template molecules were mixed in the reaction solution and imbedded in the polymer to create many close-fit cavities with the same size and shape as themselves. By this design, the three-dimensional "memory" of the template was established. Then, in the second step, the template and unreacted reagents were removed by proper repeated washing to generate the cavity specifically for the template. Finally, the sensor was prepared and ready for detection after equilibrium process. The NIP was prepared as a negative control under the same conditions without template. MIP and NIP were characterized with FT-IR spectroscopy.

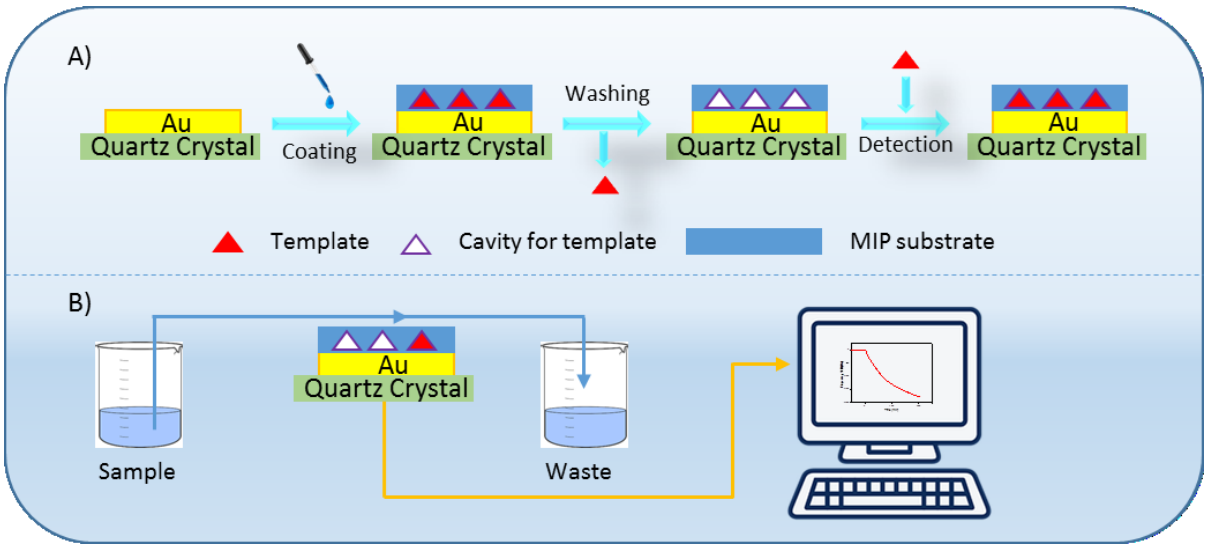

Figure 2. Schematic illustrations of fabrication of the MIP@QCM sensor and detection flow chart

**Fast evaluation of the sensor**

The QCM sensor is based on the piezoelectric properties of quartz crystals which could reflect mass and viscosity changes on the crystal surface. By the aid of the specific nature of MIP, the sensor of MIP@QCM could detect mass of the target captured in samples by reading the corresponding frequency changes according to Sauerbrey's equation in Equation 1. As shown in Figure 2b, in the detection step, the sensor was subjected to the detection of preseted target of MIP. The sample solution was pumped to pass through the surface of MIP@QCM sensor and the frequency shift was monitored in real-time. To rapidly evaluate the response to the target, we performed the detection of water samples in sequence in the interval of 30 minutes, including various concentrations of target from (0.1 to 100 μM or 0.029 to 29 ppm, b to e) as shown in Figure 3a. After 50 minutes of water-rinsing (a), the sensor was brought to resonant frequency ($f_0$). Then frequency of sensor decreased once it was treated with aqueous parathion solution. The frequency remained steady until 10 μM (2.9 ppm) of parathion. By increasing the concentration of parathion, the frequency shifts dramatically enhanced as shown in Table 1. Compared to MIP@QCM sensor, NIP@QCM sensor showed much smaller frequency shifts to the samples. MIP has larger capacity for target as it contained many cavities for binding target molecules, while NIP hold much less target molecules by the nonspecific bonding on the surface. The binding experiment illustrates that the MIP@QCM shows superior specific and sensitive response to the target compared with NIP@QCM.

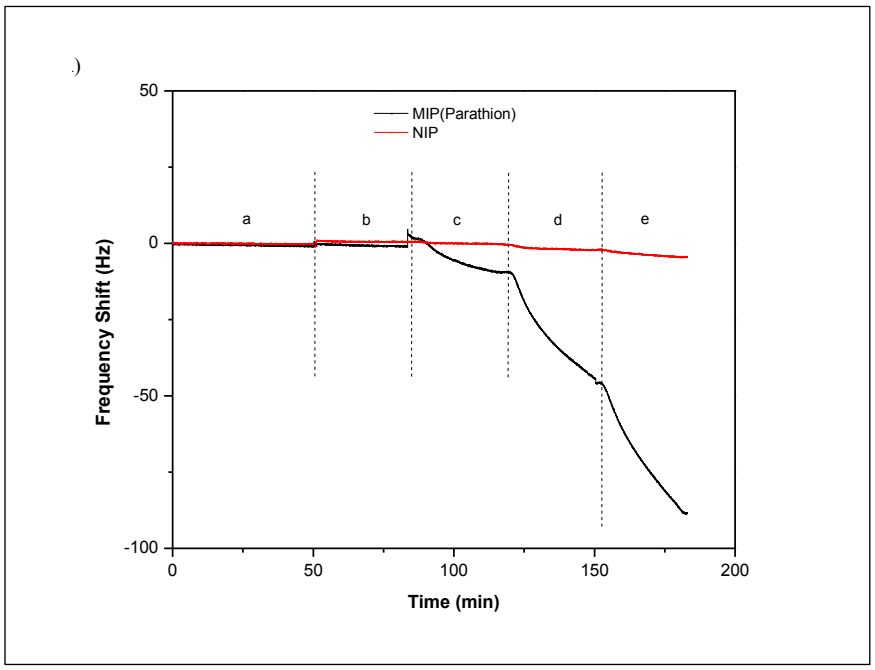

Figure 3. Evaluation of detection of MIP@QCM sensor for parathion against NIP@QCM. A) On-line frequency shift ($\Delta f$, Hz) responses of the sensor for water (a, 50 minutes) and parathion (0.1, 10, 100 µM, b-e) in the interval of 30 minutes. Flow rate: 50 µL/min.

Table 1. The frequency shifts for the corresponding samples.

| **Sample** | **a** | **b** | **c** | **d** | **e** |
|---|---|---|---|---|---|
| Concentration of parathion (µM) | 0 | 0.1 | 10 | 50 | 100 |
| Concentration of parathion (ppm) | 0 | 0.029 | 2.9 | 14.5 | 29 |
| $\Delta f$ of MIP(Hz) | -0.94 | -0.97 | -9.97 | -37.95 | -41.19 |
| $\Delta f$ of NIP(Hz) | -0.14 | 0.36 | -0.36 | -1.78 | -2.6 |

**Performance of the sensor**

After the sensor was evaluated by using aqueous parathion solution, the sensor was further studied to establish the correlation between the frequency shift and sample concentrations. As shown in Figure 4, after 20 min of water flow, the sensor was treated with various concentrations of parathion for 60 min. Compared to the blank sample (0 µM of parathion in water), aqueous parathion solution showed obvious frequency shifts. The calibration curve of frequency shift *vs* concentration of parathion is shown as insert in Figure 4. The limit of detection (LOD) was calculated as 0.83 µM. Table 2 shows the frequency shifts for the corresponding samples.

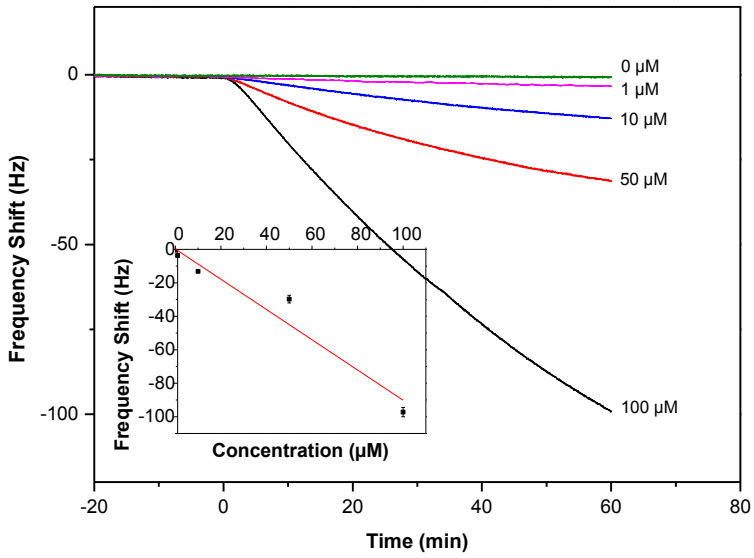

Figure 4. On-line detection of MIP@QCM sensor for parathion. A) On-line frequency ($\Delta f$, Hz) responses of the sensor for parathion (0, 1, 10, 50, 100 μM). 60 minutes of incubation time for each sample. Flow rate: 50 μL/min. Insert: the linear relationship between the frequency shifts against parathion concentration.

Table 2. The frequency shifts for the corresponding samples

| **Concentration of Parathion (μM)** | **0** | **1** | **10** | **50** | **100** |
|---|---|---|---|---|---|
| Concentration of parathion (ppm) | 0 | 0.29 | 2.9 | 14.5 | 29 |
| $\Delta f$ of MIP(Hz) | -0.50 | -3.34 | -12.85 | -31.35 | -99.22 |

**Selectivity of the sensor**

Subsequently the selectivity of MIP (parathion) was evaluated against two analogues – paraoxon and methyl parathion. As shown in Figure 5, the frequency shift of parathion (-30.28 Hz) is much larger than that of methyl parathion (-16.29 Hz) and paraoxon (-11.02 Hz), which indicated MIP (parathion) has higher selectivity to the template (parathion) than to the two analogues. Comparing parathion with paraoxon, MIP (parathion) shows distinct affinities. Although the hydrogen-bonding to the sulphur atom of parathion should be weaker than to the oxygen atom of paraoxon, the dominant interaction is the three-dimensional matching between MIP (parathion) and parathion which is much better for parathion than for paraoxon because of the differences in lone-pair repulsions of sulphur and oxygen atom. Comparing parathion with methyl parathion, the dominant interaction is the differences in three-dimensional matching because of the sizes of ethyl and methyl group. The results indicated that the designed sensor had good selectivity to parathion. Table 3 shows the frequency shifts for the corresponding samples.

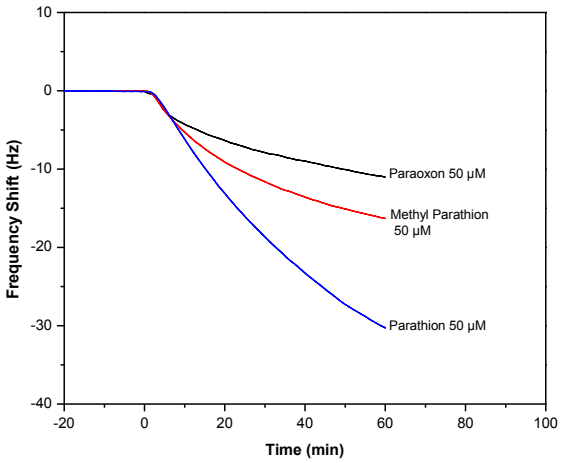

Figure 5. On-line detection of MIP@QCM sensor for parathion against paraoxon and methyl parathion. On-line frequency ($\Delta f$, Hz) responses of the senor parathion (50 µM) against paraoxon (50 µM) and methyl parathion (50 µM). 60 minutes of incubation time for each sample. Flow rate: 50 µL/min. The insets: structures of paraoxon, parathion and methyl parathion.

Table 3. The frequency shifts for the corresponding samples.

| Targets | Paraoxon | Methyl Parathion | Parathion |
|---|---|---|---|
| $\Delta f$ of MIP(Hz) | -11.02 | -16.29 | -30.28 |

## Conclusion

We have developed a novel sensor based on QCM coated with MIPs. The MIP system used methyl methacrylic acid (MAA) as monomer, divinylbenzene (DVB) as cross-linking reagent and azobisisobutyronitrile (AIBN) as initiator. With parathion as the pre-set template, the selectivity experiment showed that the MIP-based QCM sensor could selectively detect parathion in water samples as the MIP offered specific cavity for the template molecule. The sensor has wide detection range (290 ppb ~ 29 ppm) and fast response (60 minutes) to parathion. The sensor is easy to prepare and can be potentially applied to other templates including organophosphorus compounds. The biosensor could potentially be useful for monitoring CTA targets in real water samples.

**Abstract**

Aptamers are alternative bio-recognition elements to antibodies, with great advantages, such as high binding affinity and specificity, controllable structures. In this study, a novel fluorescent aptasensor for biomolecules detection has been designed by using aptamer as bio-recognition element and polydopamines as nanoquencher. Bovine catalase protein (BCP) was used as target for assay validation. BCP aptamer was selected based on previous work in our group. Polydopamine spheres (250 – 300 nm) were synthesized by addition of dopamine hydrochloride into a mixture of tris-buffer and isopropyl alcohol with stirring for more than 2 days and size/morphology of spheres has been characterized. The quenching efficiency and sensing performance were examined. It was found that the quenching efficiency was good (> 90%) owing to the interaction between aptamer and polydopamines since FAM labeled ssDNA aptamer could be adsorbed onto polydopamines surface to form a complex, resulting in the quenching of fluorescence. Upon the introduction of BCP, the fluorescence could be retained. The fluorescence intensity increased with the increasing concentration of BCP with the detection limit of 10 nM. Polydopamines could be used as sensing platform in fast and simple way for biomolecules detection and have potential to be extended to other targets.

**Keywords**: biosensors, aptamer, polydopamine, nanoquencher, protein

**Abstrak**

Aptamer adalah elemen alternatif pengecaman-bio terhadap antibodi, dengan kelebihan seperti ikatan keafinan yang kuat dan khusus, kebolehkawalan struktur. Dalam kajian ini, aptasensor pendarflour novel untuk pengesanan biomolekul telah di reka bentuk dengan mengunakan aptameter sebagai elemen pengecaman-bio dan polidopamina sebagai nanoquencher. Protein katalase Bovin (BCP) telah digunakan sebagai sasaran bagi ujian validasi. Aptameter BCP telah dipilih berdasarkan kerja terdahulu. Sfera polidopamina (250 – 300 nm) telah di sistesis melalui penambahan dopamina hidroklorik ke dalam campuran penimbal-tris dan alkohol isopropil dengan pengacauan melebihi 2 hari dan saiz/morfologi juga telah dicirikan. Keberkesanan pemelindapan dan prestasi sensor telah dikaji. Ia di dapati bahawa keberkesanan pemelindapan adalah baik (> 90%) terhadap interaksi antara aptameter dan polidopamina di ketahui bahawa aptamer ssDNA berlabel FAM berupaya menyerap ke dalam permukaan polidopamina untuk membentuk kompleks, menghasilkan pemelindapan pendarfluor. Apabila BCP didedahkan, sifat pendafluor dapat dikekalkan. Keamatan pendafluor meningkat seiring dengan peningkatan kepekatan BCP pada had pengesan ialah 10 nM. Polidopamina boleh digunakan sebagai platfom sensor yang pantas dan mudah bagi pegesanan biomolekul dan berpotensi untuk dikembangkan bagi sasaran lain.

**Kata kunci**: sensor-bio, aptamer, polidopamina, nanoquencher, protein

## Introduction

Detection of biomolecules (biotoxins, proteins) with simple, fast, cost-effective and sensitive assay is crucial to the identification of disease-causing pathogens and water or food contamination, as well as other activities. Challenges remain in accurate and comprehensive detection and quantification of these compounds in short time at low concentrations in complex samples. Catalase is a common acidic protein that can be found in various species and is responsible for the conversion of hydrogen peroxide into water and carbon dioxide [1]. Catalase is identified as a possible bio-indicator of mastitis disease in cattle and could be used to monitor the quality of the milk.

A sensor is a device that transforms chemical or biological information, ranging from the concentration of a specific sample component to total composition analysis, into an analytically useful signal [2]. Bio-recognition elements are the important part for application of biosensors. Aptamers are special nucleic acid sequences that can bind to a wide range of targets, such as proteins, organic molecules, various cell surface receptors, and whole cells. They can be used as alternative bio-recognition elements to antibodies, with great advantages, such as high binding affinity and specificity, controllable structures and stability. Hence aptamers can be an ideal bioreceptor for the detection of biomolecules in environment, food or clinical samples. Biosensor with aptamers as ligands could be called as aptasensor. Conventional methods, such as chromatography-based and MS-based assays, are time consuming, labour intensive and not able to support on site detection. Compared to conventional methods, aptamer based biosensor can offer a sensing platform for fast disease screening and biotoxin monitoring for food and water safety.

Among different transducing systems, fluorescence is a highly sensitive platform for biomolecular detection. Nanomaterials could be used as novel biosensing platforms because of their unique optical, electronic, and catalytic properties [3]. It has been reported that some kind of nanostructures like gold nanoparticles (AuNPs), single-walled carbon nanotubes (SWCNTs), graphene oxide (GO), carbon nanoparticles and polydopamines (PDAs) can quench fluorescent dyes at different emission frequencies, which could eliminate the selection issue of fluorophore-quencher pair in such assay [4-10]. It is demonstrated that PDAs would quench the fluorescence of those fluorophores due to fluorescence resonance energy transfer (FRET) [8, 9]. Furthermore, the monomer dopamine and its oxide quinone, have shown quenching ability towards fluorophores via photoinduced electron transfer (PET) [11]. Polydopamine is a biopolymer which presents excellent biocompatibility and low cytotoxicity since it could be biodegraded in the organism through metabolism [12], which facility its application on biomolecules detection.

In the present work, a fluorescence aptasensor has been developed by taking advantage of specific aptamer and polydopamine sensing platform which is based on the fluorescence recovery due to target recognition. Bovine catalase protein (BCP) was used as target since some biotoxins are under higher biosafety control and BCP can be used as simulant of protein toxins for assay development. BCP aptamer was selected based on previous work in our group [13]. The quenching efficiency of polydopamine was studied and employed for the development of quenching based aptasensing platform.

## Materials and Methods

### Reagents and materials

Dopamine hydrochloride and bovine catalase protein were purchased from Sigma Aldrich (Singapore). FAM dye-labelled ssDNA aptamer (FAM-Aptamer, listed below) ligand of sequence was purchased from Integrated DNA Technologies Pte Ltd (IDT, Singapore) and reconstituted in 10 mM PBS buffer (pH 7.4). Aptamers were renatured using a Bio-Rad DNA engine thermocycler (Bio-Rad, Singapore) by heating to 94 ℃ for 10 minutes and then cooling down to room temperature at rate of 0.5 ℃/s. 10 mM Tris–HCl buffer (pH 7.2) was used and all other reagents were of analytical reagent grade. The water used was purified through a Millipore system.

FAM-Aptamer: 5’-CTT CTG CCC GCC TCC TTC CGA CCT AGC AGT GGA CAT GTG GCA GGG TGA AGT GGC ATC GTC GGA GAC GAG ATA GGC GGA CAC T-3’

### Synthesis of polydopamine

PDAs were synthesized according to previous reported method [14] with some modification. 100 mL of Tris-buffer solution was mixed with 40 mL of isopropyl alcohol (IPA). Then, 120 mg of dopamine hydrochloride was added to the mixed solution. Finally, PDA spheres (PDAs) can be obtained after polymerization under stirring for about 60

hours. The suspension was centrifuged, washed and re-suspended with water for several times. The precipitate was dried in vacuum for sensing experiments. Characterization of PDAs was performed by SHIMADZU IR Prestige21 spectrophotometry for the Fourier transform infrared (FTIR, Japan) and JEOL JSM-6701F Field Emission Scanning Electron Microscope (FESEM, Japan), respectively.

**Quenching and detection process**

The fluorescence emission spectrum was recorded for quenching and detection process with a Gilden Photonics FluoroSENS Fluorometer (United Kingdom). The emission spectra were recorded from 500 to 650 nm at an excitation wavelength of 470 nm, and the fluorescence intensity at 517 nm was used for quantitative analysis. For the quenching process, FAM-aptamer (40 nM) was incubated with PDAs at different concentration for 10 min at room temperature before the fluorescent detection. Then different amount of concentrated catalase solution (2 μM) was added to make BCP at 10, 20, 50, 100, 200, 500 and 1000 nM in the mixtures for detection process respectively. After a gentle mixing, the mixtures were allowed to incubate for 1 hour at 37 ℃ before the fluorescence measurement.

## Results and Discussion

**The sensing scheme of the platform**

The principle of nanomaterial quenching and sensing is shown in Figure 1. 6-carboxyfluorescein (FAM), labelled the aptamer at the 5' end, has strong fluorescence emission. Free fluorophore labelled ssDNA aptamer possess a strong fluorescence emission in the presence of the fluorescein-based dye. PDAs include dihydroxyindole, indoledione, and dopamine units. The interaction between PDAs and ssDNA might be non-covalent binding due to hydrogen bonding, π–π stacking, or charge-transfer complexes between the units of PDA and nucleobases [8, 15, 16]. Thus the introduction of PDAs would result in binding with probe ssDNA to form a complex, resulting in quenching process of the fluorescence due to FRET between PDAs and the fluorescent dye FAM. However, the complementary interaction between protein and aptamer will induce the conformation of aptamer upon the introduction of targets. In consequence, fluorophore labelled aptamer would release from surface of PDAs due to the weakened interaction between them, leading to the recovery of the fluorescence. Hence, the restoration of fluorescence can be applied to the quantitative analysis of target DNA or toxin protein.

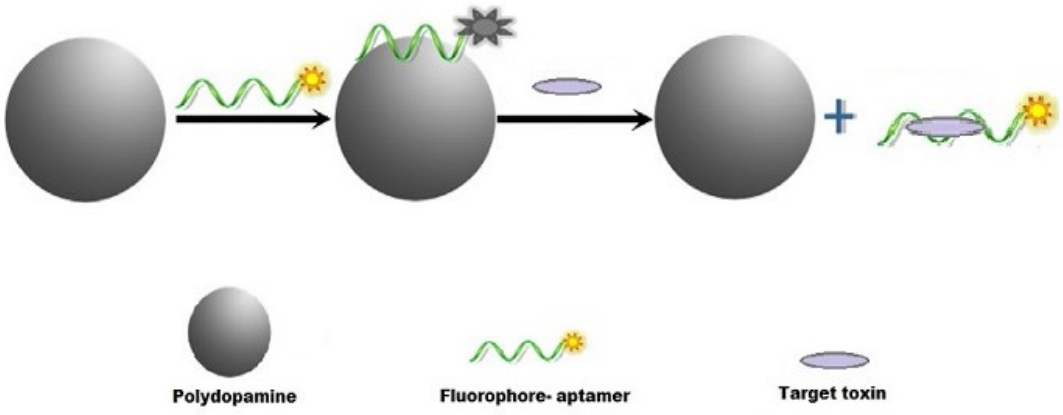

Figure 1. The principle of the sensing of protein

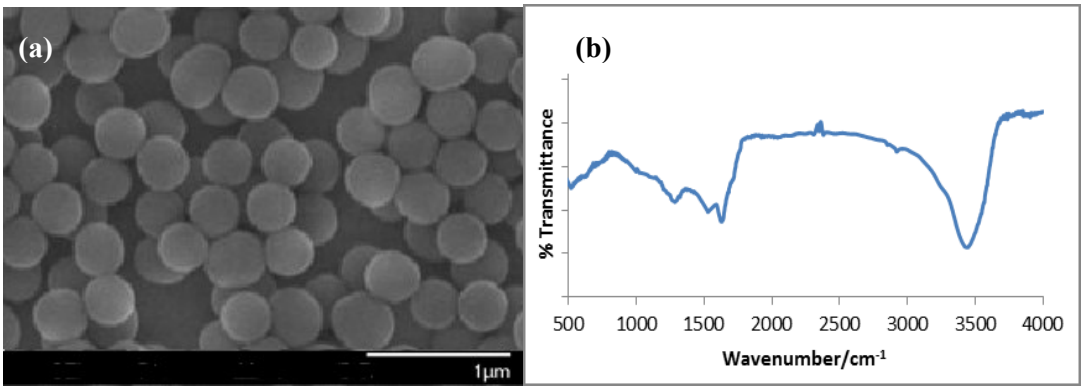
**Characterization of PDAs**

PDA spheres were synthesized in presence of IPA. The morphology and particle size of PDA spheres were characterized by FESEM, shown in Figure 2a. It could be found the size of the obtained PDA spheres is in the 250 – 300 nm range. The FTIR spectrum of PDAs, shown in Figure 2b, gives the characteristic peaks of several functional groups, such as C=O (~1625 $cm^{-1}$), C=C (~1521 $cm^{-1}$) and C–O (~1280 $cm^{-1}$), which also indicate that PDA is a π-

rich polymer. The absorption band at ~3400 $cm^{-1}$ corresponds to the stretching vibrations of –OH and N–H groups in the PDAs.



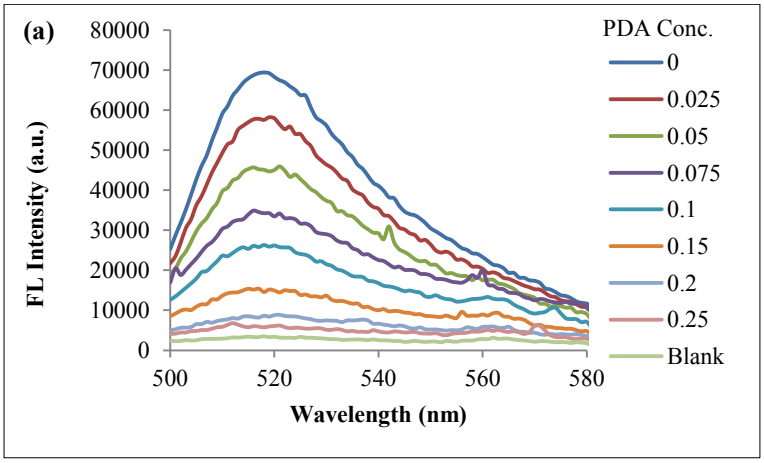


Figure 2. Characterization of PDAs. (a) SEM image and (b) FTIR spectra

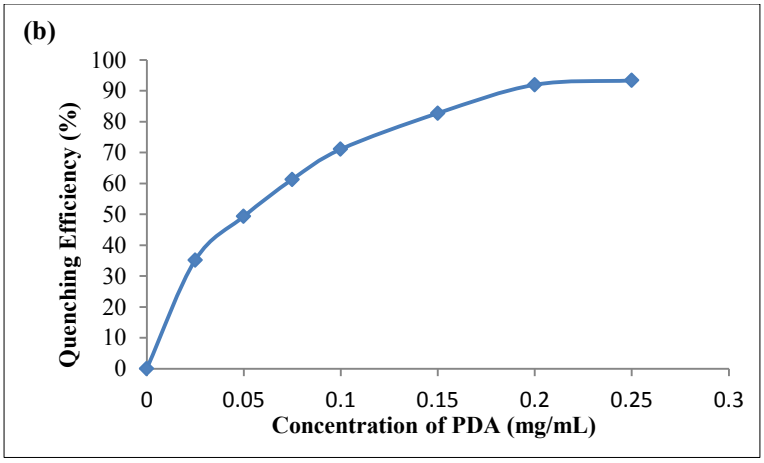
**Quenching efficiency**

The feasibility of using PDA as nanoquencher for protein detection was explored. The fluorescence quenching abilities of the PDAs to the FAM-labelled aptamer were evaluated by measurements mixture of aptamer with the PDAs after incubation for 10 min. As shown in the Figure 3a, the emission fluorescence of FAM-aptamer was partly quenched as the introduction of the PDAs. Quenching efficiency (QE) could be calculated as shown in equation 1:

$$\frac{(FLo-FLr)}{FLo} \times 100\% \quad (1)$$

where $FL_o$ and $FL_r$ are fluorescence intensities without and with PDAs, respectively. Quenching efficiency increased with the increasing concentration of PDAs due to complex formation of FAM-Aptamer-PDAs. After PDAs was more than 0.2 mg/mL, the quenching efficiency was more than 90% (Figure 3b) and almost consistent with more PDAs. Thus, 0.2 mg/mL was used for further sensing tests.



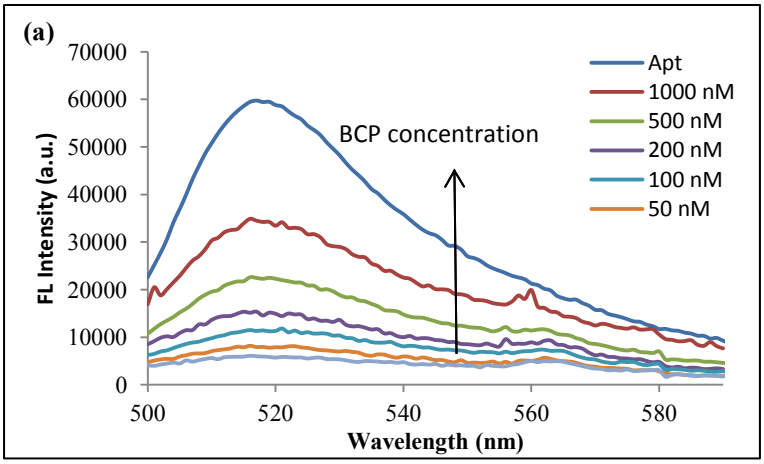


Figure 3. (a) Fluorescence spectra and (b) Quenching efficiency of FAM-aptamer with different concentrations of PDAs

**Detection process**

Fluorescence recovery was observed after the introduction of BCP with incubation time for 1 hour. Figure 4a shows the fluorescence emission spectra of FAM-Aptamer-PDAs in the presence of different concentrations of target. It could be found that more FAM-Aptamer was released which resulting in retained fluorescence with increasing concentration of BCP. By calculating difference of fluorescence intensity in presence and absence of BCP, the calibration curve can be given as shown in Figure 4b. A dynamic range of 10 – 1000 nM was established based on the fluorescence intensity. The limit of BCP detection was estimated to be 10 nM. The relative standard deviation is less than 10%, which exhibits the reproducible results for this detection system. However, the recovery of fluorescence was not high though high concentration of BCP was added which may be caused by affinity problems of aptamer to target or short incubation time for releasing. The further optimization for the detection process would facility the improvement on sensitivity and accuracy.

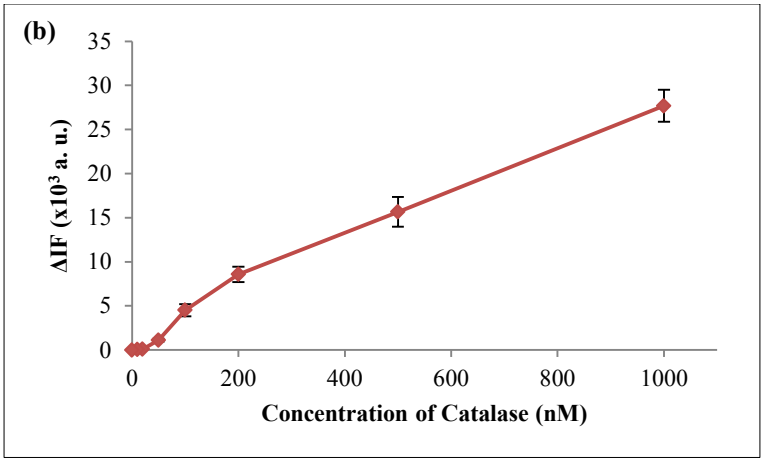

Figure 4. Fluorescence spectra (a) and calibration curve (b) for the FAM-Aptamer-PDAs in the presence of different concentrations of target BCP. Error bars are standard deviation from triplicates trial

## Conclusion

In summary, a fluorescence aptasensor has been developed by taking advantage of specific aptamer and polydopamine sensing platform. It was found that the quenching efficiency was good (> 90%) owing to the interaction between FAM-aptamer and PDAs. The retained fluorescence intensity increased with the increasing concentration of target BCP. The detection limit was confirmed at 10 nM. Further optimization of detection conditions may help to improve sensitivity. Some characterization of the developed sensor, such as interference effect by other compounds, would be performed in further study. PDAs could be used as sensing platform in fast and simple way for proteins detection and have potential to be extended to other targets.

**Abstract**

In this study, fluorescence quenching on mesoporous carbon nitride (MCN) was examined in the presence of phenol and aniline. The MCN was synthesized by thermal polymerization of cyanamide using nanocolloidal silica (7 nm) as a hard template and characterized by X-ray diffractometer (XRD), Fourier transform infrared (FTIR), transmission electron microscope (TEM), specific surface area, pore size distribution, and fluorescence spectrophotometer. The MCN showed two excitation wavelengths at 275 and 370 nm, owing to the presence of N=C and N-C terminal groups, respectively. These two excitation wavelengths gave only one emission peak at around 460 nm. Either in the presence of phenol or aniline, the emission intensity of the MCN was confirmed to be quenched in a linear function towards the concentration of phenol or aniline as the quencher molecule. N-C terminal groups were found to have slightly better interactions to phenol and aniline as compared to the N=C groups. Since the emission intensity of MCN was more quenched by phenol molecules than the aniline, it was proposed that the MCN would have stronger interaction to phenol than aniline. This result was also supported by the adsorption data, in which the MCN gave higher adsorption towards phenol than the aniline.

**Keywords**: mesoporous carbon nitride, phenol, aniline, fluorescence quenching, adsorption

**Abstrak**

Dalam kajian ini, pelindapan pendarfluor pada karbon nitrida mesoliang (MCN) telah diperiksa dengan kehadiran fenol dan anilina. MCN telah disintesis secara pempolimeran haba sianamida menggunakan silika nanokoloid (7 nm) sebagai templat keras dan telah dicirikan dengan pembelauan sinar-X (XRD), inframerah transformasi Fourier (FTIR), mikroskop elektron transmisi (TEM), luas permukaan, taburan saiz liang, dan spektroskopi pendafluor. MCN menunjukkan dua panjang gelombang pengujaan pada 275 dan 370 nm oleh kerana kehadiran masing – masing N=C dan N-C sebagai kumpulan terminal. Kedua-dua panjang gelombang pengujaan memberikan hanya satu puncak pelepasan pada kira-kira 460 nm.Sama ada dengan kehadiran fenol atau anilina, keamatan pemancaran daripada MCN disahkan mengalami pelindapan dalam fungsi linear terhadap kepekatan fenol atau anilina sebagai molekul pelindap. Kumpulan terminal N-C didapati mempunyai interaksi lebih baik sedikit untuk fenol dan anilina berbanding dengan kumpulan N=C. Oleh kerana keamatan pemancaran MCN didapati lebih terlindap oleh molekul fenol berbanding dengan anilina, adalah dicadangkan bahawa MCN berinteraksi lebih kuat dengan fenol dibandingkan dengan anilina. Keputusan ini juga disokong oleh data penjerapan, dengan MCN memberikan penjerapan yang lebih tinggi terhadap fenol dibandingkan dengan anilina.

**Kata kunci:** karbon nitrida mesoliang, fenol, anilina, pelindapan pendarfluor, penjerapan

## Introduction

Carbon nitrides (CN) are carbon materials in which some carbon atoms in the graphite-like structure are replaced by some nitrogen atoms in a regular manner. Generally, CN stands for a large family of related compounds ($C_xN_y$) [1 – 3]. Even though the CN has been reported since the 1990s, this material still receives considerable attention because of its versatility until nowadays. The CN is used in various applications while the material is just composed of C, N and H atoms [4]. Other factors that make CN being well explored is because of the abundance of these atoms on earth, non-toxic and easy to be synthesized into a desired shape where the pore of carbon nitride is tunable to form mesoporous carbon nitride (MCN) [1, 5, 6]. MCN has a larger specific surface area than the CN and it facilitated better performance for various applications [7 – 12]. Moreover, CN has many advantageous properties that make it an interesting material, such as high thermal and chemical stability, and great optical properties [13 – 15].

Recently, application of CN and MCN as fluorescence sensor has been a significant interest. Owing to the presence of fluorescent active sites (tri-*s*-triazine units), CN and MCN are potential materials to be used as an optical sensor. Despite of the fact that these materials have a strong fluorescence property, less attention was paid on its sensing ability until there was a report showing the utilities of cubic MCN as all-in-one chemosensor for sensing of trace amount of metal ions in aqueous solution [16]. Since the cubic MCN has the highest sensitivity and selectivity towards copper ions, further modification was also carried out by the research group on the cubic MCN incorporating copper ions for sensing of cyanide ions, which are very poisonous and used abundantly in metal plating industry [17]. CN has been also reported as an efficient fluorosensor for detection of copper ions. It was suggested that the fluorescence quenching was due to strong coordination of the Lewis basic sites on the CN with the Cu ions [18]. Besides metal and cyanide ions, recent studies showed that nitrogen-containing compounds can be also detected by fluorescence quenching. It was reported that MCN was able to be used as a fluorescence sensor for *N*-nitrosopyrrolidone (NPYR) [7]. The surface interaction was proposed to involve electrostatic interactions between the electropositive N and electropositive N at the NPYR molecules and terminal N-C groups of the MCN, respectively. CN was also reported as a fluorescence chemical sensor for nitrate ions [19].

In this study, fluorescence quenching on MCN was investigated in the presence of aromatic compounds, which are phenol and aniline. Phenol is considered as one of the organic pollutants that can be easily found in industrial wastewater [20 – 22]. The wastewater containing phenol may cause the contamination of groundwater and it will give bad effects for ecosystems and also for human. Meanwhile, aniline is also recognized as one of the high priority pollutants that are released from several industries, such as various manufacturers of dyes, and rubber, which caused wide distribution of aniline in the environment [23 – 25]. As an adsorbent, MCN possesses well-ordered porosity, high surface area, and basic groups (NH and $NH_2$) in the structures, which are the important criteria for the removal of organic pollutants. Due to the nitrogen rich structure of MCN with basicity property, it showed remarkable adsorptions towards one of the acidic persistent organic pollutants, *i.e*. phenol [26]. On the other hand, the MCN was also reported showing superior capability to adsorb aniline than the CN and MCM-41 [8, 9]. Therefore, based on these reported studies, the fluorescence quenching on MCN by phenol and aniline is feasible. This study demonstrated that MCN can be also used as a fluorescence sensor for the aromatic compounds.

## Materials and Methods

### Preparation of MCN

The MCN was prepared by a thermal polymerization of cyanamide as the precursor, in the similar way to the method reported in other literatures [7 – 9]. The cyanamide was mixed with the colloidal silica as a hard template 7 nm (mass ratio was 1:1), followed by stirring and heating at 363 K until a white powder was formed. The obtained white powder was ground and then heated at a temperature of 823 K for 4 hours. In order to obtain the MCN, the silica template was removed by treating the MCN powder with the $NH_4HF_2$ solution (4 M, 400 mL) under vigorous stirring and also with ethanol and distilled water. This washing step was repeated for three times. After washing and filtration, the powder was dried at 343 K overnight in an oven.

### Characterizations

The structure of the MCN was determined by an X-ray diffractometer (XRD) on a Bruker D8 Advance Diffractometer at ambient temperature, with a scan rate of 0.05 $s^{-1}$ using Cu-Kα radiation where $\lambda$ equals to

1.5406 Å at 40 kV and 40 mA. To determine the structural information and functional groups of the MCN, a Fourier transform infrared spectroscopy (FTIR) was employed using a FTIR Nicolet iS50 Thermo Scientific. For pellet preparation, a small amount of the MCN was mixed with potassium bromide (KBr) and put under a pellet press. To obtain a better background correction, nitrogen gas was purged into the system before the analysis to remove all humidity. Morphology of the MCN was measured using a transmission electron microscope (TEM) on a JEOL JEM-2100. The MCN powder was first dispersed well in acetone, and then put onto the copper grid to be observed with the TEM. The surface area of the MCN was determined by using the Brunauer-Emmet-Teller (BET) equation, while the pore size of the MCN was determined using the Barret-Joyner-Halenda (BJH) from adsorption-desorption isotherm at 77 K obtained on a Quanta chrome Autosorb-1 instrument. The fluorescence properties were measured using a JASCO Spectrofluorometer FP-8500 to obtain the excitation and emission spectra. The excitation wavelengths used to monitor the emission spectra were 275 and 370 nm, while the emission wavelength used to monitor the excitation spectra was 460 nm. The analysis was carried out at room temperature.

**Fluorescence quenching**

The quenching tests were carried out with various concentrations of phenol and aniline on the MCN (50 mg) at room temperature. The excitation wavelengths at 275 and 370 nm of the MCN were determined by observing the emission spectrum at 460 nm. Meanwhile, the emission wavelength was determined by observing excitation spectra at both excitation wavelengths. From various amounts of phenol solutions (300 – 600 ppm), 20 µL of the solution was taken and then introduced onto the MCN for the quenching test for phenol. The changes in the emission spectra of the MCN were then measured at excitation wavelengths of 275 and 370 nm. As for the quenching test for aniline, the same steps were followed using various concentrations of aniline solution (200 –700 ppm).

**Adsorption tests**

The adsorption process of phenol or aniline onto the MCN was conducted under dark condition using various concentrations of phenol (60 – 400 ppm) and aniline (100 – 500 ppm) at room temperature. Different series of concentrations were selected due to the different behaviors of the observable adsorption. A magnetic bar was put in a 30 mL beaker and 10 mL of phenol or aniline solution was poured into the beaker together with the MCN (50 mg). Inside a closed box, the beaker containing the mixture was placed on the stirring plate and stirred for 6 hours. After filtration and separation from the MCN, the solution was analysed using gas chromatography with a flame ionization detector (GC-FID) on an Agilent 7820AGC-FID. The adsorbed amount was determined by subtracting the initial phenol or aniline with the amounts of remaining phenol or aniline after the adsorption test.

## Results and Discussion

**Properties of MCN**

Shown in Figure 1(a) is the XRD pattern of the prepared MCN, which gave two diffraction peaks at $2\theta$ of 13.1 and 27.4°. The peak at $2\theta$ of 13.1° was corresponding to the distance of 0.66 nm, which indicated the in-planar repeating units and structural packing motif, such as hole-to-hole distance of the nitride pores, while the intense diffraction peak at the $2\theta$ of 27.4° could be indexed as (002) for graphitic materials, giving an interlayer distance of 0.325 nm for the graphite-like stacking of the conjugated aromatic CN layers. This result is in good agreement with values reported elsewhere [4, 7 – 11, 13, 14]. Therefore, it can be concluded that the MCN sample was successfully synthesized.

The functional groups present on the MCN were investigated by FTIR spectroscopy. As shown in Figure 1(b), the absorption peaks of the MCN were observable at the region of 809, 1200 – 1700 and 3000 – 3700 $cm^{-1}$. The bands at 809, 1252, 1319, 1428 and 1646 $cm^{-1}$ could be attributed to the vibration modes of heterocyclic tri-*s*-triazine ring ($C_6N_7$) units, while the broad peak at 3163 $cm^{-1}$ could be assigned to two overlapping bands of stretching modes of N-H and O-H groups [9, 11, 27]. The peak at 2177 $cm^{-1}$ could be attributed to the presence of C≡N or N=C=N group, which was reported in MCN prepared via thermal polymerization reaction [27]. These FTIR spectra supported that the MCN sample was successfully prepared.

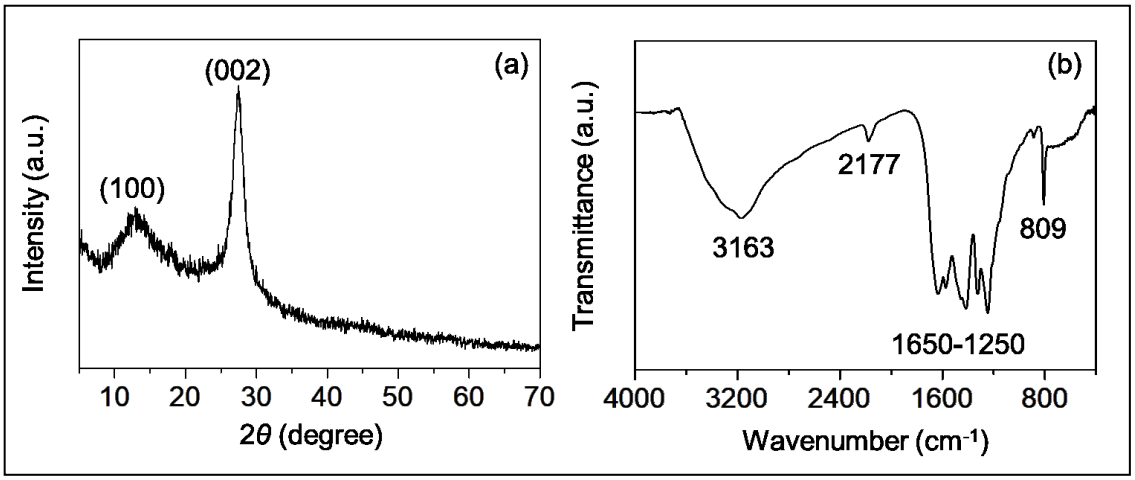

Figure 1. (a) XRD pattern and (b) FTIR spectrum of MCN

The morphology of the prepared MCN was observed by TEM as shown in Figure 2. It can be seen that the MCN has uneven layers due to the graphitic structures of the MCN. Figure 3(a) shows the nitrogen adsorption-desorption isotherms and Figure 3(b) shows the Barrett-Joyner-Halenda (BJH) pore size distribution of the MCN. The results suggested that the MCN has type IV isotherm for mesoporous material with hysteresis loop at relative pressure of 0.5 – 1 due to the capillary condensation in pores. The BET specific surface area of the MCN was determined to be 287 $m^2$ $g^{-1}$. Meanwhile, for BJH pore size distribution, the MCN showed a narrow and sharp pore size of 7 nm. This pore size reflected the size of the silica template that was used for the preparation of the MCN.

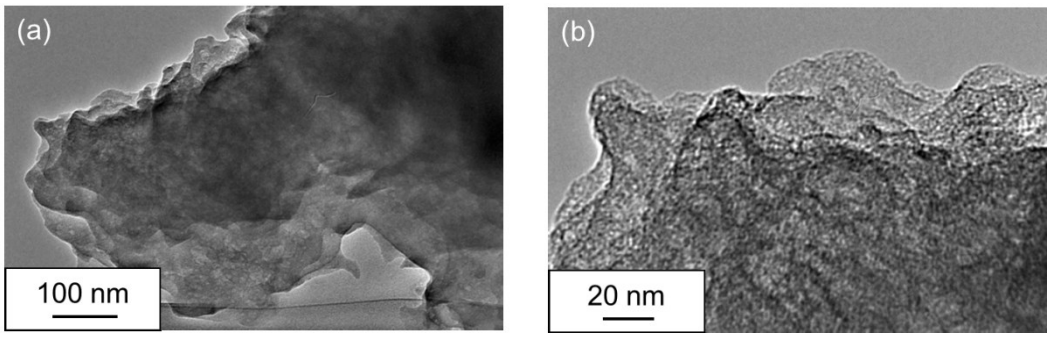

Figure 2. TEM images of MCN shown in different magnification scale bars, (a) 100 nm and (b) 20 nm

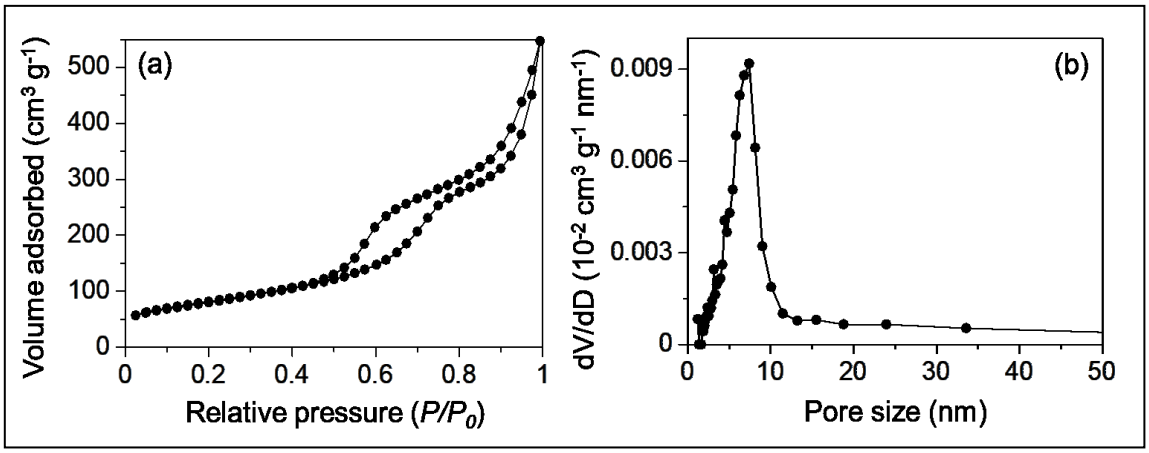

Figure 3. (a) Nitrogen adsorption-desorption isotherm and (b) BJH pore size distribution of MCN

Figure 4(a) displays the excitation spectrum of the MCN. It was clear that the MCN exhibited two excitation peaks at 275 and 370 nm. The excitation peak at 275 nm can be attributed to the $\pi$ to $\pi^*$ electronic transition of the N=C groups in the aromatic 1,3,5-triazine ring of MCN. Meanwhile, the other excitation peak at 370 nm can be attributed to $n$ to $\pi^*$ electronic transition of a terminal N-C group involving lone pairs of nitrogen atoms. As can be seen from Figure 4(b), the MCN gave one emission peak at a wavelength of 460 nm when the MCN was excited either at 275 or 370 nm. These results agree well with previous reports [7, 9, 19].

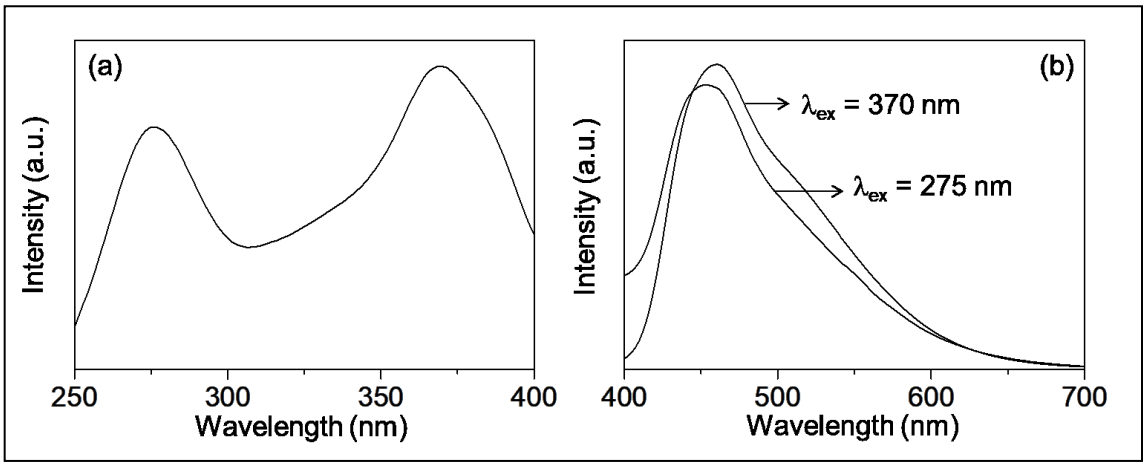

Figure 4. (a) Excitation and (b) emission spectra of MCN that were monitored at emission wavelength of 460 nm and excitation wavelengths of 275 and 370 nm

**Fluorescence quenching**

Quenching tests were conducted on the MCN by the addition of various concentrations of phenol or aniline in order to investigate the sites where the interactions occurred either at N=C groups or terminal N-C groups. The quenching tests were determined by observing the changes in the emission intensity of the MCN sample before and after the addition of phenol or aniline. Since one emission spectrum at around 460 nm was observed for both excitations at 275 and 370 nm, the quenching tests were carried out by monitoring the intensity of the emission peak at 460 nm excited at both excitation wavelengths. As illustrated in Figure 5(a) and (b), the emission intensities of the MCN

excited at both excitation wavelengths of 275 and 370 nm (N=C and terminal N-C emission sites), respectively decreased with the addition of the phenol. This result showed that phenol acted as a quenching agent to deactivate the emission sites. When the added phenol concentration increased, the emission intensity was further decreased. The decrease in the emission intensity would be due to the interactions between the emission sites of MCN at an emission wavelength of 460 nm and the added phenol.

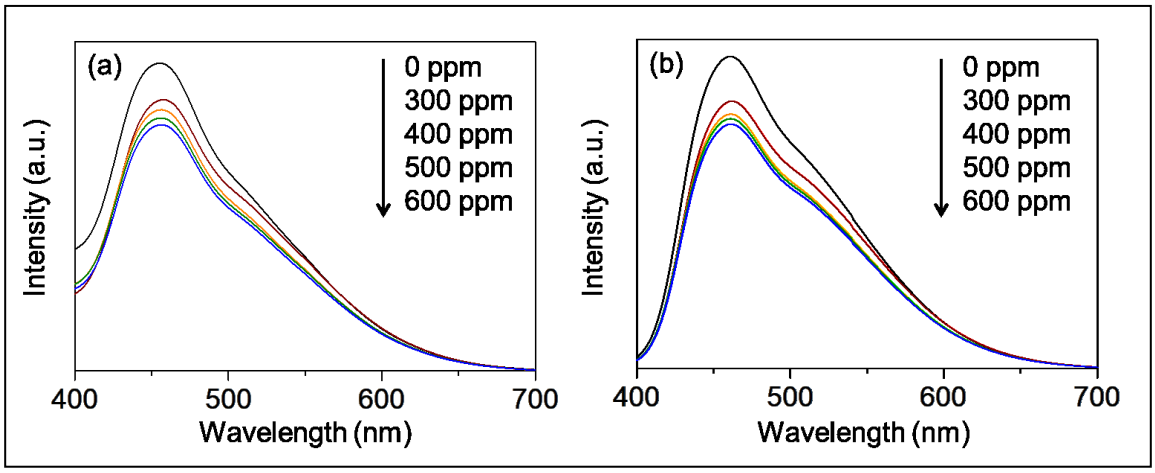

Figure 5. Fluorescence quenching on MCN in the absence and presence of phenol (0–600 ppm) when excited at (a) N=C and (b) terminal N-C groups

In order to have a better understanding about the interaction of MCN with phenol, the quenching results were plotted according to the Stern-Volmer plot following the equation 1:

$$Io/I = K_{SV}[Q] + 1 \quad (1)$$

where $Io$ and $I$ are fluorescence intensities observed in the absence and presence of phenol, $Q$ is the concentration of phenol, and $K_{SV}$ is the Stern-Volmer quenching constant.

Based on the Stern-Volmer equation, the relative emission intensity would be expressed as the function of phenol concentration when the same amount of MCN and the constant illumination intensity were taken in account. Figure 6 shows the Stern-Volmer plots of the relative emission intensity of MCN with various concentrations of phenol. In the range of 300 – 600 ppm, the relative emission intensity excited at both emission sites gave a linear Stern-Volmer plot with the concentrations of phenol. The linear Stern-Volmer plot indicated that the MCN could detect phenol using the fluorescence spectroscopy. Meanwhile, the quenching efficiency of phenol on the emission site of MCN could be obtained from the slope of the linear plot, which was matched to the quenching rate constant ($K_{SV}$ value). It was shown that the $K_{SV}$ values for the emission sites monitored at excitation wavelengths of 275 and 370 nm were $4 \times 10^{-4}$ and $5 \times 10^{-4}$ $ppm^{-1}$, respectively. These results suggested that the emission sites of MCN excited at 275 and 370 nm have almost equal interactions with phenol, which the terminal N-C groups gave slightly better interaction than the N=C groups.

Figure 7(a) and (b) show the changes on the emission intensities excited at 275 and 375 nm, respectively in the presence of aniline. Similar to the phenol addition, the addition of aniline quenched the intensity of the MCN. Aniline also acted as a quenching agent that deactivated the emission sites of MCN. When the concentration of aniline increased, the emission intensity was also further reduced. The decrease in the emission intensity of the MCN suggested that there were interactions between the N=C and terminal N-C emission sites and the aniline. As previously mentioned, the MCN has two excitation sites at 275 and 370 nm, which belong to the N=C groups

($\pi$–$\pi$*) in the aromatic 1,3,5-triazine and the terminal N-C groups ($n$–$\pi$*), respectively. In order to investigate which sites were favoured to the aniline, the Stern-Volmer plot was performed.

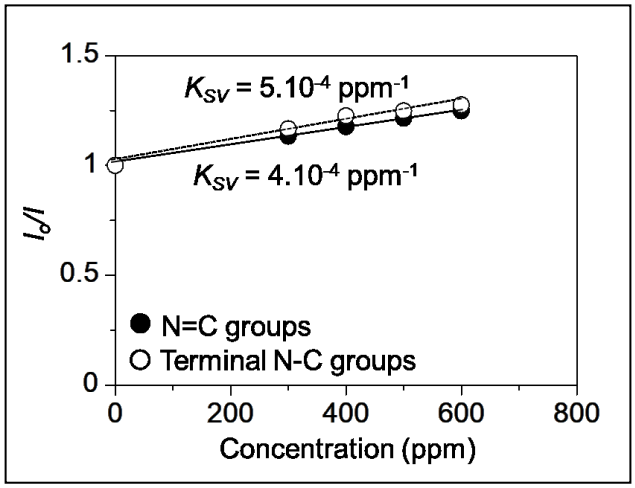

Figure 6. Stern Volmer plots of phenol quenching on MCN at N=C and terminal N-C groups

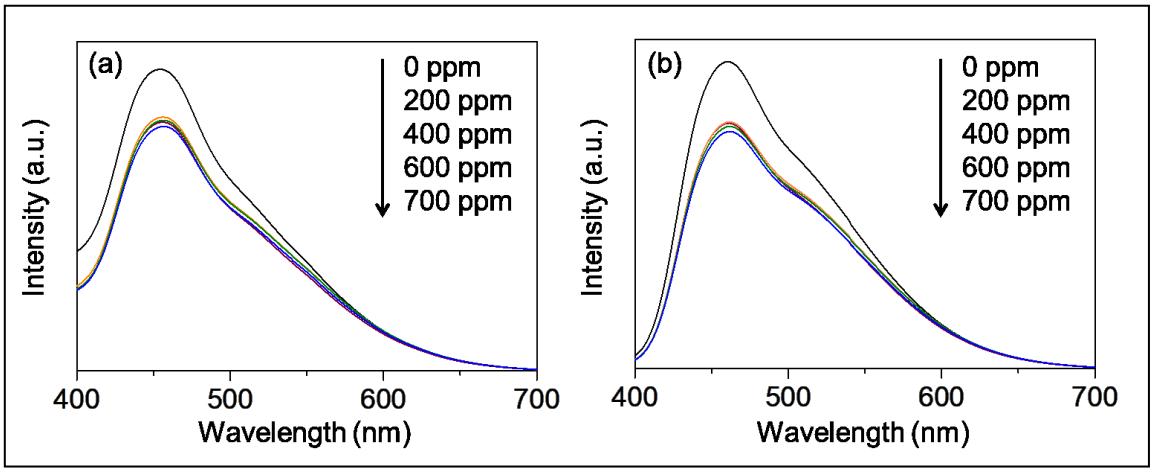

Figure 7. Fluorescence quenching on MCN in the absence and presence of aniline (0 – 700 ppm) when excited at (a) N=C and (b) terminal N-C groups

Shown in Figure 8 is the linear Stern-Volmer plots between the relative emission intensity of MCN with various concentrations of aniline in the range of 200 –700 ppm. Both emission sites, the N=C and terminal N-C groups showed the linear Stern-Volmer plots with the addition of aniline. $K_{SV}$ values obtained were $3 \times 10^{-4}$ and $4 \times 10^{-4}$ ppm$^{-1}$ for the N=C and terminal N-C groups, respectively. The slightly higher $K_{SV}$ value of the terminal N-C group suggested that similar to the results when using phenol as the quencher agent, aniline also favored the terminal N-C groups. Based on the fluorescence quenching tests, it was demonstrated that the MCN showed good interactions with phenol and aniline.

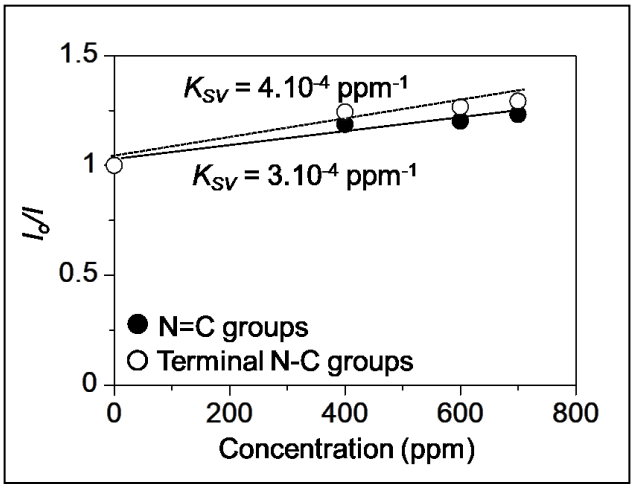

Figure 8. Stern Volmer plots of aniline quenching on MCN at N=C and terminal N-C groups

**Adsorption tests**

Adsorption capability of the MCN towards phenol or aniline was examined by using different concentrations. The adsorption test for phenol was carried out at room temperature with the concentration of phenol was varied from 60 to 400 ppm. Figure 9 presents the results of the adsorption test of phenol on the MCN. The amount of adsorbed phenol increased with the increase of the phenol concentration when it was below 100 ppm. Further increase of the phenol concentration at more than 100 ppm did not affect much the amount of adsorbed phenol. Figure 9 also shows the results of aniline adsorption on the MCN with various concentrations from 100 to 500 ppm. Separated experiments confirmed that no aniline adsorption occurred when the aniline concentration was lower than 100 ppm. At concentration of 100 ppm and above, the MCN showed an increased amount of adsorption with the increase of aniline concentration up to 500 ppm. Compared to the adsorption of phenol, higher amount of aniline was required for MCN to act as an adsorbent.

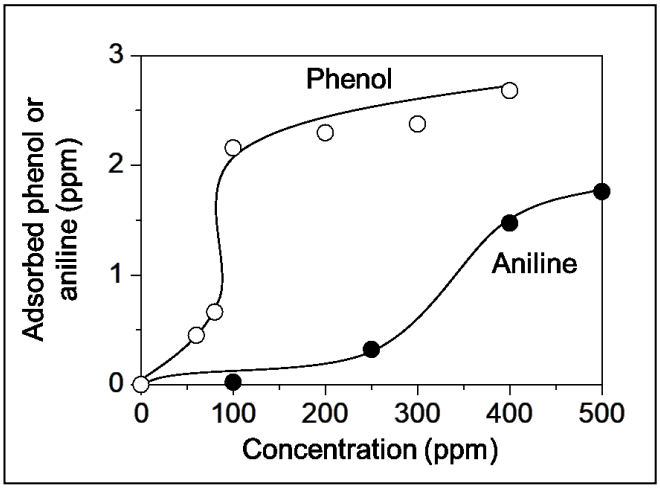

Figure 9. Adsorption of phenol and aniline with various concentrations on MCN at room temperature

From the adsorption test analyses, it can be proposed that phenol and aniline were successfully adsorbed on the MCN. However, under the same concentration for instance at 100 ppm, the MCN gave better adsorption towards phenol than the aniline, which gave adsorbed amounts of 2.16 and 0.02 ppm, respectively. The higher adsorbed

amount of phenol than aniline might be due to the fact that phenol is a weak acid, while aniline is a weak base. Therefore, basicity of the MCN would favor phenol rather than aniline. It can be proposed that phenol would give stronger interaction to the MCN, which in turn gave higher $K_{SV}$ value than the aniline. As has been reported elsewhere [7], the presence of electronegative N at the terminal N-C groups of the MCN provided the possibility for the formation of electrostatic interactions towards the analyte molecules. As phenol is a weak acid, the acid-base electrostatic interactions would occur between the electronegative N at the terminal N-C groups of the MCN and the electropositive phenolic proton. As for aniline, the electrostatic interactions would occur between the electronegative N at the terminal N-C groups of the MCN and the electropositive H at the $NH_2$ group of the aniline, which was less electropositive than the phenolic proton.

## Conclusion

Characterizations by XRD, FTIR, TEM, surface area and pore size analyzer, and fluorescence spectroscopy confirmed that the MCN was prepared successfully by thermal polymerization of cyanamide using nanocolloidal silica as the hard template. The MCN was shown to have good interactions with phenol and aniline, where its emission intensity was quenched almost linearly with the addition of these aromatic compounds. It was obtained that the terminal N-C groups gave slightly higher quenching efficiency than the N=C groups for both phenol and aniline. Phenol gave better interactions towards the emission sites of the MCN, owing to the stronger adsorption of phenol on to the MCN than the aniline caused by the acid-base electrostatic attractive force.

**Abstract**

Endotoxins are known to many as bacterial toxins. Conventional analysis of endotoxins by capillary electrophoresis-mass spectrometry is laborious and time consuming. A faster capillary electrophoresis method using direct ultraviolet (UV) detection was performed to analyze endotoxins isolated from *Escherichia coli* (*E. coli*) 055:B5 and UT189. In this study, we compared different running buffers and buffer additives to examine the effects of each on the electropherograms obtained. The optimum buffer system was then used to analyze of lipopolysaccharides (LPS) signals from the bacteria *E. coli* 055:B5 (source strain CDC 1644-70), *E. coli* K-235 (source strain ATCC 13027) and *Klebsiella pneumoniae* (source strain ATCC 15380). The data generated for each variant peak showed very good precision and high reproducibility for migration time with percentage RSD values of ≤1.2% (n = 3). Similarly, the percentage RSD for peak areas were ≤5.3% (n = 3) across the three LPS.

**Abstrak**

Endotoksin diketahui sebagai bakteria yang berbahaya. Kaedah konvensional bagi endotoksin oleh elektroforesis kapilari-jisim spektrometri adalah bersifat rumit dan memerlukan tempoh masa yang panjang. Kaedah elektroforesis kapilari yang pantas menggunakan pengesan ultralembayung telah dijalankan untuk menganalisa endotoksin yang dipisahkan dari *Escherichia coli* (E. coli) 055:B5 and UT189. Dalam kajian ini, larutan penimbal yang berbeza telah diuji dan penambahan penimbal dilakukan untuk mengkaji kesan bagi setiap elektropherogram yang terhasil. Sistem penimbal yang optimum kemudian digunakan untuk menganalisa respon lipopolisakarida (LPS) dari bakteria *E. coli* 055:B5 (sumber strain CDC 1644-70), *E. coli* K-235 (sumber strain ATCC 13027) and *Klebsiella pneumoniae* (sumber strain ATCC 15380). Data yang terhasil bagi puncak setiap varian menunjukkan ia adalah jitu dan kebolehulangan yang tinggi bagi masa pemindahan dengan nilai peratus RSD ialah ≤1.2% (n = 3). Begitu juga, peratus RSD bagi luas – luas puncak ketiga – tiga LPS ialah ≤5.3% (n = 3).

**Kata kunci**: elektroforesis kapilari, UV langsung, endotoksin, lipopolisakarida, penimbal

## Introduction

Endotoxins are of great relevance in today's research because most layman would believe that killing bacteria by boiling water alone would ensure toxin-free water. However, endotoxins are released by bacteria after lysis by cell death at high temperature. Endotoxins causes inflammatory reactions and sepsis which can be fatal [1]. Since they are found in high concentrations in wastewater from industries coupled with less than optimal waste treatment [2, 3], the efficiency for the secondary treatment of industry effluents must be addressed.

Endotoxins are found in the cell wall of Gram-negative bacteria. Essentially, endotoxins are major components of the exterior of the outer membrane of the Gram-negative cell wall. Endotoxins are lipopolysaccharides (LPS) and are known to many as bacterial toxins. They are hydrophilic and face outward from the cell membrane and into the medium in which the bacteria is growing [4]. LPS contains major antigens of the bacteria and is the most important target of Gram-negative bacteria for the immune response [5]. Each LPS molecule is unique to a particular Gram-negative bacteria and exhibits much variation in its structure [6] an example shown in Figure 1.

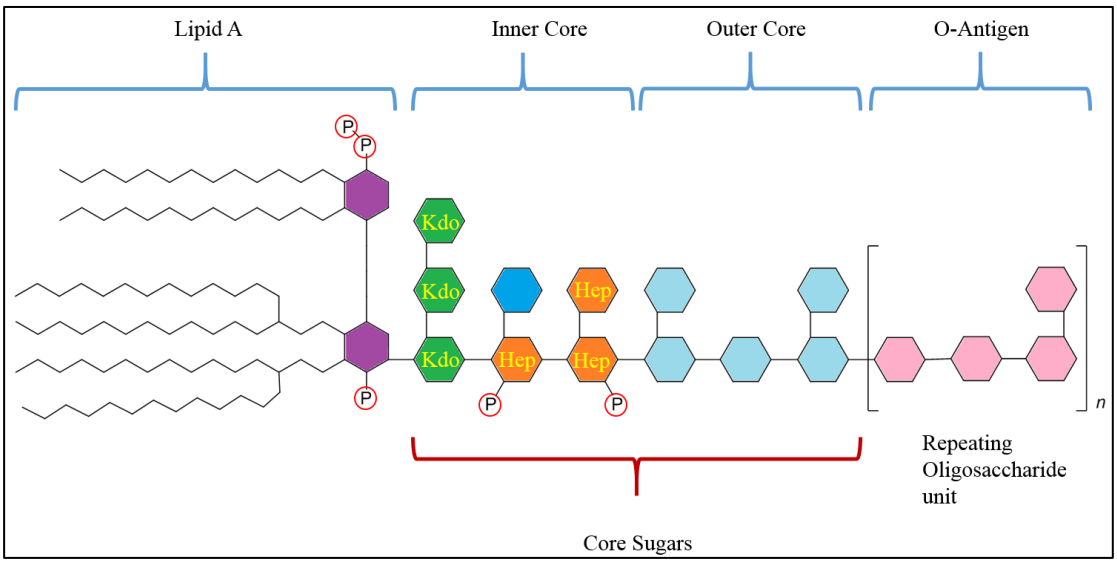

Figure 1. The general structure of lipopolysaccharide molecule, segmented primarily into lipid A, inner core, outer core, and *O*-antigen

Previous research has shown that the heterogeneity of different LPS mixtures enable scientists to distinguish them via mass spectrometric detection [7]. Their differences in molecular weight, size, and connectivity of the branched chains allow the combined use of both online and offline separation techniques [8]. Such distinct structural differences also allow the LPS to be separated via high-performance capillary electrophoresis (CE) for further analysis, as performed by Restaino et al. [9] on the *E. coli* K4 cell surface polysaccharides. LPS from *E. coli* 055:B5 has also been analyzed by CE-UV. However, in the study, only one surfactant, sodium dodecyl sulfate (SDS) was experimented in the running buffer [10]. LPS, being amphiphilic molecules, are prone to aggregation of the repeating oligosaccharide units in the *O*-antigen segment [11, 12]. Without the presence of surfactants, it is perceivable that the LPS form micelles and acquire lower solubility, giving rise to precipitates and lower reproducibility of electropherograms. Thus, it is believed that the migration behavior of LPS will alter when different surfactants are used, depending on the main buffering system. Although work has been performed on the investigation of various concentration of SDS in selected LPS electropherogram [13 – 16], no study has reported the effect of surfactants and buffering system on the LPS extracted from *E. coli* K-235, *E. Coli* UT189 and *Klebsiella pneumoniae*. In this paper, the study of different surfactants and buffering system for the optimization of LPS separation by CE is reported.

## Materials and Methods

### Chemicals

Sodium dodecyl sulfate (SDS), sodium borate, sodium hydroxide were obtained from Merck (Darmstadt, Germany). Buffers were prepared with ultrapure water obtained from Millipore equipment (Millipore, Bedford, MA, USA). Commercially prepared tris(hydroxymethyl)aminomethane (Tris), boric acid, disodium ethylenediaminetetraacetic acid (EDTA) buffer was purchased from Bio-Rad laboratories (Singapore). Poly(ethylene)oxide (PEO, Mr 600 000) was purchased from Sigma-Aldrich (Singapore). 1,4-diaminobutane (DAB) was purchased from Fluka (Münster, Germany).

### Bacteria strains and endotoxins preparation

Lyophilized lipopolysaccharides powders from *E. coli* 055:B5 (Lot #025M4040V) purified by gel-filtration chromatography, E-Toxate™ Endotoxin standard, *E. coli* K-235 purified by gel-filtration chromatography, *Klebsiella pneumoniae* purified by phenol extraction were purchased from Sigma Aldrich. *E. Coli* UT189 was donated by Bau Yi Woo of Department of Chemistry, National University of Singapore.

LPS from *E. Coli* UT189 was prepared by the following procedure: To obtain pure and lyophilized LPS we used the hot phenol–water procedure according to Westphal et al. [17]. Crude LPS was recovered from the combined aqueous phase and subjected to further purification as reported in the conventional method. Purified LPS samples were lyophilized for ~18 h to yield a white-fluffy powder that was used for analysis.

### Instrumentation

All electrophoretic separations were performed on a Beckman Coulter PA 800 plus system (AB Sciex, USA), using photodiode array (PDA) absorbance detection set at 195 nm. Uncoated fused silica capillaries (50 m ID × 360 m OD) were purchased from Polymicro Technologies Inc. (Phoenix, AZ, USA). New capillaries were flushed with 1M NaOH, ultrapure water and background electrolyte (BGE) for 10 minutes each. Preconditioning was performed by flushing with BGE for 3 minutes. The Beckman Coulter's 32 Karat™ version 9.1 software was used for data analysis, data acquisition and peak integration.

### CE–UV experiments

For CE–UV experiments the capillaries were cut to a length of 39 cm. For each capillary, a 0.30 cm transparent window was created by burning the capillary 10 cm from one of the ends. The capillary was burnt with a general butane lighter and the size of the window was consistently maintained by wrapping the capillary with an Aluminum foil with at 0.30 cm aperture. Detection was done using a CE photodiode array detectors (PDA) equipped with a deuterium lamp. The length of this irradiation window was 1 cm and the distance between lamp and capillary about 2 cm. All the measurements were carried out at 16 °C with the applied voltage set at 30 kV. All measurements were carried out at least three times. The LPS was dissolved in the BGE to make up a concentration of 5.0 mg/mL. The various buffering systems applied in this report are summarized in Table 1.

Table 1. Different running buffers used in CE-UV analysis of intact LPSs.

| Number | Buffer System/ BGE | Concentration | pH | Reference |
|---|---|---|---|---|
| 1 | SDS/$Na_2B_4O_7$/$Na_2HPO_4$ | 40 mM/10 mM/40 mM | 9.00 | [9] |
| 2 | SDS/$Na_2B_4O_7$ | 40 mM/10 mM | 9.22 | This study |
| 3 | Tris/Borate/EDTA/PEO | 3.94 mM/0.56 mM/0.013 mM/0.02% | 9.14 | [18] |
| 4 | Tris/Borate/EDTA | 445 mM/445 mM/10 mM | 8.45 | This study |
| 5 | Tris/Borate/EDTA/PEO | 445 mM/445 mM/10 mM/0.02% | 7.77 | This study |
| 6 | $Na_2B_4O_7$ | 50 mM | 9.40 | [19] |
| 7 | $Na_2B_4O_7$/DAB | 50 mM/10 mM | 9.11 | [20] |
| 8 | Tricine | 50 mM | 5.21 | This study |

## Results and Discussion

The LPS isolated from *E. coli* 055:B5 and UT189 were analyzed with the buffering systems consisting of SDS/ $Na_2B_4O_7/Na_2HPO_4$ (40 mM/10 mM/40 mM, pH 9.0) as reported by Restaino et al., although the electropherograms obtained with this buffering system could not ascertain the location of a definitive set of LPS signals, unlike the success reported for *E. coli* K4 [9]. In the electropherograms shown in Figure 2, only that of *E. coli* 055:B5 marginally provides the signature twin signals at migration times of around 6.83 minutes.

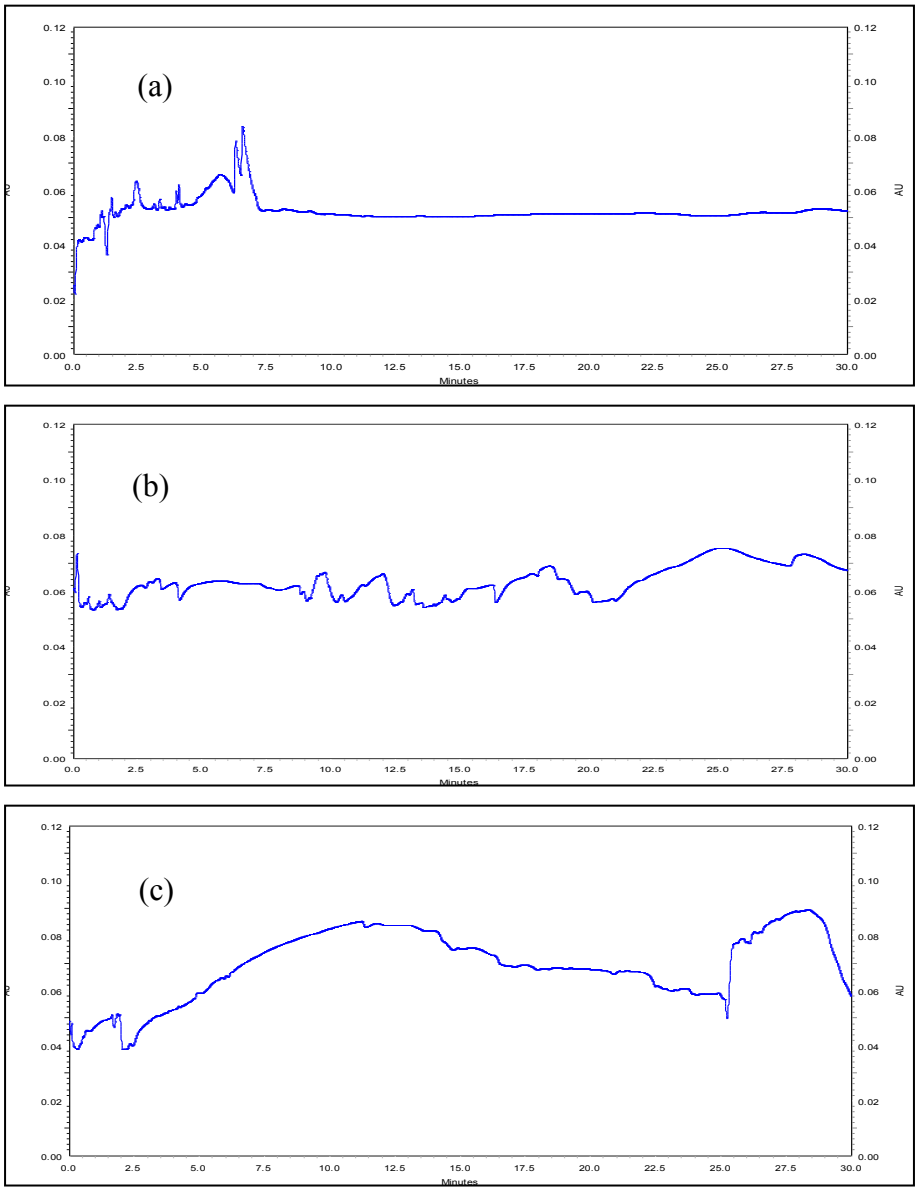

Figure 2. CE-UV electropherograms of lipopolysaccharides from Gram-negative bacteria (A) 055:B5; (B) E-Toxate™; (C) UT189. Running buffer: $SDS/Na_2B_4O_7/Na_2HPO_4$ (40 mM/10 mM/40 mM, pH 9.0). Applied voltage = 30 kV; injection time = 5 s. Capillary dimensions are indicated in experimental section

One of the reasons why the previous buffer system could not give a distinct signal in the electropherograms of LPS E-Toxate™ and UT189 is the solubility of the LPS in the buffer. As mentioned in the introduction, different strains

of bacteria vary in molecular size, and the number of repeat oligosaccharide units (*n* value) in the *O*-antigen segment of the structure. The higher the *n* value, the more likely it is for the oligosaccharide chain to form multiple intramolecular hydrogen bonds (H-bonds) within the *O*-antigen chain, creating an aggregate which may decrease its solubility in selected buffers. The surfactant used according to Restaino et al. was SDS [9], which is an anionic surfactant that increases the overall ionic strength of the buffer. A non-ionic neutral surfactant, polyethylene oxide (PEO), was used as a replacement instead on LPS E-Toxate™ and UT189, by Yu et al. using Tris/$Na_2B_4O_7$/EDTA/PEO (3.94 mM/0.56 mM/0.013 mM/0.02%, pH 9.14) as the buffer system [18]. At this pH, all the ionizable functional groups in the LPS would have been deprotonated, and they carry uniformly negatively charges, giving rise to an increase in charge density, and a more consistent electrophoretic mobility of the LPS. In Figure 3, both electropherograms exhibit the detected LPS signals: at 1.52 minutes for E-Toxate™ and 2.31 minutes for UT189.

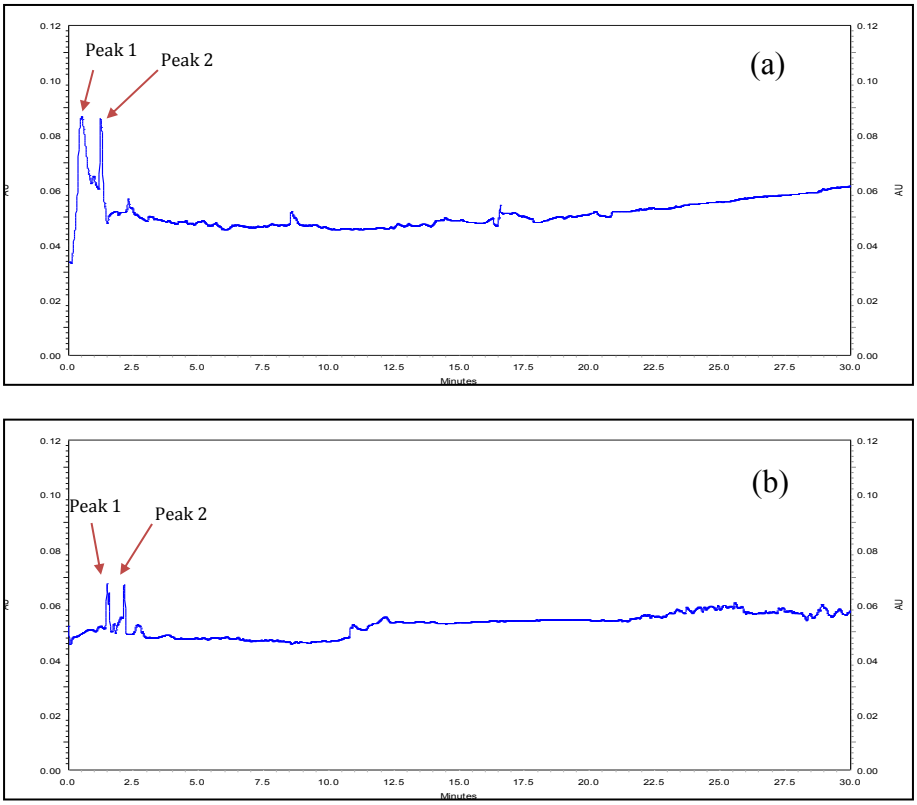

Figure 3. CE-UV electropherograms of lipopolysaccharides from Gram-negative bacteria (A) E-Toxate™; (B) UT189. Running buffer: Tris/$Na_2B_4O_7$/EDTA/PEO (3.94 mM/0.56 mM/0.013 mM/0.02%, pH 9.14). Applied voltage = 30 kV; injection time = 5 s. All other conditions are the same as stated in the experimental section.

The use of PEO in place of SDS has allowed the detection of LPS signals which were previously not seen. However, these LPS signals have relatively short migration times, which means that the use of an electroosmotic flow (EOF) marker will not be accurate. The EOF should preferably produce a signal that has a lower migration time than that of the analytes. This EOF marker signal will have the same relative differences in migration time to the respective analyte signals. Having low migration times for the analytes in this case would mean lower accuracy when comparing the mobilities of the various LPS. The three LPS were then analyzed using a modified buffering system by the use of a commercially purchased Tris/Borate/EDTA (445 mM/445 mM/10 mM, pH 7.77) buffer and the addition of PEO (0.02%). This change in the concentration of the ions and the pH provided the desired effect of delaying the migration time of the LPS signals, as seen in Figure 4. Comparing the electropherograms of the E-

Toxate™, the new buffering system with almost 900 times increase in sodium borate concentration increases the migration time from 1.52 minutes to 2.41 minutes. Likewise for UT189, the migration time increases from 2.31 minutes to 2.92 minutes.

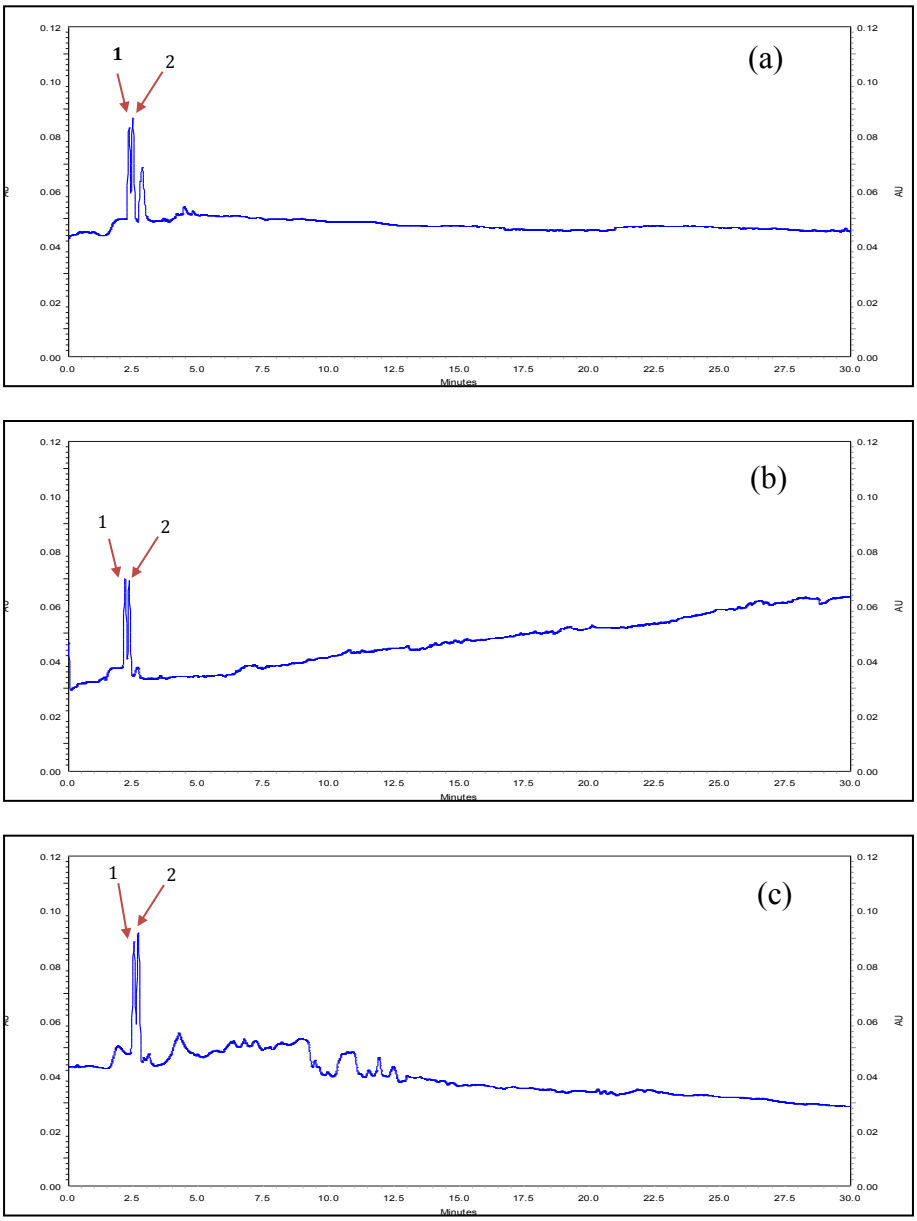

Figure 4. CE-UV electropherograms of lipopolysaccharides from Gram-negative bacteria (A) 055:B5; (B) E-Toxate™; (C) UT189. Running buffer: Tris/$Na_2B_4O_7$/EDTA/PEO (445 mM/445 mM/10 mM/0.02%, pH 7.77). Applied voltage = 30 kV; injection time = 5 s. Capillary dimensions are indicated in experimental section

Although the migration times were prolonged slightly after increasing the Tris/$Na_2B_4O_7$/EDTA concentration, we believed that this can be increased further. The same LPS were subsequently analyzed with the buffer system consisting of Tris/Borate/EDTA (445 mM/445 mM/10 mM, pH 8.45). Without the addition of PEO into this buffer

system, the migration times for all three LPS electropherograms showed marked increment. As shown in Figure 5, the migration times for 055:B5, E-Toxate™ and UT189 increased to 7.10 minute, 6.48 minute and 11.22 minute respectively. The pair of distinctive peaks at migration times of 6.07 (± 0.10) and 6.48 (± 0.10) minutes could be used to identify the presence of E-Toxate™ LPS. These twin peaks showed maximum absorbance at 195 nm in the 3D CE-UV plot (Figure 6).

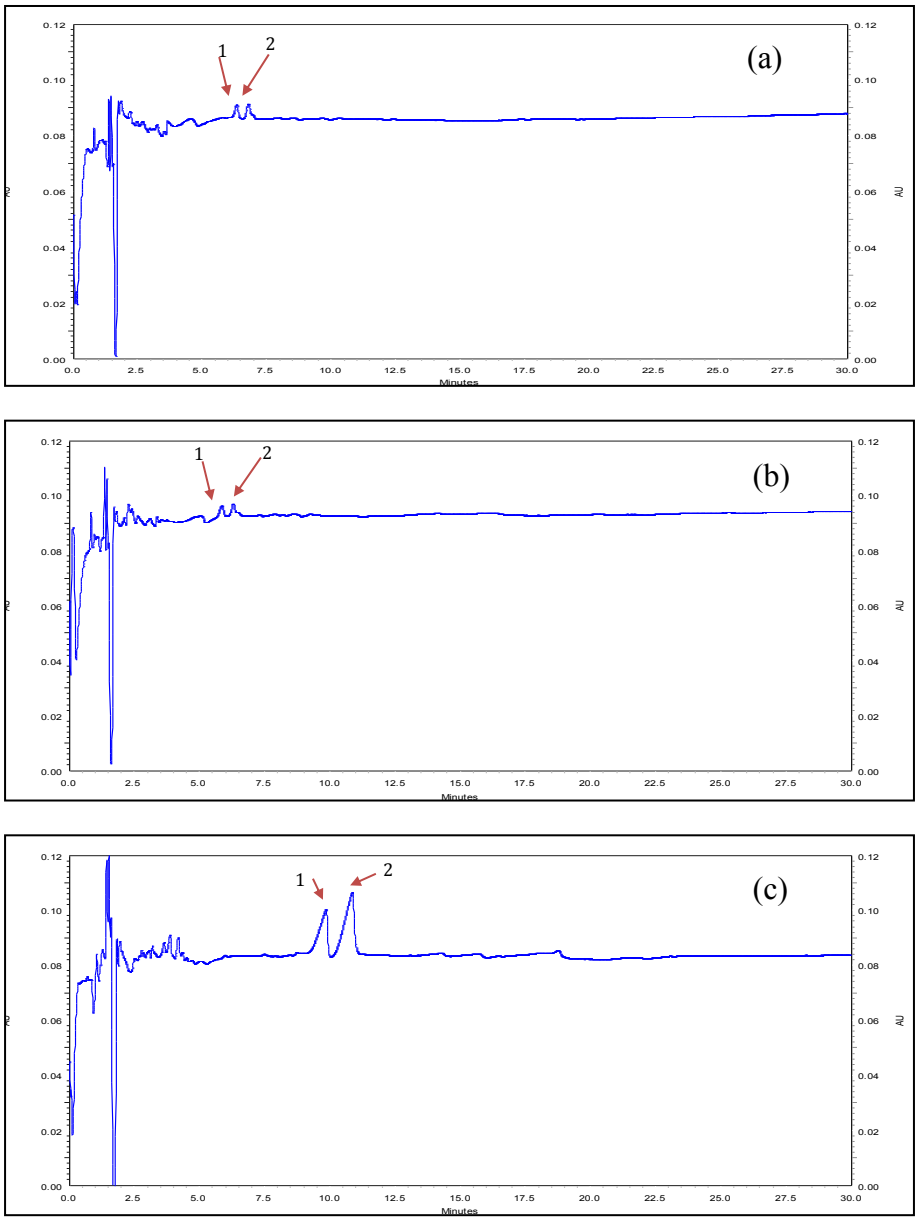

Figure 5. CE-UV electropherograms of lipopolysaccharides from Gram-negative bacteria (A) 055:B5; (B) E-Toxate™; (C) UT189. Running buffer: Tris/$Na_2B_4O_7$/EDTA (445 mM/445 mM/10 mM, pH 8.45). Applied voltage = 30 kV; injection time = 5 s. Capillary dimensions are indicated in experimental section

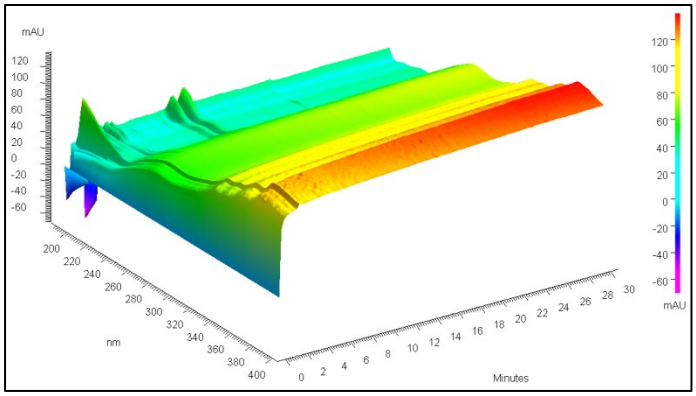

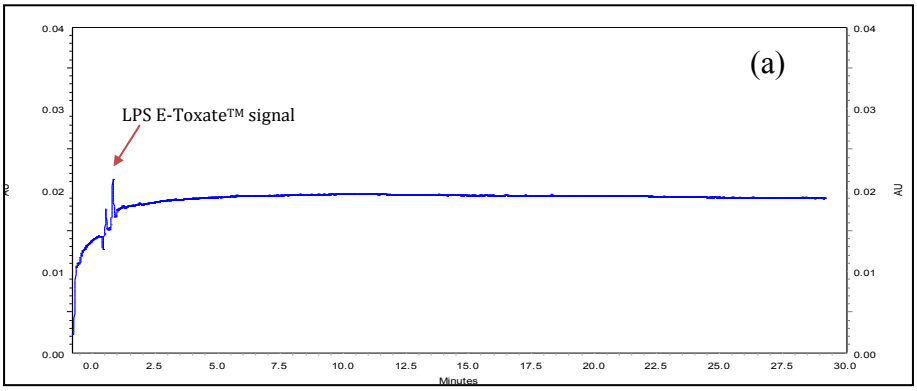

Figure 6. 3-D plot of electropherograms of E-Toxate™ LPS showing the maximum absorbance at 195 nm. Separation condition: buffer - Tris/ $Na_2B_4O_7$/EDTA 445 mM/445 mM/10 mM; pH 8.3. Applied voltage = 30 kV; injection time = 5 s. All other conditions are the same as stated in the experimental section

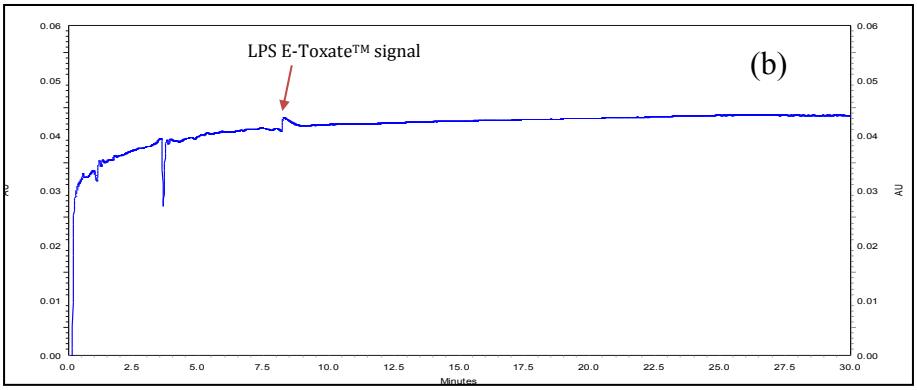
Venter et al. optimized the running buffer for LPS extracted from *E. coli* (source strain ATCC 25922) using 50 mM borate [19]. In our study, LPS E-Toxate™ was analyzed to check the effect of another surfactant, 1,4-diaminobutane (DAB), on the migration profile of the LPS. In Figure 7, results showed that after the addition of DAB the LPS signals are better resolved. The migration time increased from 1.52 minute to 8.53 minutes after the addition of DAB. This enhancement of resolution can be attributed to the shorter hydrophilic chain of DAB which allows greater interaction and promotes dispersion effect in the oligosaccharides chain of the LPS. Unlike PEO, DAB does not polymerize and form a macromolecule that can interfere with the dispersion of the repeating polysaccharide unit. With the increased London dispersion forces derived from a non-polar macromolecule, PEO exerts less interaction with the oligosaccharides, whose main intermolecular forces of attraction is H-bond. This undesired incompatible effect contrasts with that of DAB which interacts non-covalently primarily by H-bond, and as such it will minimize the aggregation of the sugar units at the *O*-polysaccharide segment. Unfortunately, the addition of DAB causes a significant impedance to the EOF, which results in longer analysis time.



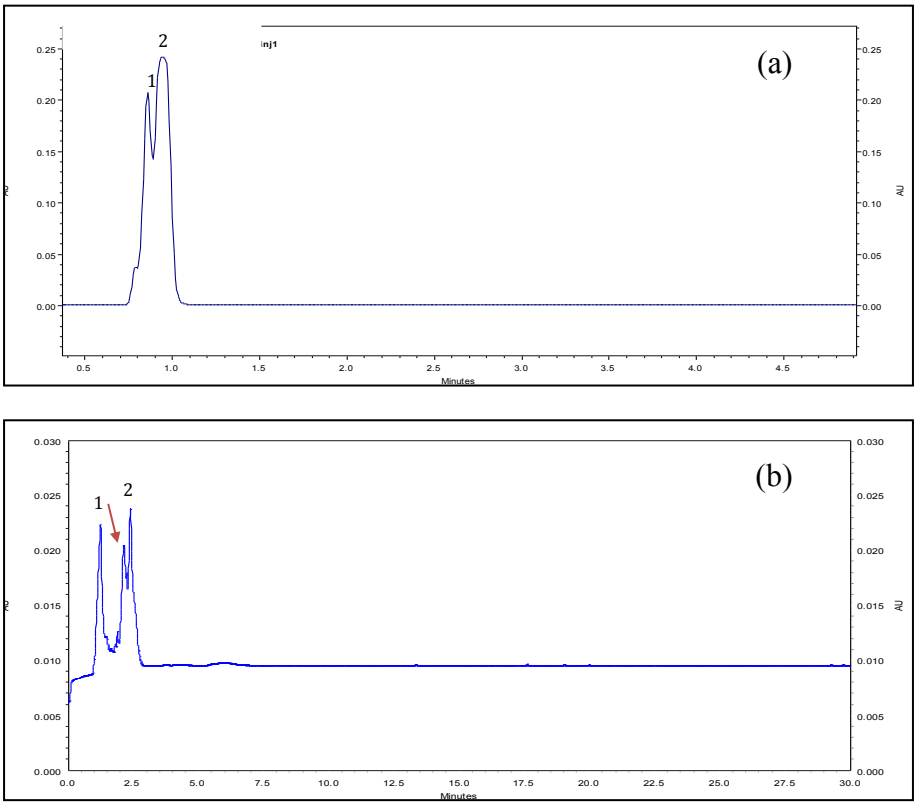


Figure 7. CE-UV electropherograms of lipopolysaccharides from E-Toxate™ (A) Running buffer: $Na_2B_4O_7$ (50 mM, pH 9.40); (B) Running buffer: $Na_2B_4O_7$/DAB (50 mM/10 mM, pH 9.11). Applied voltage = 30 kV; injection time = 5 s. All other conditions are the same as stated in the experimental section

In order to ascertain if SDS works better than DAB in borate buffer system, LPS extracted from *E. coli* 055:B5, E-Toxate™ and *Klebsiella pneumoniae* were analyzed by using SDS/$Na_2B_4O_7$ (40 mM/10 mM, pH 9.22). Figure 8 shows that the baselines for both electropherograms are more stable and exhibit a higher signal-to-noise ratio than that using DAB as the surfactant.

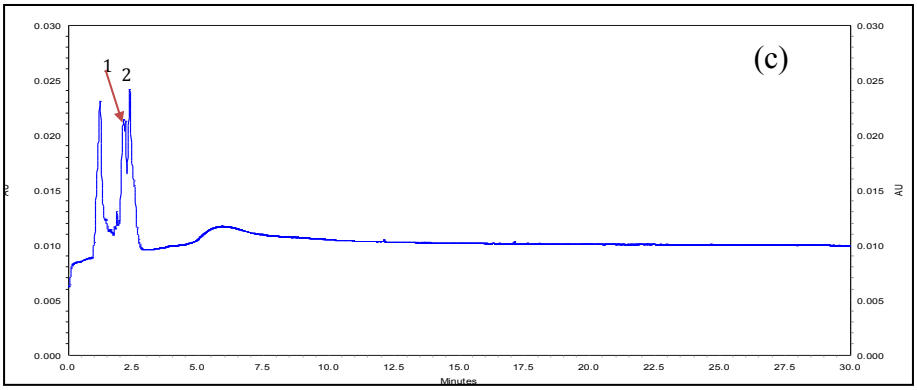

Figure 8. CE-UV electropherograms of lipopolysaccharides from Gram-negative bacteria (A) 055:B5; (B) E-Toxate™; (C) *Klebsiella pneumoniae*. Running buffer: SDS/$Na_2B_4O_7$ (40 mM/10 mM, pH 9.22). Applied voltage = 30 kV; injection time = 5 s. Capillary dimensions are indicated in experimental section

With the buffering system optimized using SDS/$Na_2B_4O_7$ (40 mM/10 mM, pH 9.22), LPS from *E. coli* 055:B5, *E. coli* K-235 and *Klebsiella pneumonia* were analyzed using the same conditions as in the experimental section, and their migration times, peak heights, and peak areas were determined. Each LPS analysis was conducted in triplicates and the results are summarized in Table 2 and Figure 9. The representative electropherograms from these three LPS also indicate the distinct similarity using CE-UV profiling, as shown in Figure 10. Each showing three prominent signals, with the first peak appearing at 1.30 minute, and an overlapping twin peaks at around 2.08 (±0.28) minutes, as shown in an enlarged scale in Figure 11.

The apparent data generated for each variant peak showed very good precision for migration time with percentage RSD values of ≤1.2% (n=3). Similarly, the percentage RSD for peak area values are ≤5.3% (n=3) across different LPS.

Table 2. Summary of data from electropherograms across three LPS types (concentration = 5.0 mg/mL in BGE)

| | | Peak 1 | | | Peak 2 | | |
|---|---|---|---|---|---|---|---|

## Conclusion

Optimization of the electrophoresis buffer was carried out for capillary electrophoresis-direct UV analysis of LPS from *E. coli* 055:B5, K-235, UT189, E-Toxate™, and Gram-negative bacteria *Klebsiella pneumonia*e. We have demonstrated three buffer systems that could provide consistent detectable signals for the separation of LPS. They are (i) Tris/Borate/EDTA (445 mM/445 mM/10 mM); (ii) SDS/$Na_2B_4O_7$ (40 mM/10 mM); (iii) $Na_2B_4O_7$/DAB (50 mM/10 mM). Reproducible electropherograms using the buffering system consisting of SDS/$Na_2B_4O_7$ (40 mM/10

mM, pH 9.22) were obtained for LPS from *E. coli* 055:B5, K-235 and Gram-negative bacteria Klebsiella pneumonia, with percentage RSD values of migration time ≤1.2% (n = 3). The percentage RSD values for peak area are ≤5.3% (n = 3) across different LPS. The optimized buffer system could provide potentially quantitative and qualitative analyzes of these LPS using capillary electrophoresis with direct UV detection.

**Abstract**

Endotoxins or lipopolysaccharides (LPS) are characteristic components of the outer cellular membrane of Gram negative bacteria, which are recognition targets of immune receptors and are responsible for inciting the bacteria's toxic effects. The toxicity and physiological effects of LPS varies diversely within and across different bacterial species. However, the current standard test for endotoxin analysis, the Limulus Amoebocyte Lysate (LAL) test, can only provide information on the presence of LPS, regardless of which bacteria the LPS is coming from. As implied from the name "lipopolysaccharide", LPS has a lipid and a carbohydrate portion. The carbohydrate component is further subdivided to the core oligosaccharide and the O-antigen polysaccharide chains, which are conserved within species and unique for each serotype, respectively. In this pilot study, we fingerprinted the oligosaccharide units generated from mild acid hydrolysis of the LPS from some serotypes of *Escherichia coli* and *Salmonella*, as well as from *Serratia marcesens* using liquid chromatography coupled to a high resolution mass spectrometer (LC-MS) after labelling them to improve MS ionization. Multivariate analysis showed distinct clustering of samples belonging to each bacterial species and revealed certain features that can be potential species and serotype-specific markers of LPS from the different bacteria under study.

**Abstrak**

Endotoksin atau lipopolisakarida (LPS) adalah komponen teras membran selular luaran bakteria Gram negatif yang bertindak untuk mengenalpasti sasaran reseptor imun dan bertanggungjawab menguatkan kesan toksik bakteria tersebut. Terdapat perbezaan dalam ketoksikan dan kesan fisiologi LPS di dalam dan antara spesies bakteria yang berbeza. Walau bagaimanapun, ujian piawai semasa bagi analisis endotoksin, ujian Limulus Amebosit Lisat (LAL), hanya boleh memberikan maklumat mengenai kehadiran LPS tanpa mengira bakteria sumber asal LPS tersebut. Nama lipopolisakarida juga menunjukkan bahawa LPS mempunyai lipid dan sebahagian unsur karbohidrat. Komponen karbohidrat juga terbahagi kepada oligosakarida teras dan rantai polisakarida O-antigen, yang terpelihara di dalam spesies dan unik untuk setiap serotip yang hadir. Dalam kajian rintis ini, kami mengenalpasti unit oligosakarida yang dihasilkan daripada hidrolisis asid lemah LPS dari beberapa serotip dari *Escherichia coli*, *Salmonella* dan juga *Serratia marcescens* menggunakan kromatografi cecair digunakan bersama spektrometri jisim resolusi tinggi (LC-MS) selepas proses pelabelan untuk meningkatkan pengionan MS. Analisis multivariat menunjukkan kelompok tertentu sampel yang datang dari setiap spesies bakteria dan mendedahkan ciri – ciri tertentu yang boleh menjadi spesies yang berpotensi dan penanda serotip spesifik LPS dari bakteria yang berbeza di bawah kajian.

**Kata kunci**: endotoksin, lipopolisakarida, oligosakarida cap jari, kromatografi cecair – spektrometri jisim

## Introduction

Endotoxins or lipopolysaccharides (LPS) are characteristic components of the outer cellular membrane of Gram negative bacteria. In the event of a bacterial infection, they are the recognition targets of the innate immune system and they are responsible for the toxicological effect of the bacteria [1]. When immune cells recognize their presence upon binding, the inflammatory response of the body will be triggered to resolve the infection. However, if the infection is overwhelming, complications may arise such as the development of endotoxic shock [2]. This can lead to multiple organ failure and can be fatal.

LPS is mainly composed of a lipid and a carbohydrate part, thus the name "lipopolysaccharide". Generally, its structure is divided into three main parts: the lipid A, the core oligosaccharide, and the O-polysaccharide or O-antigen chain. The lipid A is made up of ester or amide-linked fatty acid chains of varying lengths that is conserved for each bacterial species and is known to be the active part responsible for the bacteria's toxicity. Changes in its structure can affect the activity of the endotoxin. The core oligosaccharide is further subdivided into an inner and outer core. The inner core mainly consists of unusual sugars such as 3-deoxy-D-manno-octulosonic acid (Kdo) and L-glycero-D-manno-heptose. The outer core consists of more common sugars such as hexoses and hexosamines. The core oligosaccharide is mostly conserved within bacterial species. Lastly, there is the O-polysaccharide or O-antigen chain. It consists of repeating subunits of carbohydrate chains with varying lengths having high specificity for each serotype of the same species. It is the part that binds with immune receptors and induces the antigenic effect, thus the name O-antigen [1, 3]. It can be seen that there is great diversity in the structure of the LPS among different bacterial species and even within the same species. This diversity also results in different innate immune response, different degrees of toxicity, and trigger of different physiological responses to individuals [4].

The current gold standard for LPS analysis is the *Limulus* amoebocyte lysate (LAL) test. The test is based on the agglutination of the amoebocyte lysate obtained from horseshoe crab in the presence of endotoxins. Other methods of endotoxin analysis include rabbit pyrogenic testing, cell and antibody binding assays, molecular binding biosensors, and recombinant bacteriophage binding [5]. For tests like LAL and rabbit pyrogenic testing, there is a concern on sustainability due to their use of animals. Most of these tests are highly sensitive and quantitative. However, they are also mostly non-specific methods of endotoxin detection. They only determine and measure the amount of endotoxin present but do not provide information as to what bacterial species or serotype the endotoxin comes from. On the other hand, there are also assays and biosensors that are highly specific to certain serotypes, thus requiring multiple assays in order to detect the presence of different species and serotypes. Given that different LPS can induce different antigenic and toxicological effects, there is a need for species and serotype-specific determination of LPS.

Chemical fingerprinting has been used in different fields of application for purposes of quality control, authentication, and origin identification [6]. It is based on the understanding that different organisms, species, and even those of the same species raised in different conditions will have their own unique molecular profiles. It can be done using different compounds ranging from DNA to small molecule metabolites and using different analytical platforms. Mass spectrometry (MS)-based analysis are commonly used in fingerprinting as they provide high sensitivity and compound identity information based on mass and fragmentation data. MS analysis is usually coupled with separation techniques such as gas chromatography (GC), liquid chromatography (LC) or capillary electrophoresis (CE) in order to further improve specificity by resolving isomers and increase sensitivity by reducing the number of analytes detected at any given time that may otherwise suppress or interfere with each other. Given that the carbohydrate component of bacterial LPS provides both species and serotype information, we explore the feasibility of fingerprinting different LPS based on their oligosaccharide features.

## Materials and Methods

### Chemicals

The LPS standards of *Salmonella enterica* serotype abortus equi, *Salmonella enterica* serotype minnesota, *Salmonella typhosa*, *Serratia marcesens*, *Escherichia coli* O55:B5, and *Escherichia coli* K-235 were all purchased from Sigma-Aldrich (St. Louis, MO, USA). The reagents 7-(diethylamino) coumarin-3-carbohydrazide (CHH), as well as LC-MS grade formic acid, acetic acid, ammonium formate, and acetonitrile (ACN), were also purchased

from Sigma-Aldrich. Ultrapure water (18.2Ω) was obtained from an UltraClear TWF water purification system by EvoQua (Fahrenberg, Germany).

**Sample preparation**

Each sample of LPS standard was weighed (0.20 ± 0.05 mg) into a centrifuge vial and subjected to mild acid hydrolysis in order to remove the lipid A component. Mild acid hydrolysis was performed by adding 100 µl of 1% acetic acid to the sample followed by heating for 1 hour at 90 ˚C. The samples were then centrifuged, the supernatant was taken and freeze dried. The samples were kept in -80 ˚C until labelling and analysis. The samples were then labelled based on a modification of the method reported by Milic et al. for CHH labelling [7]. Briefly, a volume of 100 µl of 2 mg/ml CHH in 50% ACN was added to the dried LPS hydrolysate. The samples were then incubated in the dark for 3 hours in a temperature controlled shaker at 37 ˚C. All LPS standards were prepared and analyzed in triplicates.

**LC-MS analysis**

The LC-MS analysis was performed using a Dionex Ultimate 3000 RSLC system (Thermo Fisher Scientific, USA) coupled to an AB Sciex Triple TOF 5600 MS (Sciex, USA). Chromatographic separation was done using a Glycan BEH Amide column (Waters, USA) with dimensions of 2.1 x 100 mm and particle size of 1.8 micron. The mobile phase solvents used were 50 mM ammonium formate (pH 4.5) in water (A) and acetonitrile (B), with an initial flow rate of 0.4 ml/min. The gradient program employed for the separation was as follows: 85% B to 50% B for the first 25 minutes, 50 to 30% B from 25 to 27 minutes with a reduction in flow rate to 0.2 ml/min, 0% B at 28 minutes to 30 minutes with flow rate increased to 0.4 ml/min at the end of this step, 0 to 85% B from 30 to 31.5 minutes, and lastly, equilibration for 6.6 minutes. Data acquisition was done in positive electrospray ionization mode. The mass range scanned was from 100 to 2500 Dalton (Da) with an accumulation time of 0.2 second. The nebulizer and heater gases were set at 45 and 50 psi, respectively, the curtain gas was at 30 psi, heater temperature at 450 ˚C, and the ion spray voltage was set to 5,000 volts (V). The declustering potential (DP) was set at 80 V and collision energy (CE) was at 10 V. MS/MS data was obtained using information dependent acquisition (IDA) wherein the 10 highest intensity ions per cycle were subjected to product ion scan at collision energy (CE) of 35 V with CE spread of 15 V. Automated mass calibration was done every three hours using the AB Sciex APCI positive calibration solution (Sciex, USA).

**Data processing and analysis**

The MS data acquisition files were converted to mzXML format using MSConvert (Proteowizard). The files were then uploaded to XCMS online for retention time alignment, peak picking and annotation. The resulting data matrix was exported to Excel for further processing. Peaks common with the reagent blank were removed from the dataset as well as identified isotopic signals. Median normalization was performed to ensure comparability of all samples by reducing the effects of variations from sample weighing and changes in the sensitivity of the instrument through time. All values were log 2 transformed to reduce the effects of variations in high intensity variables and prevent them from masking the contributions of lower intensity variables. Multivariate analysis was performed using SIMCA P+ 12 (MKS Umetrics, Sweden). Principal Components Analysis (PCA) was performed to identify inherent clustering of samples or presence of trends and identify possible outliers. Supervised analysis was also performed using Orthogonal Projection to Latent Structures- Discriminant Analysis (OPLS-DA). Features that are either species or serotype-specific were identified by looking at the contributions plot of the OPLS-DA model.

## Results and Discussion

In this pilot study, we looked at the oligosaccharide fingerprints of two serotypes of *Escherichia coli* (EC O55:B5 and EC K-235), two serotypes of *Salmonella enterica* (minnesota and abortus equi, SEM and SEA), *Salmonella typhosa* (ST), and *Serratia marcesens* (SM). Most carbohydrates do not have functional groups that can be easily used for their detection and they are also not easily ionisable for MS detection. They can be analyzed in negative ionization mode under highly basic conditions but with lower sensitivity. Thus, they are usually derivatized or labelled with moieties that will aid in their detection [8]. Fluorescent reagents like 8-aminopyrene-1,3,6-trisulfonic acid (APTS) and MS ionisable reagents like 2-aminobenzoic acid (2-AB), 2-anthranilic acid (2-AA), and more recently, RapiFluor MS [9], are used to label sugars for detection. However, such reagents require reductive amination in order to react the reducing sugar moiety with the label. It requires the use of a highly toxic reagent,

sodium cyanoborohydride, and an SPE clean-up step. There are also labelling reagents that can react directly with the reducing sugar moiety via hydrazone formation, such as 2-(4-phenethylphenyl)acetohydrazide [10], which allows simpler sample preparation for MS analysis. For this project, we tried the use of a common fluorescent reagent, 7-(diethylamino)coumarin-3-carbohydrazide (CHH) for the labelling of the oligosaccharides via hydrazone formation and subsequent MS detection. It has been previously reported for use in MS analysis of carbonylated lipids [7] given that it can react readily with aldehydes and ketones via the hydrazide moiety and have good ionization in MS with the tertiary amine moiety. We hypothesize that we can also use it to easily tag the reducing sugar moiety of the oligosaccharides and be used for MS analysis of the oligosaccharides. Furthermore, it can also be used for fluorescence detection.

Figure 1 shows the total ion chromatogram (TIC) of the different LPS samples analyzed. It can be seen that each LPS has its own distinct profile. In the chromatographic dimension, there are peaks that appear at the same retention time across different species and serotypes. The use of MS adds another dimension of resolution by differentiating the components eluting at the same retention time based on mass. While this offers better specificity, it also produces a complex data matrix with high dimensionality. Multivariate statistical analysis, commonly used to analyze such data matrices and reveal useful information [11], was used in this study to analyze the complex data matrix.

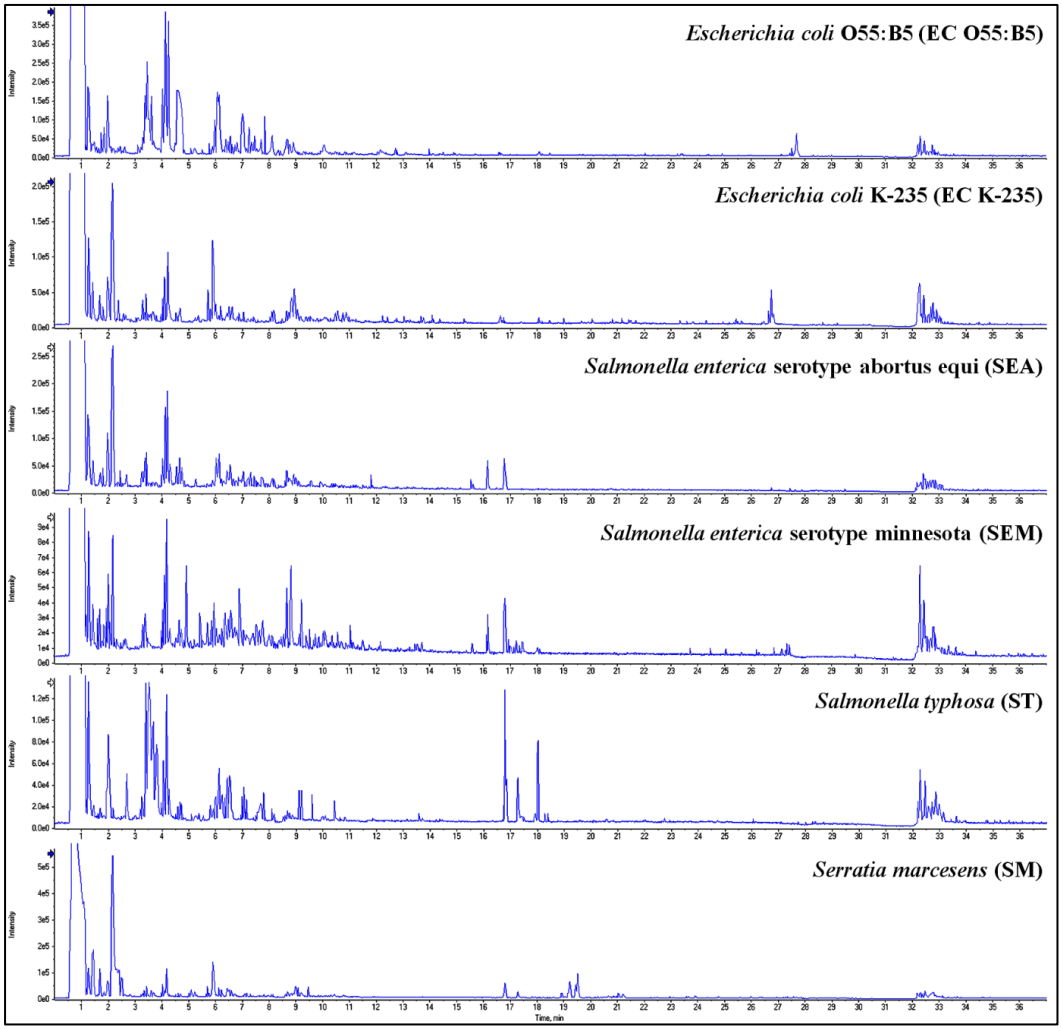

Figure 1. TIC of the different LPS samples labelled with CHH

PCA was used to reduce the high dimensionality of the data to a few components that can account for the variance across the samples. This allows for visualization of inherent groupings and trends in the data. The PCA model generated has a cumulative $R^2X$ value of 0.833 and cumulative $Q^2$ of 0.499. The cumulative $R^2X$ represents the fraction of variation from all the variables (X) that can be explained by the components of the model. The cumulative $Q^2$ is the fraction of the variation that can be predicted by the model through cross-validation using a "leave-one-out" approach [12]. Both serve as measures of the quality of the model. A good model should have $R^2X$ close to 1 with the $Q^2$ approaching or close to the $R^2X$ value. The model has a good cumulative $R^2X$ but low $Q^2$. This can be an indication of the presence of unwanted variance from the variables affecting the model. OPLS-DA, a supervised multivariate analysis technique, can be used to take out the variance that is not related to the class information by putting them into orthogonal component/s and maximize the separation between sample groups (classes). The OPLS-DA model of the dataset has a cumulative $R^2X$ of 0.838, $R^2Y$ of 0.99 and a $Q^2$ of 0.928. $R^2Y$ represents the fraction of variation related to the class information (Y) that can be explained by the components of the model. $Q^2$ in this case, represents variation of Y that can be predicted by the components of the model and it should be as close as possible to the $R^2Y$ [12]. High values of $R^2X$, $R^2Y$, and $Q^2$ show that a good model has been obtained. Cross validation was also done using CV-ANOVA resulting in a p value of $2.35x10^{-12}$ (p value <<< 0.05) showing the high reliability and significance of the model.

Figure 2 shows the score plots of the samples using PCA and OPLS-DA. There is good clustering of the samples for each LPS standard in both plots, indicating good reproducibility of the fingerprints. It can also be observed that the *E. coli* serotypes, EC O55:B5 and EC K-235 are mainly in the lower quadrant, whereas the *Salmonella* species and serotypes, ST, SEA, and SEM, are in the upper quadrant. *Serratia marcescens* (SM) samples are in the middle, between the upper and lower quadrants. It can also be seen that SEM and SEA cluster closer together away from ST, confirming the ability to distinguish species within the same genera using the oligosaccharide features.

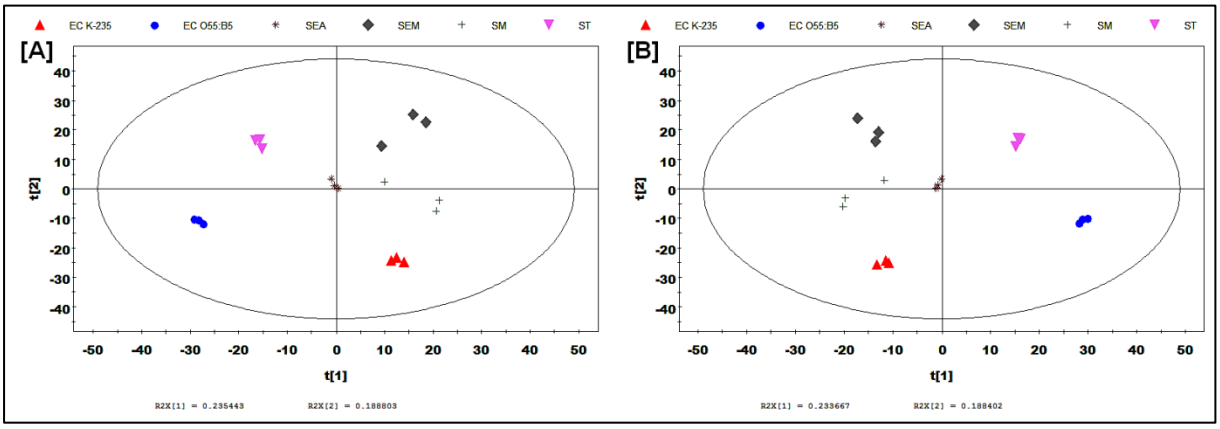

Figure 2. (a) PCA score plot showing the distinct clustering of the LPS samples from different bacterial species and serotypes, and (b) OPLS-DA score plot of the samples

Identification of variables distinct to each serotype and species were identified by looking at contribution plots of the OPLS-DA model. Contribution plots are used to visualize how an observation or group is different from others in model. It displays the differences in scaled units of the observation or group compared to the average of the rest for all variables of the model. Variables with score contribution greater than two were identified as potential species or serotype-specific oligosaccharide feature. This is confirmed by looking at the variable plot for the identified variables. Represented in Figure 3 is an example of a contribution plot showing the variables differentiating SM from the other LPS. The differentiating features are those variables whose scores are above the contribution score cut-off (orange line). The MS and MS/MS information obtained from these species and serotype- differentiating features can be used to develop targeted multiple reaction monitoring (MRM) analysis that will allow the simultaneous determination of LPS coming from different bacterial species and serotypes.

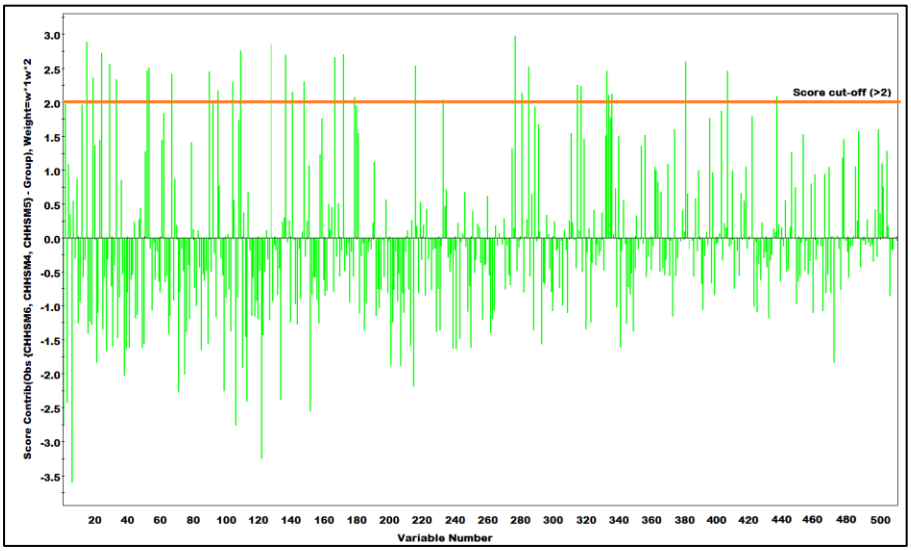

Figure 3. Contribution plot for *Serratia marcesens* (SM)

During the identification of species and serotype-specific features, it was noted that the MS/MS spectra of some of these oligosaccharide features do not have the reporter ions of CHH-labelled compounds (m/z 276 and 244, Figure 4a) [7]. Instead, their MS/MS spectra showed the presence of characteristic HexNAc ions (m/z 204 and 168, Figure 4b) [13], indicating that these oligosaccharide features are unlabelled oliogosaccharides having N-acetylamine moieties. While it is good that such distinct oligosaccharide features can be identified and differentiated based on their characteristic fragmentation pattern, this still highlights the need for further investigation and optimization of the labelling conditions.

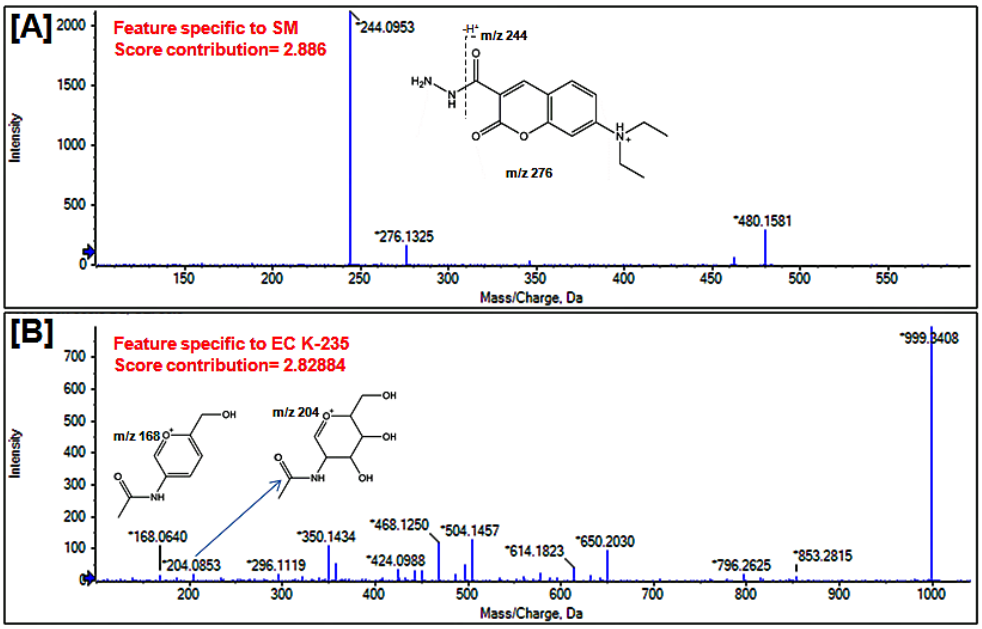

Figure 4. Sample MS/MS spectra of identified distinct oligosaccharide features

## Conclusion

The results of the study demonstrated the feasibility of using oligosaccharide fingerprinting for the species and serotype-specific determination of LPS. Good reproducibility of fingerprints has been obtained across the different bacterial species and serotypes, as shown by the good clustering of samples in the multivariate analysis models. Presence of unlabelled oligosaccharides was found from MS/MS data warranting further improvements in the labelling method. Identified species and serotype-specific oligosaccharide features from the fingerprinting can be used for the development of a targeted method for the simultaneous determination of LPS from different bacteria. It is hoped that this can eventually be used for different applications such as in environmental water and air monitoring, as well as in clinical settings.

**Abstract**

A surface plasmon resonance (SPR) sensor based on molecularly imprinted polymer (MIP) was developed for fast detection of chemical threat agents (CTAs) in water. A portable SPR platform provided a very compact-size (L*W*H of 8.5*4.5*4.5 inch) system and the SPR sensor chip was fabricated by a facile process with an inexpensive coating of silver as the SPR material, making possible the sensor chip as a disposal sensor. Using methyl parathion as the simulant of CTA, the developed SPR sensor with the recognition site showed apparent SPR signal than Non-imprinted polymer (NIP) counterpart, suggesting the excellent recognition of the targeted molecules. It also provided a fast responding within 5 minutes with the limit of detection of sub-ppm level.

**Keywords**: molecularly imprinted polymer, surface plasmon resonance, organophosphorus pesticide, chemical threat agents

**Abstrak**

Sensor permukaan plasmon resonans (SPR) berdasarkan polimer molekul tercetak (MIP) telah dibangunkan bagi pengesanan pantas ejen ancaman kimia (CTAs) di dalam air. Sistem platform SPR mudah alih bersaiz padat disediakan (L*W*H 8.5*4.5*4.5 inci) dan cip sensor SPR telah diubahsuai melalui proses mudah dengan salutan murah perak sebagai bahan SPR, menjadikan cip sensor sebagai sensor mudah dilupuskan. Menggunakan parathion metil sebagai sasaran CTA, sensor SPR yang telah dibangunkan dengan bahagian yang dikenalpasti itu menunjukkan isyarat jelas daripada SPR berbanding polimer tak tercetak (NIP), menunjukkan pengenalpastian baik bagi molekul yang disasarkan. Ia juga memberi respons yang cepat dalam masa 5 minit dengan had pengesanan pada aras sub-ppm.

**Kata kunci**: polimer molekul tercetak, permukaan plasmon resonans, racun perosak organofosforus, agen kimia berbahaya

## Introduction

The emerging concerns of terrorists using Chemical Threat Agents (CTAs) has been on the rise which has urged the governments to ensure the water safety before consumption [1, 2]. Organophosphorus compounds (OPs) is used as the simulant of a type of chemical threat agents- nerve agents. The current monitoring method includes gas chromatography-mass spectrometry [3], liquid chromatography-mass spectrometry [4] and micellar electro-kinetic capillary electrophoresis coupled with laser-induced fluorescence (MEKC-LIF) detector [5]. However, these

instruments involved in the monitoring are usually bulky in size, and highly expensive and require highly trained technicians to run the samples, which hinders the application of on-line or on-site monitoring [6]. An alternative monitoring technique is surface plasmon resonance (SPR), which is a phenomenon that occurs when the incident light on a metal film induces the propagation of electron density waves parallel to the metal-dielectric medium interface [7, 8]. SPR system is relatively low-cost and only requires a simple optical setup, rendering a high potential to be suited for on-line/on-site monitoring [9-11].

The recognition of specific CTA molecules requires a highly selective material to provide such capability. Due to their easy synthesis procedures, low cost, and chemical and physical stability in harsh environments, MIPs provide a simple and cost-effective way to fabricate selective recognition elements suitable for chemo-sensors and biosensors [12]. Preparation of MIPs usually involves copolymerizing the template molecule and functional monomers (serving as ligands) with a cross-linker under suitable conditions. The type of cross-linker used influences the morphology of the polymer matrix, and stabilizes the recognition sites. During polymerization, the template and functional monomers will interact and self-assemble to form a polymer network. The MIP will be coated on the silver film of the glass sensor chip with silver film and the template molecule is then removed from the polymer matrix to create complementary three-dimensional cavities for the template. SPR sensors coupled with MIP has been successfully applied in analysing endotoxins [13], waterborne virus [14] and dyeing agents [15] in water.

In this study, an SPR sensor is presented using MIP as the recognition sites for the detection of CTA simulant parathion-methyl. Silver is selected as the SPR coating material since it is known to be more sensitive to changes in refractive indices [16] and reflects more distinctive plasmon resonance bands than gold [17]. The potential of on-line/on-site application of the developed SPR sensor is further discussed.

## Materials and Methods

### Reagents and materials

Analytical grade Parathion-methyl and functional monomer methacrylic acid (MAA) (99%) were purchased from Sigma-Aldrich (Singapore). Absolute ethanol solvent was obtained from VWR Singapore Pte Ltd. and of analytical grade. Initiator 2, 2-azobis (2-methylpropionitrile) (AIBN) (99%) was purchased from Sinopharm Chemical Reagent Co. Ltd. (China) while cross-linker divinylbenzene (>50%) was purchased from Tokyo Chemical Industry Co. Ltd. (Japan). Deionised water (18.2 MΩ, ultrapure) was purified using Milli-Q Integral Water Purification System from Merck Millipore while the index matching oil ($\eta$=1.65) used was provided by PhotonicSys Ltd. (Israel).

### Apparatus and instruments

The SPR system and SPR analysis software (Version: Feb 2016) were from PhotonicSys Ltd. (Israel) and the 40-nm silver film sensor chips were sputter-coated and prepared by the company. The SPR system, as shown in Figure 1, is compact in size with L*W*H of 8.5*4.5*4.5 inch. It uses a diverging laser beam as the light source to illuminate the entire sensor surface in Kretschmann-Raether configuration [18, 19]. A CCD detector is employed to monitor the pattern of dark intensity line on bright background which is corresponding to the SPR dip at an angular range depending on the refractive index of the adjacent analyte [20]. A high precision of SPR signal is subsequently achieved by a forward-projection algorithm based on Radon transform for two-dimensional surface plasmon imaging [21].

For ultra-sonication, the Elmasonic S30H sonicator used was obtained from Elma Schmidbauer GmbH (Germany). The LM530R orbital shaking incubator utilized was purchased from Yihder Technology Co. Ltd. (Taiwan) while the FINEVORTEX vortex mixer was obtained from FINEPCR (South Korea).

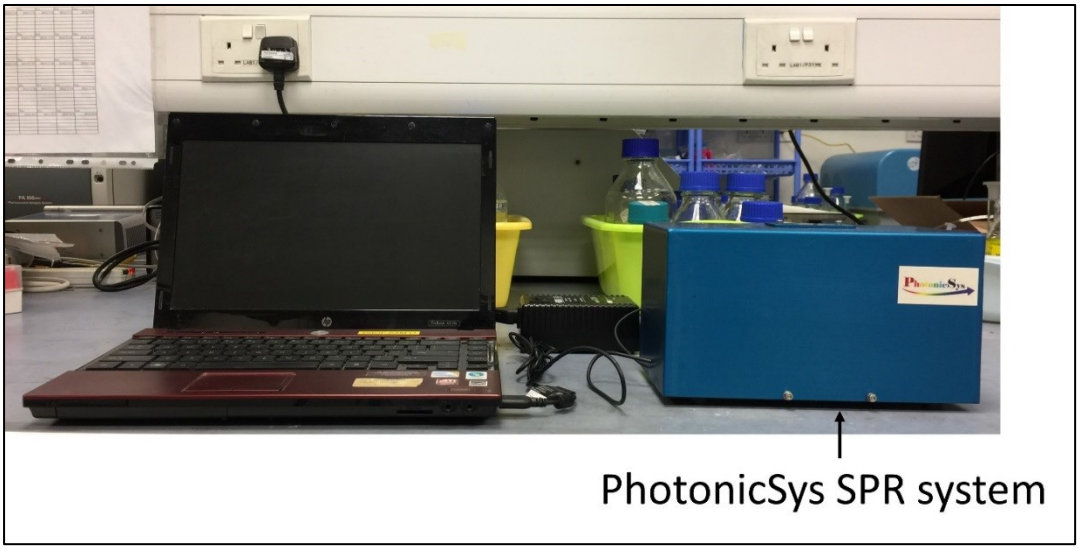

Figure 1. Photo of SPR instrument from PhotonicSys Ltd. connected to a notebook computer via USB

**Preparation of MIP sensor chips**

The MIP polymer comprises four components: MAA as functional monomer, DVB as cross-linker, AIBN as radical initiator and parathion methyl as template molecules. The mechanism behind MIP recognition is based on a combination of bonding. The carboxylic acid in MAA provides hydrogen-bonding donor, while DVB offers better stability of polymer rigidity and hydrophobic interaction with the template molecules.

Molecularly imprinted polymer was prepared by mixing 40 µL of 0.1 M parathion-methyl, 5 µL of MAA, 25 µL of DVB and 0.5 mg of AIBN in 1.5 mL centrifuge tube with 100 µL absolute ethanol. The mixture was ultra-sonicated for 10 minutes to allow thorough mixing. Subsequently, 10 $\mu$L of the MIP solution was drop-coated on a silver sensor chip, which was placed in the oven at 60 ˚C for 6 hours to allow polymerization.

The MIP chip was then soaked in absolute ethanol and left in the orbital shaker for overnight (8-10 hours) to remove the template parathion-methyl molecule from its binding sites in the polymer matrix, shown in Figure 2. The MIP chip was stored in absolute ethanol before measurement to prevent degradation and oxidation of the silver layer. Non-imprinted polymer (NIP) sensor chips were prepared using the same preparation method but without template parathion-methyl.

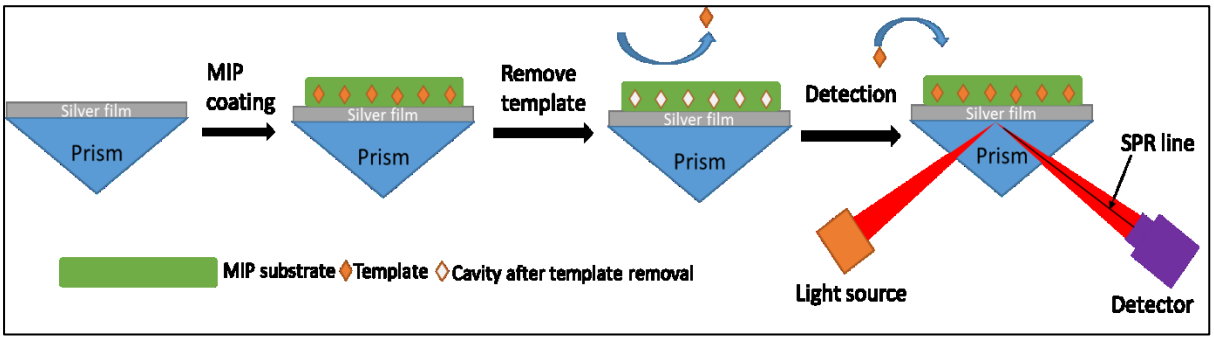

Figure 2. Schematic representation of MIP sensor design

**Preparation of sample solutions**

A 100-ppm parathion methyl solution was prepared by diluting stock solution into a 100-mL volumetric flask with ultrapure water made up to the 100-mL mark. All sample solutions (10 mL each) were prepared accordingly by diluting appropriate volumes of the stock solution in centrifuge sample tubes.

**SPR sensing procedure**

The SPR sensing procedure included the following steps, as illustrated in Figure 3. Firstly, SPR prism was wiped and cleaned with ethanol to remove any dirt or oil residuals. A small amount (approx. 50 µL) of RI matching oil was then applied on the prism. The MIP sensor chip was rinsed with ethanol and followed by deionised water before drying with nitrogen gas.

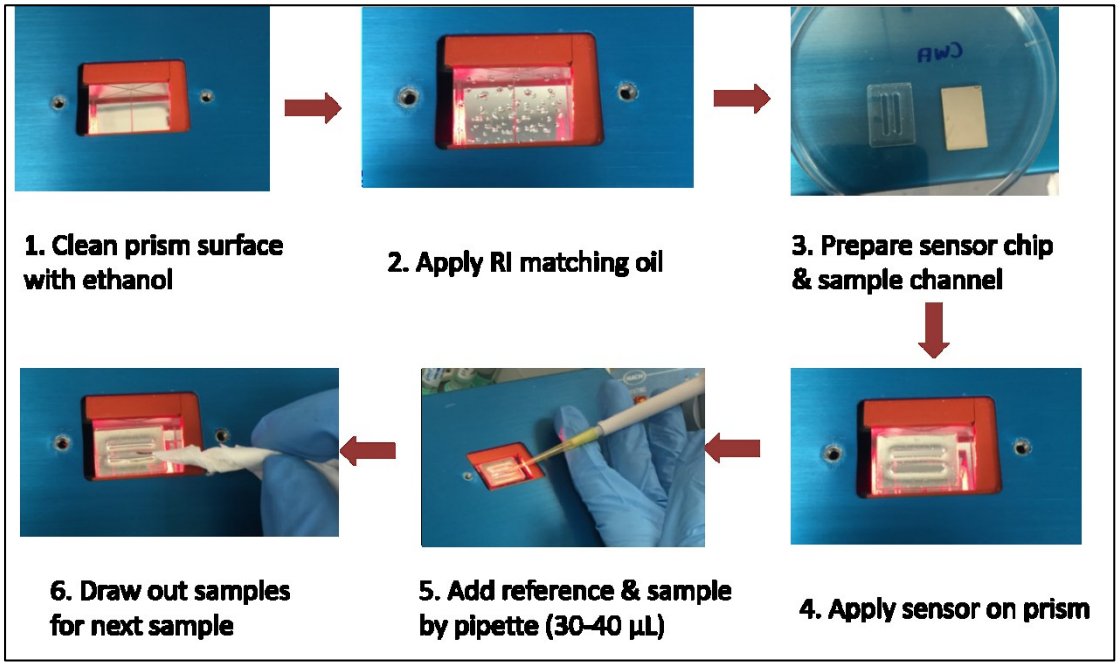

Figure 3. Experimental operation of SPR sensing

The MIP chip was mounted onto the prism by firstly placing the chip on its edge over the prism then carefully lowering it in place using a pair of forceps. It was important to ensure that no dark regions or lines were observed from the camera image. A polydimethylsiloxane (PDMS) sample holder with two identical channels was subentry applied onto the MIP sensor chip and gently pressed to form a sensing substrate.

A reference solution (deionised water) and a sample solution with 30 – 40 µL were added into left and right channels. The channels were rinsed thrice with the respective solution before measurement. The regions of interest (ROIs) were defined by choosing the rectangle cursor and draw the ROI rectangle around the dark line. After each measurement, the solutions were drawn out by a tissue paper on the edge of the channels before adding a new solution.

The software interface allowed the user to view real-time images of the plasmon resonance bands and perform runs based on the difference in RI between the analyte and reference against time [22]. The sensing performance was highly dependent on the image sensor and thus it required optimisation before measurements. The optimised values for image sensor of SPR system was shown in Table 1.

Table 1. Attributes and their respective values of image sensor

| Attributes | Value |
|---|---|
| Brightness | 67 |
| Contrast | 1.28 |
| Exposure | 0.0625 |
| Focus | 50 |
| Gain and saturation | 0 |
| Sharpness | 39 |
| White Balance | 3000 |
| Zoom | 100 |

**Characterization of MIP and NIP**

Both MIP and NIP were soaked in ethanol under same conditions to remove unreacted reagents and dried in a vacuum oven. The respective polymer was then mixed and ground with KBr in 0.99% w/w before being pressed into a transparent pellet. FT-IR spectra were collected using ALPHA FTIR Spectrometer (Bruker). The key infrared peaks for MIP included 3018 $cm^{-1}$ (alkene), 2960 $cm^{-1}$ (alkane), 2925 $cm^{-1}$ (carboxylic acid), and 1700 $cm^{-1}$(carbonyl), while key peaks for NIP included 3019 $cm^{-1}$ (alkene), 2960 $cm^{-1}$ (alkane), 2926 $cm^{-1}$ (carboxylic acid), and 1699 $cm^{-1}$ (carbonyl).

## Results and Discussion

**Detection time**

The SPR sensor in this study was a static-mode sensor which depended on the diffusion of targeted molecules into the cavity of MIP through either binding or space or both interactions. Figure 4a illustrates a real-time image of the SPR sensor of two channel signals. On the left was SPR image of deionised water as the reference, while on the right was SPR image of parathion-methyl as the analyte. Figure 4b is an example of equivalent time of RI signal of the detection of 8 ppm parathion methyl. RI signal increased until it reached a plateau at 300 seconds, i.e. 5 minutes. Similar RI response patterns were observed; therefore 5 minutes was chosen for each test.

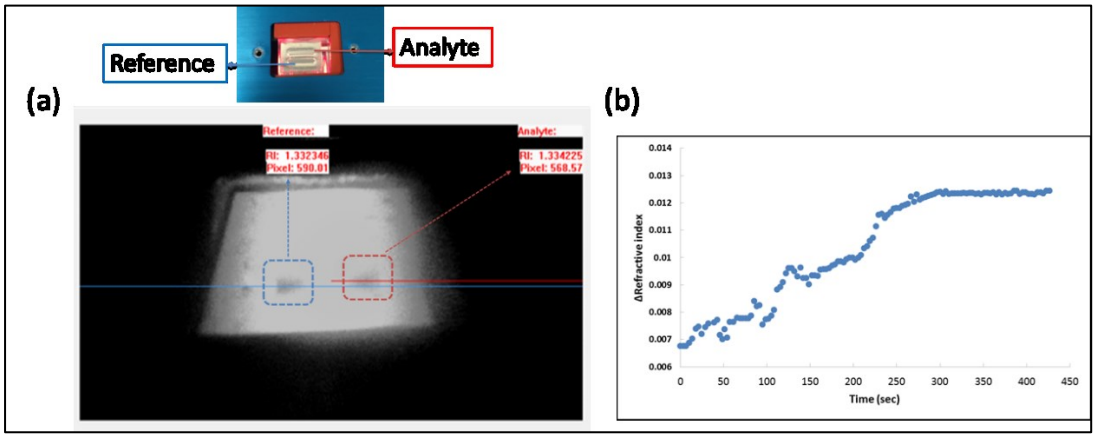

Figure 4. (a) Real-time image of SPR sensing of parathion-methyl and (b) refractive index response relative to time with 8 ppm parathion methyl

**Detection of parathion methyl**

The wavelength of light or the incidence angle at which the SPR is excited, are strong functions of the refractive index of the dielectric medium adjacent to the metal surface, i.e. silver film. The dielectric medium can be a fluid such as water or any other fluids with varying refractive index (RI) due to variations in the concentration in water [22]. The current version of the PhotonicSys SPR system can detect down to $10^{-6}$ refractive index units (RIU).

Different concentration of parathion-methyl was prepared and spiked into water samples before measurements. The RI of molecularly imprinted polymers sensing and non-imprinted polymers sensing were compared. As can be seen from Figure 5, non-imprinted polymer (NIP) showed no apparent signal changes from low concentration to high concentration, whereas MIP showed increased SPR signals (ΔRI) from 2 ppm to 30 ppm and a plateau was observed above 30 ppm. As such, the linear range for the developed SPR sensor was determined to be 2 – 30 ppm with a good correlation ($R^2$ = 0.8783). The limit of detection (LOD), based on the standard deviation of the response and the slope, was calculated to be 13.8 ppm from the calibration curve.

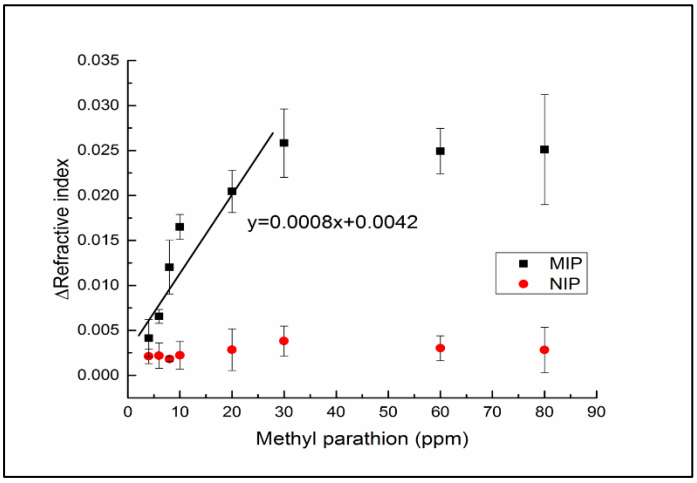

Figure 5. SPR refractive index responses on both imprinted molecular polymer (MIP) and non-imprinted polymer (NIP) toward the injection of different concentrations of methyl parathion in water

## Conclusion

A fast responding (~5 min) SPR sensor based on MIP recognition for the detection of CTA simulant methyl parathion in water has been developed successfully. Due to the portability and fast responding capability, the MIP sensor can be easily deployed for on-site/on-line detection of toxic compounds in water. This method can be easily transferred to measure other organophosphorus compounds in water by adding the organophosphorus compounds as MIP templates. Improvement of sensitivity of SPR sensor can be improved by a flow SPR system. In contrast to the static system, where the interaction is only dependent on the diffusion, a flow SPR system will provide an ever-refreshing interaction of targeted molecules with the developed MIP system. Therefore, the sensitivity can be significantly enhanced. Such flow SPR system will be developed and further tested in our future studies.

**Abstract**

A low-molecular-weight liquid epoxidized natural rubber (LENR) was prepared through photosensitized degradation of epoxidized natural rubber with 50 mol percent of epoxy content (ENR-50). LENR was modified into hydrogenated liquid epoxidized natural rubber (HLENR) via *in situ* thermal degradation of arylsulfonyl hydrazide as a hydrogenating agent. The chemical structures of LENR and HLENR were characterized using Fourier transform infrared (FTIR) and $^{1}$H nuclear magnetic resonance (NMR) spectroscopies. The thermal behaviour of LENR and HLENR were analysed using thermogravimetric analysis (TGA). The molecular weight and polydispersity index (PDI) of LENR and HLENR were determined using gel permeation chromatography (GPC). The parameter studies on the hydrogenation of LENR were investigated based on the source of diimide, weight ratios of LENR: *p*-toluenesulfonyl hydrazide (TSH), temperature, reaction time and solvent of the reaction. The highest conversion of hydrogenation was achieved at 130 °C for 4 hours reaction time, with 1:1 weight ratio of LENR: TSH using *o*-xylene as a solvent.

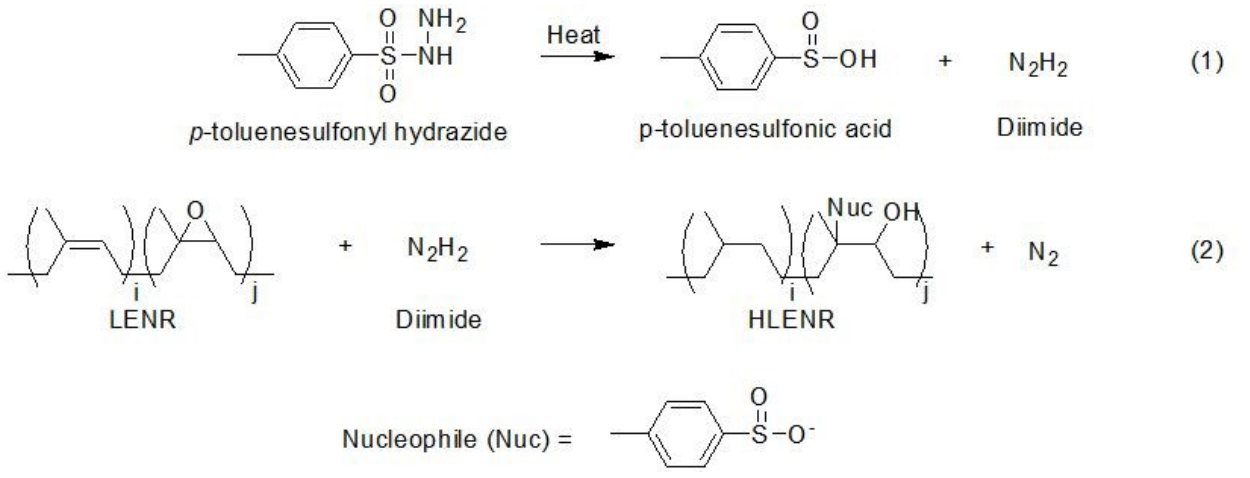
**Keywords**: hydrogenation, liquid natural rubber, epoxidized, hydroxylated

**Abstrak**

Getah asli cecair terepoksida (LENR) dihasilkan melalui penguraian fotopemeka yang dijalankan ke atas getah asli terepoksida yang mempunyai 50 mol% kandungan epoksi (ENR-50). LENR dihidrogenkan kepada LENR terhidrogen (HLENR) melalui penguraian terma *in situ* dengan menggunakan agen penghidrogenan iaitu arilsulfonil hidrazida. Struktur kimia LENR dan HLENR dicirikan menggunakan spektroskopi inframerah transformasi Fourier (FTIR) dan resonans magnet nukleus $^{1}$H. Sifat terma LENR dan HLENR dikaji menggunakan analisis termogravimetri (TGA). Berat molekul dan indeks kepoliserakan (PDI) dikaji menggunakan kromatografi penelapan gel (GPC). Kajian mengenai penghidrogenan LENR dikaji berdasarkan beberapa parameter tindak balas seperti sumber diimida, nisbah berat LENR: *p*-toluenasulfonil hidrazida (TSH), suhu, masa dan pelarut tindak balas. Penukaran penghidrogenan yang tertinggi diperolehi apabila tindak balas dijalankan pada suhu 130 °C selama 4 jam, dengan nisbah berat LENR:TSH sebanyak 1:1 serta menggunakan *o*-xilena sebagai pelarut.

**Kata kunci:** penghidrogenan, getah asli cecair, terepoksida, terhidroksil

## Introduction



Natural rubber (NR) produced from *Hevea brasiliensis* trees is a crucial raw material for the production of industrial products such as tyres, gloves, adhesives, sealants, medical devices and consumer products [1-3]. NR had been used in various fields of applications due to its high elasticity and flexibility, resilience, abrasion resistance, efficient heat

dispersion, impact resistance and tear strength [4, 5]. However, NR deteriorates against ozone, sunlight, and weathering due to the unsaturated in its polymeric chains [4, 6]. Thus, chemical modifications of NR are very important in order to enhance the chemical, physical and mechanical properties of NR.

Previously, there are many chemical modifications that had been done to NR such as, hydrogenation, epoxidation, halogenation, grafting, metathesis and cyclization [1]. Among these modifications, hydrogenation of NR is significance to improve the properties in terms of its thermal stability, weather resistance and oxidative [7]. There are two types of hydrogenation that had been done to NR, which are catalytic and non-catalytic. Catalytic hydrogenation requires high pressure autoclave and the presence of transition metal catalyst systems such as nickel, titanium, rhodium, ruthenium or palladium [8 – 11]. On the other hand, non-catalytic hydrogenation method is more convenient because it only requires a simple apparatus preparation at atmospheric pressure and employed diimide intermediate from thermal decomposition of arylsulfonyl hydrazide [12]. Mahittikul et al. reported an *in situ* hydrogenated natural rubber latex via thermolysis of *p*-toluenesulfonyl hydrazide (TSH) [13].

Epoxidized natural rubber (ENR) is a chemically modified form of NR, having epoxy functional group and also showed slightly similar drawbacks as NR due to its remaining unsaturated double bonds in polymeric backbones. Hence, hydrogenation of ENR will overcome the drawbacks by saturating the remaining double bonds and ring opened the epoxy groups into hydroxyl groups. Research on the hydrogenation of ENR conducted in latex form requires a deproteinization process to remove the protein in the rubber [11]. Although, chemical reactions conducted in latex form often encountered with problems of latex stability, uneven particle size distribution and contamination due to non-rubber components of natural rubber latex [14]. To overcome the problems encountered by latex, liquid form of ENR is the best solution. The liquid form of ENR which is liquid epoxidized natural rubber (LENR), a partially depolymerized ENR can be produced via mechanical milling, chemical degradation initiated by potassium peroxodisulfate and photooxidation initiated by ultraviolet irradiation [15].

In the present work, we made an attempt to hydrogenate liquid epoxidized natural rubber through the thermal degradation of TSH. The diimide ($N_2H_2$) generated from thermolysis of TSH gives hydrogen molecules ($H_2$) to the C=C and C-O-C of the LENR (Scheme 1) [13, 16, 17]. We also optimize the effect of TSH concentration, temperature, solvent and reaction time. The analysis of the hydrogenated products have been performed using FTIR, $^1$H NMR, TGA and GPC.

Scheme 1. Hydrogenation of LENR using TSH

## Materials and Methods

### Materials

Epoxidized natural rubber-50 (ENR-50) was supplied from Malaysian Rubber Board. Toluene, *o*-xylene, hexane and methanol were supplied by R&M Chemicals. Methylene blue, rose Bengal, *p*-toluenesulfonyl hydrazide (TSH) and 2,4,6-trimethylbenzenesulfonyl hydrazide (MSH) were purchased from Sigma Aldrich.

### Synthesis of LENR

LENR was prepared by photosensitized degradation of ENR-50 [18]. 1 kg of ENR-50 was cut into smaller cube and soaked in 2 L of toluene overnight. Methylene blue (0.10 g) and Rose Bengal (0.15 g) were dissolved in methanol before added into rubber mixture. The mixture was stirred continuously using a mechanical stirrer in the presence of visible light at 70 °C for 10 to 14 days. The mixture was centrifuged to separate the gel formation.

### Hydrogenation of LENR

TSH was used as a diimide source in the hydrogenation reaction. Different amounts of TSH were added to a fixed volume of LENR solution at TSH/LENR weight ratios of 1:1 to 3:1 to determine the effect of TSH concentration on the percentage of hydrogenation. Each mixture was heated to temperature ranging from 90 °C until 150 °C and stirred for 1–5 hours to study the effect of reaction time on the percentage of hydrogenation. The products were filtered and coagulated with hexane to remove the residual TSH. Finally, it was dried in a vacuum oven to remove any remaining solvent. In this work, we also studied the effect of solvent by using *o*-xylene and toluene on the percentage of hydrogenation LENR.

### Characterization

Attenuated total reflectance-Fourier transform infrared (ATR-FTIR) spectroscopy (Perkin Elmer) was used to determine any changes in the functional groups that might have been induced by the hydrogenation reaction. The samples were analysed in the wavenumber range of 4000 – 600 $cm^{-1}$. NMR spectroscopy was used to examine the microstructure of the product. Samples were dissolved in deuterated chloroform ($CDCl_3$) for measurements with the Fourier Transform Nuclear Magnetic Resonance 400MHz Cryoprobe (FT-NMR 400MHz Cryo). Integration of signals from proton NMR ($^1$H NMR) was used to estimate the percentage of conversion of the hydrogenation, content of the epoxy group, content of the residual double bonds and content of the hydroxyl group of HLENR as shown in equation 1 – 4 below:

$$W_{\text{conversion}}\,[\text{mol\%}] = \frac{I_{1.25}/2}{I_{1.25}/2 + I_{2.71} + I_{3.35} + I_{5.14}} \times 100 \quad (1)$$

$$X_{\text{epoxy}}\,[\text{mol\%}] = \frac{I_{2.71}}{I_{1.25}/2 + I_{2.71} + I_{3.35} + I_{5.14}} \times 100 \quad (2)$$

$$Y_{\text{double bond}}\,[\text{mol\%}] = \frac{I_{3.35}}{I_{1.25}/2 + I_{2.71} + I_{3.35} + I_{5.14}} \times 100 \quad (3)$$

$$Z_{\text{hydroxyl}}\,[\text{mol\%}] = \frac{I_{5.14}}{I_{1.25}/2 + I_{2.71} + I_{3.35} + I_{5.14}} \times 100 \quad (4)$$

where *I* is the integration at chemical shifts 1.25, 2.71, 3.35 and 5.14 ppm that correspond to methylene of hydrogenated isoprene units, epoxy methine of epoxidized-*cis*-1,4-isoprene units, hydroxylated methine and olefinic methine of unsaturated *cis*-1,4-isoprene units, respectively, in $^1$H NMR spectrum [11].

Thermogravimetric analysis (TGA) and differential thermal analysis (DTA) were performed on TGA/SDTA 851$^e$, Mettler Toledo. Gel permeation chromatography (GPC) was employed to determine the molecular weight ($M_w$) and polydispersity index (PDI) of LENR and HLENR (Waters 1515 Isocratic HPLC Pump equipped with a Waters 2414 Refractive Index detector, Waters Corporation, USA).

## Results and Discussion

Hydrogenated liquid epoxidized natural rubber (HLENR) was produced via non-catalytic hydrogenation of LENR using diimide intermediate from arylsulfonyl hydrazide such as *p*-toluenesulfonyl hydrazide (TSH) and 2,4,6-trimethylbenzenesulfonyl hydrazide (MSH).

**Microstructure of LENR and HLENR**

Figure 1 depicts the FTIR spectra of LENR and HLENR. The main features of LENR appears at 1251 and 870 $cm^{-1}$ are attributed to the symmetric and asymmetric stretching of the epoxide ring, respectively. The absorption at 1664 and 828 $cm^{-1}$ in LENR spectrum correspond to C=C stretching and olefinic C–H bending, respectively. Both LENR and HLENR spectra show broad absorption bands at 3600-3100 $cm^{-1}$ due to O-H stretching, and the intensities of the absorption bands for HLENR are intense than LENR [19]. The increment of HLENR intensity at 3600-3100 $cm^{-1}$ arised due to the ring opening of epoxy groups into hydroxyl groups.

$^{1}$H NMR spectra of LENR and HLENR were shown in Figure 2. In LENR spectrum, six major signals appeared at 1.30, 1.68, 2.10, 2.20, 2.71 and 5.14 ppm were assigned to methyl of unsaturated *cis*-1,4-isoprene units (*b*), methyl of epoxidized-*cis*-1,4-isoprene units (*e*), methylene of *cis*-1,4-isoprene units (*c*), methylene of epoxidized-*cis*-1,4-isoprene units (*f*), epoxy methine (*d*) and olefinic methine (*a*), respectively. HLENR spectrum showed the appearance of hydrogenated methylene (*a'*) hydroxylated methine (*h*) and hydroxyl proton (*i*) at chemical shifts 1.25, 3.35 and 3.90 ppm, respectively. The signals appeared at 2.30-2.50 ppm on HLENR spectrum correspond to benzylic protons of the remaining TSH and the nucleophile ($CH_3C_6H_5SO_2^-$) [12, 17, 20].

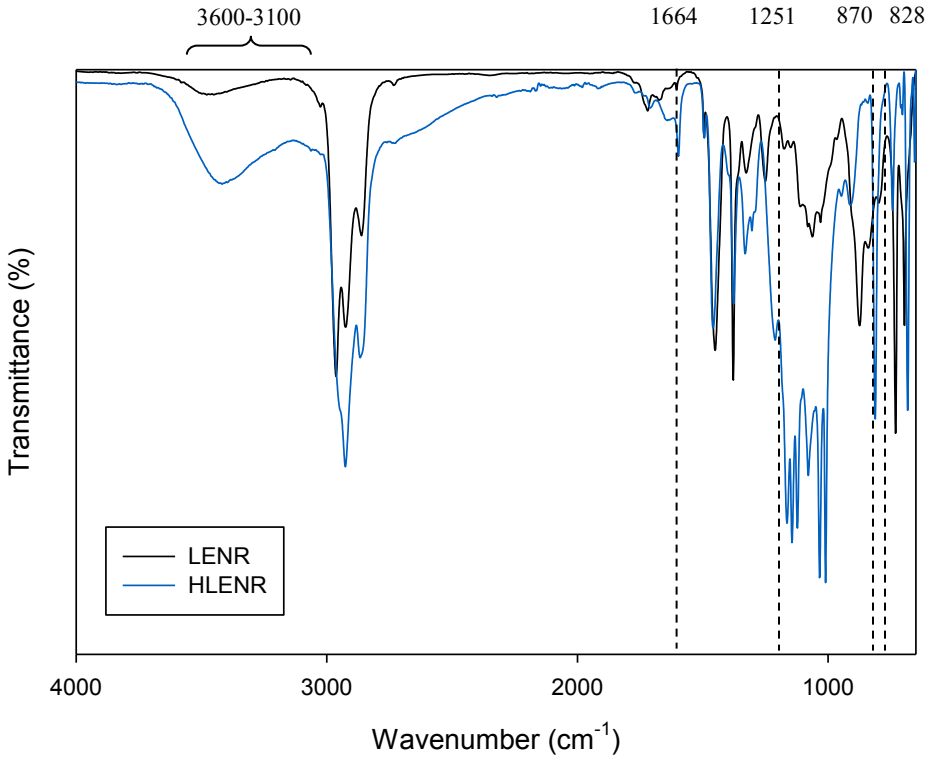


Figure 1. FTIR spectra of LENR and HLENR

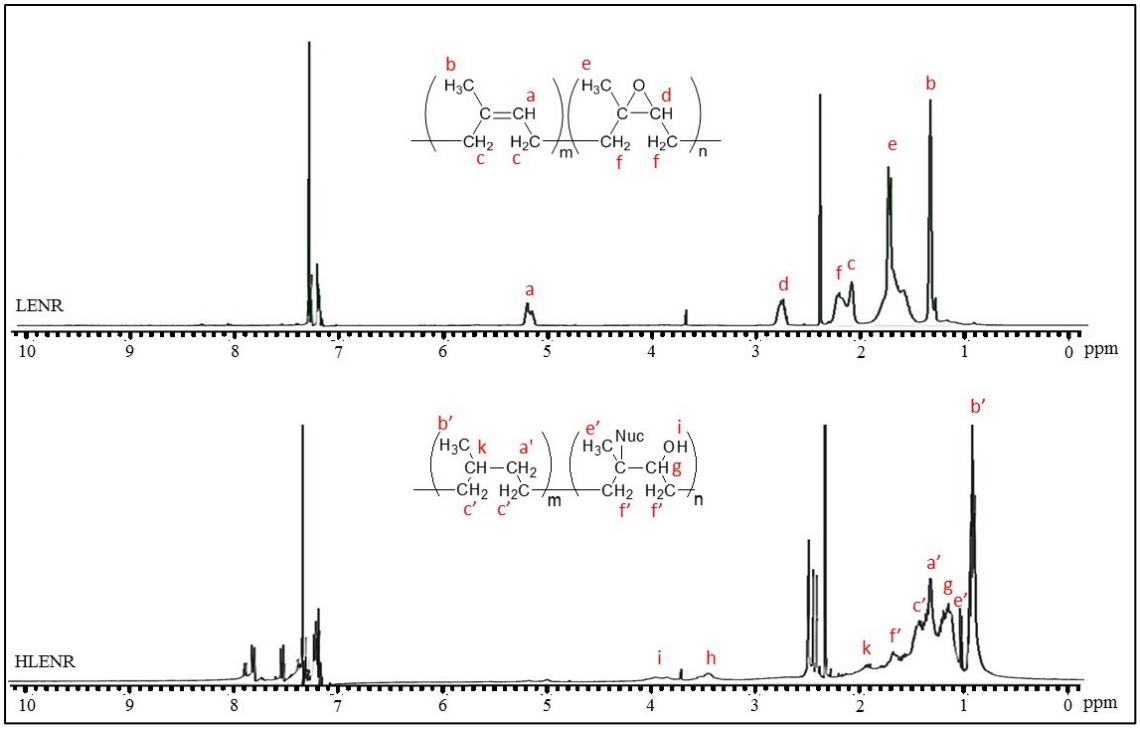

Figure 2. $^{1}$H NMR spectra of LENR and HLENR

**Parameter Studies on Hydrogenation of LENR: Effect of diimide source**

*p*-toluenesulfonyl hydrazide (TSH) and 2,4,6-trimethylbenzenesulfonyl hydrazide (MSH) had been study to produce diimide for the non-catalytic hydrogenation of LENR (Table 1). TSH showed a higher conversion of hydrogenation which is 90.29%. The hydrogenation of LENR using MSH produced more hydroxyl content caused by the stronger nucleophilic attack in the epoxide ring compare to TSH. The content of epoxy group and residual double bonds decreased as the conversion of hydrogenation increased. However, the content of hydroxyl for hydrogenation LENR using MSH was higher compared to TSH because, MSH was quite unstable to undergo hydrogenation.

Table 1. Effect of diimide source on hydrogenation of LENR

| Experiment | Diimide Source | Conversion of Hydrogenation (mol%) | Content of Epoxy Group (mol %) | Content of Residual Double Bonds (mol %) | Content of Hydroxyl Group (mol %) |
|---|---|---|---|---|---|
| 1 | TSH | 90.29 | 0.81 | 0.45 | 8.46 |
| 2 | MSH | 40.80 | 7.94 | 3.80 | 47.47 |

Condition: weight ratio of TSH: LENR = 1:1, temperature = 130 °C, reaction time = 4 hours, solvent = *o*-xylene

**Effect of LENR: TSH weight ratio**

The weight ratio of LENR: TSH was varied for 1:1, 1:2 and 1:3. Table 2 showed the increase in the amount of TSH, resulted to reduce the conversion of hydrogenation of LENR. Higher amount of TSH was expected to undergo side reaction which interrupt the hydrogenation of LENR and reduced the hydroxyl content. The epoxy content increased as the conversion of hydrogenation decreased.

Table 2. Effect of LENR: TSH weight ratio on hydrogenation of LENR

| Experiment | Weight Ratio of LENR:TSH | Conversion of Hydrogenation (mol%) | Content of Epoxy Group (mol%) | Content of Residual Double Bonds (mol%) | Content of Hydroxyl Group (mol%) |
|---|---|---|---|---|---|
| 3 | 1:1 | 90.29 | 0.81 | 0.45 | 8.46 |
| 4 | 1:2 | 56.27 | 40.00 | 0.95 | 2.77 |
| 5 | 1:3 | 56.27 | 42.16 | 0.16 | 1.40 |

Condition: temperature = 130 °C, reaction time = 4 hours, solvent = *o*-xylene

**Effect of temperature**

The effect of temperature was investigated from 90 °C until 150 °C (Table 3). From 90 °C until 130 °C, the conversion of hydrogenation gradually increase to the highest conversion of hydrogenation. TSH solubility with *o*-xylene increased with the increasing temperature because rate decomposition of TSH increased. However, when the temperature was increased to 150 °C, the conversion of hydrogenation slightly dropped due to the occurrence of unduly wasteful side reaction [13]. The content of epoxy group and residual double bonds decreased while content of hydroxyl increased as the conversion of hydrogenation increased.

Table 3. Effect of temperature on hydrogenation of LENR

| Experiment | Temperature (°C) | Conversion of Hydrogenation (mol%) | Content of Epoxy Group (mol%) | Content of Residual Double Bonds (mol%) | Content of Hydroxyl Group (mol%) |
|---|---|---|---|---|---|
| 6 | 90 | 46.78 | 37.27 | 11.42 | 4.53 |
| 7 | 110 | 53.44 | 35.74 | 5.49 | 5.33 |
| 8 | 130 | 90.29 | 0.81 | 0.45 | 8.46 |
| 9 | 150 | 86.6 | 0.18 | 0.77 | 12.45 |

Condition: weight ratio of TSH: LENR = 1:1, reaction time = 4 hours, solvent = *o*-xylene

**Effect of reaction time**

Table 4 showed the increasing trend of reaction time has increased the conversion of hydrogenation. At the reaction of 5 hours, the conversion of hydrogenation almost the same with the conversion of hydrogenation for 4 hours because the reaction already completed at 4 hours reaction time. The content of epoxy group and residual double bonds decreased while content of hydroxyl increased when the conversion of hydrogenation increased.

Table 4. Effect of reaction time on hydrogenation of LENR

| Experiment | Reaction Time (hours) | Conversion of Hydrogenation (mol%) | Content of Epoxy Group (mol%) | Content of Residual Double Bonds (mol%) | Content of Hydroxyl Group (mol%) |
|---|---|---|---|---|---|
| 10 | 1 | 33.71 | 56.78 | 5.87 | 3.64 |
| 11 | 2 | 53.94 | 42.95 | 1.26 | 1.85 |
| 12 | 3 | 78.99 | 15.75 | 2.15 | 8.70 |
| 13 | 4 | 90.29 | 0.81 | 0.45 | 8.46 |
| 14 | 5 | 90.11 | 0.01 | 1.29 | 8.59 |

Condition: weight ratio of TSH: LENR = 1:1, temperature = 130 °C, solvent = *o*-xylene

**Effect of solvent**

There were two types of solvent had been studied on the hydrogenation of LENR. Based from Table 5, *o*-xylene resulted in higher conversion of hydrogenation due to *o*-xylene is more likely to dissolve TSH and easily produced diimide. However, the hydrogenation of LENR using toluene produced a lower conversion of hydrogenation but higher in hydroxyl group.

Table 5. Effect of solvent on hydrogenation of LENR

| Experiment | Solvent | Conversion of Hydrogenation (mol%) | Content of Epoxy Group (mol%) | Content of Residual Double Bonds (mol%) | Content of Hydroxyl Group (mol%) |
|---|---|---|---|---|---|
| 15 | Toluene | 46.45 | ~0 | 2.24 | 51.31 |
| 16 | *o*-xylene | 90.29 | 0.81 | 0.45 | 8.46 |

Condition: weight ratio of TSH: LENR = 1:1, temperature = 130 °C, reaction time = 4 hours

**Thermal analysis of LENR and LNR-OH**

TGA and DTG thermograms of LENR and HLENR were shown on Figure 3 and 4, respectively. LENR and HLENR thermograms showed multi step changes. The first step changes (30 °C – 310 °C) of LENR and HLENR were due to the loss of solvent, moisture and low-molecular-weight oligomers [21]. After 310 °C to 400 °C, the weight loss were due to the unstable intermediates in hydrogenation of LENR. The Figure 4 clearly showed the maximum degradation temperature of LENR and HLENR at 413 °C and 445 °C, respectively. The maximum degradation temperature of HLENR showed a higher temperature compared to LENR because of the hydrogenation reaction had proven to saturate the unsaturated part of LENR.

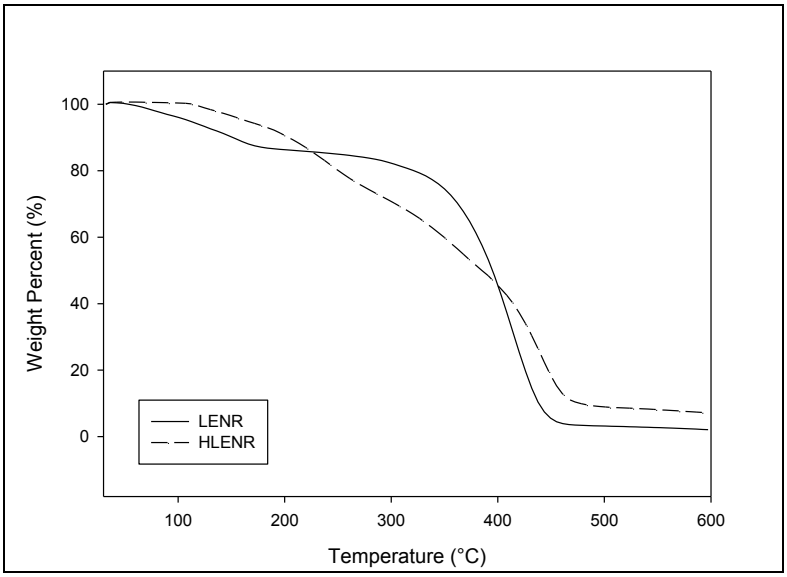

Figure 3. TGA thermograms of LENR and HLENR

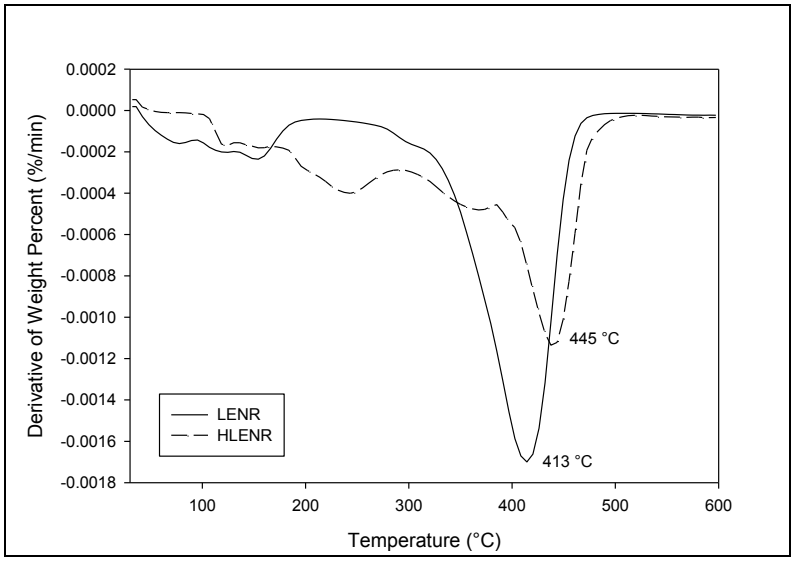

Figure 4. DTG thermograms of LENR and HLENR

**Molecular Weight of LENR and LNR-OH**

Table 6 showed the number average molecular weight ($M_n$), weight average molecular weight ($M_w$) and polydispersity index (PDI) of LENR and HLENR. $M_w$ of LENR and HLENR were reduced from 47900 g/mol to 17000 g/mol due to the high reaction temperature in the hydrogenation of LENR. The high reaction temperature depolymerized the polymeric chains of HLENR.

Table 6. Molecular weight of LENR and HLENR

| Sample | $M_n$ | $M_w$ | PDI |
|---|---|---|---|
| LENR | 18200 | 47900 | 2.63 |
| HLENR | 4600 | 17000 | 3.69 |

## Conclusion

Non-catalytic hydrogenation of LENR using diimide was efficiently conducted to produce hydrogenated rubber containing hydroxyl group. The optimum reaction condition was achieved using TSH as diimide source with 1:1 of LENR: TSH weight ratio at 130 °C for 4 hours of reaction time using *o*-xylene as solvent.

**Abstract**

10-oxodehydrobotrydial (**1**) and 4β-Acetoxy-9β,10β,15α-trihydroxyprobotrydial (**2**) have been isolated from *Hypoxylon rickii* mycelia extract. Compound **2** is probably an intermediate of botrydial, which is a known sesquiterpene phytotoxin. Cluster Omega and Artemis software analysis suggested that *HRT6,* a possible botrydial-like gene cluster with four genes shows more than 50% similarities compared to *Botrytis cinerea* botrydial gene cluster, *BcBOT*. A comparison between proposed 4β-Acetoxy-9β,10β,15α- trihydroxyprobotrydial (**2**) producing pathway and *BcBOT* proposed pathway shows compatible function of each gene prediction. Further confirmation using RNA gene knock-outs is on-going.

**Keywords**: *Hypoxylon rickii*, botryane, terpene synthase

**Abstrak**

10-oksodehidrobotridial (**1**) dan 4β-Asetoksi-9β,10β,15α-trihidroksiprobotridial (**2**) telah dipencilkan dari ekstrak miselia *Hypoxylon rickii*. Sebatian **2** dijangkakan sebagai sebatian perantara dalam pembentukkan botridial iaitu sejenis fitotoksin sesquiterpena. Penggunaan dua perisian Cluster Omega dan Artemis telah berjaya mengenalpasti gen kelompok yang berkemungkinan dari *H. rickii* sebagai *HRT6* dengan empat gen menunjukkan persamaan lebih daripada 50% berbanding gen kelompok *Botrytis cinerea*, *BcBOT*. Perbandingan antara dengan cadangan laluan biosintesis 4β-Asetoksi-9β,10β,15α-trihidroksiprobotridial (**2**) dengan *BcBOT* menunjukkan persamaan fungsi – fungsi gen. Pengesahan lanjut menggunakan RNA (mendiamkan gen) sedang dijalankan.

**Kata kunci:** *Hypoxylon rickii*, botrien, terpene sintes

## Introduction

Terpene is a diverse class of secondary metabolite (SMs) produced notably by fungi. These compound have a cycloaliphatic basic structure built from isoprene units [1]. Most of the terpenes produced by fungi have various biological functions. Terpene include commercially fascinating compounds due to their properties, such as paxilline an indole diterpene, gibberelic acid, a pentacyclic diterpene plant growth hormone and trichothecenes a sesquiterpene mycotoxin [2, 3].

Botryane are a group of sesquiterpenes produced notably by *Botrytis cinerea* which is a fungus causing gray-rot disease in economically important crops such as grapes, strawberries and many more. They are known as broad spectrum toxins with botrydiol derivatives causing leasions to the leaves [4]. Other bioactivities include fungicide

and cytotoxic activities [5]. Even though sesquiterpenes form the largest group of terpenes and include commercially important compounds, they are difficult to chemically synthesize because of the complex structure that often leads to low yield [6].

*Hypoxylon* sp. was first identified by Ju and Rodgers in 1996 and belong to the Xylariaceae family which has interesting characteristics in producing a variety of secondary metabolites [7]. *Hypoxylon fragiforme* is known to produce frangiformins A and B, cytochalasin H and mitorubin azaphilones [8] while *Hypoxylon rutilum* produces rutilin A and B, entonaemin A, rubiginosin A and B [9].

*Hypoxylon rickii* colonies grown on agar plate, are at first whitish, then becoming fulvous, velvety to felty, azonate, with diffuse margins and a reverse dull green colour can be seen [7]. *Hypoxylon rickii* has a nodulisporium-like conidiogenous structure that differentiates it from other *Hypoxylon* taxa with red to orange red granules in a wild species [7].

The research group of Prof. Marc Stadler in Helmholz Center for Infection Research Institute previously has identified various type of secondary metabolites from *H. rickii* such as Silphiperfolene-type terpenoids, diketopiperzine, botryenanol, α-ramulosin**,** α-eleostearic acid and many more [10]. Recently, they manage to isolate new botryane ((1S)-7-[(2E)-but-2-enoyl]-1,3,3,6-tetramethyl-2,3-dihydro-1H-indene-1 carbaldehyde **3**, (3aS)-6-hydroxy-3a,5,5,8-tetramethyl-3,3a,4,5-tetrahydro-1H-cyclopenta [de] isochromen1-one **4**, (3aS)-7-hydroxy-3a,5,5,8-tetramethyl-3,3a,4,5-tetrahydro-1H- cyclopenta[de]isochromen-1-one **5** with 3 known botryanes (3aS)-3a,5,5,8-tetramethyl-3,3a,4,5-tetrahydro-1H-cy-clopenta[de]isochromen-1-one **6**, (3aS,8R)-3a,5,5,8-tetramethyl-3,3a,4,5,7,8-hexahydro-1H-cy-clopenta[de]isochromen-1-one **7** and botryenanol **8** and many more [11] (Figure 1).

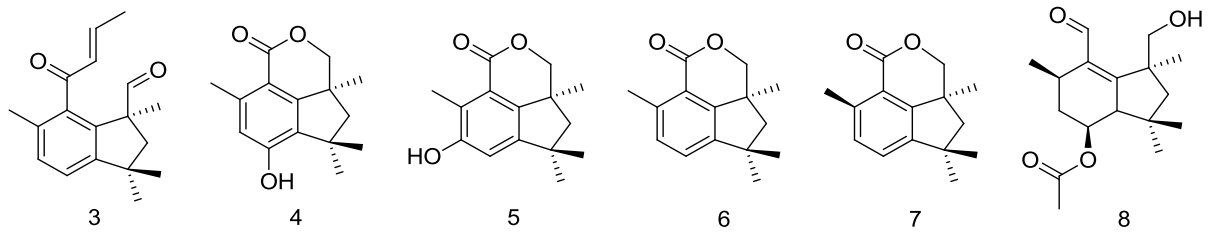

Figure 1. Botryanes isolated from *Hypoxylon rickii*

Genome mining provides information on the gene cluster responsible for producing of respective SMs. Generally, biosynthetic genes for fungal SMs are located in clusters and it can consist of more than 10,000 bases. These clusters contain one or several central biosynthetic genes encoding extremely large multidomains or multimodular enzymes belonging to the polyketide synthases (PKSs), terpene synthases (TSs), non-ribosomal peptide synthases (NRPSs) or a mix of them [12]. Each of the genes in a gene cluster has its own functions corresponding to step of the biosynthesis [13]. This knowledge enables us to manipulate and produce derivatives of the SMs tailored to our needs.

## Materials and Methods

### Material

Strain 53309 from Prof Marc Stadler's group, collected in Martinique, France was used. The sample has been deposited at the public culture collections (MUCL 53309, CBS 129345). It was identified based on comparing the *H. rickii* sample ITS sequence JQ009313 with deposited ITS sequences in the NCBI database under accession number AJ390408 and KC968932.

### Culturing

*Hypoxylon rickii* was grown in the yeast malt glucose (YMG) liquid medium at 25 $^{o}$C with 200 rpm rotation for 3 to 4 days except for isolation of secondary metabolites where 7 to 15 days of cultivation in malt extract medium and tomato medium were required. Each medium was inoculated with a mycelium suspension (100 – 500 µL, 50%

glycerol). For solid medium cultures the plate were inoculated with mycelium from a liquid culture (200 µL) or from an agar plate and incubated at 25 °C.

**Extraction and Isolation**

The production culture was centrifuged (10,000 rpm, 4 $^{o}$C, 25 min). The supernatant was filtered under vacuum to remove any cells that were not pelleted out and its pH adjusted to 4.0. The supernatant was extracted thrice with ethyl acetate. The organic layers were combined and dried over anhydrous magnesium sulphate (Fisher) and filtered under vacuum. Mycelium from previous extraction was extracted thrice with acetone. The organic layers were combined and dried over anhydrous magnesium sulphate (Fisher) and filtered under vacuum.

The supernatant organic extract was evaporated to leave a dark green oil which was dissolved in methanol and analysed by LCMS while the mycelium organic extract was evaporated to leave a dark reddish oil which was dissolved in methanol and analysed by LCMS.

Analytical chromatographic analysis were perform on a Waters Platform 2695 LC system comprising of a Waters 600 pump system, a Waters 2998 diode array detector (detecting between 210 and 400 nm), a Waters 2420 ELS detector, a Waters QuatroMicro Platform LC mass spectrometer (detecting between 150 and 600 *m/z* units $ESI^{+}$) with a Kinetex 2.6 µm $C_{18}$ (Phenomenex, 100 × 4.6 mm) reverse phase column. The mobile phase gradient program was run as follows: 0 – 10 minutes (90% A), 10 – 13 minutes (ramped to 90% B), 13 – 15 minutes (ramped to 90% A). Solvent A: water + 0.05% TFA, solvent B: MeCN + 0.04% TFA. Flow rate: 1 mL/min. Injection volume: 20 µL. Concentration of the sample: 20 mg/mL.

Preparative chromatography was carried out on a Waters Platform 2695 LC system that include diode array detector (detecting between 210 and 400 nm), ELS detector, LC mass spectrometer (detecting between 150 and 600 *m/z* units $ESI^{+}$) with the Kinetex 5 µm $C_{18}$ (New Coloum, 250 × 21.2 mm) reverse phase column. The program was run 0 – 4 minutes (90% A), 4 – 8 minutes (reduced to 70% A), 8 – 17 minutes (ramped to 95% B), 17 – 18 minutes (ramped to 90% A), 18 – 20 minutes (90% A). Solvent A: water + 0.05% TFA, solvent B: MeCN + 0.04% TFA. Flow rate: 20 mL/min. Injection volume: 50 – 200 µL. Concentration of the sample: 20 mg/mL.

NMR spectra recorded on a Bruker 400 MHz Ascend or a Bruker 500 MHz Ultrashield with DRX console and 5 mm TCI 1H-13C/15N (Z-GRD) cryo-probe and BACS sample changer and HR-ESI-MS data were obtained using Micromass GCT.

**Isolation of fungal genomic DNA**

Cells were separated from the liquid medium culture by centrifugation (10,000 rpm, 25 mins, 4 $^{o}$C) and the supernatant removed. The sample then freeze-dried for overnight. The cells (approx. 100 mg) were crushed with a pestle and mortar in liquid nitrogen. The genomic DNA was obtained by following the manufactures instructions of the GenElute Plant Genomic DNA Kit (Sigma) with 100 mg of tissue. gDNA was analysed by gel electrophoresis. Full length genome sequence were obtained using Illumina sequencing service provided by CeBITEC, University of Bielfield, Germany (later transferred to Bioinformatics & Systems Biology Justus-Liebig-University Giessen, Germany).

## Results and Discussion

**Structural elucidation**

Structural elucidation of both compounds was carried out using several spectroscopic techniques including $^{1}$H and $^{13}$C NMR, 2D-COSY, HSQC and HMBC and compare with previous data. The isolated compounds include the following:

***(3aS)-3a,5,5,8-tetramethyl-3,3a,4,5-tetrahydro-1H-cy-clopenta[de]isochromen-1-one (10-oxodehydrobotrydial)*** (**1**):

Colourless oil; Yield 0.8 mg; $^{1}$H NMR (500 MHz) and $^{13}$C NMR (150 MHz) data were consistent with those previously reported [11] are tabulated in Table 1; HRESIMS m/z 231.1392 $[M + H]^{+}$ (calculated for $C_{15}H_{19}O_2$ m/z 231.1380); Rt = 12.2 min; Compound **1** have been previously isolated from *H. rickii* [11]. The structure of

compound **1** was further confirmed using 2D NMR experiments including HMBC. Correlation HMBC showed in Figure 2.

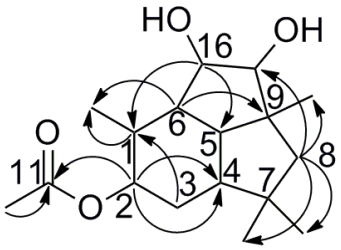

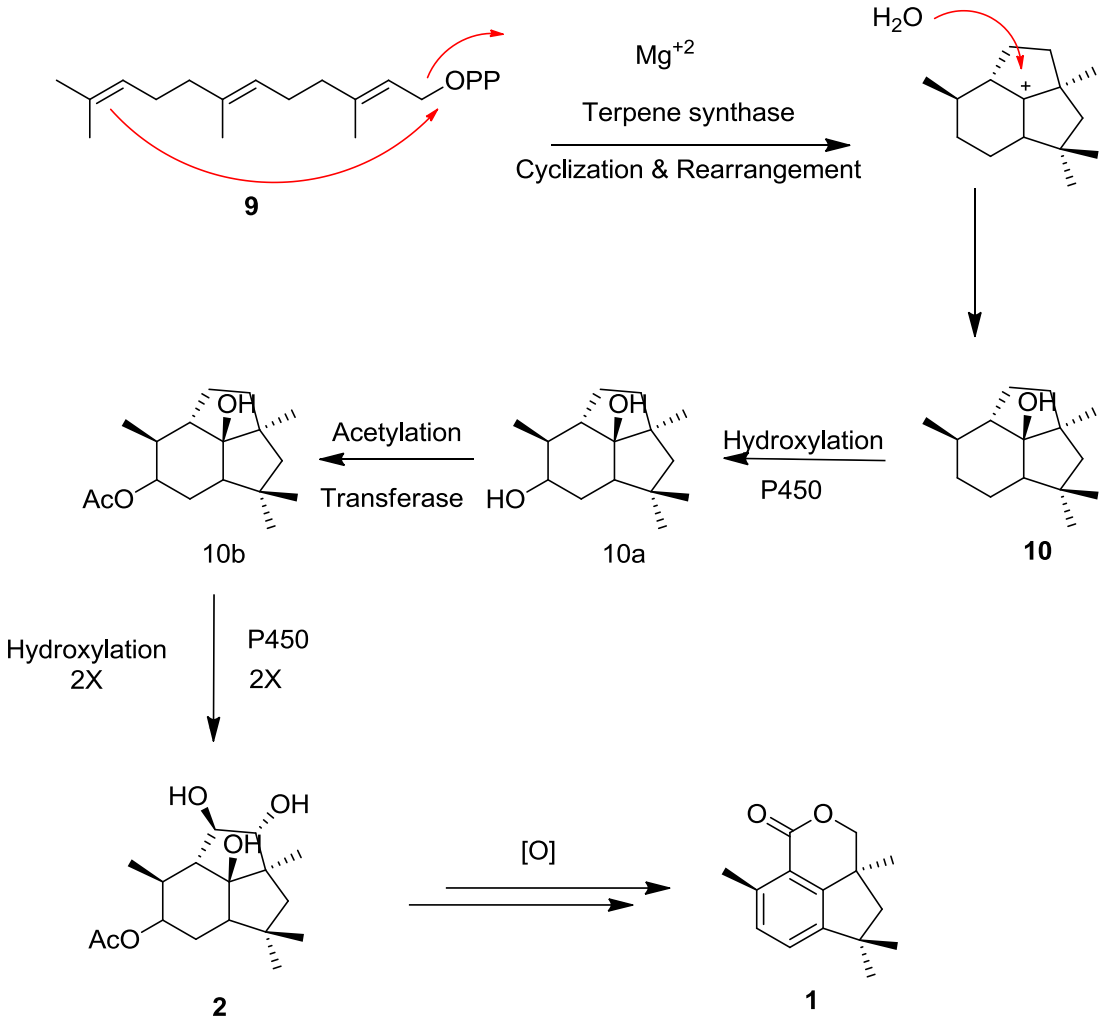

Figure 3. HMBC correlation of 4β-Acetoxy-9β,10β,15α-trihydroxyprobotrydial (**2**)

**Pathway**

It is proposed that both compounds derived from the botryane biosynthetic pathway. The proposed biosynthesis of **2** is shown on Scheme 1. The biosynthesis starts with farnesyl pyrophosphate (FPP) **9**, a sesquiterpene**.** Terpene synthase or sesquiterpene synthase will bind to the pyrophosphate (PP) of FPP via $Mg^{2+}$ and nucleophilic prenyl chain close concurrent to PP cleavage. A few rearrangement and cyclization of the structure produce the intermediate that eventually quenched by $H_2O$ resulting in presilphiperfolan-8β-ol **10**. Hydroxylation at carbon 2 of presilphiperfolan-8β-ol **2** by cytochrome P450, allowed the acetylation of acetate into carbon 2 aided by transferase enzyme. Further hydroxylation via cytochrome P450 at carbon 10 and 15 might produce 4β-Acetoxy-9β,10β,15α-trihydroxyprobotrydial **2** as suggested from previous study using isotope labeling acetate experiment [6].

Farnesyl diphosphate, FPP **9** catalyzed by terpene synthase will undergo multiplestep cyclization to produce tricyclic sesquiterpene alcohol, presilphiperfolan-8β-ol **10**. Trihydroxylbotrydial **1**, is converted to botrydial by the action of cytochrome P450s as well as by an acetyl transferase. As for 10-oxodehydrobotrydial **2**, their oxidative steps are yet to be determined.

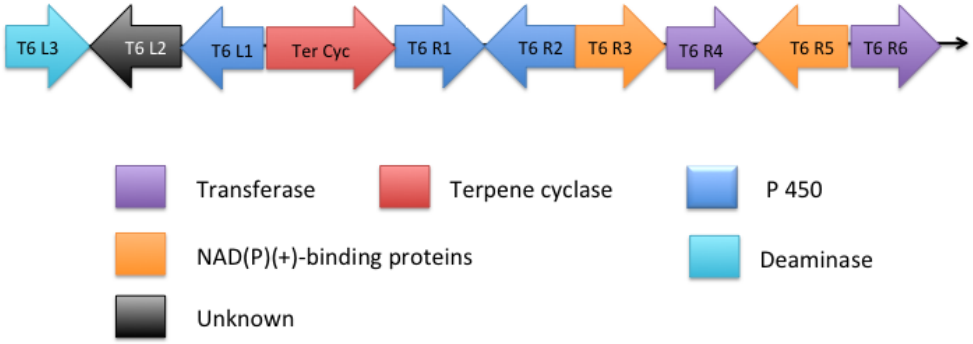
Scheme 1. Proposed biosynthetic pathways of botryane

**Gene clustering**

Genome data are stored in the GenDBE system of Bioinformatics & Systems Biology Justus-Liebig-University Giessen, Germany. *Hypoxylon rickii* genes have been annotated to have 59 secondary metabolite producing gene clusters as in Table 3. From this data, the 6th terpene gene cluster out of 12, has been named as *HRT6* gene cluster, consist of terpene cyclase with three cytochrome P450s and two transferases (Figure 4).

Table 3. Number of annotated secondary metabolite gene clusters in *Hypoxylon rickii*

| SM Gene Cluster | No. |
|---|---|
| NRPS-PKS | 4 |
| PKS | 26 |
| NRPS | 5 |
| Terpene | 12 |
| Terpene –PKS | 1 |
| Others | 11 |
| Total | 59 |



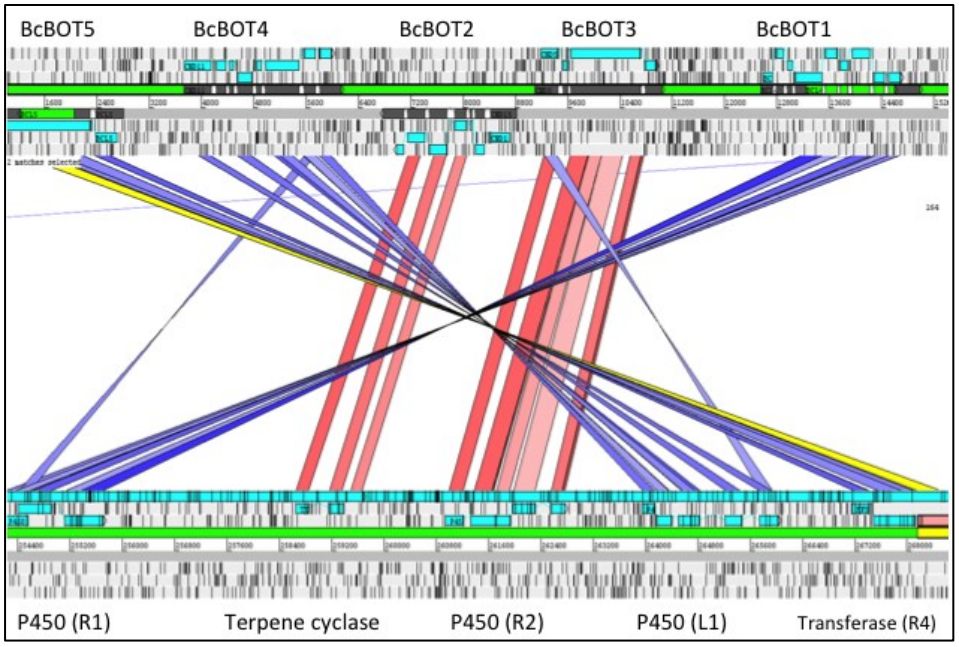


Figure 4. *HRT6* gene cluster of *Hypoxylon rickii*

Comparison of the *HRT6* have been conducted with previously studied *BcBOT* botrydial gene cluster from *Botrytis cinera* using ARTEMIS ACT software and cluster OMEGA. ARTEMIS ACT software allows comparison according to the gene sequences similarities and orientation, while cluster OMEGA allows comparison of the conserved region. Comparison between *BcBOT* and *HRT6* using ARTEMIS ACT shows similarities for five genes, namely three P450s (T6 R1, T6 R2 and T6 L1), one terpence cyclase (Ter Cyc) and one transferase (T6 R4) (Figure 5). All genes showed more than 50% similarities between all conserved regions except for transferases (Table 4).

*Comparison based on ARTEMIS ACT software. Red lines indicate similarities of gene sequence from 5' to 3' and blue lines 3' to 5' respectively

Figure 5. Comparison of gene sequence of *BcBOT* gene cluster with *HRT6* gene cluster

Table 4. Percentage comparison between *BcBOT* gene cluster and *HRT6* gene cluster

| **BcBOT Gene Cluster** | **HRT6 Cluster 6 *H. rickii*** | **% Similarities** |
|---|---|---|
| BcBOT1 P450 | T6 R1 (P450) | 59.17 |
| BcBOT2 (Sesquterpene synthase) | Terpene cyclase | 53.70 |
| BcBOT3 P450 | T6 R2 (P450) | 51.99 |
| BcBOT4 P450 | T6 L1 (P450) | 62.45 |
| BcBOT5 (acetyl Transferase) | T6 R4 (Transferase) | 21.18 |

*Comparison based on Cluster OMEGA program

Study by Pinedo et al. [14] have examined the *BcBOT2* gene as sesquiterpene synthase by knocking it out and the mutant culture did not produce any botryanes. It is presumed that cyclization of FPP **9** to the key probotryane alcohol intermediate presilphiperfolan-8β-ol **10**, thus verifying the biosynthetic pathways of these secondary metabolites. Isotope labeling study also confirmed the backbone arrangement pathway [14].

Recent publication by Moraga et al. [15] have identified successfully the function of all 5 gene in *BcBOT* gene cluster and its as proposed in this *HRT6* gene cluster. *BcBOT4* have catalyzes the first regio- and stereospecific hydroxylation of the probotryane skeleton of presilphiperfolan-8β-ol **10** at C-3, however in *HRT6* gene the first hydroxylation was at carbon 2. For further reaction, *BcBOT1* was responsible for the regiospecific hydroxylation at carbon 16 and *BcBOT3* is involved in the regio- and stereospecific β-hydroxylation at carbon 17 [15] suggesting the same pattern of hydroxylation happen in proposed *HRT6* pathways.

As for the formation of 10-oxodehydrobotrydial **1**, the same study by Moraga et al. [15] have suggest that *BcBOT1* also produce the key intermediate to the structure by cleavage the bond between carbon 16 and 17. *HRT6* gene cluster have an additional transferase (T6 R6) and NAD(P) binding protein that might have mechanism to remove the acetoxyl group at carbon 2 and turned it into benzene ring.

## Conclusion

*Hypoxylon rickii HRT6* gene cluster was annotated to be similar to *BcBOT* botrydial gene cluster isolated from *Botrytis cinera.* Four out of ten genes in the HRT6 gene cluster showed more than 50% similarities to genes from *BcBOT* botrydial gene cluster and similarities in function as well by comparing to the recent study. These findings suggested that *HRT6* highly possible into producing 4β-Acetoxy-9β,10β,15α-trihydroxyprobotrydial and it also might produce 10-oxodehydrobotrydial in right condition. An on-going project is to conduct gene knockout or gene knockdown of the terpene cyclase gene from *HRT6* to support this hypothesis.

## Acknowledgement

We would like to thank Prof. Dr. Marc Stadler of Helmholtze Center for Infection Research, Braunchwig, Germany for the *H. rickii* strain provided. We would also like to thank Prof. Dr. Russell Cox of Leibniz Universität Hannover for assistance in isolation and elucidation of the compounds. Ms Afnani would like to thanks Universiti Sultan Zainal Abidin and Kementerian Pendidikan Tinggi Malaysia for her scholarship.

**Abstract**

Aging process makes our skin getting thinner and drier. Antioxidant based on nanoemulsion system is favourable because of its effectiveness. This study was conducted to develop nanoemulsion system based on palm olein as a carrier of vitamin E and the physicochemical behaviours of the system were studied. Palm olein as oil phase, polyoxyethylene (4) lauryl ether (Brij 30) was used as a surfactant and vitamin E as an anti-aging agent. The mixtures of Brij 30 and palm olein at certain ratios were thoroughly mixed and titrated with 5 – 95% wt. of water and homogenized by using homogenizer. The Palm olein/Brij 30/Water mixtures that produced a clear solution and no birefringence after observation under polarized light microscopy are labelled as nanoemulsion. Nanoemulsion region was shown in ternary phase diagram. Based on the ternary diagram, these systems were formed at oil: surfactant (O/S) ratio 4:6, 5:5 and 6:4 and 20 – 50% wt of water. These systems were then characterized for stability test, particle size, electrical conductivity, viscosity and pH. Stability test was done at three temperatures, which were 4, 25 and 40 °C for one month and four cycles of freeze-thaw at storage temperature for 12 hours at each temperature. The systems were stable and no phase separation was observed. Particle size analysis showed that most systems have a particle size within the range of nanoemulsion (20 – 500 nm). Electrical conductivity tests showed that water-in-oil system formed at low water percentage (20 – 30% wt. of water) and bicontinuous at a higher percentage (30 – 50% wt. of water). Viscosity of both systems vitamin E-loaded and unloaded is very low. All systems have a pH value in a range of 6 – 7, which are suitable to be applied to human skin. Based on the physical characteristics of the system, it shows high potential as a vitamin E carrier.

**Keywords**: nanoemulsion, palm olein, vitamin E, ternary phase diagram, anti-aging agent

**Abstrak**

Proses penuaan menyebabkan kulit kita menjadi semakin nipis dan kering. Antioksida yang berasaskan sistem nanoemulsi lebih digemari kerana kesannya yang lebih berkesan. Penyelidikan ini dijalankan untuk membangunkan sistem berasaskan olein sawit sebagai pembawa vitamin E dibangunkan dan sifat fizikokimianya dikaji. Olein sawit sebagai fasa minyak, polioksietilena (4) lauril eter (Brij 30) digunakan sebagai surfaktan dan vitamin E sebagai bahan aktif. Campuran Brij 30 dan olein sawit dikacau sehingga sebati dan seterusnya dititratkan air sebanyak 5 – 95% (berat/berat) dan dihomogenkan menggunakan alat penghomogenan. Campuran Olein Sawit/Brij 30/Air yang menghasilkan larutan jernih dan tiada dwibiasan dilabelkan sebagai nanoemulsi selepas pemerhatian di bawah mikroskop cahaya terkutub. Rantau nanoemulsi ditunjukkan di dalam gambar rajah fasa ternari. Berdasarkan kepada gambar rajah fasa ternari, sistem ini terhasil pada nisbah minyak:surfaktan (M/S) sebanyak 4:6, 5:5 dan 6:4 dengan peratusan air sebanyak 20 – 50% (berat/berat). Seterusnya, sistem tersebut dicirikan melalui ujian kestabilan, saiz partikel, kekonduksian elektrik, kelikatan dan pH. Ujian kestabilan dilakukan pada setiap suhu berbeza iaitu 4 °C, 25 °C dan 40 °C selama sebulan dan empat kitaran pemanasan-penyejukan dengan suhu penyimpanan selama 12 jam pada setiap suhu. Sistem-sistem tersebut adalah stabil dan tidak berlaku perubahan fasa. Ujian pengukuran saiz partikel menunjukkan bahawa

kebanyakan sistem bersaiz di dalam julat saiz nanoemulsi iaitu di antara 20 –500 nm. Melalui ujian kekonduksian elektrik, dijangkakan sistem air-dalam-minyak pada 20% hingga 30% (berat/berat). Kelikatan nanoemulsi tanpa atau dengan bahan aktif pula adalah sangat rendah. Semua sistem mempunyai nilai pH yang berada dalam julat 6 – 7, di mana ianya sesuai diaplikasi pada kulit. Berdasarkan kepada sifat fizikal sistem, ia sesuai diaplikasikan sebagai pembawa vitamin E.

**Kata kunci**: nanoemulsi, olein sawit, vitamin E, rajah fasa ternari, agen anti-penuaan

## Introduction

Aging process is usually associated with changes in skin quality and appearance such as thinning, reduced elasticity and wrinkling of the skin [1]. The term cosmeceuticals was created by Dr. Albert Kligman who identified cosmeceuticals as a hybrid of drugs and cosmetics [2]. Cosmeceuticals are formulated with pharmaceutical-type ingredients that have special ability to treat and enhance the beauty of the skin from inside out [3]. Cosmeceuticals are currently very popular, especially for products that are designed and developed to help in prevention and treatment of aging skin. [4].

In the recent years, nanoemulsion has gain interest as a colloidal delivery system within the food, pharmaceuticals, cosmeceuticals, and other industries to encapsulate, protect and deliver bioactive lipophilic components, such as drugs, vitamins, neutraceuticals and antioxidants [5-7]. Nanoemulsion is defined as emulsion system having particle size ranging from 20 – 500 nm [8, 9]. The size range may vary depending on authors, in which some authors consider 500 nm as the upper limit [10]. Due to small particle size, nanoemulsion possess stability against sedimentation, flocculation or creaming [11]. Nanoemulsion is a non-equilibrium system and cannot be formed spontaneously. Nanoemulsion is only kinetically stable [12], in which it differs from microemulsion, which is also transparent or translucent but thermodynamically stable [13]. The attractions of nanoemulsion in personal care and cosmetics applications are due to the use of low surfactant concentration (3 – 10%) compared to microemulsion (usually 20% or higher) [14], small droplet size for uniform distribution on the skin [15] and efficient drug delivery of active ingredients through the skin [16]. Nowadays, nanoemulsion has been used as nanocarrier to deliver the active component in the product to its targeted cells more effectively due to advancement in nanotechnology [3]. Basically, nanoemulsion can be prepared using two methods: the high energy method that involves the use of mechanical devices (e.g. ultrasonicator, rotor/stator system and high pressure homogenizer) and low energy method in which the chemical potential of the component is used such as phase inversion temperature (PIT), phase inversion composition (PIC) and spontaneous emulsification method [6-7, 10].

Anti-aging agent such as antioxidant has been shown to decrease sunburn cells after UV exposure, neutralize free radicals and act as a humectant when applied on the skin [2]. Vitamin E is the most renowned type of antioxidant [3] and widely used in cosmeceuticals and pharmaceutical industries. It exists in eight different isomers including α, β, γ and δ derivatives of tocopherol and tocotrienol [17]. Among these isomers, α-tocopherol is the form of vitamin E with the highest abundance and biological activity that is important to protect cellular membranes from lipid peroxidation by free radicals [4]. Vitamin E is a lipid soluble antioxidant that scavenges free radicals and protects membrane lipids from peroxidation when taken orally [2]. However, the α-tocopherol form of vitamin E is highly unstable to oxidation due to its chemical degradation [18]. A system that can encapsulate these lipophilic nutraceuticals may able to protect from chemical degradation during storage and increase their bioavailability [19, 20]. For this reason, there has been increasing studies on nanoemulsion-based delivery system as vitamin E carrier [21].

Palm olein is the liquid fraction that is obtained from fractionation of palm oil. It is reported to have a higher content of monounsaturated fatty acid especially oleic acid (C 18:1; 39.8 – 43.9%) [22]. Palm olein has been considered to possess higher antioxidant activity due to presence of natural antioxidants such as α-tocopherol and α-tocotrienol [23, 24]. These natural antioxidants contains in palm olein are physiologically active as vitamin E [25, 26]. There was a research that proved its role as a natural antioxidant supplement that was capable in protecting the brain against oxidative damage [27]. Furthermore, it also possess free radical scavenger properties, which is to protect biological systems against oxidative and carcinogenic stress [28-30], in addition to inhibiting cholesterol biosynthesis and platelet aggregation [31, 32].

In this study, the formulation of nanoemulsions was developed by using palm olein as the oil phase (O), polyoxyethylene (4) lauryl ether (Brij 30) as surfactant (S) and vitamin E as anti-aging agent. This study was conducted to formulate and improve the stability of nanoemulsion system based on palm olein as a carrier of vitamin E and the physicochemical behaviour of the system were studied.

## Materials and Methods

Refined palm olein used in this study was obtained from Delima Oil Products Sdn. Bhd. Vitamin E was purchased from Sigma Aldrich (USA). Nonionic surfactant, polyoxyethylene (4) lauryl ether (Brij 30), $C_{20}H_{42}O_{5;}$ was purchased from ACROS Organics (Singapore). Distilled water was used throughout the experiments. All the chemicals were analytical grade and directly used without further purification.

To determine the concentration range of components that can form nanoemulsions, pseudo-ternary phase diagrams were constructed using water titration method at 25 °C. Brij 30 was mixed with palm olein at oil: surfactant (O/S) ratio of 1:9, 2:8, 3:7, 4:6, 5:5, 6:4, 7:3, 8:2 and 9:1 [33, 34]. The mixtures of oil and surfactant at each specific weight ratios were thoroughly mixed and heated at 50 °C, and then cooled to ambient temperature before titrating with water drop wise from 5 – 95% wt. at 5% wt. of water intervals. The mixtures were then homogenized using homogenizer (IKA® T25 digital ULTRA-TURRAX®) for 3 minutes at 5000 rpm. The mixtures were assessed visually and the regions that formed clear mixtures were mapped on pseudo-ternary phase diagrams. Samples that did not show birefringence under polarized light microscopy were labelled as nanoemulsion. 1% wt. of vitamin E was added to selected nanoemulsion mixtures as shown in Table 1. The vitamin E-loaded and unloaded systems were characterized for stability, particle size, electrical conductivity, viscosity and pH [35, 36].

Table 1. List of the nanoemulsion systems

| System | Details of the System |
|---|---|
| N1 | Palm Olein/Brij 30/Water, ratio O/S=4:6 |
| N2 | Palm Olein/Brij 30/Water, ratio O/S=5:5 |
| N3 | Palm Olein/Brij 30/Water, ratio O/S=6:4 |
| NE1 | N1 with 1% wt. of vitamin E |
| NE2 | N2 with 1% wt. of vitamin E |
| NE3 | N3 with 1% wt. of vitamin E |

The chemical and physical stability of nanoemulsions were studied via clarity and phase separation observation during a period of one month at different storage conditions at 4, 25 and 40 °C. Freeze-thaw cycle test was conducted for four cycles by keeping the nanoemulsion systems at different storage temperature of 12 hours at each temperature. The droplet sizes of nanoemulsions were determined by Particle Size Analyzer Zeta-Sizer (Malvern Instrument, England).

Conductivity measurements were performed at 25 ± 0.2 °C using a conductometer (inoLab cond. Germany). A solution of 0.01 mM sodium chloride (NaCl) was used in the preparation of the nanoemulsion samples instead of distilled water for the electrical conductivity [37]. The viscosity of various nanoemulsions was measured using Anton Paar Rheometer (Physica MCR 301, Austria) at 25 ± 0.2 °C. For pH values determination, the samples were calibrated with pH buffer before the measurements were done. The measurements were carried out triplicate using pH meter (Mettler Toledo MP 200, Switzerland) at 25 °C. All systems were tested and each measurement repeated three experiments.

## Results and Discussion

### Construction of ternary phase diagram

The region of nanoemulsion can be explained with the help of the pseudo-ternary phase diagrams. The phase diagram was constructed based on 'water dilution lines' which demonstrated an increase of water content while

decreasing surfactant content that is represented by the arrow line as shown in Figure 1. The phase diagram of Palm Olein/Brij 30/Water nanoemulsion system which was prepared using homogenizer. Subsequently, the nanoemulsion systems prepared were investigated with a polarizing light microscope. This was to identify the isotropic spherical structure of nanoemulsion (non-birefringent) from a liquid crystalline structures (birefringent) of non-nanoemulsion [33, 34, 38]. The shaded region in Figure 1 represents the nanoemulsion system of Palm Olein/Brij 30/Water with no birefringence under polarized light microscope. A successful pharmaceutical nanoemulsion system should not only have a stable and transparent, but also with a low content of surfactant to avoid skin irritation [14, 39]. Obtained nanoemulsion systems seem to meet these criteria, since it involved a low amount of surfactant as shown by the shaded region that located in the center of phase diagram. Therefore, six formulations N1, N2, N3, NE1, NE2 and NE3 were selected for further investigation (Table 1).

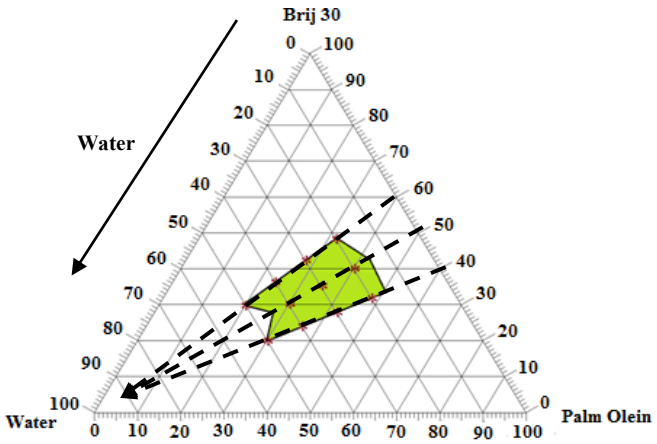

Figure 1. Pseudo-ternary phase diagram of the system Palm olein/Brij 30/Water. The shaded area represents the stable, clear and transparent formulations were produced. Dotted line arrow ( - - → ) shows the water dilution line that representing an increase of water content while decreasing surfactant levels

**Particle size**

The droplet size of the nanoemulsions were measured by assuming a monodispersed phase based on spherical globules. Table 2 show the mean droplet size of nanoemulsion systems. Addition of vitamin E into the system N1 and N2 did not significantly affect the particle size of the nanoemulsion system. However, it seems to significantly affect the particle size of system N3. Both NE1 and NE2 systems with vitamin E-loaded have a particle size in the range of nanoemulsion (20-500 nm). Meanwhile, the NE3 systems resulted on larger particle size (>500 nm). These can be explain that the component's composition may have a considerable effect in the droplet size of system [39]. The larger droplet size (>500 nm) were observed from these formulations might be due to the incompatibility or inhomogeneousity of nanoemulsion's components that caused on particle coagulation [40]. Regarding to the smaller droplet size range as low as <100 nm, the NE1 and NE2 systems should be advantage in dermal and transdermal delivery system of vitamin E [41]. These nano-sized droplets system may have the potential to penetrate to virtually every organ of the body, including lymph nodes and the deep vasculature of solid tumors, yet too small to be readily removed by the liver [42].

Table 2. Particle diameter of Palm olein/Brij 30/Water for system N1, N2, N3, NE1, NE2 and NE3 along the water dilution line

| Water Content (%) | Average Particle Size (nm) | | | | | |
|---|---|---|---|---|---|---|
| | N1 | N2 | N3 | NE1 | NE2 | NE3 |
| 20 | 11.74±0.50 | 10.56±0.66 | 559.95±2.05 | 31.45±0.06 | 28.63±6.97 | 346.10±18.48 |
| 30 | 30.53±1.51 | 546.9±2.69 | 894.05±11.20 | 38.48±8.03 | 27.19±10.66 | 72.99 ± 0.19 |
| 40 | 14.51±0.08 | 42.23±0.06 | 868.15±3.32 | 42.58±24.93 | 47.50±6.84 | 550.70±17.50 |
| 50 | 134.50±2.97 | 625±34.51 | 791. 35±16.41 | 46.50±3.83 | 42.66±7.25 | 560.10±19.56 |

**Stability studies**

Stability studies were imposed on nanoemulsion systems for a month at three different temperatures (4 °C, 25 °C and 40 °C) to observe for any phase separation, sedimentation, flocculation, coalescence or creaming during storage. Based on the observation, all systems are clear and stable at these temperatures with no phase separations as shown in Fig. 2. The samples are also subjected to four freeze-thaw cycle test at 4 °C, 25 °C and 40 °C for 12 hours storage at each temperature. The result shows that nanoemulsion systems with- and without addition of vitamin E are stable during the test cycle. This is due to higher content of oleic acid in palm olein that may have considerable stabilization effect against droplet coalescence [17].

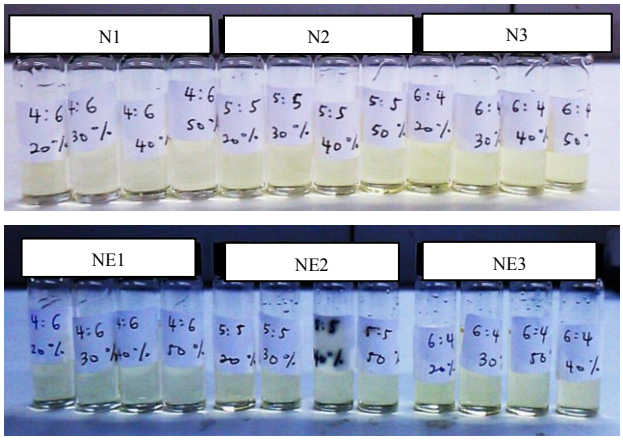

Figure 2. A transparent and stable nanoemulsion systems upon storage after a month

**Conductivity**

Electrical conductivity provide structural information and can be used to differentiate water-in-oil (w/o), bicontinuous (bc) and oil-in-water (o/w) types of nanoemulsion. The conductivity of nanoemulsion system tends to increase with an increase of water content, from (w/o) to (o/w) phase through bicontinuous phase [33-34, 43]. Fig. 3 shows the phase transitions of Palm olein/Brij 30/Water nanoemulsion along water dilution line. All systems shows slow incensement in conductivity from 20 to 30% wt. of water, but start to increase significantly up to 50% wt. of water. The low conductivity region with water content up to 30% wt. represented w/o region of nanoemulsion. At this stage, water droplets were discrete in an oil continuum and possess weak interactions [44, 45]. Subsequently, as the water content is raised up to 50% wt., the conductivity increasing due to increasing interactions between the aqueous domains forming interconnected conductive channels (bc structure). This is due to the attractive interaction between the spherical microdroplets of aqueous phase of w/o nanoemulsion [46, 47] as they changed from w/o structures to the bicontinuous region. Therefore, all systems can be classified as water-in-oil (w/o) at range 20 to 30% wt. of water and bicontinuous (bc) at >40% wt. of water.

The effect of solubilised vitamin E on the microstructure of the nanoemulsions only resulted on small increase in the electrical conductivity of the systems. However, these effect is not significant, especially when water is entrapped in the oil phase (w/o nanoemulsion), but it becomes larger once the continuous phase is water (>40% wt. of water) [48]. In conclusion, this can be considered that there is no major differences between the vitamin E-loaded and unloaded systems at which the phase transition occurs.

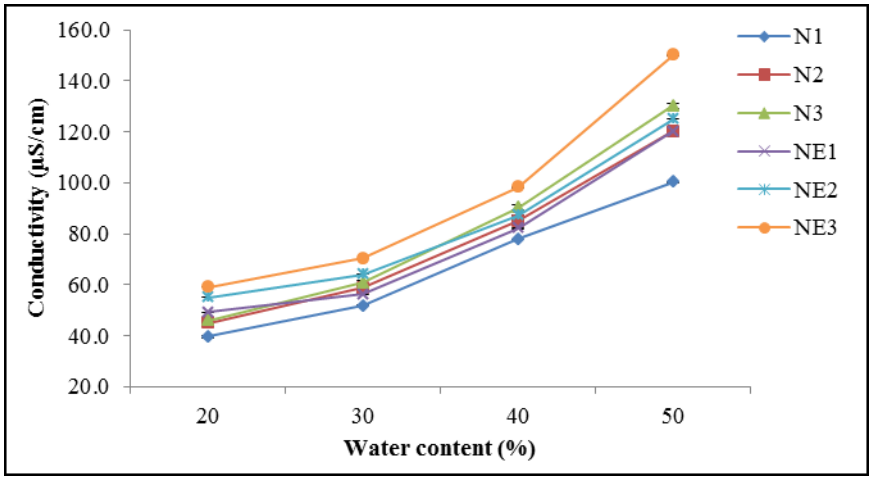

Figure 3. Electrical conductivity of Palm olein/Brij 30/Water nanoemulsion systems

**Viscosity and pH**

The values of pH and viscosity of the nanoemulsion system along water dilution line at 25 ºC as shown in Table 2. Each data point is the mean (± SD) of three experiments. Addition of vitamin E seem not significantly effect the viscosity of the nanoemulsion system. Plus, all systems show a very low viscosity that lies in the range of 0.04 to 0.07 Pa.S. These such low-viscosity colloidal dispersions consisting of micro domains of oil or water stabilized by an interfacial film of surfactant may be a good strategy to enhance the rate of drug delivery [49]. Most likely, the o/w nanoemulsion systems resulted on the lower viscosity compared to w/o nanoemulsion. The o/w nanoemulsion could act as drug reservoirs, where the loaded drug in the dispersed phase is released from the internal phase to the external phase and then improved the rate of drug delivery [50]. As an addition, all systems resulted on the pH values in the range of 6-7. These properties are acceptable in pharmaceutical application, for example, for the use as topical or transdermal drug delivery systems [51].

Table 2. Viscosity and pH of Palm olein/Brij 30/Water nanoemulsion systems

| Formulations | Water Content (% wt.) | Viscosity (Pa.S) | pH |
|---|---|---|---|
| N1 | 20 | 0.0614 ± 0.0024 | 6.10 ± 0.01 |
| | 30 | 0.0702 ± 0.0064 | 6.30 ± 0.01 |
| | 40 | 0.0537 ± 0.0011 | 6.40 ± 0.01 |
| | 50 | 0.0460 ± 0.0000 | 6.40 ± 0.01 |
| N2 | 20 | 0.0625 ± 0.0012 | 6.00 ± 0.01 |
| | 30 | 0.0451 ± 0.0001 | 6.20 ± 0.01 |
| | 40 | 0.0507 ± 0.0002 | 6.50 ± 0.01 |
| | 50 | 0.0447 ± 0.0005 | 6.80 ± 0.01 |

Table 2 (cont'd). Viscosity and pH of Palm olein/Brij 30/Water nanoemulsion systems

| Formulations | Water Content (% wt.) | Viscosity (Pa.S) | pH |
|---|---|---|---|
| N3 | 20 | 0.0510 ± 0.0004 | 6.30 ± 0.01 |
| | 30 | 0.0502 ± 0.0003 | 6.40 ± 0.01 |
| | 40 | 0.0504 ± 0.0001 | 6.50 ± 0.01 |

| | 40 | 0.0509 ± 0.0006 | 6.70 ± 0.01 |
| | 50 | 0.0493 ± 0.0005 | 6.90 ± 0.01 |

## Conclusion

Nanoemulsion with low content of surfactant were successfully formulated as a carrier of anti-aging agent. The pseudo-ternary phase diagram of nanoemulsion systems were constructed. All systems show high stability in various temperatures (4, 25 and 40 °C). Addition of vitamin E slightly changes the mean droplet size, electrical conductivity, viscosity and pH of system, however, these effects does not alter the microstructure of the system. The electrical conductivity measurement shows the transitions of these microemulsion systems from water-in-oil to bicontinuous phase without undergo phase separation. The antioxidant activity of palm olein together with vitamin E should enhanced the anti-aging activity of these nanoemulsion systems.

**Abstract**

The purpose of the present study was to investigate the effect of different oil and chain lengths of co-surfactant on microemulsion region. Oleic acid and isopropyl myristate were used as the oil phase, transcutol, polyethylene glycol 400 (PEG 400) and propylene glycol as co-surfactant and Brij 97 as a surfactant. From the ternary phase diagrams, isopropyl myristate based system is more feasible oil phase to formulate microemulsion compared to oleic acid based system. Moreover, transcutol (medium chain length) is the most suitable co-surfactant to blend with a single-chain surfactant, Brij 97 in order to have a high stability and a large area of microemulsion region.

**Keywords:** microemulsion, oleic acid, isopropyl myristate, transcutol, propylene glycol

**Abstrak**

Kajian ini bertujuan untuk mengkaji kesan minyak yang berbeza dan panjang rantai ko-surfaktan terhadap rantau mikroemulsi. Asid oleik dan isopropil miristat telah digunakan sebagai fasa minyak, transcutol, polietilena glikol 400 (PEG 400) dan propilena glikol sebagai ko-surfaktan dan Brij 97 sebagai surfaktan. Berdasarkan rajah fasa tenari, sistem berasaskan isopropil miristat adalah fasa minyak yang lebih sesuai untuk membentuk mikroemulsi berbanding sistem berasaskan asid oleik. Selain itu, transcutol yang berantai sederhana panjang adalah ko-surfaktan yang sesuai untuk diformulasikan bersama surfaktan rantai tunggal, Brij 97 yang memberikan rantau kawasan mikroemulsi yang besar dengan kestabilan yang tinggi.

**Kata kunci**: mikroemulsi, asid oleik, isopropil miristat, transcutol, propilena glikol

## Introduction

Microemulsions are versatile systems and can be used in various applications such as for cutting oils, corrosion inhibitors, biotechnology, fuels, coating and textile finishing, food industries, lubricants, and also in pharmaceuticals [1]. Microemulsions have generated extensive interest over the years as potential drug delivery systems, especially for the delivery of the hydrophilic and lipophilic drug [2]. It is because of its several characteristics such as improved drug solubilization, longer shelf life, ease of preparation and improvement of bioavailability of poorly soluble drugs [3]. It is also can be used to deliver drugs via several routes and making them as a promising dermal delivery of the drug through an efficient route of drug administration [4].

The idea of microemulsion was introduced by Hoar and Schulman as early as the 1940s where they successfully obtained a clear single-phase solution by titrating a milky emulsion with hexanol [5]. That discovery is still used until now even after seven decades had passed. In general, microemulsion is a colloidal dispersion composed of three or four components which are the oil phase, an aqueous phase, surfactant and co-surfactant at applicable ratios. It is a single optically isotropic and thermodynamically or homogeneously stable liquid solution with a nanodroplet diameter [1, 6]. Microemulsion systems formed spontaneously and have low viscosity which behaves as a Newtonian liquid [4]. Microemulsion has been shown to have an ultra low interfacial tension as it can load a large fraction of surfactant/co-surfactant mixture at interface thus thermodynamically stable [7]. Globule size of stable microemulsions is usually within the range of 10 – 100 nm (100 – 1000°A) therefore the whole system is transparent and the globules became invisible to the naked eye due to the fact that dispersed phase droplet does not refract the light [8]. The size of the droplets makes the term of 'microemulsion' is misleading while these systems are actually nano-sized emulsions [1].

Microemulsion is easy to develop and require a low energy contribution during preparation to form a thermodynamic stability, however, it depends on each of the components. This paper will focus on the effect of the oil phase and co-surfactant to the microemulsion system. The oil phase is the most important excipients in the formulation since it governs the selection of the other ingredients for the microemulsion and there are two main factors that need be considered before selecting the appropriate oil phase. The first one is the capability of the oil in solubilizing the active pharmaceutical ingredient (API). Second, the chosen must be such that can result in the large existence area of the microemulsion. Oils with shorter hydrocarbon chains are more facile to form a microemulsion as compared to oils with long hydrocarbon chains. Meanwhile, an oil potentiality to solubilize lipophilic groups is directly proportional to the chain length of the oil [1]. The most common esters used and act as a permeation enhancer in formulations which is isopropyl myristate, IPM ($C_{17}H_{34}O_2$) and also an unsaturated C18 alkyl chain, oleic acid, OA ($C_{18}H_{34}O_2$) are frequently used in microemulsion formulations.

Microemulsions can be formulated using single-chain surfactants or double chain surfactants. Single chain surfactants do not lower the oil-water interfacial tension sufficiently and hence cosurfactants are required [9]. Co-surfactant accumulates substantially at interface layer, increasing the fluidity of interfacial film by penetrating into the surfactant layer. The presence of co-surfactants contributes the interfacial film sufficient flexibility to take up different curvatures required to form a microemulsion over a wide range of composition. If a single surfactant film is desired, the lipophilic chains of the surfactant should be sufficiently short or contain fluidizing groups (e.g. unsaturated bonds). Short to medium chain length alcohols (C3-C8) are commonly added as co-surfactants which further reduce the interfacial tension and increase the fluidity of the interface [1]. The roles of a co-surfactant are to increase the fluidity of the interface, destroy liquid crystalline or gel structure which would prevent the formation of the microemulsion and adjust the HLB value and spontaneous curvature of the interface by changing surfactant partitioning characteristic [4].

In this preliminary study, our aim is to identify the effect of oil and chain lengths of co-surfactant in resulting a large area of the microemulsion region by using oleic acid and IPM as the oil phase, and various co-surfactant, which are transcutol, PEG 400, and propylene glycol.

## Materials and Methods

Oleic acid (OA) was obtained from Bendosen Laboratory Chemical. Isopropyl myristate (IPM) was purchased from Friedemann Schmidt Chemical. Brij 97 (polyoxyethylene-10-oleyl ether), propylene glycol (PG), transcutol (diethylene glycol monoethyl ether), polyethylene glycol 400 (PEG400) were obtained from Sigma-Aldrich Chemical Co. Deionized water was used throughout the experiments. All other chemicals utilize in the experiments were analytical grade.

### Construction of pseudo-ternary phase diagrams

The pseudo-ternary phase diagrams of oil, surfactant, co-surfactant and water were constructed using water titration method to obtain the components and their appropriate ratio which can result to the large existence area of the microemulsion. In brief, the graph was constructed based on water dilution lines, which represent increasing water content and, thus, decreasing a surfactant-cosurfactant concentration. The oils employed in the present study were

oleic acid and IPM. A non-ionic surfactant (Brij 97) was mixed with various co-surfactant (transcutol, propylene glycol, and PEG-400) at a weight ratio of $K_m$ 1:1, $K_m$ 2:1, or $K_m$ 3:1 to obtain surfactant and co-surfactant mixture, S/CoS ($K_m$). Aliquots of each S/CoS were then mixed with oil at room temperature (25 °C). For each phase diagram, the ratio of oil to the S/CoS was varied as 1:9, 2:8, 3:7, 4:6, 5:5, 6:4, 7:3, 8:2, 9:1 (w/w) and the resulting mixtures were subsequently titrated with water under vigorous stirring with a vortex mixer at room temperature. After equilibrium, the samples were visually checked and determined as being clear microemulsions, or emulsions, or gels. The samples were marked as points in the phase diagram. The area covered by these points was considered as the microemulsion region of existence. Quantities of all three phases were taken in % w/w.

**Polarized light microscopy**

Visual inspection was first made after each addition of water to the oil and surfactant and co-surfactant mixture. The samples were identified as microemulsions when they appear as transparent/translucent and easily flowable liquid. The samples were identified as emulsions when they appeared as milky or turbid liquids. The samples were identified as a gel when they did not show a change in the meniscus after tilting to an angle of 90°. Then, the microemulsion samples were verified their isotropic nature under cross-polarizes light microscopy from the image performed. It is expected that the isotropic substance like microemulsion will not reflect the polarized light and the image viewed will remain dark [10].

## Results and Discussion

**Construction of pseudo-ternary phase diagrams**

Pseudo-ternary plot identifies phase boundaries and distinct regions of the ternary mixture (oil, water, surfactant/cosurfactant) where it may exist as biphasic or monophasic, non-isotropic, or liquid crystalline in nature and co-existed in a state of dynamic equilibrium. When four or more components are used pseudo-ternary phase diagrams are used to depict these systems in which each corner represents binary mixtures of two components such as surfactant/co-surfactant, surfactant/water, oil/drug, and water/drug mixtures [1, 11]. Each corner of the ternary phase diagram represents 100% concentrations of a particular component [12].

Three types of system combinations (Brij 97/PEG400/Water, Brij 97/PG/Water, and Brij 97/Transcutol/Water) were developed with specific ratios of S/CoS ($K_m$ = 1:1, 2:1, and 3:1). Two common oil phase used in these systems are oleic acid and isopropyl myristate. Study of the ternary phase diagrams was done to investigate the effect of OA and IPM with the various mixtures of S/CoS on the formation of the stable microemulsion.

**Effect of OA and IPM on the system of Brij 97/PEG 400/Water**

The pseudo-ternary phase diagrams of the Brij 97/PEG 400/Water system using OA and IPM as the oil phase were shown in Figure 1 and 2 where the shaded region represents the microemulsion region. IPM (molecular volume 528.2 g/cm$^3$) based microemulsion system showed a smaller area of microemulsion as compared to a system based on OA (molecular volume 523.9 g/cm$^3$). This result is in accordance with literature reported by [13] that also indicate the smaller area of microemulsion region when used PEG 400 as a co-surfactant, IPM as an oil phase and Brij 30/Brij 35 (HLB ~11.1) as a surfactant. Meanwhile, the result of OA based system is in good agreement with the previous study conducted by [14] that shows stable microemulsion system consisting of oleic acid (oil phase), Tween 20 (surfactant), PEG 400 (co-surfactant), water (aqueous phase). These results might be due to the fact that the lower the molecular volume of oils, the greater the surfactant efficiency [15]. In terms of ratio, $K_m$ 1:1 of oleic acid based system give a larger region compare to $K_m$ 2:1 and $K_m$ 3:1. The further increment of surfactant concentration i.e. S/CoS ratio $K_m$ 2:1 (Figure 1b) and $K_m$ 3:1 (Figure 1c) appeared to have a destabilizing effect on the formation of the microemulsion and led to considerable reduction in microemulsion area. It might be due to insufficient co-surfactant concentration, required to reduce the interfacial tension and provide the flexibility of the interfaces [15]. Both systems show the lower concentration of water except for the phase diagram in Figure 1(a). This might be due to the inversion phase from w/o to o/w system, where a number of liquid crystalline phase are considered as possible intermediates during the process [16]. For those systems that remain clear at higher concentration of water are expected to be the o/w phase with low percentage of oil in the system.

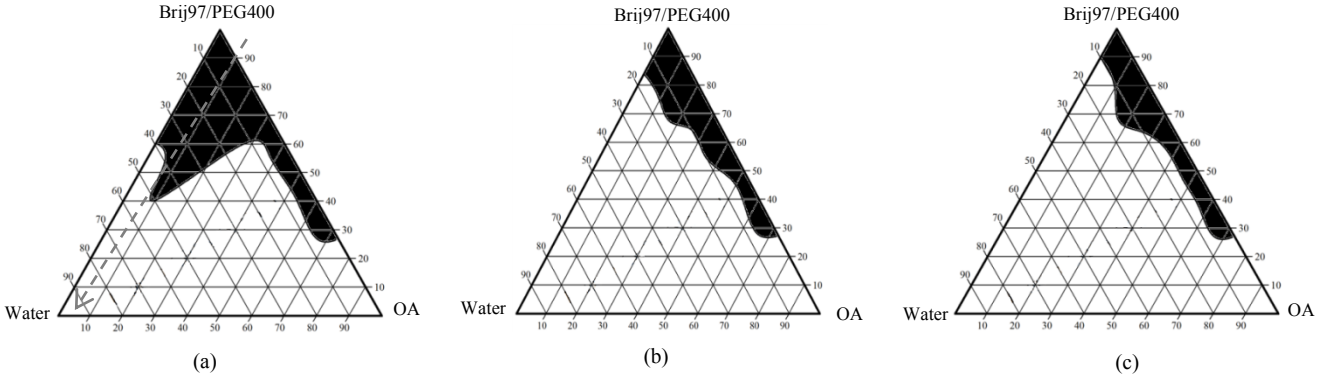

Figure 1. Pseudo-ternary phase diagrams composed of OA/Brij=97/PEG400/water(a)$K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1. The shaded region is microemulsion area and ( - - -> ) water dilution line.

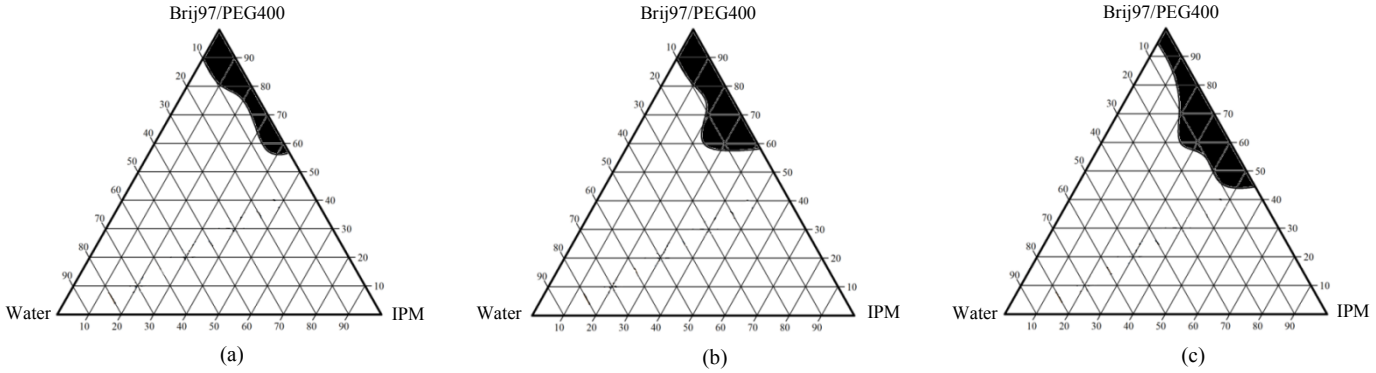

Figure 2. Pseudo-ternary phase diagrams composed of IPM/Brij 97/PEG400/water (a) $K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1

**Effect of OA and IPM on the system of Brij 97/PG/Water**

These systems contain PG as a co-surfactant which is a short chain of co-surfactant. The results in Figure 3 and 4 shows that IPM based system give the bigger area of microemulsion region compared to OA based system. This result is similar to the study conducted by Abd-Allah et al. [16] where the clear microemulsion region was from 10 to 30 wt.% of water content in OA based system and when further dilution with the amount of water, resulting in the formation of a gel. This result also ascribed to the large molecular weight, MW of OA (MW = 282.46 g/mol) compared to IPM (MW = 270.45 g/mol) which is not favored to the formation of microemulsion [16]. For IPM based system, $K_m$ 1:1 give the highest concentration of water content (95 wt. %) at a ratio of oil to S/CoS 1:9. However, at $K_m$ 2:1 and $K_m$ 3:1, the region of microemulsion become smaller because of increasing concentration of Brij 97 make the interfacial tension unstable. This is probably due to an inadequate amount of co-surfactant to assist surfactant in lowering the interfacial tension. Furthermore, using propylene glycol in the microemulsion system, increase viscosity and hence gives the high possibility of the gel formation [17].

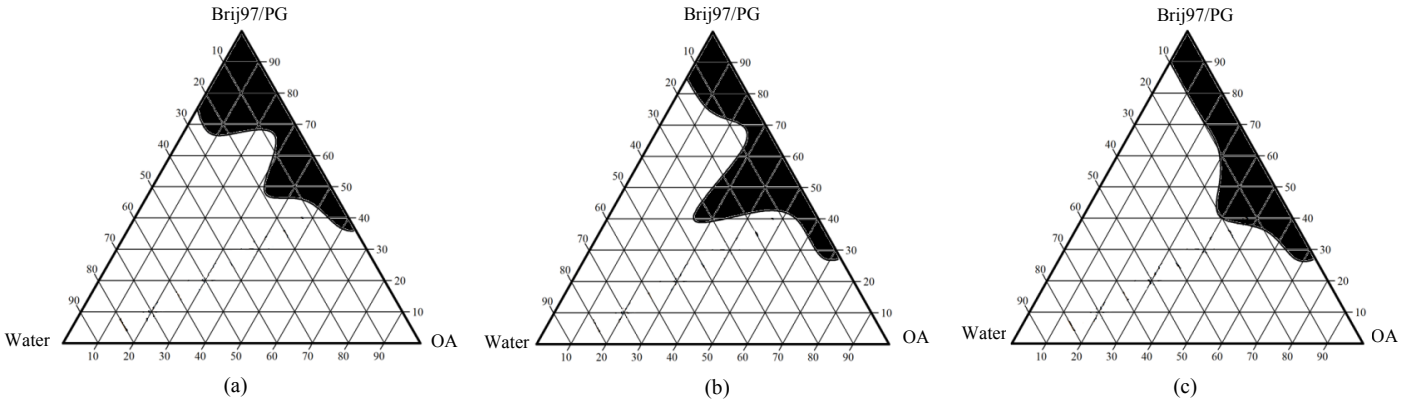

Figure 3. Pseudo-ternary phase diagrams composed of OA/Brij 97/PG/water (a) $K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1

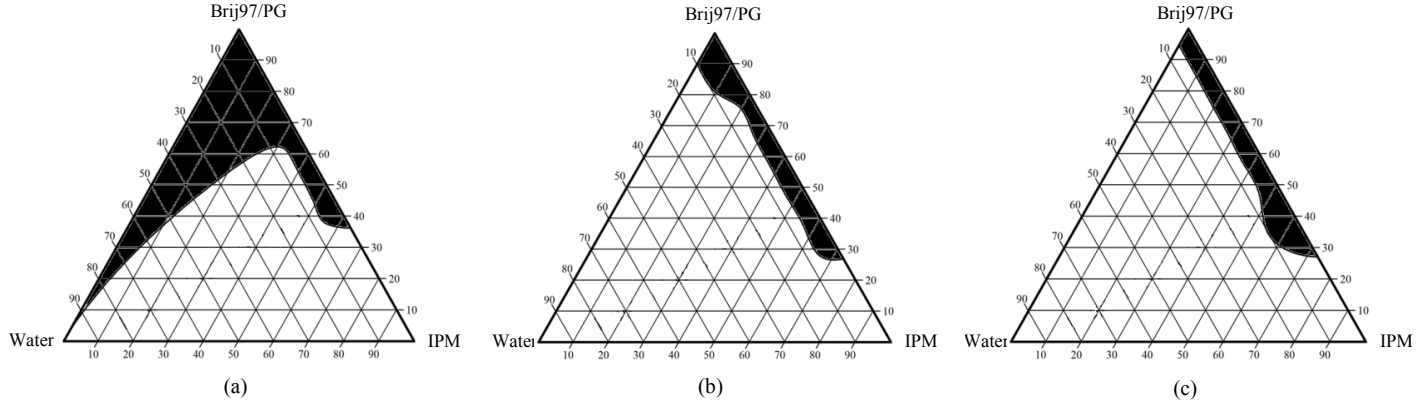

Figure 4. Pseudo-ternary phase diagrams composed of IPM/Brij 97/PG/water (a) $K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1

**Effect of OA and IPM on the system of OA/Brij 97/Transcutol/Water**

Transcutol is a medium chain length act as a co-surfactant and frequently proposed as less irritant and alternatives to the medium chain alcohols [18]. The region of microemulsion using transcutol as a co-surfactant form bigger area comparable to PEG 400 and PG for both oleic acid and IPM based formulation as shown in Figure 5 and 6. The best result is still favored to IPM based formulation where both $K_m$ 1:1 and $K_m$ 2:1 give the highest concentration of water (95 wt.%) at ratio oil to S/CoS 1:9. This result attributable to the function of medium chain length alcohols which can increase the flexibility of the hydrocarbon tail and also allow better penetration of the oil into the region of hydrocarbon. In addition, the solubility properties of aqueous and oil phases could also be increased by medium chain length alcohols due to their partitioning behavior between the two phases. [12].

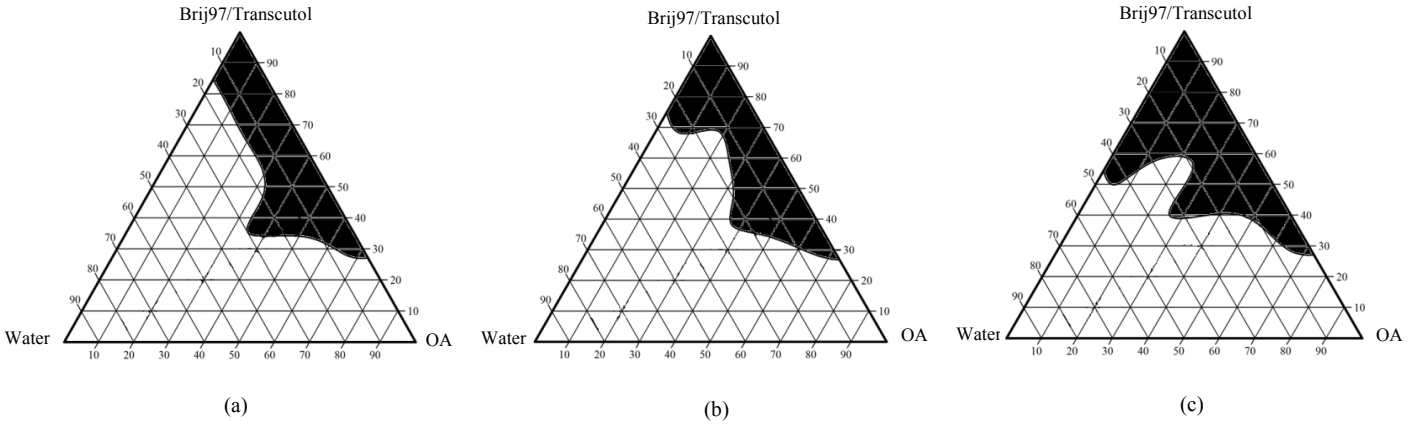

Figure 5. Pseudo-ternary phase diagrams composed of OA/Brij 97/Transcutol/water (a) $K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1

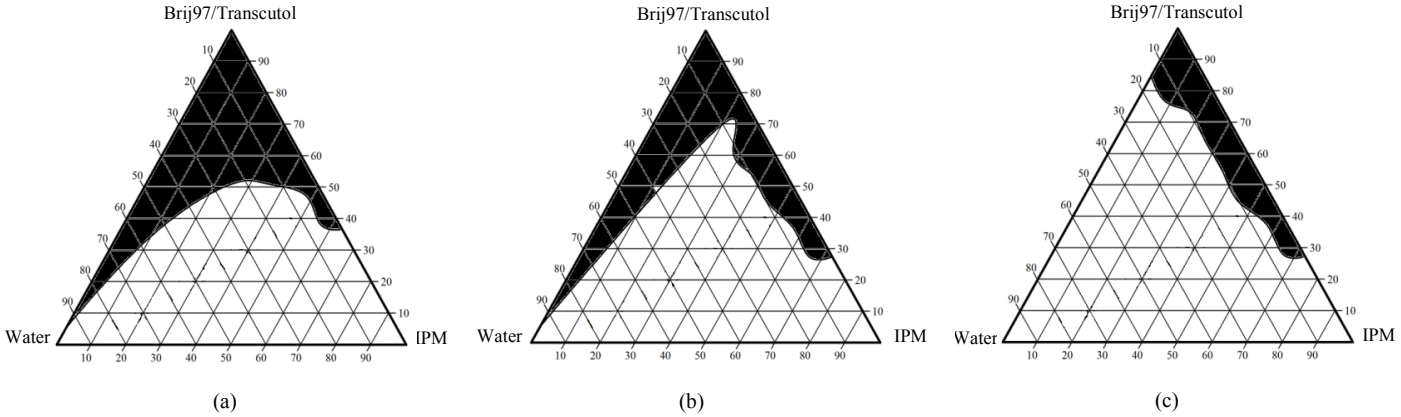

Figure 6. Pseudo-ternary phase diagrams composed of IPM/Brij 97/Transcutol/water (a) $K_m$ 1:1, (b) $K_m$ 2:1 and (c) $K_m$ 3:1

A system which comprises of IPM (oil), Brij 97 (surfactant), transcutol (co-surfactant) and water (aqueous) shows a high stability and a broad microemulsion area (Figure 7) thus, it is potential to utilize in various applications especially in pharmaceutical application due to their safe and pharmaceutical accepted components.

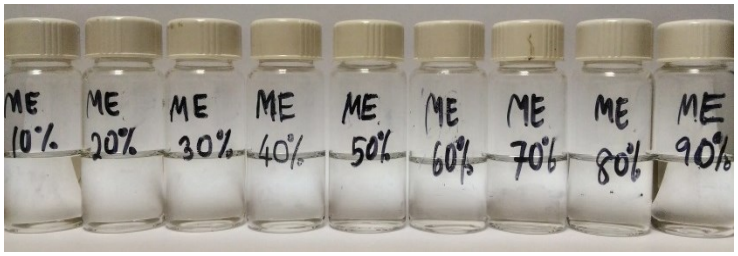

Figure 7. The clear and isotropic of IPM/Brij 97/Transcutol/Water microemulsion system

## Conclusion

A total of 18 phase diagrams were constructed successfully and each formulation gives significant effect on the area of microemulsion region. This study gives two conclusions that could make. First, oleic acid based system (OA/Brij 97/PEG 400/Water, OA/Brij 97/PG/Water, and OA/Brij 97/Transcutol/Water) could not form a large region of microemulsions. Therefore, IPM shows a better choice in order to get a larger area of microemulsion with a higher concentration of water with transition phase from water-in-oil (w/o) to oil-in-water (o/w). Second, the effect of a co-surfactant depends on its chain length, where only appropriate chain lengths are suitable for good microemulsion formation [14]. PEG 400 (long chain), transcutol (medium chain) and propylene glycol (short chain) were used in this study to evaluate the effect of co-surfactants on the formation of microemulsions. In this case, medium chain length is the most suitable co-surfactant in combination with the single-chain surfactant, Brij 97 followed by short and long chain length.

**Abstract**

Magnetic polymer nanocomposites (MPNCs) based on poly(lactic acid)/liquid natural rubber (PLA/LNR) (90:10) blend and nickel zinc (NiZn) ferrite magnetic nanoparticles were fabricated via melt-blending technique. The effect of NiZn ferrite nanofiller concentration (1 – 5 wt.%) on the tensile and thermal properties of PLA/LNR/NiZn ferrite nanocomposites was investigated. Tensile tests showed that as the tensile strength and modulus increased with the increase of nanofiller concentration until the optimum values of nanofiller concentration was achieved. The thermal behaviour of MPNCs including degradation temperature and its shiftment as well as the remaining residues after complete degradation were determined by thermogravimetric analysis (TGA) measurement. As the NiZn ferrite nanofiller concentration increased, it was noted that the $T_{end}$ of nanocomposites at low amount of nanofillers (1 – 2 wt.%) was higher than neat PLA/LNR and nanocomposites containing high concentration of nanofillers. The current work proves that NiZn ferrite could be served as an excellent reinforcement filer in PLA/LNR matrix. The improved tensile properties and thermal stability of PLA/LNR composites achieved at 2 – 3 wt.% NiZn due to the good dispersion of NiZn ferrite within the PLA/LNR matrix and strong filler-matrix interfacial adhesion, as can be confirmed by the scanning electron microscope (SEM).

**Abstrak**

Nanokomposit polimer magnetik (MPNC) berasaskan adunan asid polilaktik/cecair getah asli (PLA/LNR) (90:10) dan nanozarah magnetik nikel zink ferit (NiZn) dihasilkan melalui teknik pengadunan leburan. Kesan kandungan NiZn ferit (1-5 %bt) terhadap sifat regangan dan terma nanokomposit PLA/LNR/NiZn telah dikaji. Ujian regangan menunjukkan bahawa peningkatan kekuatan dan modulus regangan dengan peningkatan kandungan pengisi nano sehingga nilai optimum tercapai. Tingkah laku terma bagi MPNCs termasuk suhu degradasi ($T_{end}$) dan anjakannya serta baki sisa selepas degradasi lengkap telah ditentukan melalui analisis termogravimetri (TGA). Apabila kandungan NiZn ferit pengisi nano meningkat, didapati $T_{end}$ bagi nanokomposit berpengisi nano dalam kandungan kecil (1 – 2 %bt) adalah lebih tinggi daripada PLA/LNR dan nanokomposit terkandung pengisi yang banyak. Hasil kajian ini membuktikan bahawa NiZn ferit boleh bertindak sebagai pengisi pengukuhan yang baik dalam matriks PLA/LNR. Penambahbaikan sifat regangan dan kestabilan terma komposit PLA/LNR tercapai pada 2 – 3 %bt NiZn disebabkan penyebaran NiZn ferit yang baik dalam matriks PLA/LNR dan lekatan antaramuka pengisi-matriks yang kuat, seperti yang disahkan oleh mikroskop elektron imbasan (SEM).

## Introduction

In recent years, the development research works based on the use of biodegradable materials such as poly(lactic acid) (PLA) which served as biopolymer, have been attracted lots of attention from academic and industrial area. Due to the renewability issue and comparable properties with petroleum based polymers, PLA is gaining its popularity [1]. However, as well-established, high brittleness is the main weakness for PLA to be applied in most of the commercial applications [2]. As for that, toughening of PLA by blending with rubber is an applicable method, as a result of the ductility properties imparted by natural rubber (NR). Another advantage could be, NR is derived from renewable sources. Therefore, blending of PLA and NR such as liquid natural rubber (LNR) which is a low molecular weight version of NR, could be a good choice to enhance the toughness of PLA without affecting its biodegradability [1,2]. Somehow, PLA based blending does not provide any high end performance, for examples, electrical, magnetic, conductivity properties and etc. In which these limit its applications in various high performance fields and industries.

Magnetic polymer nanocomposites (MPNCs) are known as materials consisted of an inorganic magnetic component with at least one dimension in the nanometer scale whether in the form of fibers, particles, or lamellae that embedded in an organic polymer [3]. By combining the polymeric matrix materials that are non-magnetic properties with the magnetic nanoparticles as fillers, a new composite material that possesses magnetic properties can be produced and its applications and usefulness can be further expanded. The combination of organic and inorganic materials in magnetic polymer nanocomposites (MPNCs) has produced new properties that could not be obtained by single organic or inorganic material. The applications for MPNCs can be extended from the fields related to the environment [3, 4] until medical field [5]. For instances, technological fields have recently getting more and more attention in the market, especially, in the microwave, electronics and telecommunication industries such as microsensors, magnetic refrigeration, microelectromechanical system, controlling drug delivery and etc. [3, 6].

As well-known, nickel zinc (NiZn) ferrite is soft magnetic material which possesses versatile properties such as high saturation magnetization, electrical resistivity, mechanical hardness, thermal conductivity and chemical stability as well as low coercivity and dielectric losses [7, 8]. In actual sense, not much researchers have studied the use of NiZn ferrite in PLA/LNR matrix [9]. The selection of PLA and LNR to form blend matrix was made because of their biodegradability and cost effectiveness as well as high strength and modulus. Instead of magnetic properties, the objective of this current work is to investigate the effect of NiZn ferrite as nanoparticles on the tensile, thermal and morphological behaviours of nanocomposites based on poly(lactic acid)/liquid natural rubber (LNR) blend.

## Materials and Methods

### Raw materials

The chosen thermoplastic resin, a commercial poly(lactic acid) with the trade name of Natureworks Ingeo Biopolymer 3251D, density of 1.24 g/cm$^3$ and melt flow index of 30 – 40 g/10 min (190 °C/2.16 kg), was obtained from Unic Technology Ltd, China. SMR-L grade natural rubber (NR) which supplied by Malaysian Rubber Board (MRB) was used to synthesize the liquid natural rubber (LNR) via photosensitized chemical oxidation technique. The nanofiller used in this study, nickel zinc (NiZn) ferrite nanoparticles powder with the chemical formula of $Ni_{0.5}Zn_{0.5}Fe_2O_4$, 98.5% purity and 10 – 30 nm particle size was purchased from Nanostructured & Amorphous Materials Inc, USA.

### Preparation of nanocomposites

Prior to mixing, PLA was dried in the oven at 100 °C for 24 hours to eliminate trapped moisture in PLA. PLA/LNR blend and PLA/LNR/NiZn ferrite nanocomposites were melt-blended using an internal mixer machine (Haake Rheomix 600P) at 180 °C, 100 rpm and complete mixing time of 15 minutes. Indirect mixing technique (IDT) was applied to prepare nanocomposites, by pre-mixing the NiZn ferrite powder into LNR before being introduced in the mixer. The ratio of PLA and LNR was mixed at 9:1, whereas the NiZn ferrite nanoparticles was varied from 1 to 5 wt.%. PLA was first introduced into the internal mixer for melting about 3 minutes, then the pre-mixture of LNR and NiZn ferrite was added. The whole mixing process was completed for 15 minutes. In order to produce the composite specimens for characterization, compression molding was carried out via hot/cold pressing process. The temperatures of the upper and lower plates were applied at 180 °C, whereas the pressure was set at 6.9 MPa. The

preheating of 4 minutes, venting of 4 minutes, full pressing of 5 minutes and cold pressing of 3 minutes were applied.

**Characterization**

Tensile testing was conducted using Testomeric tensile machine (Model Testomeric M350-10CT) with load cell of 5 kN and at a crosshead speed of 50 mm/min using 1 mm thickness test specimens in accordance with ASTM 412. At least five replicate specimens were tested for each formulation. Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) were carried out using Mettler Toledo TGA/SDTA851$^e$ and DSC 882$^e$, respectively. For TGA, samples were tested at a heating rate of 10 °C/min from 100 °C to 500 °C. The surface morphology of tensile-fractured specimen was analysed using scanning electron microscope (SEM) (Philips XL 30). Energy dispersive X-ray spectroscopy (EDX) was carried out to determine the elemental composition of the nanocomposites containing different NiZn ferrite concentrations.

## Results and Discussion

The effect of NiZn ferrite loadings on the tensile strength and Young's modulus of PLA/LNR nanocomposites is described in Table 1. The tensile results indicates that both tensile strength and Young's modulus exhibited the same trend, that is the increasing concentration of NiZn ferrite increased the tensile properties until an optimum level of nanofillers, and then decreased for higher nanofiller concentrations. Neat PLA/LNR blend possessed 29.93 MPa of tensile strength and 5.29 GPa of Young's modulus. Comparing to that, the highest tensile strength (40.90 MPa) and Young's modulus (7.50 GPa) were achieved at nanocomposite incorporated with 2 wt.% NiZn ferrite, which are increased by 36.65% and 41.78%, respectively. This could be ascribed to the good interfacial interaction between the PLA and NiZn ferrite as a result of the enhanced nanofiller dispersion [2]. When NiZn ferrite nanoparticles added at above 2 wt.%, the tensile strength and Young's modulus decreased gradually from 3 to 5 wt.%. The possible reason is the presence of nanoparticles' agglomerates within the matrix when the content of NiZn ferrite exceeded the optimum level.

Table 1. Tensile strength and Young's modulus of PLA/LNR nanocomposites with various NiZn ferrite loadings

| Sample (wt.% NiZn Ferrite) | Tensile Strength (MPa) | Young's Modulus (GPa) |
|---|---|---|
| PLA/LNR | | |
| 0 | 29.93 ± 0.81 | 5.29 ± 0.04 |
| 1 | 36.70 ± 2.51 | 7.34 ± 0.34 |
| 2 | 40.90 ± 1.61 | 7.50 ± 0.17 |
| 3 | 38.01± 1.50 | 7.14 ± 0.45 |
| 4 | 36.96 ± 1.65 | 6.90 ± 0.04 |
| 5 | 35.45 ± 2.13 | 6.78 ± 0.04 |

Thermogravimetric analysis (TGA) has been carried out to study the mass changes the increase temperature. The mass loss of sample was due to the vaporization process occurred when the temperature increased until a certain high temperature. Figure 1 presents TGA curves of PLA/LNR nanocomposites with various NiZn ferrite loading. Table 2 summarizes the data obtained from TGA testing for all investigated formulations, including temperature of weight loss at 3% ($T_3$) and 50% ($T_{50}$), final degradation temperature ($T_{end}$) as well as residue left after 400 °C. The results of weight loss at 3% ($T_3$) are important to understand the thermal behaviour at initial stage and to determine the thermal stability of nanocomposites. Based on Figure 1, neat PLA/LNR blend and PLA/LNR/NiZn ferrite nanocomposites experienced a dramatic weight loss at around 300 – 350 °C. This represents the degradation of PLA/LNR blend components, as reported by Bijarimi et al. [2]. It was found that PLA/LNR nanocomposites incorporated with 1 and 2 wt.% NiZn ferrite underwent the degradation process at higher temperature.

As compared to neat PLA/LNR blend ($T_3$ = 283.98 °C, $T_{50}$ = 324.75 °C and $T_{end}$ = 396.69 °C), nanocomposite with 1 wt.% NiZn ferrite exhibited $T_3$ = 285.29 °C, $T_{50}$ = 325.44 °C and $T_{end}$ = 412.78 °C while nanocomposite with 2 wt.% NiZn ferrite demonstrated $T_3$ = 285.35 °C, $T_{50}$ = 326.79 °C and $T_{end}$ = 401.91 °C. These phenomenons suggest the improved thermal stability by adding nanofiller in small amount. Similar results were observed for thermoplastic natural rubber (TPNR)/NiZn ferrite nanocomposites [8]. Further increasing the concentration of NiZn ferrite in the PLA/LNR blend matrix, the weight loss curves seemed to be similar (3 and 4 wt.%) and shifted to the left (5 wt.%), as depicted in Figure 1 and Table 2. This might be due to the agglomeration of nanofillers (as shown by 4 wt.% NiZn ferrite in Figure 2(c)) which negatively affects the dispersion and distribution of NiZn ferrite within the PLA/LNR matrix. As the agglomerated NiZn ferrite poorly distributed within the PLA/LNR matrix, the heat transfer from matrix to filler is restricted or delayed in the inhomogenous parts of the composites, and thus, induces the reduced thermal stability of nanocomposites. As the temperature reached to about 400 °C, the change in weight loss as a function of temperature can be considered negligible as a result of the complete degradation of PLA/LNR matrix into carbonaceous products. Therefore, the obtained weight percentages of residues could imply the remaining non-decomposed magnetic nanofillers [8]. As expected, the residues increased with the concentration of NiZn ferrite added from 1 to 5 wt.%.

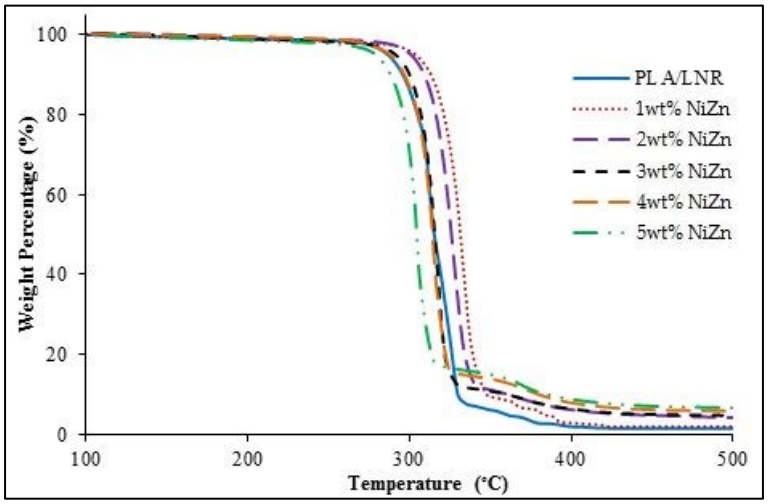

Figure 1. TGA curves of PLA/LNR nanocomposites with various NiZn ferrite loadings

Table 2. TGA data of PLA/LNR nanocomposites with various NiZn ferrite loadings

| Sample (wt.% NiZn ferrite) | $T_3$ (°C) | $T_{50}$ (°C) | $T_{end}$ (°C) | Residue (%) |
|---|---|---|---|---|
| PLA/LNR | | | | |
| 0 | 283.98 | 324.75 | 396.69 | 1.46 |
| 1 | 285.29 | 325.44 | 412.78 | 1.96 |
| 2 | 285.35 | 326.79 | 401.91 | 3.35 |
| 3 | 270.33 | 313.06 | 396.57 | 4.19 |
| 4 | 250.41 | 312.89 | 386.53 | 5.27 |
| 5 | 235.15 | 302.90 | 381.88 | 5.73 |

Figure 2 illustrates the SEM micrograph of PLA/LNR with (a) 0 wt.%, (b) 2 wt.% and (c) 4 wt.% NiZn ferrite nanoparticles. In Figure 2(a), the neat PLA/LNR blend (without NiZn ferrite nanoparticles) showed a one-phase

surface morphology with the existence of holes that indicates rubber particles in the PLA matrix. For Figure 2(b), the presence of holes seemed getting lesser as filled by homogenous dispersion of NiZn ferrite nanoparticles. At higher concentration of NiZn ferrite, for instance at 4 wt.% (Figure 2 (c)), there were many agglomerations of nanoparticles within the matrix, as shown in white circle, and the holes were visible. This observation indicates the poor dispersion of NiZn ferrite nanofillers when the nanofiller concentration exceeds the optimum level, which resulting in the decrease of mechanical and thermal properties. As described in Table 3, the presence of NiZn ferrite in the PLA/LNR matrix was proven by the existence of Ni, Zn and Fe elements in the nanocomposites. It was interesting to observe that the percentage changes in these elements seemed to be inconstant, in which the increase for 3 – 4 wt.% NiZn ferrite was getting larger as compared to low amount (1 to 2 wt.%) and a sudden decrease for 5 wt.% NiZn ferrite. This might be due to (1) the agglomeration of NiZn ferrite within the polymeric matrix, and (2) the EDX analysis had been done in a spot area of morphology.

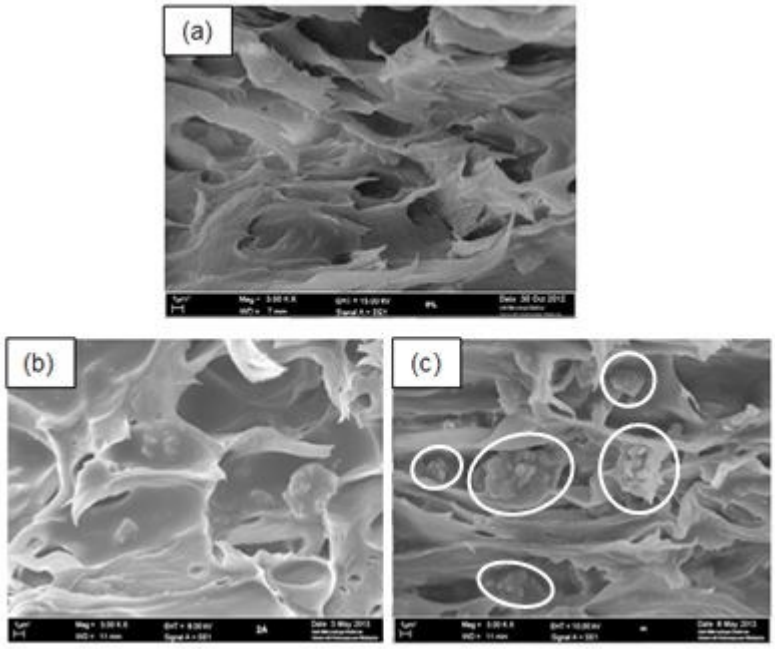

Figure 2. SEM micrograph of PLA/LNR with (a) 0 wt.%, (b) 2 wt.% and (c) 4 wt.% NiZn ferrite

Table 3. Weight and atomic percentage of elements presented in nanocomposites with different concentration of NiZn (obtained from EDX)

| NiZn Ferrite (wt.%) | Weight Percentage of Element (%) | | | | |
|---|---|---|---|---|---|
| | C | O | Ni | Zn | Fe |
| 1 | 54.14 | 44.98 | 0.24 | 0.04 | 0.60 |
| 2 | 53.11 | 44.40 | 0.94 | 0.43 | 1.12 |
| 3 | 50.15 | 41.56 | 1.61 | 0.93 | 5.75 |
| 4 | 47.20 | 35.28 | 4.11 | 1.26 | 12.15 |
| 5 | 47.05 | 43.14 | 2.05 | 0.78 | 6.17 |

## Conclusion

Nanocomposites PLA/LNR embedded with NiZn ferrite at different concentrations were prepared using internal mixer. In overall, the incorporation of NiZn ferrite nanoparticles resulted in positive effect to the mechanical and thermal properties of nanocomposites based on PLA/LNR blend. As the NiZn ferrite nanofiller increased from 0 to 2 wt.%, the tensile strength and modulus of nanocomposites increased up to 36 – 42%. By adding small amount of NiZn ferrite into biodegradable matrix, the thermal stability of nanocomposites enhanced significantly. Once higher NiZn ferrite was introduced, > 2 wt.%, tensile properties and thermal behavior reduced due to the agglomeration of NiZn ferrite, as shown in SEM micrograph. The residues after complete degradation increased accordingly with the filler concentration.

**Abstract**

Refined, bleached and deodorized (RBD) palm oil is one of the interesting renewable resources in biolubricant application. It is due to some advantages such as biodegradable, non-toxic, excellent lubricity and high viscosity index properties. However, direct application of RBD palm oil as biolubricant is restricted due to its poor low temperature property, which limits its use at low operating temperature. This drawback can be overcome by molecule structural redesign through chemical modification process. To produce palm oil based biolubricant with good pour point, epoxidized palm oil (EPO) was chemically modified via ring opening process. EPO was reacted with oleic acid in the presence of *p*-toluenesulfonic acid (PTSA) as catalyst. The molecular structure confirmation of ring opening product which is palm oil hydroxy oleate (POHO) was proven through the oxirane oxygen content (OOC) value, iodin value, hydroxyl value, Fourier transformation infra-red (FTIR), proton and carbon nuclear magnetic resonance ($^{1}$H-NMR and $^{13}$C-NMR) spectroscopy analysis. The physicochemical properties of POHO were determined through its pour point and flash point values. The results showed that the ring opening process for putting bending and branching molecule structures of the oil have improved the pour point (-8.5 $^{o}$C) and increased the flash point of the biolubricant (255 $^{o}$C).

**Keywords**: epoxidized palm oil, oleic acid, ring opening, pour point

**Abstrak**

Minyak sawit tertapis, terluntur dan terbau (RBD) merupakan salah satu sumber boleh diperbaharui yang menarik dalam penghasilan biopelincir. Ini adalah disebabkan oleh kelebihannya seperti boleh dibiodegradasikan, tidak bersifat toksik, mempunyai kebolehpelinciran yang cemerlang dan indeks kelikatan yang tinggi. Walau bagaimanapun, penggunaan secara terus mintak masa RBD sebagai biopelincir adalah terhad disebabkan oleh sifat suhu rendah yang lemah, yang telah mengehadkan penggunaannya dalam operasi bersuhu rendah. Kelemahan ini boleh diatasi dengan melakukan ubahsuai struktur molekul melalui pengubahsuaian kimia. Dalam usaha untuk menghasilkan biopelincir berasaskan minyak sawit dengan nilai takat tuang yang baik, minyak sawit terepoksida telah diubahsuai secara kimia melalui proses pembukaan gelang epoksida. Minyak sawit terepoksida ditindakbalaskan dengan asid oleik dengan kehadiran asid *p*-toluenasulfonik (PTSA) sebagai mangkin. Pengecaman struktur molekul hasil pembukaan gelang epoksida iaitu hidroksi oleate minyak sawit (POHO) dibuktikan melalui nilai kandungan oksigen oksiran, nilai iodin, nilai hidroksil, spektroskopi Infra merah transformasi Fourier (FTIR), proton dan karbon resonans magnetik nuklear ($^{1}$H-NMR dan $^{13}$C-NMR). Sifat fiziko-kimia POHO ditentukan melalui nilai takat tuang dan takat kilat. Hasil kajian menunjukkan proses pembukaan gelang epoksida dengan penambahan struktur molekul bercabang dan bengkok minyak telah memperbaiki nilai takat tuang (-8.5 $^{o}$C) dan meningkatkan nilai takat kilat biopelincir (255 $^{o}$C).

**Kata kunci**: minyak sawit terepoksida, asid oleik, pembukaan gelang, takat tuang

## Introduction

Nowadays, plant oil become one of the interesting renewable resources in biolubricant production in order to replace mineral oil. It is due to some advantages such as biodegradable, non-toxic, excellent lubricity and high viscosity index property [1 – 4]. However, plant oil has some drawback such as poor low temperature properties and it need to be resolved [1]. Poor low-temperature properties include cloudiness, precipitation, poor flowability and solidification at relatively high temperatures [1, 2]. Its poor cold flow property will also limit its use at low operating temperature [5]. The possible way to improve this low temperature properties is molecule structural redesign through chemical modification process. Chemical modifications of the vegetable oils to give more complex structures should improve the low-temperature properties [1]. In general, one of the important modification in plant oils is epoxidation. Refined, bleached and deodorized (RBD) palm oil become one of the potential plant oil for epoxidation to produce biolubricant. RBD palm oil contain high percentage of unsaturated fatty acid (49.4%) which makes it as good starting material for the epoxidation process [6].

The most important modification that can be used to improve poor low temperature properties of plant oil is ring opening reaction. The oxirane ring opening by acidic or alkaline catalyzed reaction with suitable reagent provides interesting polyfunctional compounds [2, 7] whereas reducing structural uniformity of the oil by attaching alkyl side chains would improve the low-temperature performance [2, 8]. The branching group which resulted from ring opening reaction will interfere the formation of macro-crystalline structures during low-temperature applications and provide enhanced fluidity to plant oils [9]. These modified plant oils with chain branching were reported to have superior performance of the physicochemical properties and are promising as biolubricant [9]. Products obtained from ring opening can be used as low-temperature lubricants [10].

Epoxidized RBD palm oil become a promising reactive intermediate, since the epoxy group can be converted to other functional groups through ring-opening reaction due to high reactivity of the oxirane ring [11]. The oxirane ring opening reaction can be carried out through epoxy moiety and takes place through cleavage the carbon oxygen bonds which can be initiated by either electrophiles or nucleophiles, or catalyzed by either acids or bases [12]. The epoxide can react with different nucleophiles to produce alcohols, diols, alkoxyalcohols, hydroxy esters, N-hydroxyalkylamides, mercaptoalcohols, aminoalcohols and so forth [12, 13]. Amongst these classes of products, hydroxy esters find application as biolubricants, polyurethane foams, or casting resins [12]. The physicochemical properties of biolubricants derived from hydroxy esters can be modified using different carboxylic acids [12, 14].

In this paper, we reported the modification of epoxidized palm oil (EPO) molecule structure via ring opening process to produce a base stock oil for lubricant application. Epoxidized palm oil (EPO) was reacted with oleic acid in the presence of *p*-toluenesulfonic acid (PTSA) as catalyst to enhance the lubrication properties. The product of ring opening process which is palm oil hydroxy oleate, (POHO) was screened for low-temperature property through determination of pour point. The pour point of a biolubricant is a good indicator of its low-temperature fluidity. The product also monitored by oxirane oxygen content (OOC) value, iodin value (IV) and hydroxyl value (HV) tests. The physicochemical properties analysis was performed according to the standard methods for pour point and flash point.

## Materials and Methods

### Materials

RBD palm oil was obtained from Sime Darby Jomalina, Teluk Panglima Garang, Selangor, Malaysia. Formic acid (88%) was obtained from Fisher Scientific and hydrogen peroxide 30% from Merck, Germany. Sodium hydrogen carbonate, sodium sulphate, sodium chloride, potassium iodide, Wijs solution, ethyl acetate and *p*-toluenesulfonic acid (PTSA) were purchased from Systerm. Hydrogen bromide 33 wt.% in acetic acid, glacial acetic acid and oleic acid (90%) were obtained from Sigma Aldrich.

### Epoxidation of RBD palm oil

In epoxidation reaction, the mole ratio of RBDPO, formic acid and hydrogen peroxide is 1:5:3. The epoxidation process began by adding RBDPO with formic acid into 250 mL three necks round bottom flask equipped with mechanical stirrer, thermometer and reflux condenser. The mixture of RBDPO and formic acid were heated and

continuously stirred (900 rpm). Hydrogen peroxide was added slowly drop wise. The reaction was carried out for 2.5 hours at 45 $^{o}$C. At the end of reaction, heating was stopped, and product was neutralized with sodium hydrogen carbonate solution (5%), sodium chloride solution (5%) and distilled water. The product which is epoxidized palm oil was kept for overnight by adding anhydrous sodium sulphate to remove water. Then, product was filtered using Whatmann No. 1 filter paper.

**Ring opening of epoxidized palm oil**

In ring opening reaction, the mole ratio of epoxidized palm oil (EPO) and oleic acid is 1: 3. EPO and oleic acid were weighed into a 250 mL three-neck round bottom flask and heated at 70 $^{o}$C to 80 $^{o}$C for 15 minutes. Then, 1% of *p*-toluenesulfonic acid (PTSA) was added to the mixture. The reaction was carried out for 5 hours at 110 $^{o}$C with continuous stirring of 900 rpm using a magnetic stirrer. At the end of reaction, the heating was stopped. The product was neutralized with sodium hydrogen carbonate solution, sodium chloride solution and ethyl acetate. The product which is palm oil hydroxy oleate (POHO) was kept for overnight by adding anhydrous sodium sulphate. The product was filtered by Whatmann No 1 filter paper and the solvent used was isolated by rotary evaporator at 70 $^{o}$C.

**Characterizations**

The formation of palm oil hydroxy oleate (POHO) was confirmed using Fourier Transform Infrared (FTIR) and Nuclear Magnetic Resonance (NMR) spectroscopy. FTIR spectra was recorded on a Perkin Elmer Infrared Spectrophotometer in the range 500 – 4000cm$^{-1}$. NMR spectroscopy was carried out to confirm the molecular structure of the product. $^{1}$H and $^{13}$C NMR were recorded on JEOL-ECP 400 spectrometer (400 MHz $^{1}$H/100.61 MHz$^{13}$C) using $CDCl_3$ as a solvent.

**Determination of oxirane oxygen content**

Oxirane oxygen content (OOC) determines the quantity of oxygen of epoxy groups in percent of mass. Oxygen is directly titrated with hydrobromic acid in acetic acid under defined conditions according to the AOCS Analysis Method Cd 9-57[15]. OOC percentage can be calculated using the following equation 1:

$$\text{Oxirane oxygen content (\%)} = \frac{\text{Volume of hydrobromic acid solution (mL) x N x 1.60}}{\text{Weight of sample (g)}} \quad (1)$$

whereas N is normality of hydrobromic acid solution

**Determination of iodine value**

Iodine value (IV) is a parameter that determines the degree of unsaturation in oils and fats, which are associated with the double bond or triple bond. IV shows the value in grams of iodine absorbed by 100g of fat or oil in the condition specified. Determination of IV generally practiced by Wijs method according to Ainie et al. [16]. IV can be determined by following equation 2:

$$\text{Iodin value (IV)} = \frac{12.69 \text{ x N x } (V_2\text{-}V_1)}{W} \quad (2)$$

whereas N is normality of sodium thiosulphate solution, $V_2$ is volume of sodium thiosulphate solution (mL), required for titration of sample, $V_1$ is volume of sodium thiosulphate solution (mL), required for titration of blank and W is weight of sample (g).

**Determination of hydroxyl value**

The hydroxyl value (HV) is the weight of potassium hydroxide in milligrams (mg) balanced with hydroxyl content of one gram of sample. HV is applied in the determination of oil or its derivatives that have the oxirane ring structure. HV was performed according to the method AOCS Analysis Method Tx 1a-66 [15]. HV can be determined using this following equation 3:

$$\text{Hydroxyl value (HV)} = \frac{B + (WA/C) - S \times N \times 56.1}{W} \quad (3)$$

whereas A is volume of potassium hydroxide solution (mL), required for titration for acidity value and B is volume of potassium hydroxide solution (mL) required for titration of blank test. C is weight of sample (g) used in acid titration, S is volume of potassium hydroxide solution (mL), required for titration in samples that have undergone acetylation process, W is weight of sample (g) used in acetylation and N is normality of potassium hydroxide solution.

**Datermination of flash point value**

Flash point is the lowest temperature at which the vapor sample burns or ignite at a pressure of 101.3 kPa (760 mmHg). Determination of the flash point was carried out by Cleveland open cup method according ASTM D92-05a [17] with modifications.

**Determination of pour point value**

Pour point is the lowest temperature at which the sample begins to flow. Pour point is a good indicator for low temperature fluidity determination. Determination of pour point was conducted according to ASTM D97-98 [17] method with modifications.

## Results and Discussion

Many nucleophilic reagents are known to add to an oxirane ring, resulting in ring opening [13]. The ester branching groups produced from oxirane ring opening based esterification reactions are effective for attaining the desired molecular spacing [13]. Most of the oxirane ring groups were opened and converted into ester bonds in the molecule with hydroxyl group [13]. The modified plant oils with chain branching are reported to have superior performance properties and are promising as biodegradable lubricant [13, 18].

This study reports the oxirane ring opening reaction of epoxidized palm oil (EPO) by the nucleophilic addition of oleic acid (OA) in the presence of homogenous acid catalysts which is *p*-toluenesulfonic acid (PTSA). PTSA was preferred to use in the reactions due to the maximum yield of epoxy ring opening and no evidence of any side reaction occurs during the reaction [9]. The nucleophilic attack by fatty acid molecule which is oleic acid on the oxirane ring of epoxidized palm oil (EPO) in the presence of PTSA as catalyst resulted in the ring opened product which is palm oil hydroxy oleate (POHO).

The results for the ring opening process are shown in Table 1. The average percentage yield of ring opening is 82% (by weight). The ring opening process can be monitored through the OOC value which the value should be as smaller as possible after ring opening process. There is a significant different was observed between the OOC values before and after ring opening process. The initial OOC value of epoxidized palm oil (EPO) before ring opening process is 3.42%. The value of OOC obtained for POHO after ring opening process was significantly low approaching zero (0.04%) with 98% conversion. The reduction of OOC value is proportional to significant number of epoxide ring opening and it prove that the entire epoxide ring was successfully opened during the ring opening reaction with the oleic acid to produce POHO.

The entire epoxide ring has been successfully converted to hydroxyl oleate ester functional groups during the ring opening reaction with oleic acid. This can be evidenced by the increasing of iodine value and hydroxyl value of the product. The addition of the olefin which exist from oleate acyl group has increased the iodine value from initial iodine value of epoxidized palm oil (EPO) which is 0.45 mg/g to 59.9 mg/g after ring opening process.

There is also increasing of hydroxyl value which is from 25 mg/g to 124.8 mg/g after ring opening process. Figure 1 shows the schematic reactions for the modification of RBD palm oil via the epoxidation and ring opening reactions represented by the structure of 1,3-dipalmitoyl-2-oleoyl-gliserol (POP) as the dominant triacylglycerol in RBD palm oil.

Table 1. Analysis tests for ring opening process of epoxidized palm oil

| Compound | EPO | POHO |
|---|---|---|
| Yield (%) | 85 | 82 |
| OOC value (%) | 3.42 | 0.04 |
| Conversion (%) | 98 | 98 |
| Iodine value (mg/g) | 0.45 | 59.9 |
| Hydroxyl value (mg/g) | 25 | 124.8 |

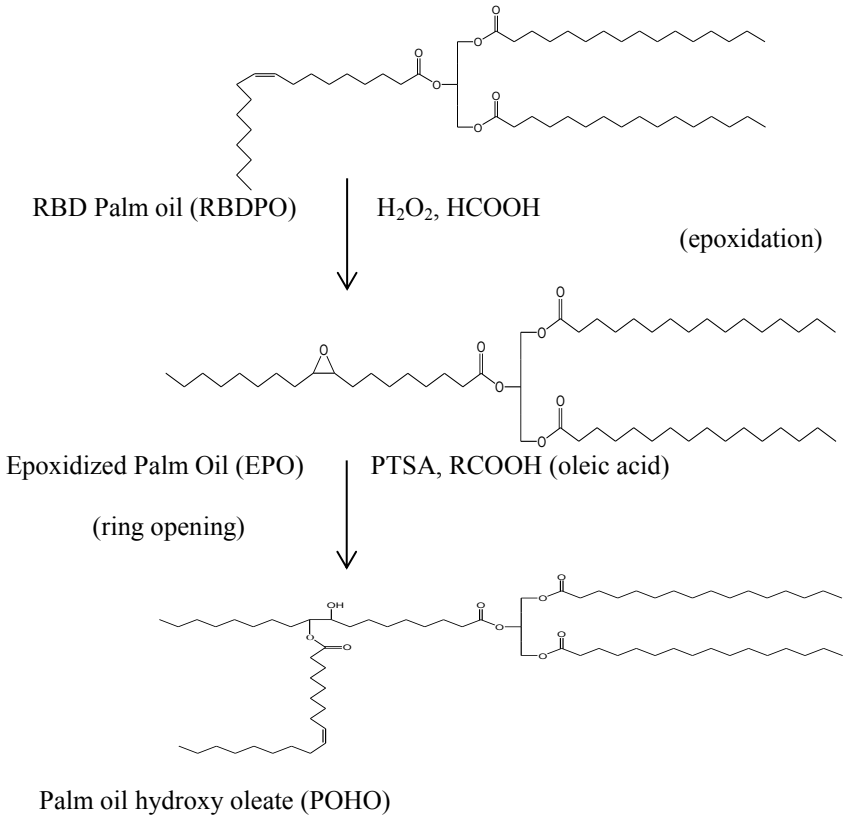

Figure 1. The schematic reactions for the modification of RBD palm oil via epoxidation and ring opening reactions

**FTIR spectra**

The presence of functional groups in the POHO produced were identified by using FTIR spectroscopy. Figure 2 shows comparison of FTIR spectra between RBDPO, EPO and POHO. The disappearance of double bond functional group peak at 3007 $cm^{-1}$ which initially present in RBDPO spectra indicates the conversion of double bond to epoxy group. It can be proved by presence of C-O-C epoxide peak at 826 $cm^{-1}$ in EPO spectra.

The disappearance of the epoxide peak showed that the entire oxirane ring has been successfully converted to hydroxyl oleate ester functional groups in POHO during the ring opening reaction with oleic acid. This is evidenced by the increasing of peaks intensity of the hydroxyl (OH) functional group at 3470 $cm^{-1}$ and C=O stretching at 1741

$cm^{-1}$ in POHO spectra. A significant change in the ring opening process is also can be evidenced by existence of C=C olefin peak of oleate acyl group at 3005 $cm^{-1}$ in POHO spectra.

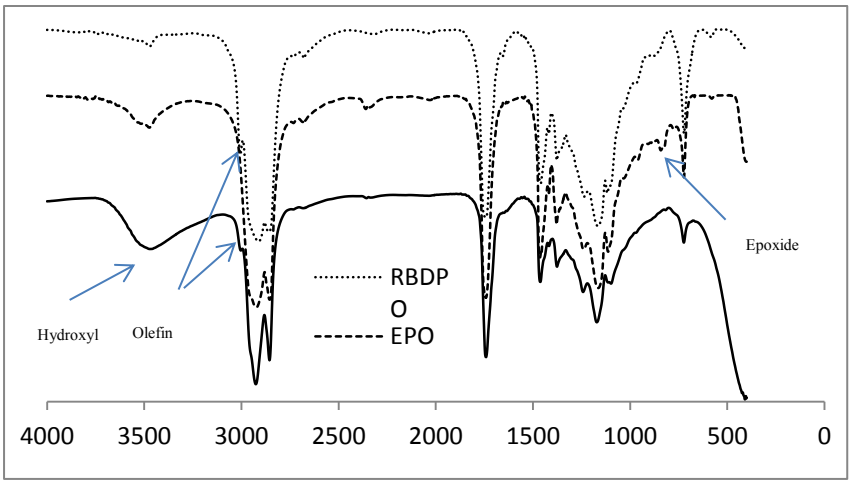

Figure 2. FTIR spectra of RBDPO, EPO and POHO

**NMR spectroscopy**

Table 2 shows the chemical shifts of $^{1}H$ NMR and Table 3 shows chemical shifts of $^{13}C$ NMR spectra for RBDPO, EPO and POHO. In Figure 3(a), the signal at 5.3 ppm is corresponding to vinyl proton (-CH=CH-), while the signal at 2.1 - 2.0 ppm indicate the presence of allylic proton (C=C-C-H), both represent double bond peaks in RBDPO.

Table 2. Chemical shifts of $^{1}H$ NMR spectra for RBDPO, EPO and POHO

| Compound | Chemical shift, ppm | Chemical shift, ppm (Theoretical[19]) | Remarks |
|---|---|---|---|
| RBDPO | 2.1 - 2.0 | 1.6-2.6 | C=C-C-H |
| | 5.3 | 4.5-6.5 | C=C-H |
| EPO | 1.4-1.5 | 1.4-1.5 | $CH_2$-CHOCH-$CH_2$ CHOCH |
| | 2.8 | 2.5-3.5 | |
| POHO | 2.0-1.9 | 1.6-2.6 | C=C-C-H |
| | 4.9 | 0.5-5.0 | C-O-H |
| | 5.3 | 4.5-6.5 | C=C-H |

Table 3. Chemical shifts of $^{13}C$ NMR spectra for RBDPO, EPO and POHO

| Compound | Chemical shift, ppm | Chemical shift, ppm (Theoretical[19]) | Remarks |
|---|---|---|---|
| RBDPO | 130.1- 129.6, 128.0-127.8 | 100-150 | C=C |
| EPO | 57.2-56.6, 54.3-54.1 | 40-80 | C-O-C |

**Physicochemical properties of palm oil hydroxyl oleate (POHO)**

The physicochemical properties results obtained are shown in Table 4. The ability of a substance to remain liquid at low temperatures is an important attribute for many industrial application materials, such as biolubricants, surfactants and fuels [1, 5]. The cold flow property of plant oils is extremely poor, and this limits their use at low operating temperature especially as automotive and industrial fluids [5]. Plant oils tend to form macrocrystalline

structures at low temperatures through uniform stacking of the 'bend' triacylglycerol (TAG) backbone [5]. Such macrocrystals restrict the easy flow of the system due to loss of kinetic energy of individual molecules during self-stacking [2, 5, 20]. The low temperature properties can be screened by determination of pour point. The pour point of a biolubricant is a good indicator of its low-temperature fluidity. In this study, pour point of RBDPO, EPO and POHO were -3.8 °C, 0.1 °C and -8.5 °C, respectively. After ring opening process, POHO shows a lowest pour point which is -8.5 °C, due to the branching in carbon chain and bent structure. It makes more restrict to self-stacking and more hollows in structure, thus easier to flow which contributed to the lowest pour point. In general, the presence of branching group in the molecule will disrupt this stacking process and create a steric barrier around the individual molecules and inhibits crystallization [11]. This will result in the formation of microcrystalline structures rather than macro structures. At lower temperatures, such microcrystalline structures can easily tumble and glide over one another resulting in better fluidity of the total matrix [5], resulting in lower pour point.

Table 4. The physicochemical properties of RBDPO, EPO and POHO

| Compound | RBDPO | EPO | POHO |
|---|---|---|---|
| Pour point (°C) | -3.8 | 0.1 | -8.5 |
| Flash point (°C) | 240 | 245 | 255 |

Another important factor that determine the efficiency of oil as biolubricant is flash point. The flash point is often used as a descriptive characteristic of fuel oil and it is also used to describe oils that are not used as fuels such as lubricant [5]. Flash point refers to both flammable oils and combustible oils [5]. The oils with a flash point less than 43 $^{o}$C are flammable, while those having a flash point above this temperature are combustible [5]. High flash point is important to ensure that the lubricant is not burned in the engine during its operation. Biolubricant which has a low flash point value is considered to have been contaminated by volatile and usually requires precautions special care when handling this biolubricant [2]. In this study, flash point of RBDPO, EPO and POHO were 240 °C, 245 °C and 255 °C, respectively. After ring opening process, POHO shows the highest flash point which is 255 °C. This is due to an increase in carbon number causes an increasing molecular weight that gives a higher flash point. In addition, POHO also have branched carbon chain molecular structure. The big branched-chain structure requires more energy to burn. This will increase the flash point of POHO.

## Conclusion

The chemically modified epoxidized palm oil (EPO) has improvement in pour point and flash point. The ring opening product which is palm oil hydroxy oleate (POHO) has lowest pour point due to the greater ability of the branching chain esters to disrupt crystalline formation. A bent and branching structure make the molecule less compact, thus improve the lubricity of lubricant. This shows that the cold flow property of biolubricant has improved by reducing the pour point value.

**Abstract**

In this study, a charcoal base metallic composite electrode which is low in cost and effective to treat wastewater from landfill leachate by electrochemical oxidation technique has been fabricated. The charcoal base metallic composite electrode was prepared by mixing together a weighed portion of charcoal, graphite and metals powder in different composition percentage with PVC as a binder in 4 mL THF which act as a solvent. Metals used in the preparation of the electrodes are Ag, Al, Co, Cu and Ni. The results show that the mixture of commercially available charcoal, metals and PVC at a composition of 50:20:30 (w/w), known as C50M20PVC30 electrode give a good stability, low cost and high formation of hypochlorite ion. Hypochlorite ion has been produced linked to the presence of chloride ions, thus having capability to degrade chemical pollutants in wastewater.

**Keywords**: charcoal, electrode, treatment, wastewater

**Abstrak**

Dalam kajian ini, elektrod komposit logam berasaskan arang dengan kos rendah dan efektif dalam merawat air buangan daripada tanah larut resap melalui teknik pengoksidaan elektrokimia telah dibangunkan. Elektrod komposit logam berasaskan arang telah disediakan dengan mencampurkan arang, grafit dan serbuk logam pada peratus komposisi yang berbeza di mana polivinil klorida sebagai pengikat di dalam 4 mL tetrahidrofuran (THF) sebagai pelarut. Logam yang digunakan dalam penyediaan elektrod ialah Ag, Al, Co, Cu dan Ni. Keputusan menunjukkan campuran arang komersial, logam dan PVC pada nisbah 50:20:30 (w/w), yang dikenali sebagai elektrod C50M20PVC30 memberi kestabilan yang baik, berkos rendah dan menghasilkan ion hipoklorit yang tinggi. Semasa pengoksidaan elektrokimia, ion hipoklorit telah dihasilkan disebabkan oleh kehadiran ion klorida yang membawa kepada keupayaan untuk penyingkiran bahan pencemar kimia di dalam air buangan.

**Kata kunci**: arang, elektrod, rawatan, air buangan

## Introduction

Water purification is one of the most pervasive problems affecting people throughout the world [1]. Various methods of wastewater treatment have been reported and this process is divided into three, namely chemical, physical and biological [2]. Up to now, electrochemical oxidation process has been proved to be promising for

wastewater treatment mainly due to its high effectiveness, easy to operate and more economic [3, 4]. In the case of landfill leachate, it was known having high concentration chloride ions and good conductivity. Many researchers have investigated the effectiveness of electrochemical oxidation process toward various types of wastewater including leachate wastewater [5, 6]. Leachate also known having high chemical oxygen demand (COD), high levels of ammonia and phosphorus as well as total dissolved solid content (TDS) [7]. To reach environmental friendly criteria for landfill leachate, chemical pollution should be minimized to an acceptable discharge limit [8].

Therefore, the aim of this study is to evaluate the effectiveness of charcoal base metallic composite electrode for color removal during electrochemical oxidation process. Characterization of prepared charcoal base metallic composite electrodes also has been studied.

## Materials and Methods

### Preparation of electrodes

Composite electrodes based on ratio composition of charcoal-metals-PVC were prepared. A weighed portion of charcoal powder, metals with PVC in 4 mL tetrahydrofuran (THF) solvent was mixed together and swirled flatly to homogeneous, followed by drying in an oven at temperature set 100˚ C for 3 hours. The mixture was then placed in 1 cm diameter stainless steel mould and pressed at 10 ton/cm [9]. The pellets were connected to silver wire with epoxy gum and coated silver conducting paint.

### Experimental procedures

All experiments were carried out at ambient temperature. The lab scale electrochemical cell was designed by using DC set power supply, glass reactor and magnetic stirrer. Leachate sample (50 mL) was then added into cell with known concentration supporting electrolyte. Sample in the electrochemical cell was kept stirred at 300 rpm for homogenise condition. The effect of pH was studied by adjusting leachate sample using HCl or NaOH solution. The effect of sodium chloride concentration as the supporting electrolyte also was carried out. Electrochemical reaction was started once the specified voltage was introduced into the system. Leachate samples were treated at different time and different operating parameters. The removal efficiency (% R) of color sample during electrochemical oxidation process was calculated using following equation 1 [10].

$$\% \, R = \frac{[100 \, (R_0 - R_t)]}{R_0} \tag{1}$$

where % R is the removal percentage for color, $R_0$ is initial value of color, $R_t$ is the value color at time t.

### Sampling

Leachate samples were collected from Jeram Sanitary Landfill, situated in oil palm plantation near Mukim Jeram, Kuala Selangor. Leachate samples were transported to chemical laboratory and stored in a refrigerator at 4˚C prior analysis.

## Results and Discussion

### The stability of electrode

Different compositions of commercially available charcoal powder base metallic composite electrode with PVC were prepared. Different types of metals such as silver, aluminum, cobalt, copper and nickel were used as metal based. All electrodes hardness was tested to determine whether composition of charcoal and metal powders having high stability to use it during electrochemical treatment process. Table 1 depicted the stability of charcoal base metallic composite electrode.

Finding study shows ten composition of electrodes having good stability which can be used in electrochemical treatment process. The stability of composite electrode was improved once the percentage of PVC was increased. The characterization explains that PVC acts as a binder, filled the porosity of charcoal and increase resistivity of electrode [10, 11]. Nonetheless, the amount of PVC was kept as low as possible, to avoid reducing surface area or conductivity of composite electrode during this study.

Table 1. The stability of commercially available charcoal powder base metallic composite electrode

| Percentage % (w/w) | | | Electrode Stability |
|---|---|---|---|
| Charcoal | PVC | Metal Powder | |
| 10 | 10 | 80 | Hard |
| 20 | 10 | 70 | Hard |
| 30 | 15 | 60 | Hard |
| 40 | 15 | 45 | Hard |

Note: stability of electrode = The hardness of pellet after preparation

**Optimization of anode material composition**

Electrode based materials was known having influence toward the efficiency of electrochemical process include for wastewater treatment [12, 13]. Good composite electrode was evaluated based on the efficiency of color removal in leachate samples. The operating condition: applied voltage (10 V) and NaCl concentration (1.5% w/v) was remain constant during treatment process. Expenses costs of all composite electrodes used in this study were calculated based on manufacturer prices (Sigma-Aldrich, USA). The results obtained is summarised as in Table 2.

Table 2. Electrochemical oxidation of landfill leachate under different operating condition

| Electrode | Electrolysis Time (min) | Color Removal (%) | Observation | | Cost USD | $ClO^-$ Production (Abs) |

| C70Ni10PVC20 | 240 | 6 | Color unchanged | Completely corroded | 0.67 | - |

Note: $OCl^-$ = the formation of hypochlorite ion in 50 mL deionized water, 1.5% (w/v) NaCl and 30 minutes electrolysis time for only the stable electrodes.

Finding study shown that the best composite electrode (C50Co20PVC30) gave 58% of color removal without any changes on physical properties. Although C50Ag20PVC30 composite electrode record color removal till 61% but the stability of electrode is low and the cost to fabricate the electrode was higher. As the main criteria electrode used in any electrochemical process should be stable chemically and physically [14, 15]. Therefore, the selection of good composite electrode is not only based on the ability to remove the color, but chemical stability as well. The composition of C50Co20PVC30 was identified as best composite, then it was used in the next experiment.

In further experiment, formation of hypochlorite ion has been investigated by adding 1.5% (w/v) NaCl solution to 50 mL of deionized water in electrochemical cell. During treatment process, hypochlorite ions production was linked to presence of chloride ions. It was believed that the presence of hypochlorite ions able to degrade chemical pollutants in leachate samples [16]. The formation of hypochlorite ion in aqueous solution was determined using UV-visible spectrophotometer. Comparison of four characteristics (color, cost, hypochlorite ion formation and electrode stability) to determine the best composite electrode is shown in Figure 1.

## Conclusion

The present study successfully proves the most suitable charcoal base metallic composite electrode is C50Co20PVC30 as anode in electrochemical oxidation process for the treatment of landfill leachate. It was successfully performed for color removal and good stability. The color removal efficiency (58%) linked to increase the presence of hypochlorite ion, then lead the degradation of organics present in the effluent.
